The MDL is elevated for 4,4'-DDE in Method Blank KWG0902339-3. The chromatogram indicated the presence of non-target background components, which were apparently introduced as laboratory artifacts. The contamination prevented adequate resolution of the target compounds at the MDL. Note the level of background was relatively low compared to the MDL, so the affect on the results was minimal. The results are flagged to indicate the problem.

The reporting limit is elevated for all analytes in sample FO095330. The sample extract was diluted prior to instrumental analysis due to relatively high levels of non-target background components. Clean-up of the extract was performed within the scope of the method, but did not eliminate enough of the background components to prevent dilution. A semiquantitative screen was performed prior to final analysis. The results of the screening indicated the need to perform a dilution. The result is flagged to indicate the matrix interference.

The reporting limit is further elevated for several analytes in sample FO095330. The chromatogram indicated the presence of non-target background components. The matrix interference prevented adequate resolution of the target compounds at the reporting limit. The results are flagged to indicate the matrix interference.

No other anomalies associated with the analysis of these samples were observed.

Semivolatile Organic Compounds by EPA Method 8270C_LL

Elevated Method Reporting Limits:
The reporting limits are elevated for sample FO095330. The sample extract was diluted prior to instrumental analysis due to relatively high levels of non-target background components. A semi-quantitative screen was performed prior to final analysis. The results of the screening indicated the need to perform a dilution.

No other anomalies associated with the analysis of these samples were observed.

Cooler Receipt and Preservation Form

Client / Project: City of Portland. Service Request K09 02283

Received: 3-17-09 Opened: 3-17-09 By: BW

1. Samples were received via? *US Mail* *Fed Ex* *UPS* *DHL* *GH* *GS* *PDX* *Courier* *Hand Delivered*
2. Samples were received in: (circle) *Cooler* *Box* *Envelope* *Other* _____ *NA*
3. Were custody seals on coolers? NA Y N If yes, how many and where? _____
   If present, were custody seals intact? Y N If present, were they signed and dated? Y N
4. Is shipper's air-bill filed? If not, record air-bill number: _____ NA Y N

5. Temperature of cooler(s) upon receipt (°C): 4.3
   Temperature Blank (°C): 4.7
   Thermometer ID: SMO-245
6. If applicable, list Chain of Custody Numbers:
7. Packing material used. *Inserts* *Baggies* *Bubble Wrap* *Gel Packs* *Wet Ice* *Sleeves* *Other* _____
8. Were custody papers properly filled out (ink, signed, etc.)? NA Y N
9. **Did all bottles arrive in good condition (unbroken)?** *Indicate in the table below.* NA Y N
10. Were all sample labels complete (i.e analysis, preservation, etc.)? NA Y N
11. Did all sample labels and tags agree with custody papers? *Indicate in the table below* NA Y N
12. **Were appropriate bottles/containers and volumes received for the tests indicated?** NA Y N
13. Were the pH-preserved bottles tested* received at the appropriate pH? *Indicate in the table below* NA Y N
14. Were VOA vials and 1631 Mercury bottles received without headspace? *Indicate in the table below.* NA Y N
15. **Are CWA Microbiology samples received with >1/2 the 24hr. hold time remaining from collection?** NA Y N
16. Was C12/Res negative? NA Y N

Sample ID on Bottle	Sample ID on COC	Sample ID on Bottle	Sample ID on COC

Sample ID	Bottle Count	Bottle Type	Out of Temp	Head-space	Broken	pH	Reagent	Volume added	Reagent Lot Number	Initials

*Does not include all pH preserved sample aliquots received. See sample receiving SOP (SMO-GEN).

RE: NPDES

Enclosed are the results of analyses for samples received by the laboratory on 03/17/09 18:10. The following list is a summary of the Work Orders contained in this report, generated on 04/02/09 12:22.

If you have any questions concerning this report, please feel free to contact me.

Work Order	Project	ProjectNumber
PSC0533	NPDES	36238

TestAmerica Portland

Howard Holmes, Project Manager

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report shall not be reproduced except in full, without the written approval of the laboratory.

Notes and Definitions

Report Specific Notes:

M7 - The MS and/or MSD were above the acceptance limits. See Blank Spike (LCS).

M8 - The MS and/or MSD were below the acceptance limits. See Blank Spike (LCS).

Laboratory Reporting Conventions:

DET - Analyte DETECTED at or above the Reporting Limit. Qualitative Analyses only.

ND - Analyte NOT DETECTED at or above the reporting limit (MDL or MRL, as appropriate).

NR/NA - Not Reported / Not Available

dry - Sample results reported on a Dry Weight Basis. Results and Reporting Limits have been corrected for Percent Dry Weight.

wet - Sample results and reporting limits reported on a Wet Weight Basis (as received). Results with neither 'wet' nor 'dry' are reported on a Wet Weight Basis.

RPD - RELATIVE PERCENT DIFFERENCE (RPDs calculated using Results, not Percent Recoveries).

MRL - METHOD REPORTING LIMIT. Reporting Level at, or above, the lowest level standard of the Calibration Table.

MDL* - METHOD DETECTION LIMIT. Reporting Level at, or above, the statistically derived limit based on 40CFR, Part 136, Appendix B. *MDLs are listed on the report only if the data has been evaluated below the MRL. Results between the MDL and MRL are reported as Estimated Results.

Dil - Dilutions are calculated based on deviations from the standard dilution performed for an analysis, and may not represent the dilution found on the analytical raw data.

Reporting Limits - Reporting limits (MDLs and MRLs) are adjusted based on variations in sample preparation amounts, analytical dilutions and percent solids, where applicable.

Electronic Signature - Electronic Signature added in accordance with TestAmerica's *Electronic Reporting and Electronic Signatures Policy.* Application of electronic signature indicates that the report has been reviewed and approved for release by the laboratory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

C1 Introduction

This appendix describes the methodology and approach for statistically evaluating the stormwater data collected at City of Portland (City) outfalls discharging to the Willamette River within the Portland Harbor Study Area. The purpose of the evaluation is to identify City outfall basins and associated stormwater analytes that may warrant further source tracing to identify potentially significant uncontrolled upland sources in City outfall basins. This appendix is intended to provide background, technical details, and supporting information regarding the statistical evaluation presented in Section 4 of the *Stormwater Evaluation Report* (BES, 2010).

The evaluation of the stormwater data for City outfalls comprises a multiple-step process, summarized below in Sections C2 through C5. The approach includes screening and statistical analyses to provide context for interpreting the potential significance of stormwater results and as a basis for identifying City outfall basins where further source tracing may be warranted for specific analytes. The available stormwater data used in these analyses were collected by the City, Lower Willamette Group (LWG), and others for City and non-City outfalls discharging to the Study Area (harborwide data set). The results of the stormwater data evaluation are carried forward into the basin-specific assessments of source-tracing needs, presented in Section 5 of the *Stormwater Evaluation Report* (BES, 2010).

C2 Preliminary Harborwide Data Evaluation

This section describes the process used to evaluate the 2007/2008 stormwater data and inform the development of the statistical evaluation approach described in Section C4. Data sources are described in Section 3 of the *Stormwater Evaluation Report* (BES, 2010).

C2.1 Preliminary Summary Statistics

Characteristics of the data set were initially assessed by calculating various summary statistics of the stormwater concentration data for each outfall (such as the mean, maximum, minimum, and range) for use in comparing harborwide concentrations and assessing potential stormwater concentration variables (e.g., land use) using graphical methods. Understanding the general characteristics of the stormwater data set was important in selecting appropriate data analyses and statistical evaluation procedures.

C2.2 Preliminary Data Plots

Stormwater data were plotted in several ways to help assess potential data evaluation methodologies. One of the original objectives for preparing these preliminary graphics was to attempt to identify outfall basins for further source tracing using natural breaks in the harborwide stormwater concentrations. One set of graphics (i.e., bar graphs) that was initially generated to assess the distribution of stormwater concentrations is presented in Attachment C1. These bar graphs rank harborwide outfalls by mean concentration and also provide individual sampling event concentrations for each outfall. Plots were prepared for total polychlorinated biphenyls (PCBs), total polycyclic aromatic hydrocarbons (PAHs), bis(2-ethylhexyl)phthalate (BEHP), total DDx, and selected metals (arsenic, chromium, copper, lead, mercury, and zinc). The bar graphs were generated using the following assumptions and conventions:

A. Arithmetic mean concentrations were calculated for each individual outfall sample location using the results of all individual sampling events (typically 3 to 5 events per location).
B. Concentration values reported as below the laboratory method reporting limit (MRL) were set to zero for calculating the mean concentration.
C. Results for duplicate samples were averaged with the corresponding primary sample results to achieve a mean value for that sample event that was then used to calculate the basin arithmetic mean concentrations shown on the bar graphs.
D. Extreme data values (i.e., potential outliers) are included.

C2.3 Data Set Characteristics

The stormwater data set was characterized by reviewing the representativeness of sampling locations and using the preliminary summary statistics and data plots to aid in the selection of an appropriate statistical method for data evaluation. Characteristics of the stormwater data set are listed below:

- The sample population includes more than 50 outfalls, including both City and non-City outfalls.
- Analytical stormwater discharge data collected at or near the end of the conveyance system is assumed to be representative of "basin" conditions.
- Outfall sampling locations are spatially distributed throughout the Portland Harbor Study Area.
- The number of individual storm events sampled at each outfall location is small (typically 3 to 5 samples per location).
- Analytical results have a lower concentration bound of zero (i.e., no negative values).
- Analytical results are censored (i.e., some concentration data are reported as below MRLs).
- Some individual event concentrations appear high or extreme when compared to harborwide concentrations (i.e., possible outliers). These higher values may be due to:
    - A measurement or recording error;
    - An observation from a population different from the rest of the data; or
    - A rare event from a single population that is heavily skewed (i.e., log normal distribution).
- Data from individual outfalls appear to be right or positively skewed (i.e., data are not symmetric around the mean or median and the asymmetric tail extends to the right).

C2.4 Preliminary Data Evaluation Findings

The harborwide stormwater concentration bar graphs presented in Attachment C1 were evaluated to assess whether City outfall basins that might require additional source tracing activities could be readily identified. The following general observations were made, based on these bar graphs:

- About half of the sampled outfall basins have low concentrations falling within a narrow range of values; this outcome is attributable in part to the convention of assigning all non-detected results a value of zero.
- The higher mean values are distributed along curves with gradual or steeper increases in slope; however, the graphs do not exhibit breaks in the slopes that are sufficiently abrupt to define a "natural" boundary of "high" stormwater analyte concentrations relative to the harborwide range of average values.
- Stormwater data from individual outfall basins are generally positively skewed (asymmetric tail extends to the right of the mean).
- Plots are useful for:
    - Presenting the variability of concentrations (range of concentration values) between individual stormwater sampling events at each location.
    - Providing context of the mean stormwater concentration for an individual outfall basin against harborwide outfall basin data.
    - Identifying a few outfalls with concentrations that are clearly elevated compared to general harborwide concentrations

- The graphs do not readily lend themselves to the primary objective of the City's stormwater data evaluation (i.e., identifying City basins that might warrant additional source tracing activities).

The preliminary data evaluation did not clearly identify individual or groups of City outfall basins that might be considered for additional source tracing activities, based on individual event or mean stormwater concentrations. Therefore, it was determined that more robust evaluation of the stormwater data was needed to identify City outfall basins with higher analyte concentrations within the Harborwide data set that could indicate the presence of significant upland sources and the need for additional source tracing. The statistical evaluation methodology is described in the following sections of this appendix.

C3 Selection of Stormwater Analytes for Statistical Evaluation

This section describes the process used to select analytes for the harborwide statistical evaluation. The objective of this process is to identify analytes in each City outfall basin sampled for consideration of further source tracing activities.

Steps in Selection of Stormwater Analytes for Statistical Evaluation

1. Screen individual stormwater event data points for City outfall basins against JSCS SLVs (Appendix A)
2. For any analyte >SLV in at least one sample, calculate arithmetic and geometric mean concentrations for each City and non-City outfall basin (Attachment C-2)
3. Screen geometric mean concentrations for City outfall basins against JSCS SLVs (Appendix D).
4. For any analyte with geometric mean concentration >JSCS SLV, carry forward to harborwide statistical analysis (Section C4).

C3.1 Step 1 – Screen Individual Stormwater Event Concentrations

Stormwater sampling results from City outfall basins were compared to the recommended screening level values (SLVs) identified in the Joint Source Control Strategy (JSCS; DEQ and EPA 2005 [amended in 2007]) and DEQ's *Guidance for Evaluating the Stormwater Pathway at Upland Sites* (DEQ, 2009a). Data tables for City outfall basins sampled by the City are presented in Appendix A of the *Stormwater Evaluation Report*.

Analytes[1], including individual PAHs, that exceeded their respective SLVs in at least one sample event at one or more outfall basins were identified and carried forward to Step 2 for further evaluation. Analytes were carried forward regardless of how much the concentration exceeded the JSCS SLVs or how many outfalls exceeded the SLVs. It should be noted that "…exceedance of an SLV does not necessarily indicate the upland source of contamination poses an unacceptable risk to human or ecological receptors" (DEQ and EPA, 2005). DEQ and EPA recognize the conservative nature (i.e., low concentrations) of the SLVs in the JSCS and that some SLVs are less than laboratory practical quantification limits (PQLs) using standard methods. As stated in the JSCS:

> "The SLVs were developed to conservatively identify potential threats to human health and the environment including potential toxicity to ecological receptors and bioaccumulation... It should be noted that the SLVs are not cleanup levels; they are comparisons used to establish priority for potential source control. The EPA Portland Harbor ROD(s) will establish contaminant specific cleanup levels for the Superfund Site using applicable or relevant and appropriate requirements (ARARs) or risk-based levels…. DEQ and EPA recognize that some of the SLVs are below naturally occurring background levels. Both DEQ cleanup regulations and CERCLA allow consideration of naturally occurring background in site characterization, risk assessment, and when developing cleanup levels."

[1] Only detected concentrations were used to select the analytes for statistical analysis; results reported as non-detected were not considered for further source tracing even if the method reporting limit (MRL) exceeded the JSCS SLV.

The stormwater data for all City outfall basins include numerous SLV exceedances, due in part to the very low SLVs established for some analytes (e.g., PAHs). For this reason, and due to the inherent variability of stormwater, SLV screening of individual storm events alone was not effective in targeting City outfall basins or analytes for potential future City source tracing efforts. The outcome of this step indicated that the City needed a process other than comparing individual stormwater sample results to the JSCS SLVs to differentiate significant sources from lower contributing sources. Because the SLVs are conservative screening values selected to be protective of inriver receptors, application of these values to in-pipe media (stormwater and stormwater solids) results in the identification of analytes that in some cases are below estimated background concentrations or concentrations from areas with no sources, such as Forest Park. Additionally, SLVs do not recognize state-authorized NPDES discharges to the City's system (i.e., metals benchmarks are one to two orders of magnitude higher than the SLVs) and therefore are not always useful in evaluating where significant sources may be present. In light of these limitations, and given the City's primary objective in the stormwater data evaluation, the City's evaluation approach (described in Section C4) is to compare City outfall data to a broader harborwide dataset to identify where more significant sources occur.

C3.2 Step 2 – Screen Mean Outfall Basin Stormwater Concentrations

Stormwater discharges are highly variable both in terms of rain event conditions (e.g. intensity, duration, antecedent dry period), resulting flow characteristics (i.e., intermittent vs. continuous) and pollutant concentrations, making the relationship between discharges and water quality complex. Therefore, mean concentrations for each basin in the harborwide data set were calculated to provide an estimate of "representative" stormwater outfall concentrations. For each analyte identified in Step 1, both the arithmetic and geometric means for each outfall basin were calculated. The arithmetic mean and geometric mean concentrations for the outfall basins included in the harborwide data set are shown with the data presented in Attachment C2. The following assumptions and conventions were used in calculating the mean concentrations:

- Arithmetic and geometric mean concentrations were calculated for each outfall using the results of all individual sampling events (typically 3 to 5 events per location).
- Concentration values reported as below the laboratory method reporting limit were set to the concentration of the MRL for calculating the mean concentrations. (Note: This assumption is conservative and may overestimate the true mean concentration.)
- Extreme data values (i.e., potential outlier concentrations) were included in the calculations.
- Duplicate samples from a single storm event were first averaged (each duplicate sample averaged together with its corresponding primary sample), and the average concentration was then included as a single value in the basin mean calculations.
- All stormwater data collected to represent the same basin — including data collected by different sampling methods (i.e., grab sampling and flow-weighted composite sampling) — were combined in calculating the mean concentrations (e.g., OF 19, OF 53).
- Samples that were collected from different locations within a given outfall basin were not combined if they represented different drainage areas (i.e., OF M-1, OF M-2, and OF 22C).

- Total PCBs, total PAHs, total DDx, and total Chlordane concentrations for results including one or more detections of an individual constituent were calculated by assigning a value of zero to non-detected concentrations. For results in which *no* individual constituents were detected, the total concentration is reported as the highest MRL among the individual constituents.

The mean and geometric mean concentrations calculated for City outfalls were compared to JSCS SLVs, and the results are presented in Appendix D of the *Stormwater Evaluation Report.* Analytes whose geometric mean concentration exceeded the JSCS SLV in at least one City outfall basin were selected for statistical evaluation. These analytes are summarized in Table C-1, below.

Twenty-two analytes (identified in Table C-1), including 13 individual PAH compounds, were carried forward into the harborwide statistical evaluation to categorize City outfall basins for potential source tracing activities.

The mean and geometric mean concentrations for the outfall basins are generally comparable, and geometric mean concentrations were used to estimate the central tendency of individual stormwater outfall basin concentrations. The arithmetic mean values are provided in Attachment C-3 and *Stormwater Evaluation Report* Appendix D for informational purposes only. Geometric means are appropriate to describe data which are lognormally distributed (EPA, 1992), can take on only positive values, can vary significantly (e.g., by orders of magnitude), and are positively skewed. Use of the geometric mean is consistent with DEQ's use of the annual geometric mean concentration as a protective compliance limit in the City's Underground Injection Control (UIC) permit (DEQ, 2005), DEQ-issued NPDES 1200Z permits (DEQ, 2006), and DEQ's Industrial Stormwater Advisory Committee discussions regarding monitoring approaches under DEQ's NPDES program (DEQ 2009b, 2009c, and 2009d).

Table C-1. Stormwater Analytes Selected for Statistical Evaluation. (1), (2)

PCB Congeners:
Total PCBs

PAHs:
Acenaphthene
Benzo(a)anthracene
Benzo(a)pyrene
Benzo(b)fluoranthene
Benzo(g,h,i)perylene
Benzo(k)fluoranthene
Chrysene
Dibenzo(a,h)anthracene
Fluoranthene
Indeno(1,2,3-cd)pyrene
Naphthalene
Phenanthrene
Pyrene
Total PAHs (3)

Pesticides:
2,4'-DDD
2,4'-DDE
2,4'-DDT
4,4'-DDD
4,4'-DDE
4,4'-DDT
Aldrin
Total chlordane
Dieldrin
Heptachlor
Heptachlor epoxide

Phthalates:
Bis(2-ethylhexyl)phthalate (BEHP)

Metals (total metals):
Arsenic
Cadmium
Copper
Lead
Manganese
Silver
Zinc

Other SVOCs:
Pentachlorophenol

Notes:

(1) This list includes all detected analytes for which any City outfall basin geometric mean concentration exceeded the JSCS SLV. The analytes identified above are listed regardless of the magnitude by which the geometric mean exceeds the conservative JSCS SLV. Exceedance of an SLV does not necessarily indicate an unacceptable risk to human or ecological receptors (DEQ and EPA, 2005). DEQ and EPA recognize the conservative nature (i.e., low concentrations) of the SLVs in the JSCS (DEQ and EPA, 2005, Table 3-1 revised July 2007) and that some SLVs are less than laboratory practical quantification limits (PQLs) using standard methods.

(2) Analytes shown in italics were analyzed and/or detected in a limited number of outfall basins (one to three basins); therefore, adequate data are not available to perform a meaningful statistical evaluation. These analytes are further evaluated in Section 5 for those basins in which these analytes were detected.

(3) The JSCS does not include an SLV for total PAHs; however, because individual PAH compounds do not typically occur alone, total PAHs were carried forward as an analyte for the harborwide statistical analysis.

C4 Statistical Evaluation of Stormwater Discharge Data

The methodology and results of the statistical analysis of harborwide stormwater data are described in this section. The objective of the statistical analysis was to identify City outfall basins with stormwater analyte concentrations in the upper end of the harborwide range as a basis for identifying outfall basins where additional source tracing activities may be needed. Harborwide stormwater data used in the statistical analyses are tabulated in Attachment C2.

Steps in Statistical Evaluation

1. Select analytes for statistical evaluation (Section C3, Table C-1).
2. For each analyte, selected:
   a. Statistically group harborwide outfalls by geometric mean concentrations (Section C4)
   b. Categorize concentrations to identify those City outfalls with the highest likelihood of having significant unidentified sources. (Section C5, Table 4-2 of *Stormwater Evaluation Report*)
3. Carry analytes identified as Category 2 or 3 in each basin forward for further evaluation/screening (Section 4.2 of *Stormwater Evaluation Report*).

C4.1 Statistical Evaluation Methodology

A statistical model was selected that would identify groups of stormwater outfalls basins with similar levels of contamination (by analyte) within the stormwater data set. The conceptual model for the evaluation is that there are three groups of outfall basins in the stormwater data set with similar characteristics (described below). The conceptual model used for the statistical evaluation assumes that those outfall basins falling into the higher concentration group warrant consideration for further source tracing activities.

Statistical analysis was performed on selected stormwater analytes without consideration of the significance of the outfall basin concentration (i.e., greater than or less than applicable screening levels, background concentrations, etc.). Use of the full harborwide data set allowed stormwater concentrations in City outfall basins to be ranked and analyzed relative to other stormwater discharges to the Portland Harbor Study Area. City outfall basins with analyte concentrations in the upper range of the concentration distribution were identified for further evaluation of the need for source tracing.

This approach provides the City a means to determine if additional source tracing may be warranted. It does not include evaluation of the inriver sediment data from the vicinity of City outfalls to determine if there is a complete pathway for upland contributions (e.g., an outfall may be identified for further source tracing even if there are no elevated sediment concentrations adjacent to the outfall).

C4.1.1 Approach

A finite mixture model was selected to identify group membership of outfall basins within the stormwater data set with similar concentrations and to define the characteristics of the groups. In statistical terminology, the problem of finding groups of observations within a dataset is

called "unsupervised learning" or "clustering". A simplified description of the problem is that the observed data are a mixture of data from several groups where the group labels have been lost. The goal of the analysis is to recover the group labels and to learn something about the group characteristics.

A three-component normal mixture model was used to analyze the distribution of the geometric (i.e., logarithmic) mean concentrations of the outfall basins. For each analyte, the model assumes that three distinct groups (subpopulations) of stormwater basins, as defined based on unique group statistical characteristics (e.g., mean, standard deviation), are represented in the harborwide stormwater data set. This concept is consistent with the JSCS process for identifying low, medium, and high priority sites. As illustrated conceptually in Figure C-1, these groups were defined in the conceptual site model (CSM) as follows:

- Group A: Lower analyte concentrations (CSM assumes lower concentrations likely associated with open space or residential land uses);
- Group B: Moderate analyte concentrations (CSM assumes moderate concentrations likely associated with commercial or light industrial land uses); and
- Group C: Higher analyte concentrations (CSM assumes higher concentrations likely associated with heavy industrial land use).

A Bayesian finite mixture model was used in the analyses. The Bayesian methodology employed was selected to explicitly model results below the MRL using censored data methods. The use of a Bayesian model eliminated the need to use a substitution method for including concentrations below the MRL, such as replacing such values with ½ the detection limit.

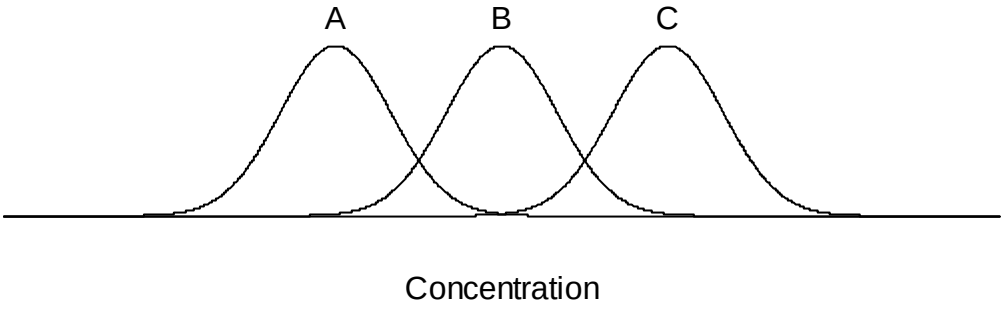

Figure C-1. Mixture Model Assumed Groups.

Assumptions included in the conceptual model for the finite mixture model include:

- Stormwater concentration data from each outfall basin are lognormally distributed with a different logarithmic mean concentration (i.e., geometric mean) and the same log standard deviation (i.e., geometric standard deviation) for each basin.
- At least one outfall basin in each of these groups for each analyte is evaluated.
- A high degree of variability exists in the stormwater data set, related to factors including the following:

  - Characteristics of the outfall basins in this study vary widely, ranging from basins that primarily represent heavy industrial land uses to basins that represent mostly forest and open space.
  - A number of pollutants evaluated may have numerous sources (e.g., upland sites, source materials) and characteristics (e.g., concentrations, source material media, transport pathways).
- Grab and flow-weighted composite data are both representative of basin discharges and can be combined to estimate of the "true mean" concentration of the outfall basin.
- There is no known bias in the data set.

C4.1.2 Technical Model Description

This section provides a technical summary of the Bayesian finite mixture model used to evaluate the stormwater data set. Simplistically, the model can be written in the following form:

$$\log(y_{ij}) \sim N(\mu_j, \sigma_y^2),$$
$$\mu_j \sim N(\boldsymbol{\theta}^T \mathbf{m}_j, \sigma_\mu),$$
$$\mathbf{m}_j \sim Multinomial(1, \boldsymbol{\lambda})$$

Where:

y_{ij} represents the i^{th} sample result from outfall basin j

μ_j represents the mean concentration of the natural logarithms of the sample results from outfall basin j which are assumed to be normally distributed

σ^2_y represents the variance of the natural logarithms of the sample results from outfall basin j which are normally distributed with mean μ_j and variance σ_y^2

$\boldsymbol{\theta}^T$ represents the vector of group mean concentrations.

$\mathbf{m}_j$ represents the choice of whether the basin mean μ_j is from subpopulation (group) A, B, or C.

$\boldsymbol{\lambda}$ represents the vector of probabilities that the basin mean comes subpopulation (group) A, B, or C.

Thus, the natural logarithms of the sample results from outfall basin j are normally distributed with mean μ_j and variance σ_y^2 (Note: the variance was assumed to be the same for every basin). The variation among basins is handled by modeling the basin means (μ_j) as a three-component normal mixture model, as described in Section C4.1.1. The vector $\boldsymbol{\theta}$ is a three-dimensional random vector (a vector with three components) containing the subpopulation means (i.e., group means θ_1, θ_2, and θ_3). The vector $\boldsymbol{\lambda}$ is a three dimensional random vector containing the overall probabilities that an outfall basin mean concentration is from subpopulation one (i.e., Group A), two (i.e., Group B), or three (i.e., Group C). The variance of each subpopulation is assumed to be the same and is modeled with a common variance parameter (σ_y^2).

The multinomial distribution is a multivariate version of the binomial distribution. For this model, the multinomial vector $\mathbf{m}_j$ represents the unobserved "label" that determines which subpopulation (lower, moderate, or higher concentration) each basin was drawn from. The product $\boldsymbol{\theta}^T\mathbf{m}_j$ (dot or inner product of the vectors) is a single value equal to the subpopulation means (θ_1, θ_2, or θ_3). To make the model numerically stable and to prevent the "label switching" problem common in fitting mixture models, two positive random variables: the difference in mean concentrations for subpopulations one and two (θ_{dist12}) and the difference in mean concentrations for subpopulations two and three (θ_{dist23}) were introduced as follows:

$$\theta_2 = \theta_1 + \theta_{dist12}$$
$$\theta_3 = \theta_2 + \theta_{dist23}$$

In this way, the model can enforce the conceptual model constraint that $\theta_1 < \theta_2 < \theta_3$ (mean of Group A is less than the mean of Group B, etc.)

Draws from the posterior distribution of model parameters were generated using Markov chain Monte Carlo with the software WinBUGS (Lunn et al., 2000), R (R Development Core Team, 2009), and R2WinBUGS (Sturtz et al., 2005). Vague priors (i.e., initial model inputs) were used in the model for θ_1, $\boldsymbol{\lambda}$, σ_y and σ_μ. Priors for θ_{dist12} and θ_{dist23} were half-normal distributions with mean 0 and variance 10. The assumed prior distributions were used to constrain the distances between subpopulation means (θ_1, θ_2, and θ_3) such that extremely large differences between these values are unlikely. This prevents the estimated proportion of the population in one of the groups from approaching zero during the simulation. The fit of the model was obtained by attempting to match the model results with the parameterized subpopulation distributions used in the set up of WinBUGS. Five chains of 40,000 samples each were run for each analyte. The first half (20,000 samples) of each chain were discarded as the burn-in period. Every 100th sample was selected from each of the five chains (for a total of 1,000 samples), to estimate the $\hat{R}$ statistic (Gelman and Rubin, 1992) calculated using the R *coda* package (Plummer et al., 2009) to monitor convergence of the samples. The simulation was determined to converge when all $\hat{R} < 1.1$ for all parameters of interest (Gelman et al., 2004).

C4.2 Statistical Evaluation Results

The finite mixture model evaluated group membership for each outfall basin sampled for each of the 22 analytes identified in Section C3.2. For each analyte, the model assigned each outfall basin within the harborwide data set to one of the three concentration groups (i.e., A - lower, B - moderate, or C - higher) based on the posterior probabilities of the basin belonging to each group. These posterior probabilities were calculated by averaging the simulated values of $\mathbf{m}_j$ for each basin and selecting the group with the largest posterior probability as the predicted group for that basin.

Attachment C3 presents figures depicting the results the harborwide statistical evaluation by analyte. These figures rank the harborwide outfall concentrations by the basin geometric mean concentrations for each analyte. The figures include the concentrations of the individual

sampling events and the geometric mean concentration for each basin. For each analyte, the figures identify the group assigned by the mixture model for each outfall by color [blue (Group A), black (Group B), red (Group C)]. Figure C-2 provides a key to results.

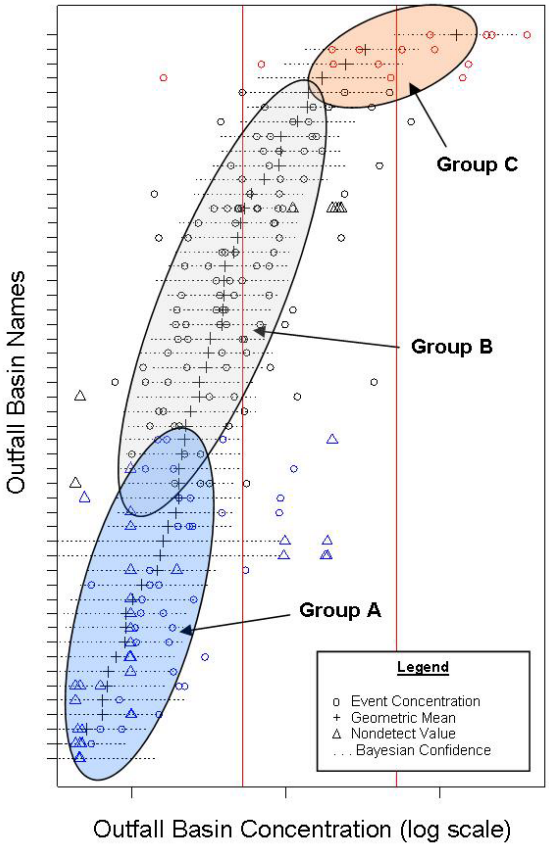

Figure C-2. Key to Basin Mixture Model Results.

C4.3 Model Uncertainties

The finite mixture model was built to reflect the City's conceptual model of stormwater basin discharge concentrations (see Section C4.1.1). There are many assumptions associated with the development of the conceptual model and the mathematical model used for the analysis of this stormwater dataset. A summary of uncertainties in the statistical evaluation is provided below:

- The distribution and pattern of stormwater analyte concentrations may be much more complicated than observed. For example, the analyte distribution plots, presented in Attachment C3, often do not show distinct breaks between subpopulations (i.e., groups), but rather a continuous spread of concentrations. This indicates the use of a three-component model may be an oversimplification of a much more complex system. However, the three-component model is useful as a data driven method for identifying groups of basins that are most similar in order to simplify a complex system for policy purposes (i.e., source tracing).

- Stormwater sample results for individual sampling events are assumed to be random samples of the underlying distribution of analyte concentrations in each outfall basin.

To the extent that these samples are not random, they may provide a biased view of the conditions in each basin.

- The model fits well enough to represent the stormwater data set for the purpose of identifying basins for consideration of additional source tracing activities. Inferences obtained from a faulty or ill fitting model may be misleading. There is no gross evidence of lack of fit in the model for the analytes evaluated. However, some variances were noted. For example, the stormwater sample concentrations from one non-City outfall were noted to be more variable than concentrations in other outfall basins; all four copper concentrations in this basin were outside the model estimated 95% confidence intervals for copper. The chance for this condition to have occurred randomly if the variances were the same in each basin is small. It is more likely that the variance of analyte concentrations varies from basin to basin according to other factors. However, investigating factors (grab versus composite sampling, size of basin) that might affect concentration variance did not reveal any way to explain this excess variance in some basins. In addition, the problem seems to affect a small number of basins, with most basins having variability that is consistent from basin to basin.

- In the model, composite and grab samples are pooled to calculate geometric mean concentrations within each basin. This pooling assumes that grab and composite samples are identically distributed. This is unlikely to be true. For basins where grab and composite data were collected there does not appear to be a consistent difference in grab versus composite results. Therefore, this approach is not assumed to introduce significant error or bias for identifying City outfall basins for potential source tracing activities.

C5 Outfall Basin Categorization

Prior to performing the statistical evaluation, it was assumed that for most analytes the three groups would have natural breaks to distinguish them from each other, and then could be used to identify City outfall basins for further source tracing. While the initial application of the model accomplished the intended grouping function, there was significant overlap among the groups (i.e., group concentration ranges), and only a few outfalls were assigned to Group C (higher concentration group) for each analyte. One of the working assumptions when the statistical evaluation was initiated was that City outfalls identified as belonging to Group C (higher relative concentrations) would be further evaluated to determine if additional City source tracing activities were needed. While the application of the model accomplished the intended grouping of the harborwide outfalls, there was significant overlap among the groups (i.e., group concentration ranges), and only a few outfall basins were assigned to concentration Group C for each analyte. Consideration of only the upper group for source tracing may have excluded basins with significant unidentified sources. Therefore, additional statistical analysis was performed to categorize the City's outfall basins in the upper end of the concentration distribution to identify City outfall basins potentially needing further source tracing

Starting with the output from initial application of the mixture model, source tracing categories were defined by evaluating confidence limits for each of the three outfall groups initially defined by the model. Table 4-2 of the *Stormwater Evaluation Report* summarizes the source tracing categorization results by City outfall basin and by analyte.

For each analyte included in the statistical evaluation, each outfall basin is assigned to one of three source tracing categories defined by the 50th percentile confidence interval of concentration Group C. Category break lines are shown on the figures included in Attachment C3, and Figure C-3 provides a key of the categorization results. The statistical model assigned outfall basins to groups and categories, based on the distribution of harborwide outfall concentrations and without consideration of JSCS SLVs or background concentrations. Therefore, care should be taken in the use of the groups and categories, and the categories should not be perceived as an indication of potential threat to the river, or the need or priority for source control.

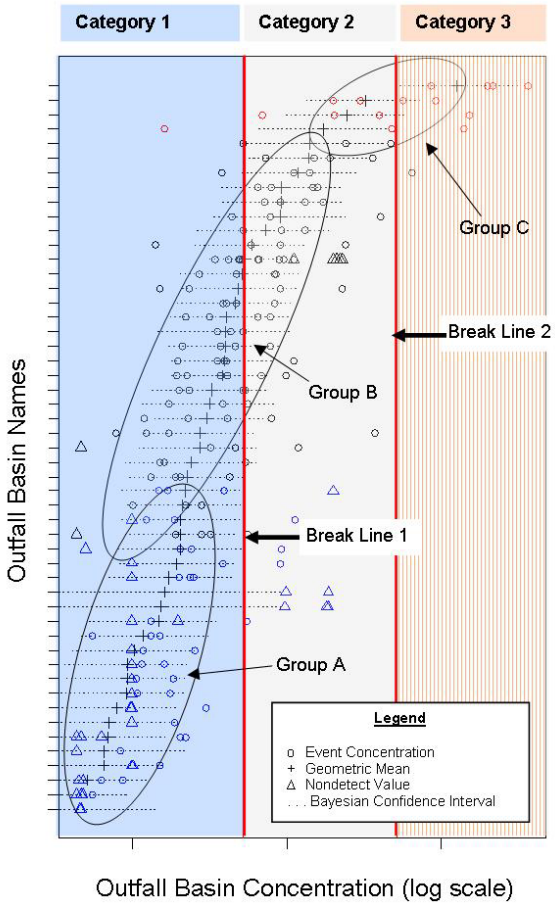

Figure C-3. Key to Basin Categorization Results. Three categories are defined to identify outfalls for further source tracing activities. Category break lines are based on concentration Group C confidence intervals.

Source tracing category definitions are provided below:

- **Category 1**. This category is defined as those outfalls with geometric mean concentrations less than or equal to the concentration of Break Line 1 shown on the figures presented in Attachment C3 (see Figure C-3). Break Line 1 represents the 25th percentile line of Group C (red) (i.e., 25% percent of the Group C outfalls theoretically fall below this line or 75% percent of Group C outfalls theoretically fall above this line). *Significance*: Stormwater analyte concentrations in these basins are lower relative to stormwater concentrations harborwide (i.e., relative to other private and public outfalls) and are least likely to have significant unidentified sources. The need for performing additional source tracing in City outfall basins within Category 1 basins is low.
- **Category 2**. This category is defined as those outfalls with geometric mean concentrations greater than the concentration of Break Line 1 and less than or equal to the concentration of Break Line 2 shown on the figures presented in Attachment C3 (see Figure C-3). Break Line 2 represents the 75th percentile line of Group C (i.e., 75% percent of the Group C (red) outfalls theoretically fall below this line or 25% percent of Group C outfalls theoretically fall above this line). *Significance*: Stormwater analyte concentrations in these basins generally fall within a narrow moderate range and may or

may not have significant unidentified sources. The need for performing additional source tracing in City outfall basins within this category should be considered, unless otherwise indicated.

- **Category 3**. This category is defined as those outfalls with geometric mean concentrations greater than the concentration of Break Line 2 shown on the figures presented in Attachment C3. Break Line 2 represents the 75th Percentile line of Group C (red) (i.e., 25% percent of the Group C (red) outfalls theoretically fall above this line). *Significance*: Stormwater analyte concentrations in these basins are higher relative to harborwide concentrations presented in this report and are the most likely to have significant unidentified sources. The need for performing additional source tracing in City outfall basins in this category should be considered.

Table C-2 summarizes the distribution of source tracing categories by major analyte type for City outfall basins. As indicated in Table C-2, for each analyte, a predominance of the basins were as assigned to Category 1 and less than a third were as assigned to Category 2. Three basins had analytes identified as Category 3:

- OF 22B – cadmium
- OF 22C – acenaphthene
- OF S-1 – fluoranthene and total PAHs

Table C-2. Summary City Outfall Basin Source Tracing Categorization for Selected Analytes (1)

Category	Definition	Percent of City Outfall Basins Assigned to Category (by analyte)		
		Total PCBs (2	**PAHs** (2, 3)	**Metals** (2, 4)
1 (lower)	Least Likely to Have Unidentified Significant Sources	64 %	80 %	69 %
2 (moderate) (5)	May or May Not Have Unidentified Significant Sources	36 %	27 %	31 %
3 (higher) (5)	Most Likely to Have Unidentified Significant Sources	0 %	1 %	1 %

Notes:

(1) Categories ≠ Risk. Categories are based on distribution of harborwide concentrations and without consideration of the significance of the outfall basin concentration (i.e., greater than or less than applicable screening levels, background concentrations, etc.).

(2) The percentage of City Outfalls within each category was estimated by combining the results for outfalls with multiple locations (OF M1, OF M2). For these outfalls the higher category was used. The results representative of Forest Park (OF 22C – Tualatin Hills) were not included in the results presented in this table.

(3) The percentage of City Outfalls within each category for PAHs is based on the cumulative results of the thirteen individual PAHs presented in Table 4-2 of the *Stormwater Evaluation Report.*

(4) The percentage of City Outfalls within each category for metals is based on the cumulative results of the six individual metals presented in Table 4-2 of the *Stormwater Evaluation Report.*

(5) Use of the full harborwide data set allowed stormwater concentrations in City Outfall basins to be ranked and evaluated relative to other stormwater discharges to the Portland Harbor Study Area. City outfall basins with analyte concentrations potentially in the upper range of the concentration distribution were identified for further evaluation of the need source tracing.

Attachment C1

Bar Graphs of Results (Simple Averages) for Selected Contaminants, 2007 – 2008 City Outfall Stormwater Data

Attachment C1 -- Notes

General notes regarding figures showing analyte concentrations in stormwater discharging to Portland Harbor Study Area:

(1) Section 3 and Table 3-1 of the *Stormwater Evaluation Report* (BES, 2010) presents the sources of data used in these figures. Appendix C presents the assumptions and data used in calculating the arithmetic mean concentrations for outfall basins presented on these figures. Appendix D presents the individual analyte data used in calculating the mean concentration for City outfall basins. The mean concentrations shown on these figures differ from those presented in Appendix D in the way non-detected (ND) values were used in the calculations. For these figures, ND values were set to zero and in Appendix D, ND values were set to the analytical method reporting limit (MRL).

(2) Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin arithmetic mean concentrations shown on these figures.

(3) Flow-weighted composite and grab sample results from City and LWG/Port sampling activities are not combined in these figures; however, sampling locations utilized in two basins (i.e., OF 19 and OF 53) are representative of the same respective basin area. Paired sample locations include:
- OF 19 LW3 / OF 19 MS4 City
- OF 53 Port / OF 53 City

(4) Outfall basin sampling locations utilized by the City and the LWG in three basins (OF M-1, OF M-2, and OF 22C) represent different drainage areas. In each of these three basins, the City sampling location represents a larger drainage area that includes the drainage area evaluated by LWG. City sampling locations were selected to represent stormwater discharges from the entire basin, to the extent feasible. Flow-weighted composite and grab sample results from City and LWG sampling activities are not combined in these figures. Basins with multiple sample locations include:
- OF M-1
- OF M-2
- OF 22C

(5) Sample location nomenclature on X axis: Sample Location_Sampling Entity. Examples include:
- OF 45 City - indicates City Outfall Basin 45 sampled and analyzed by the City of Portland
- Sulzer LW3 – indicates private Sulzer outfall sampled and analyzed by the LWG
- WR183 Basin R Port – indicates private Port of Portland Outfall WR183 (also referred to as Basin R) sampled and analyzed by the Port.

(6) Total PAH and total PCB concentrations for results including one or more detections of individual PAH/PCB constituents were calculated by assigning a value of zero to non-detected concentrations. For results in which *no* individual PAH or PCB constituents

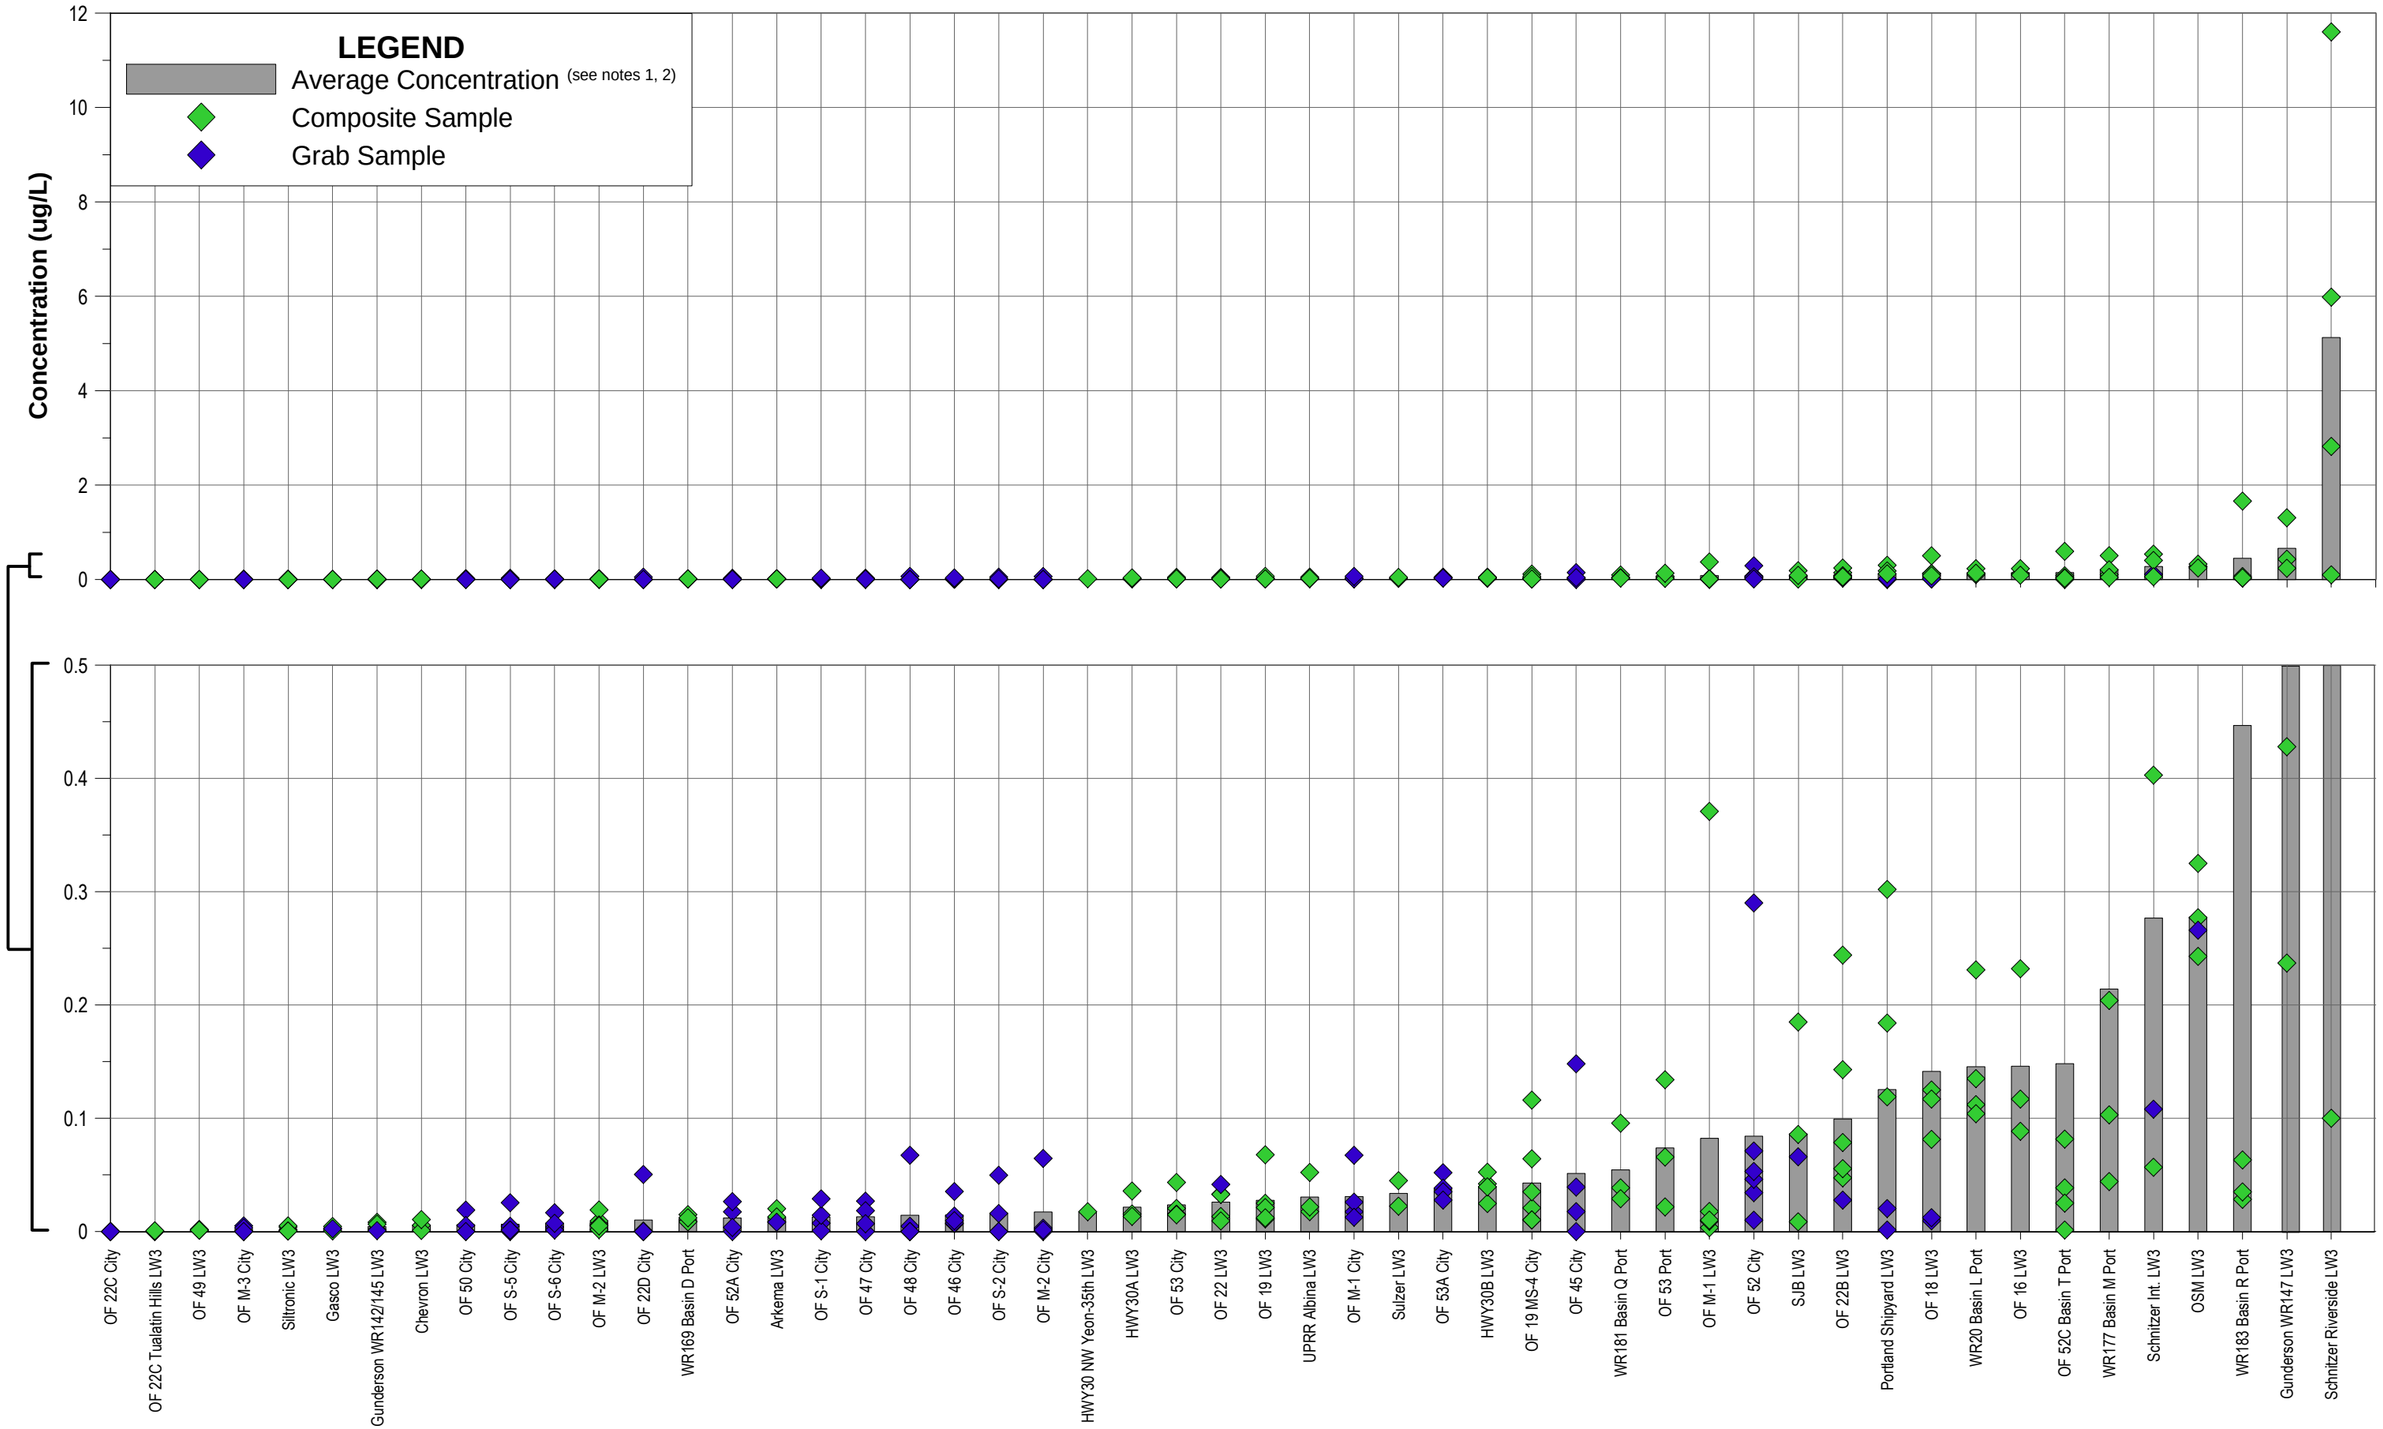
were detected, the total concentration is reported as the highest MRL among the individual PAH/PCB constituents.

Summary of Acronyms included on the figures:

ug/L = micrograms per liter
OF = City of Portland (City) outfall
LW3 = sample collected by the Lower Willamette Group (LWG) during the LWG's Round 3 stormwater sampling
Port = sample collected by the Port of Portland (Port)
SJB = outfall adjacent to St. Johns Bridge
MS4 = sample collected for the stormwater conveyance system discharge monitoring conducted under the City's NPDES Municipal Separate Storm Sewer System (MS4) Discharge Permit
WR = non-City outfall to the Willamette River

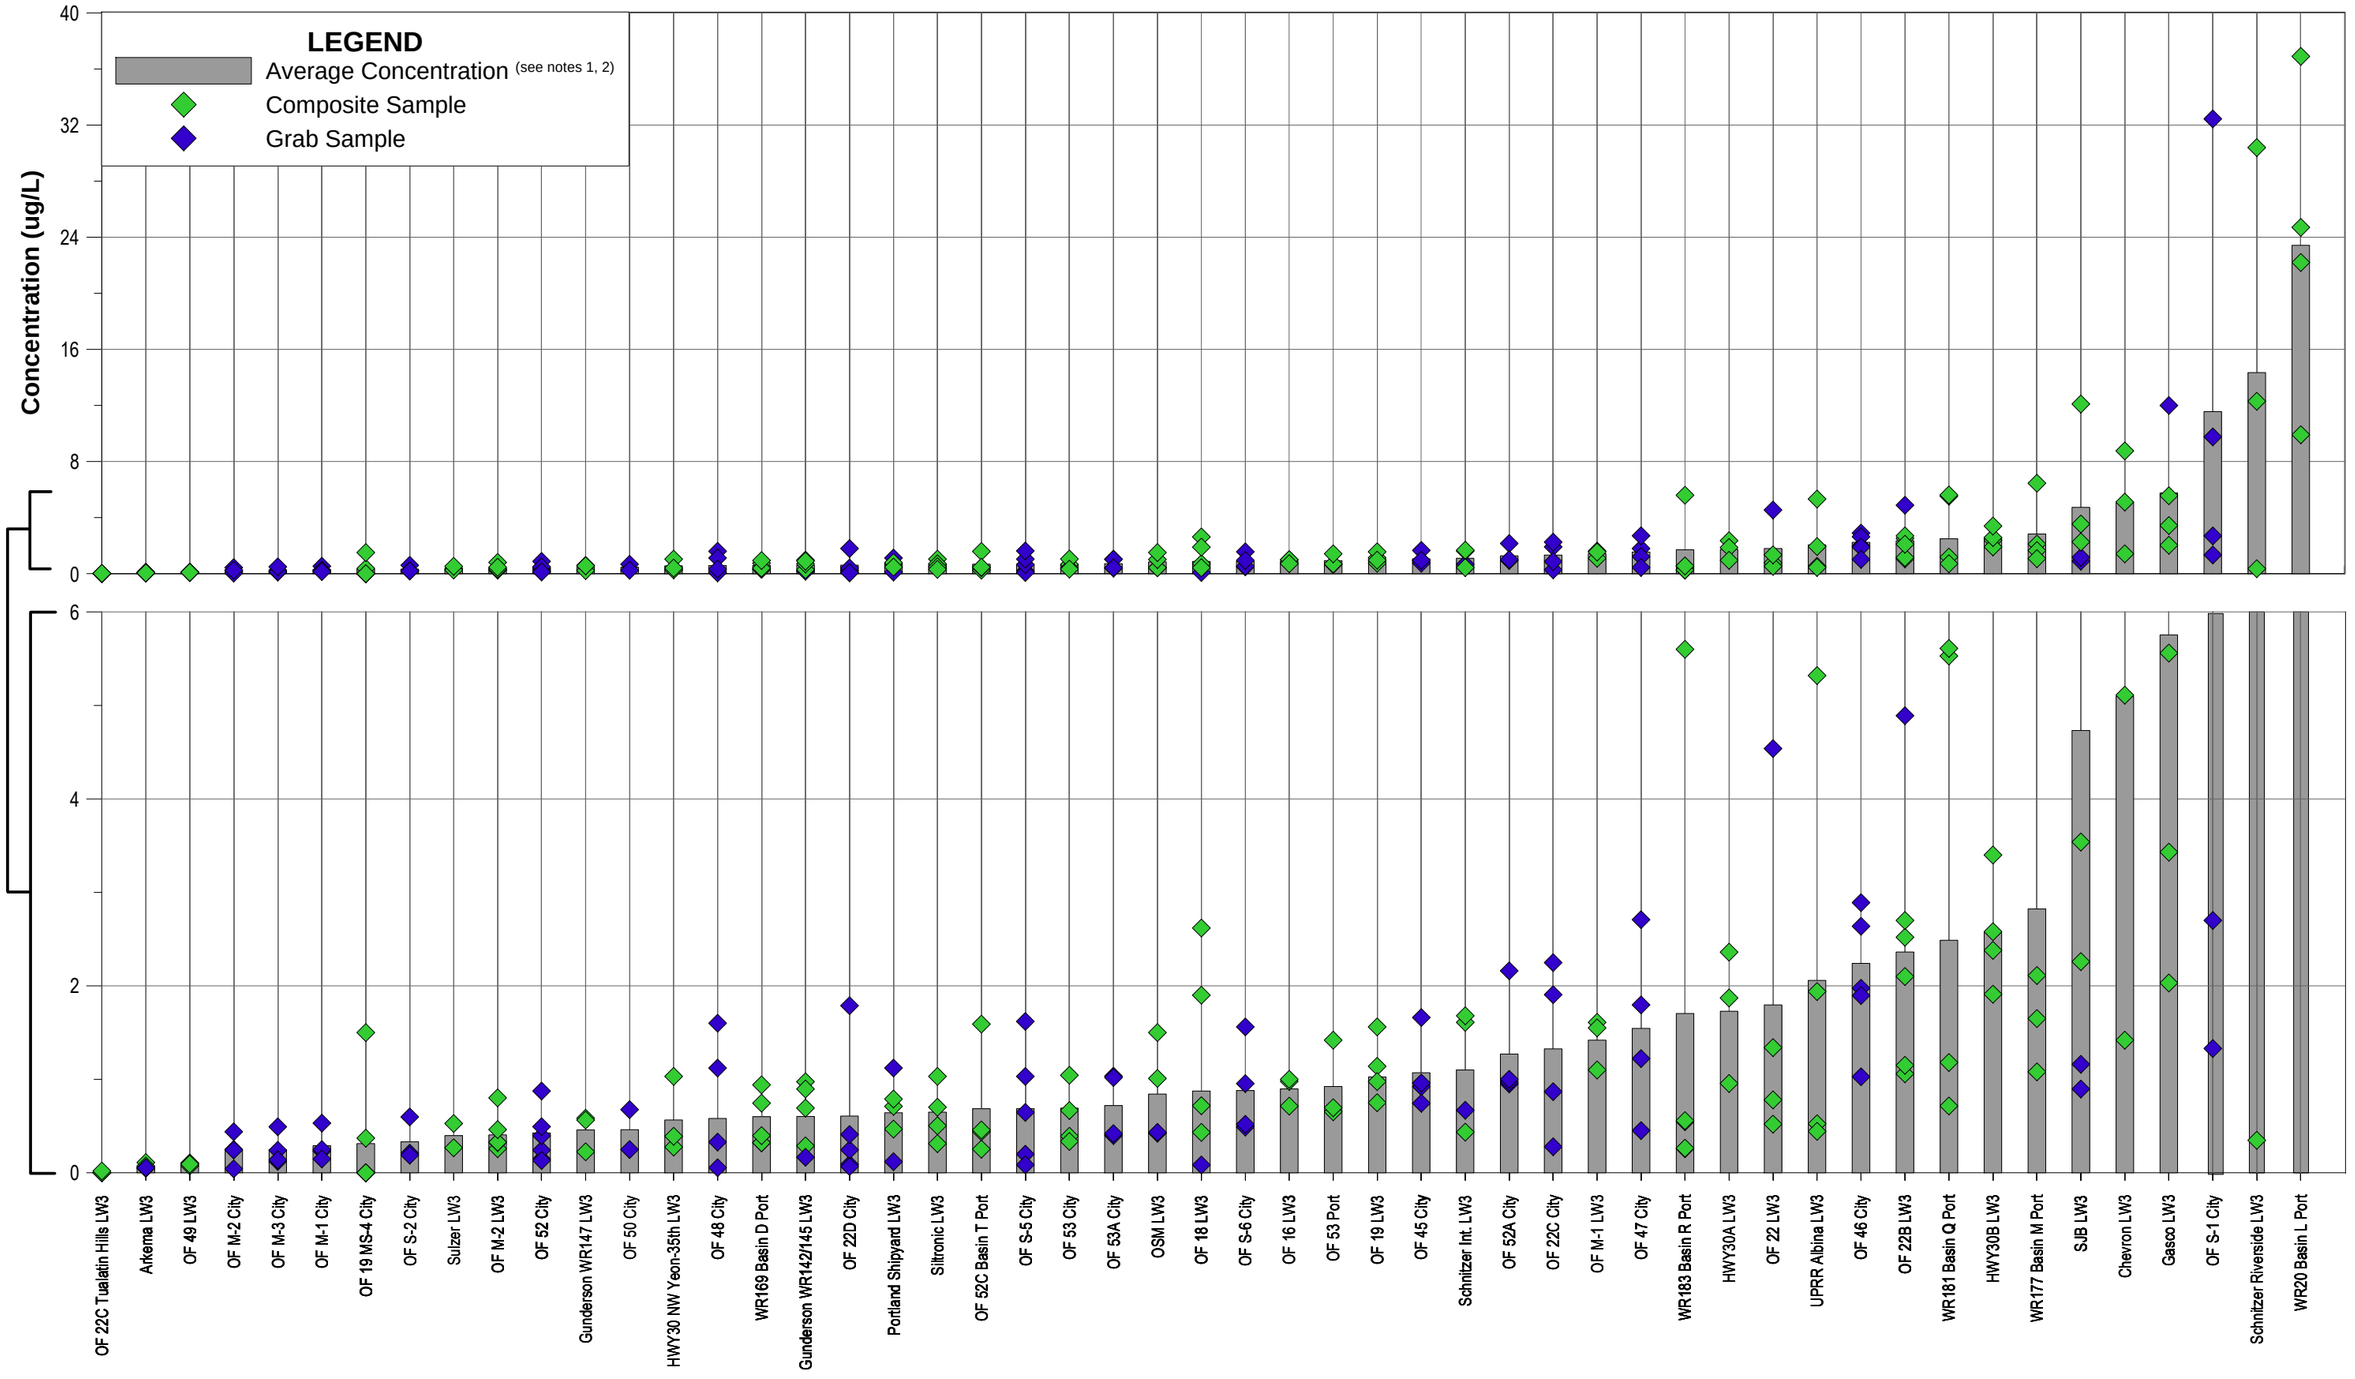
Total PCB Congeners Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



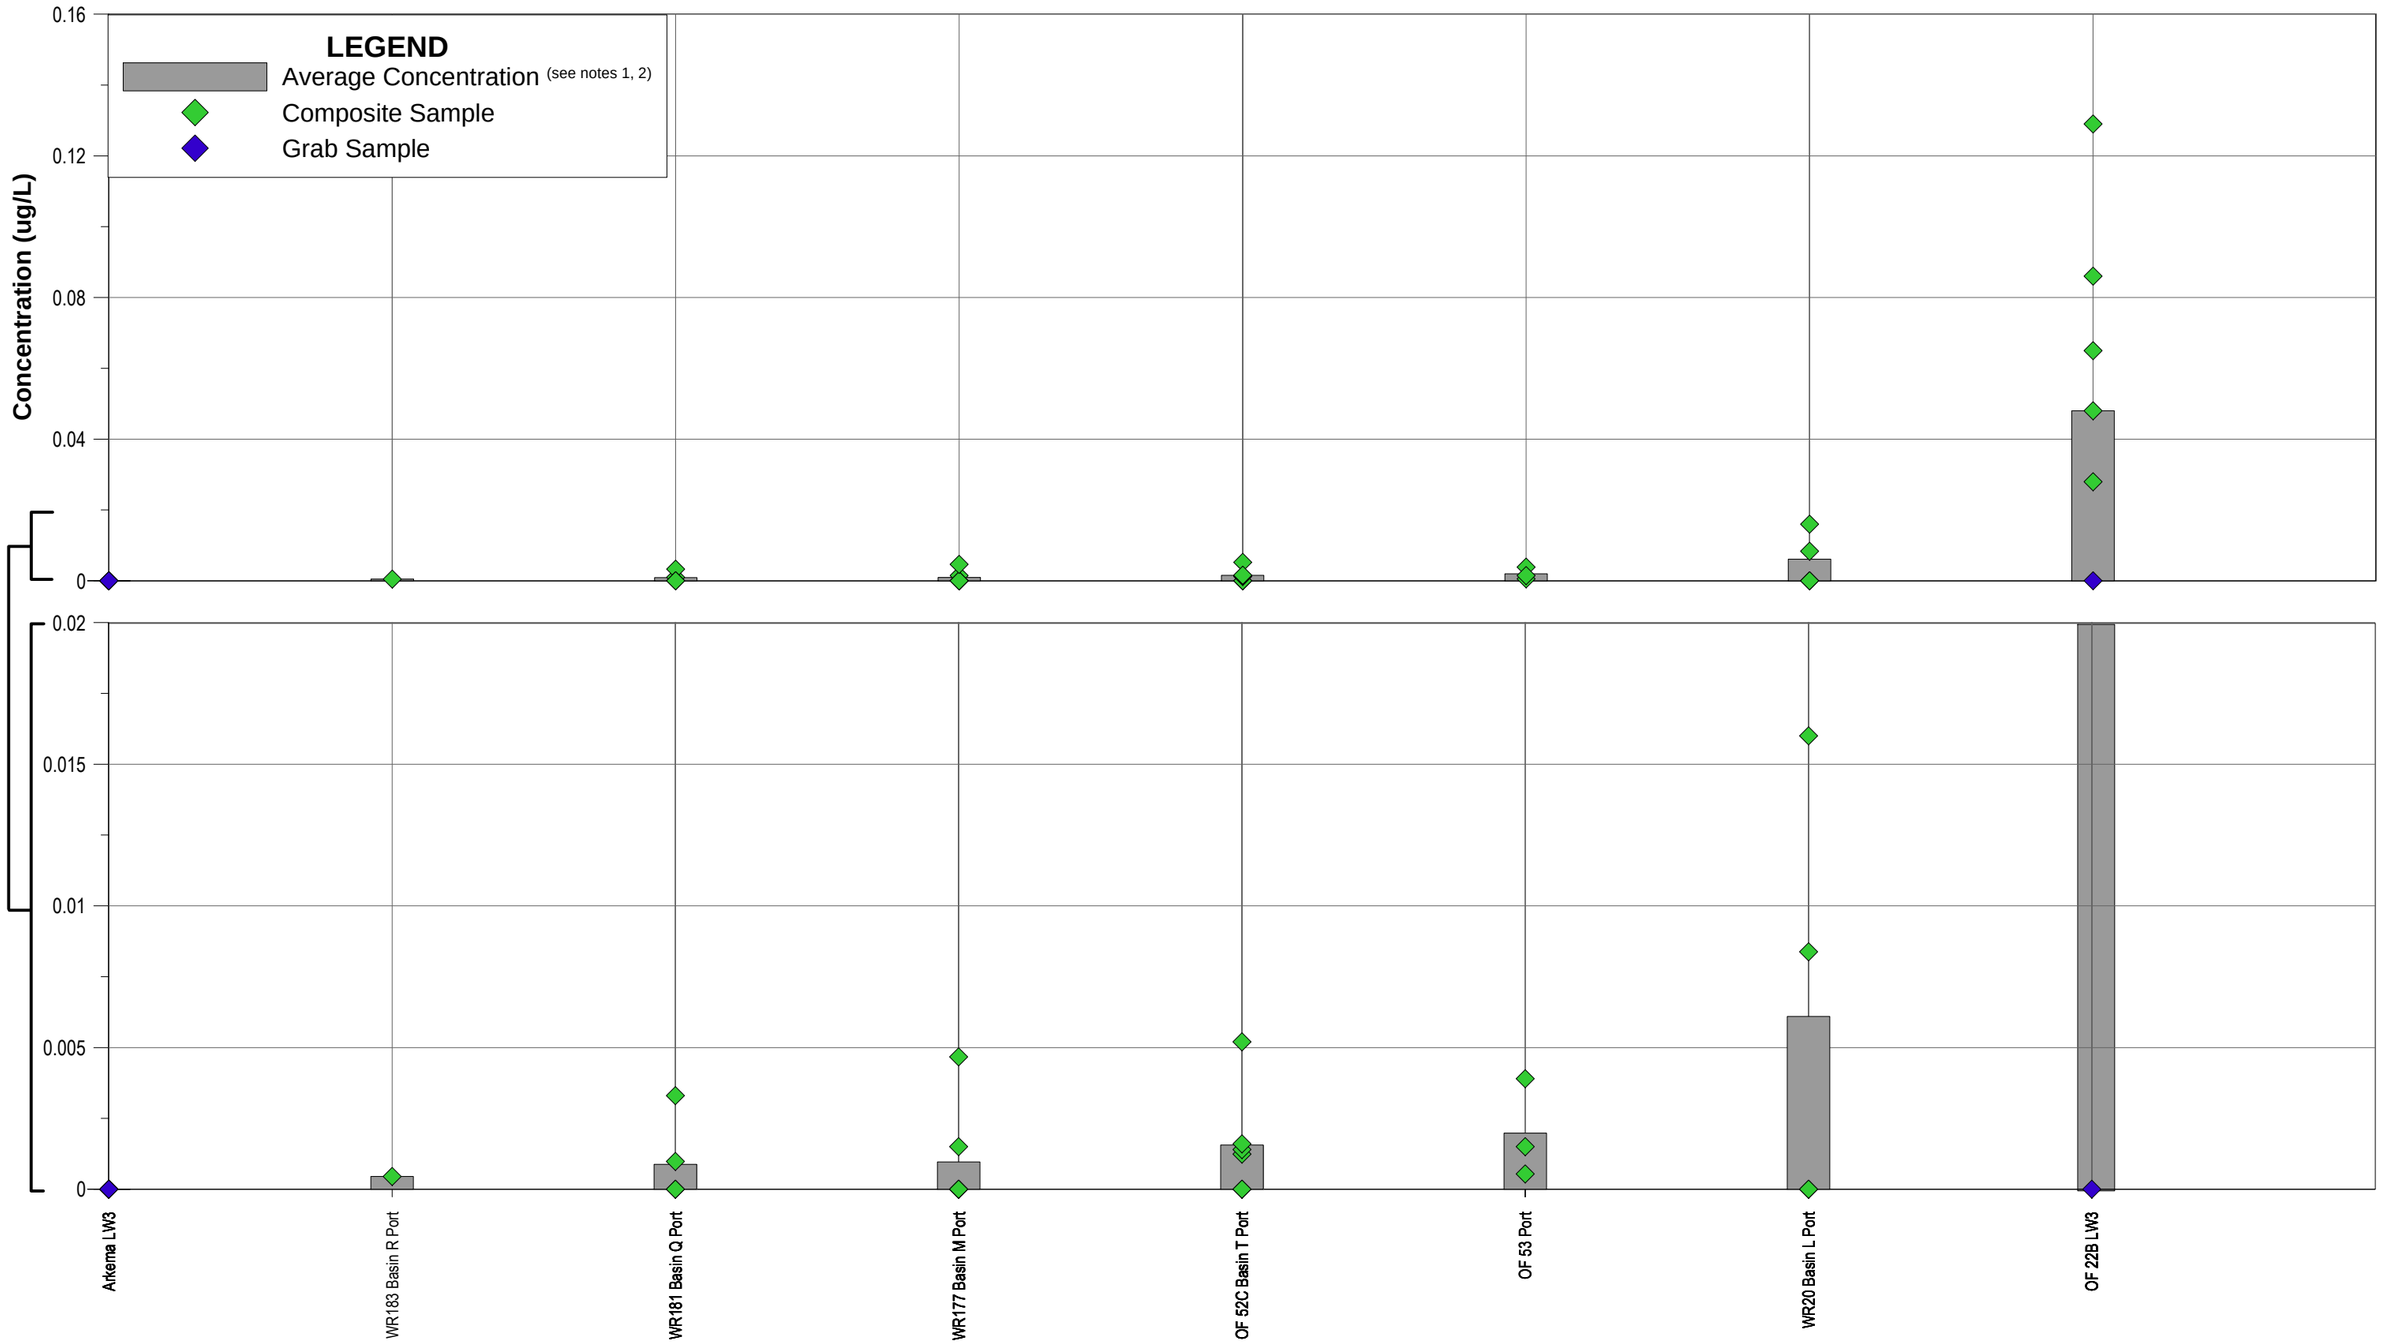
Total PAH Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



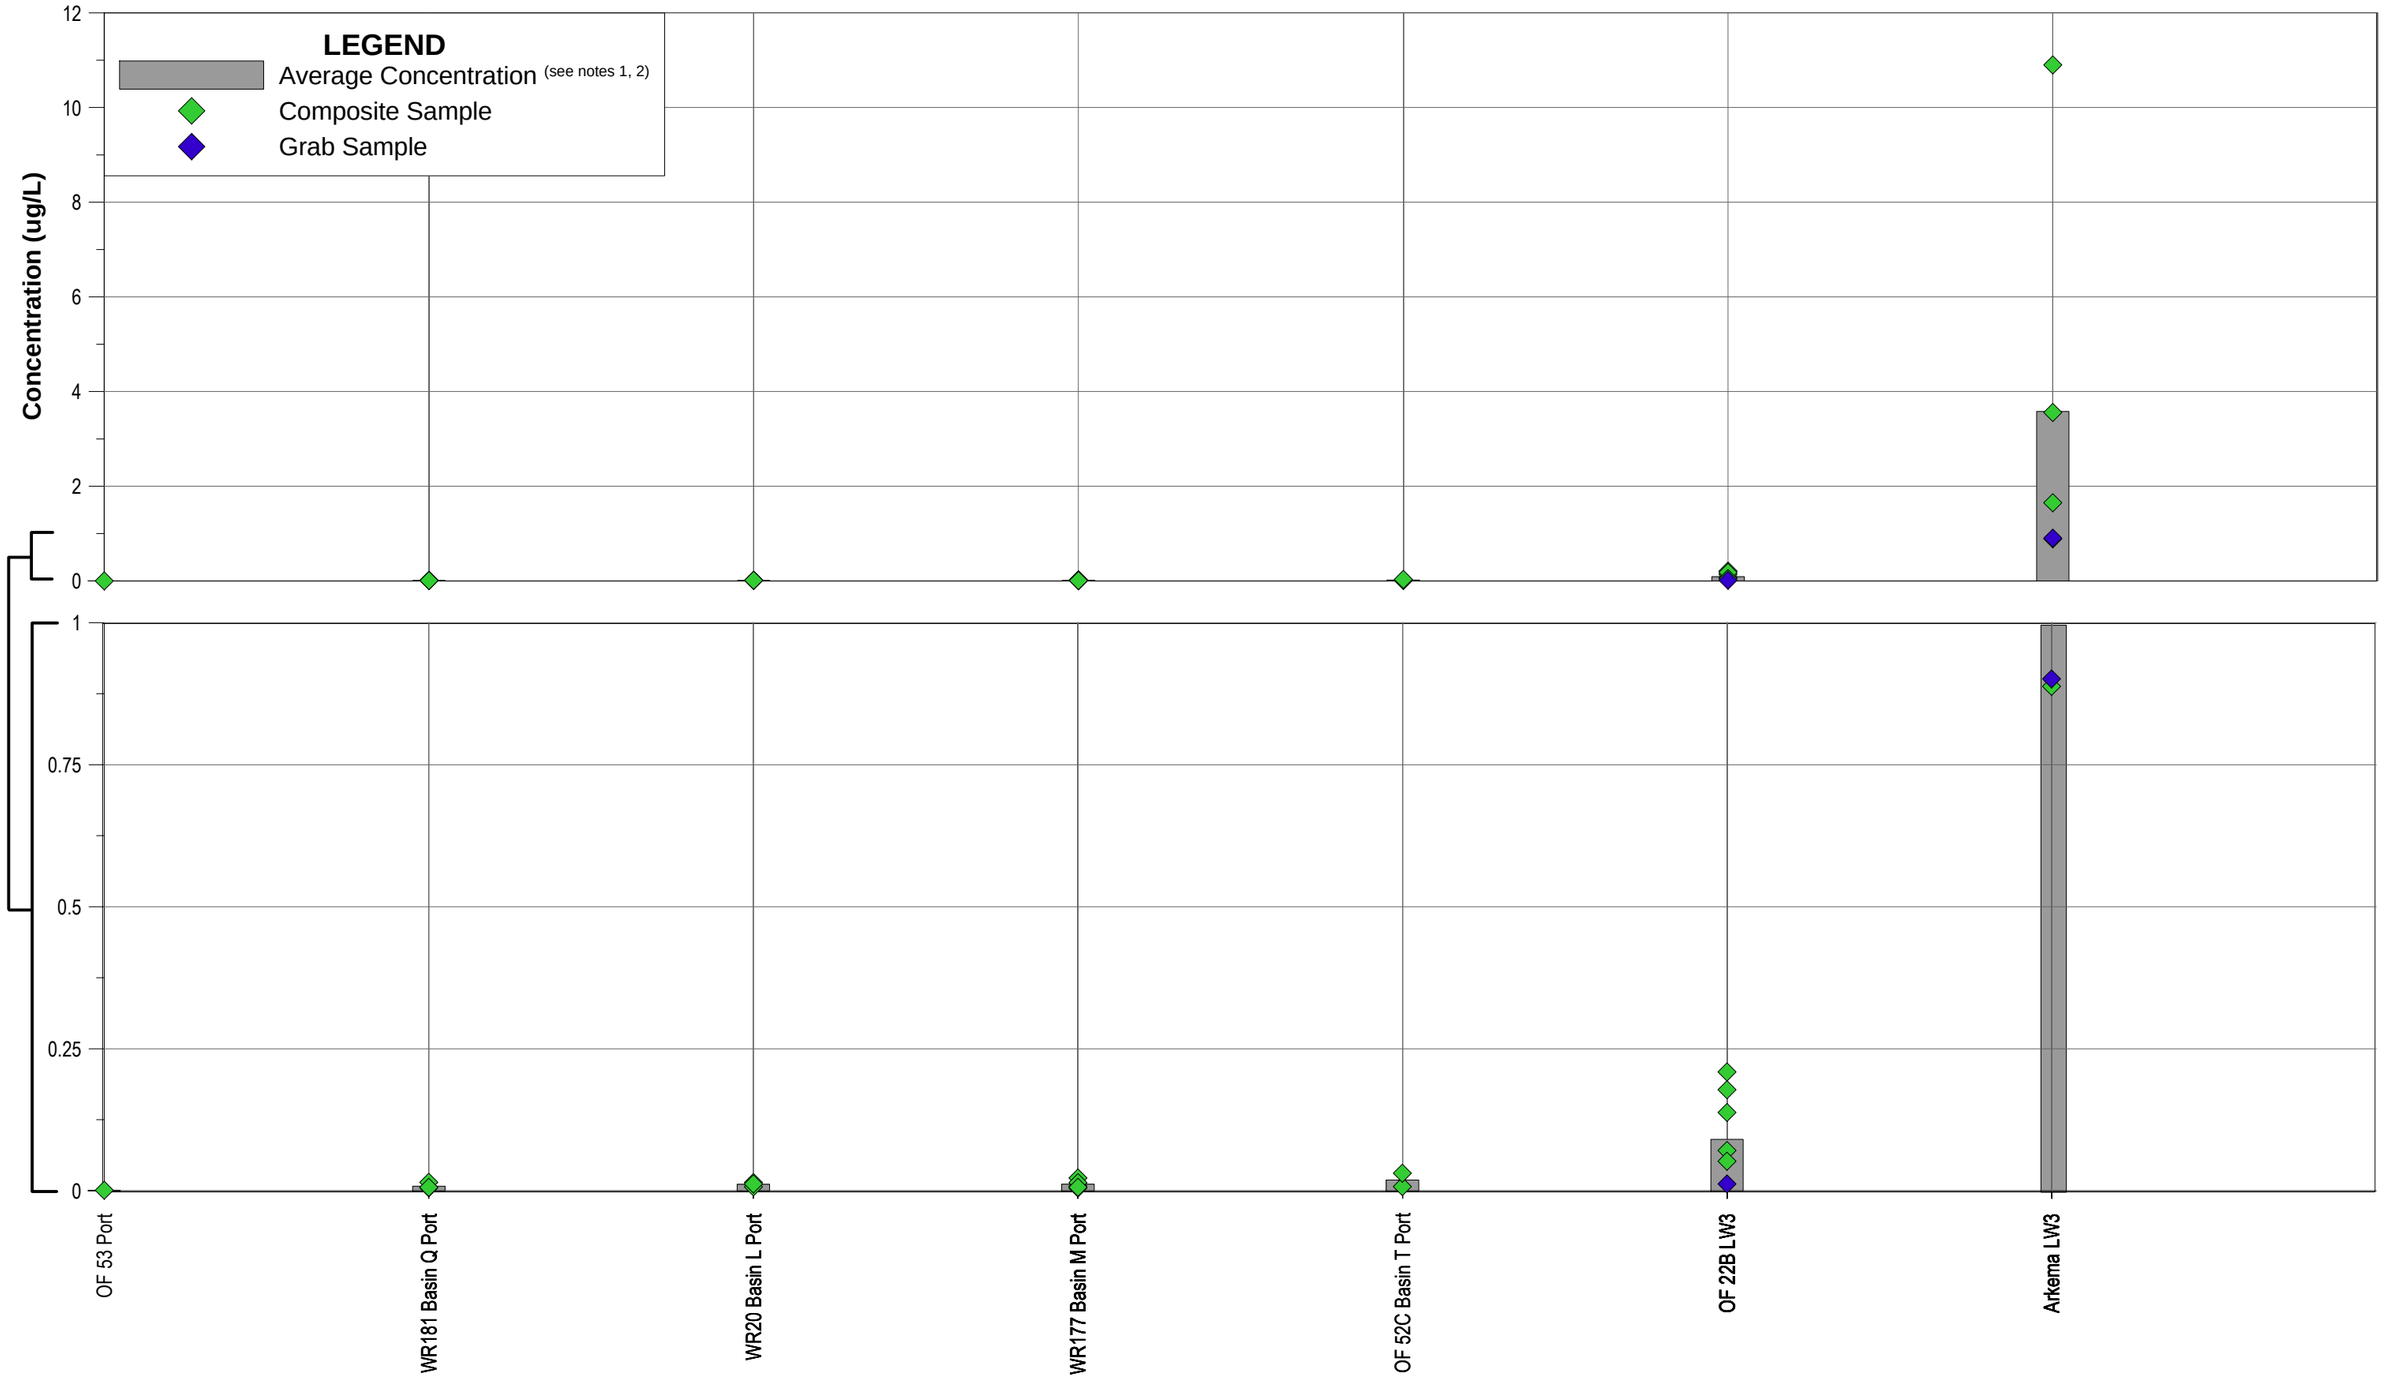
Total Chlordane Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



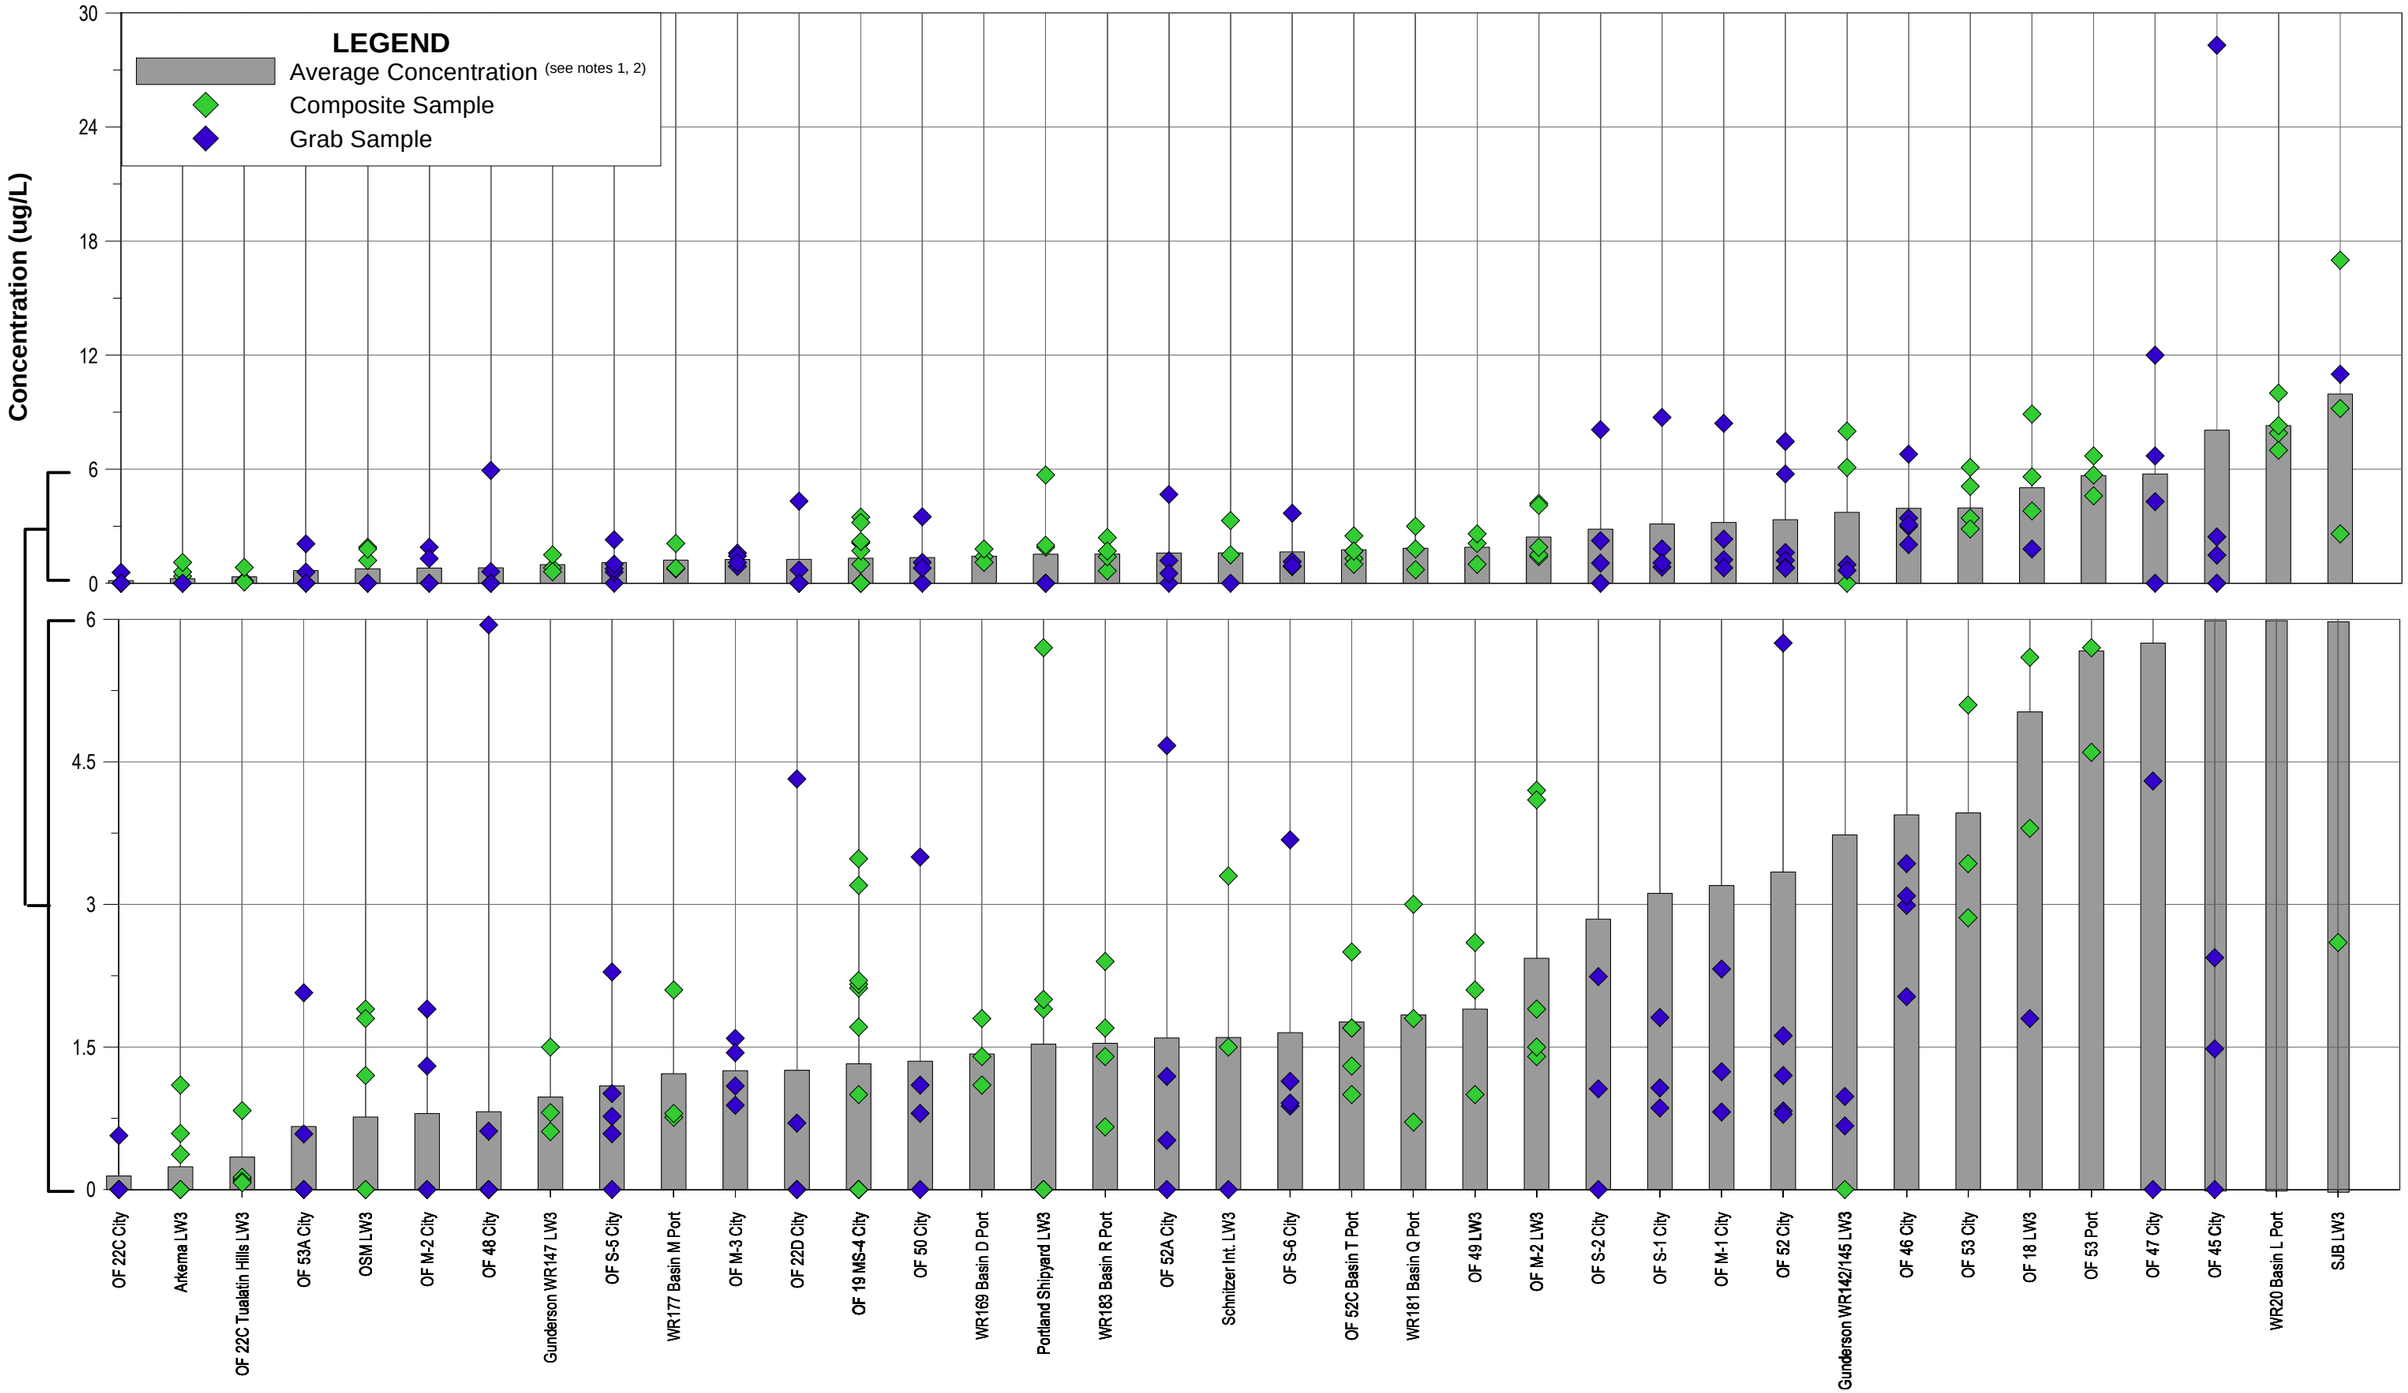
Total DDx Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



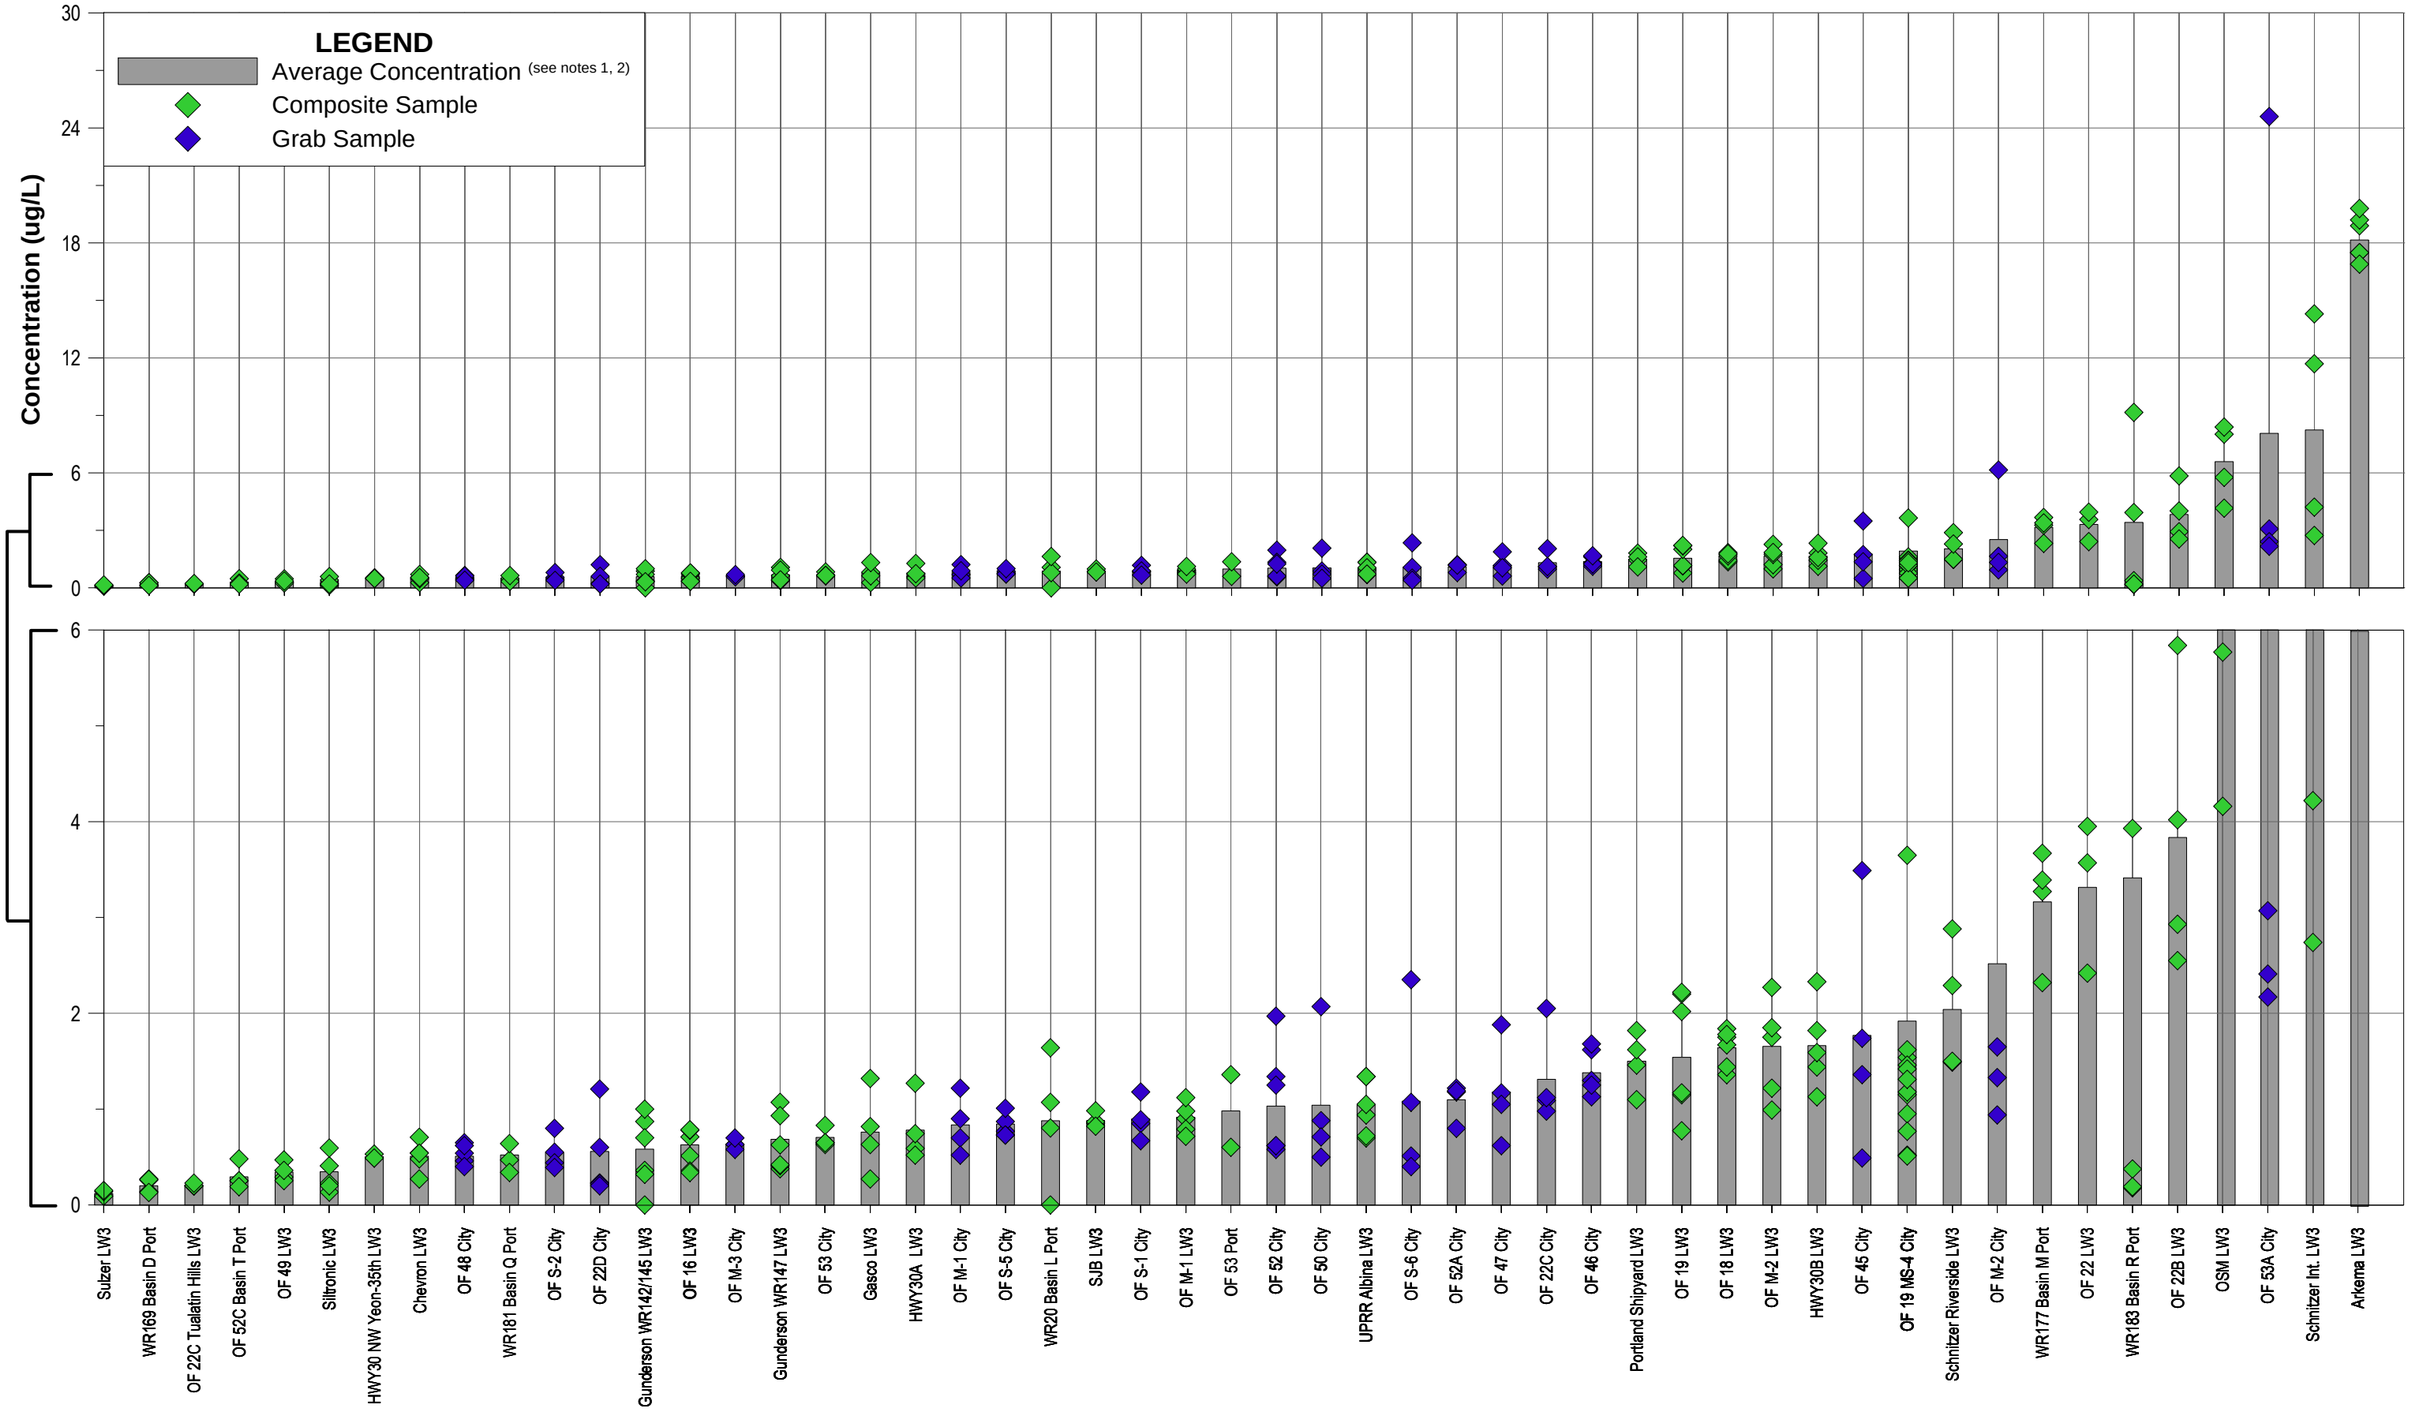
Total BEHP Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



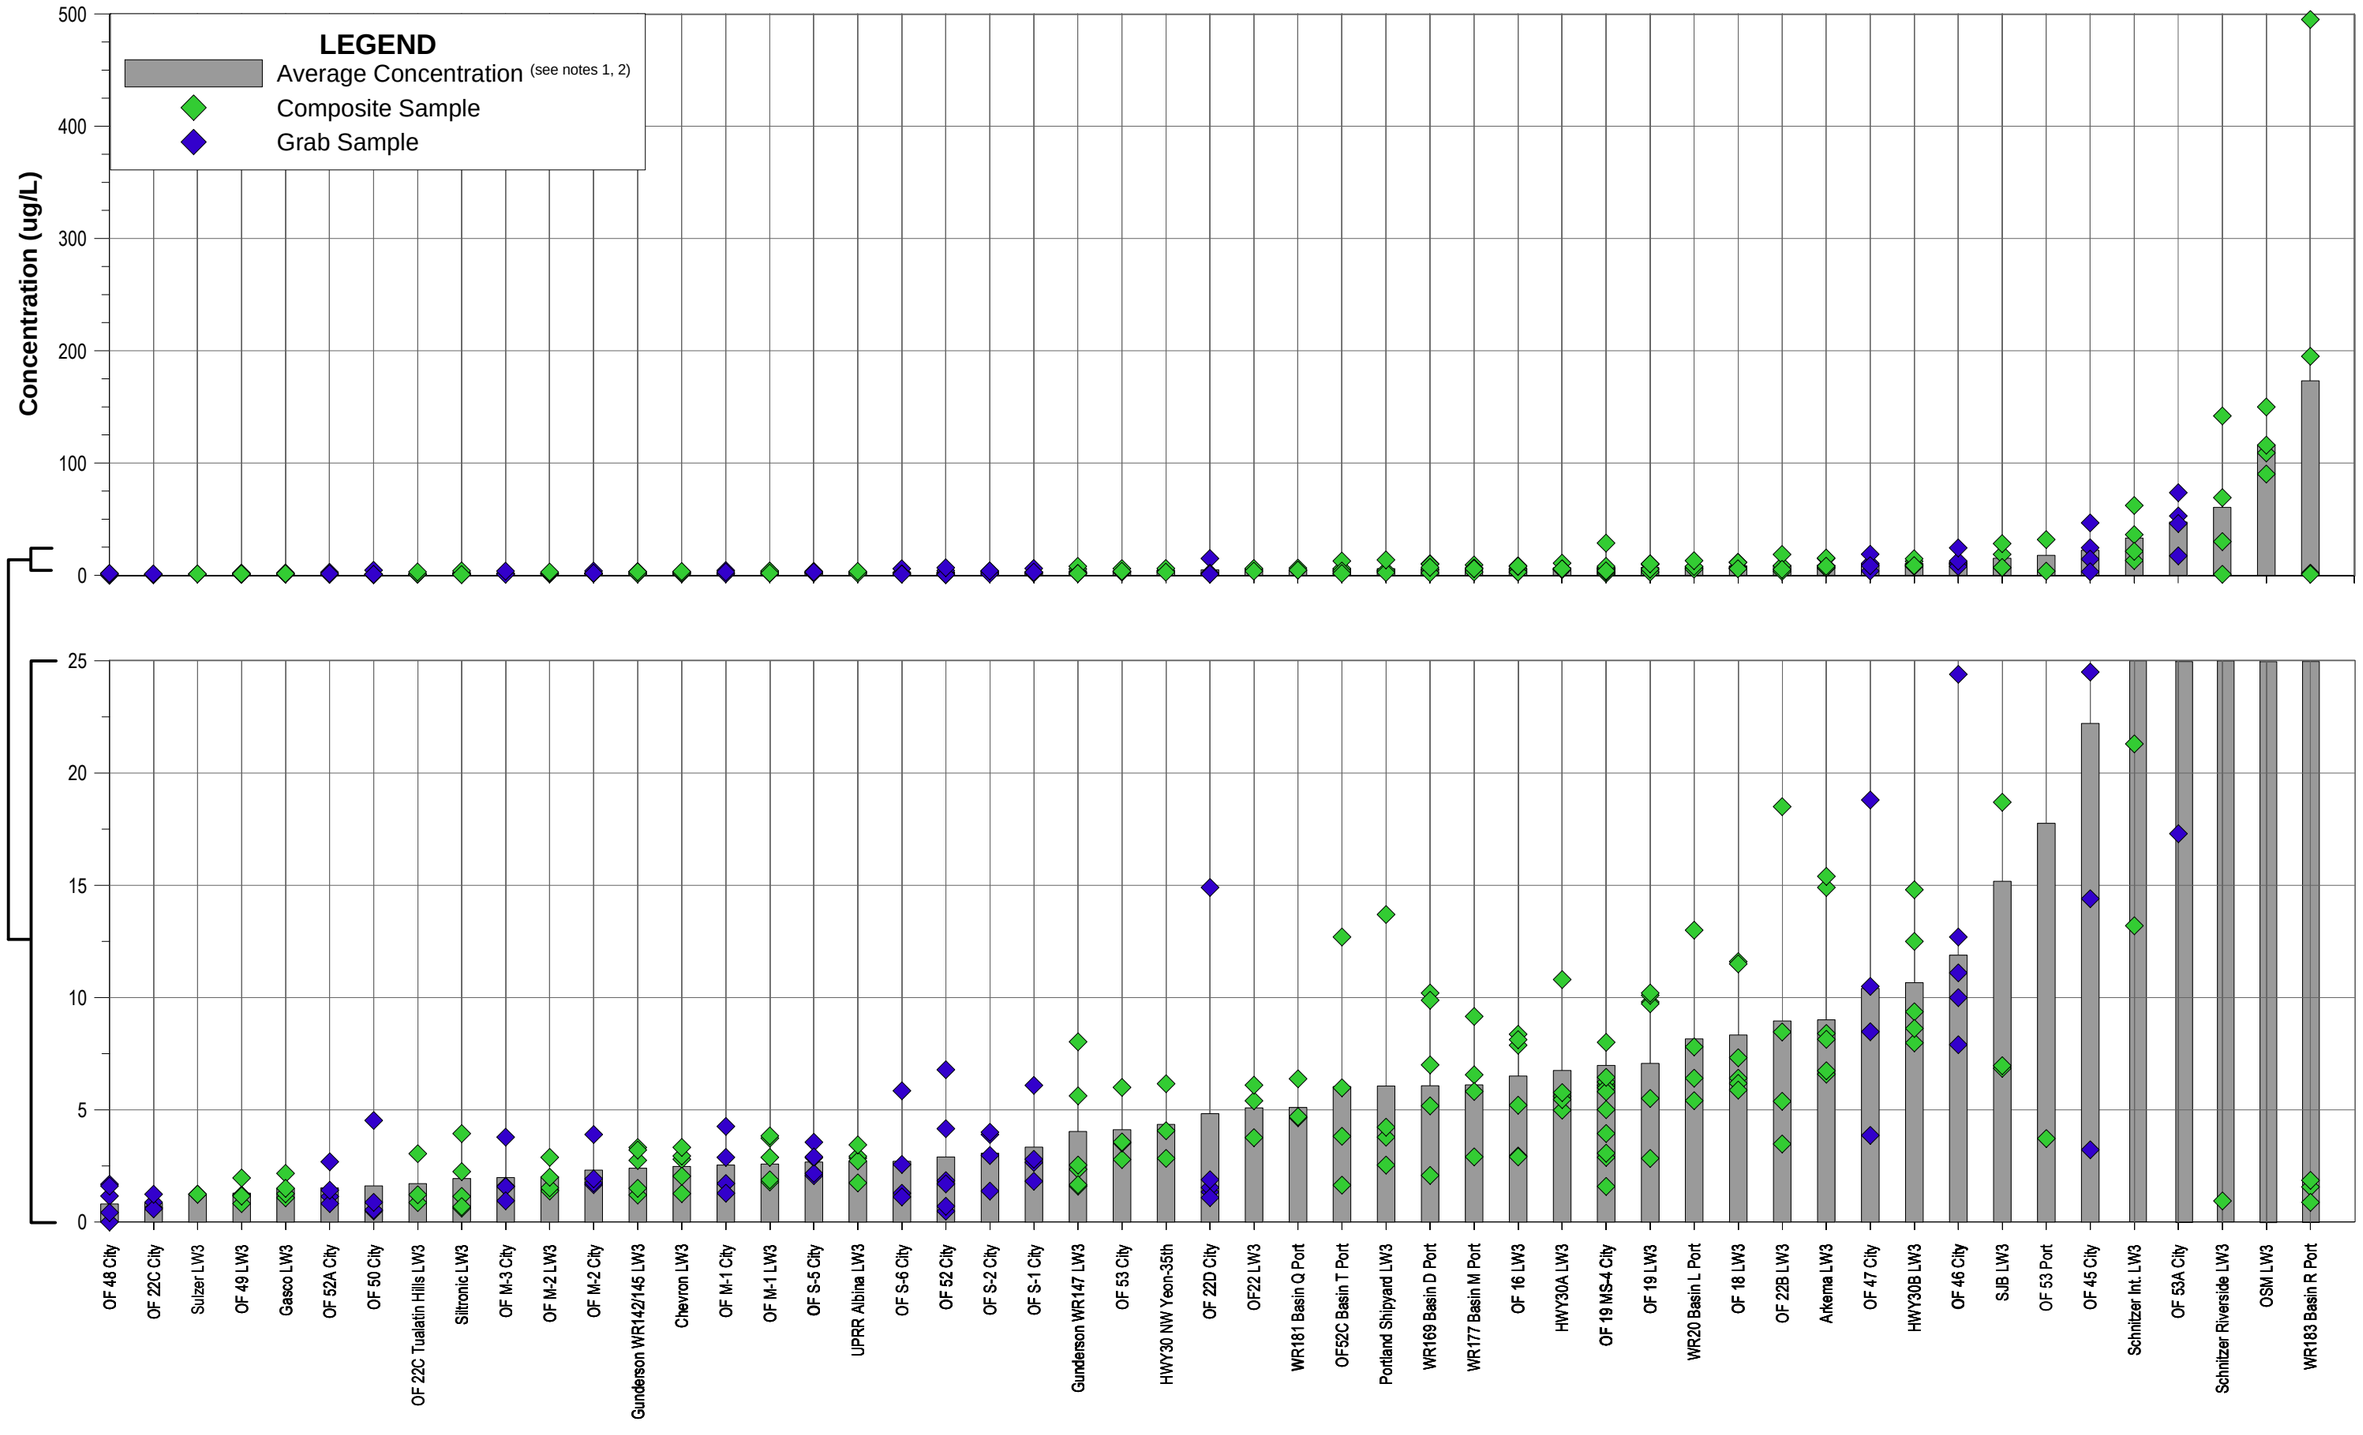
Total Arsenic Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



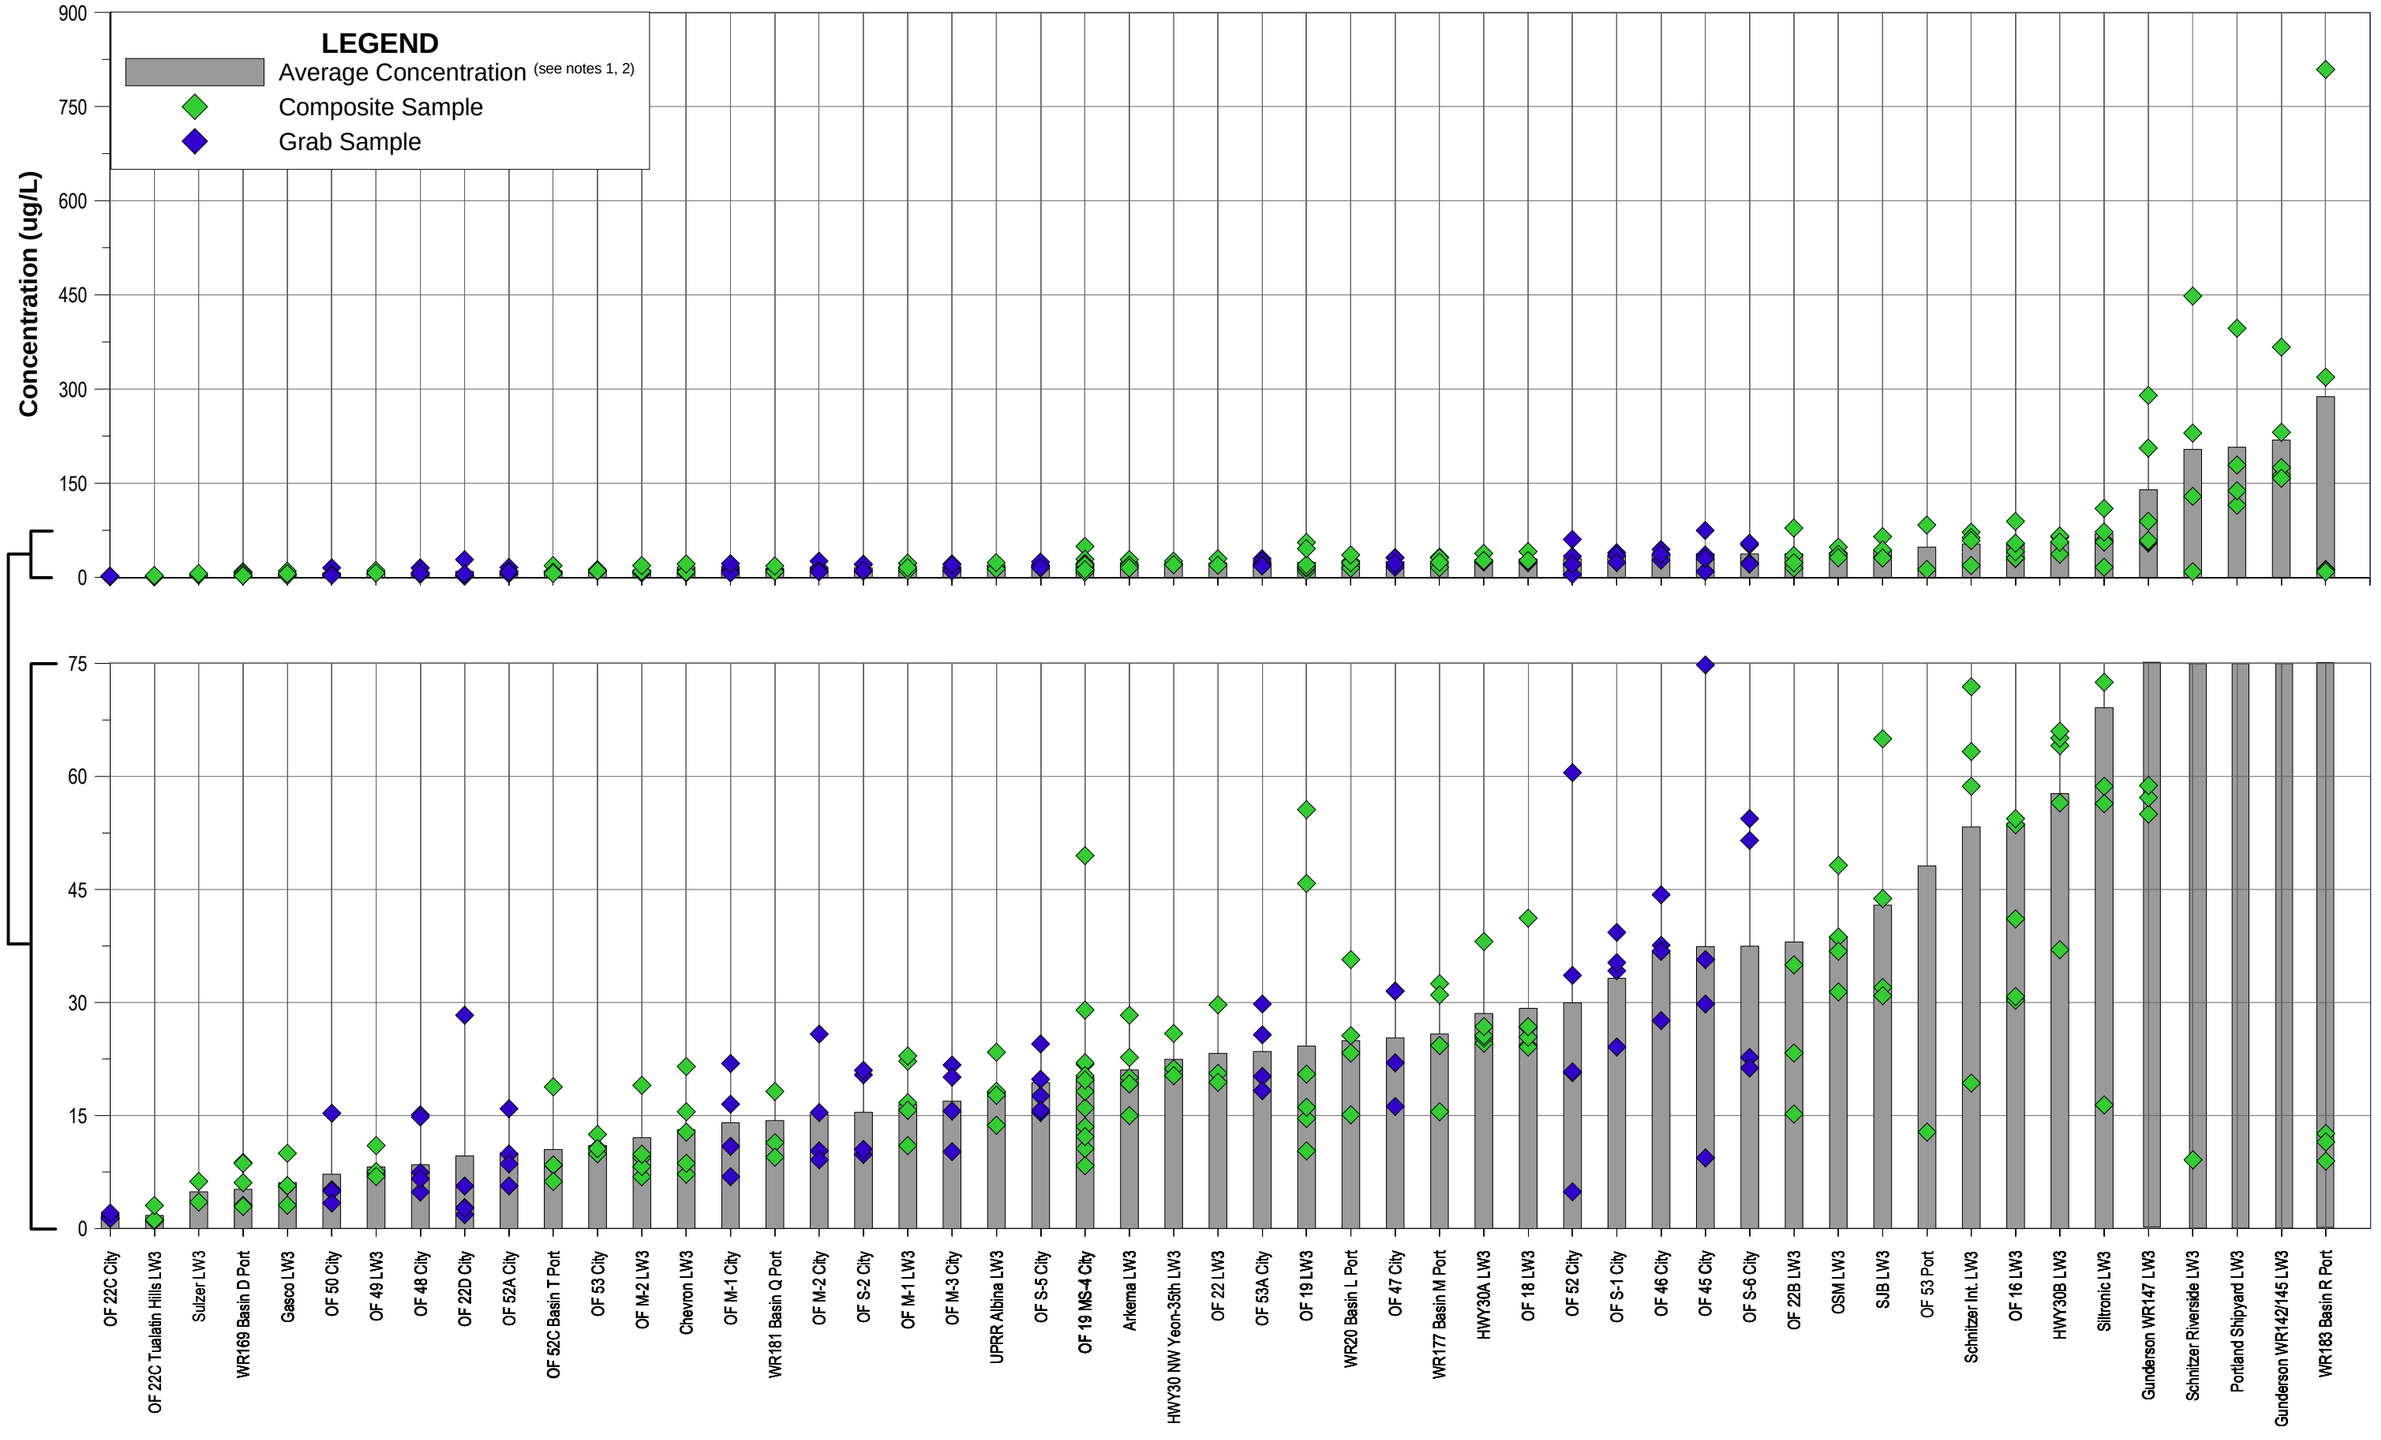
Total Chromium Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



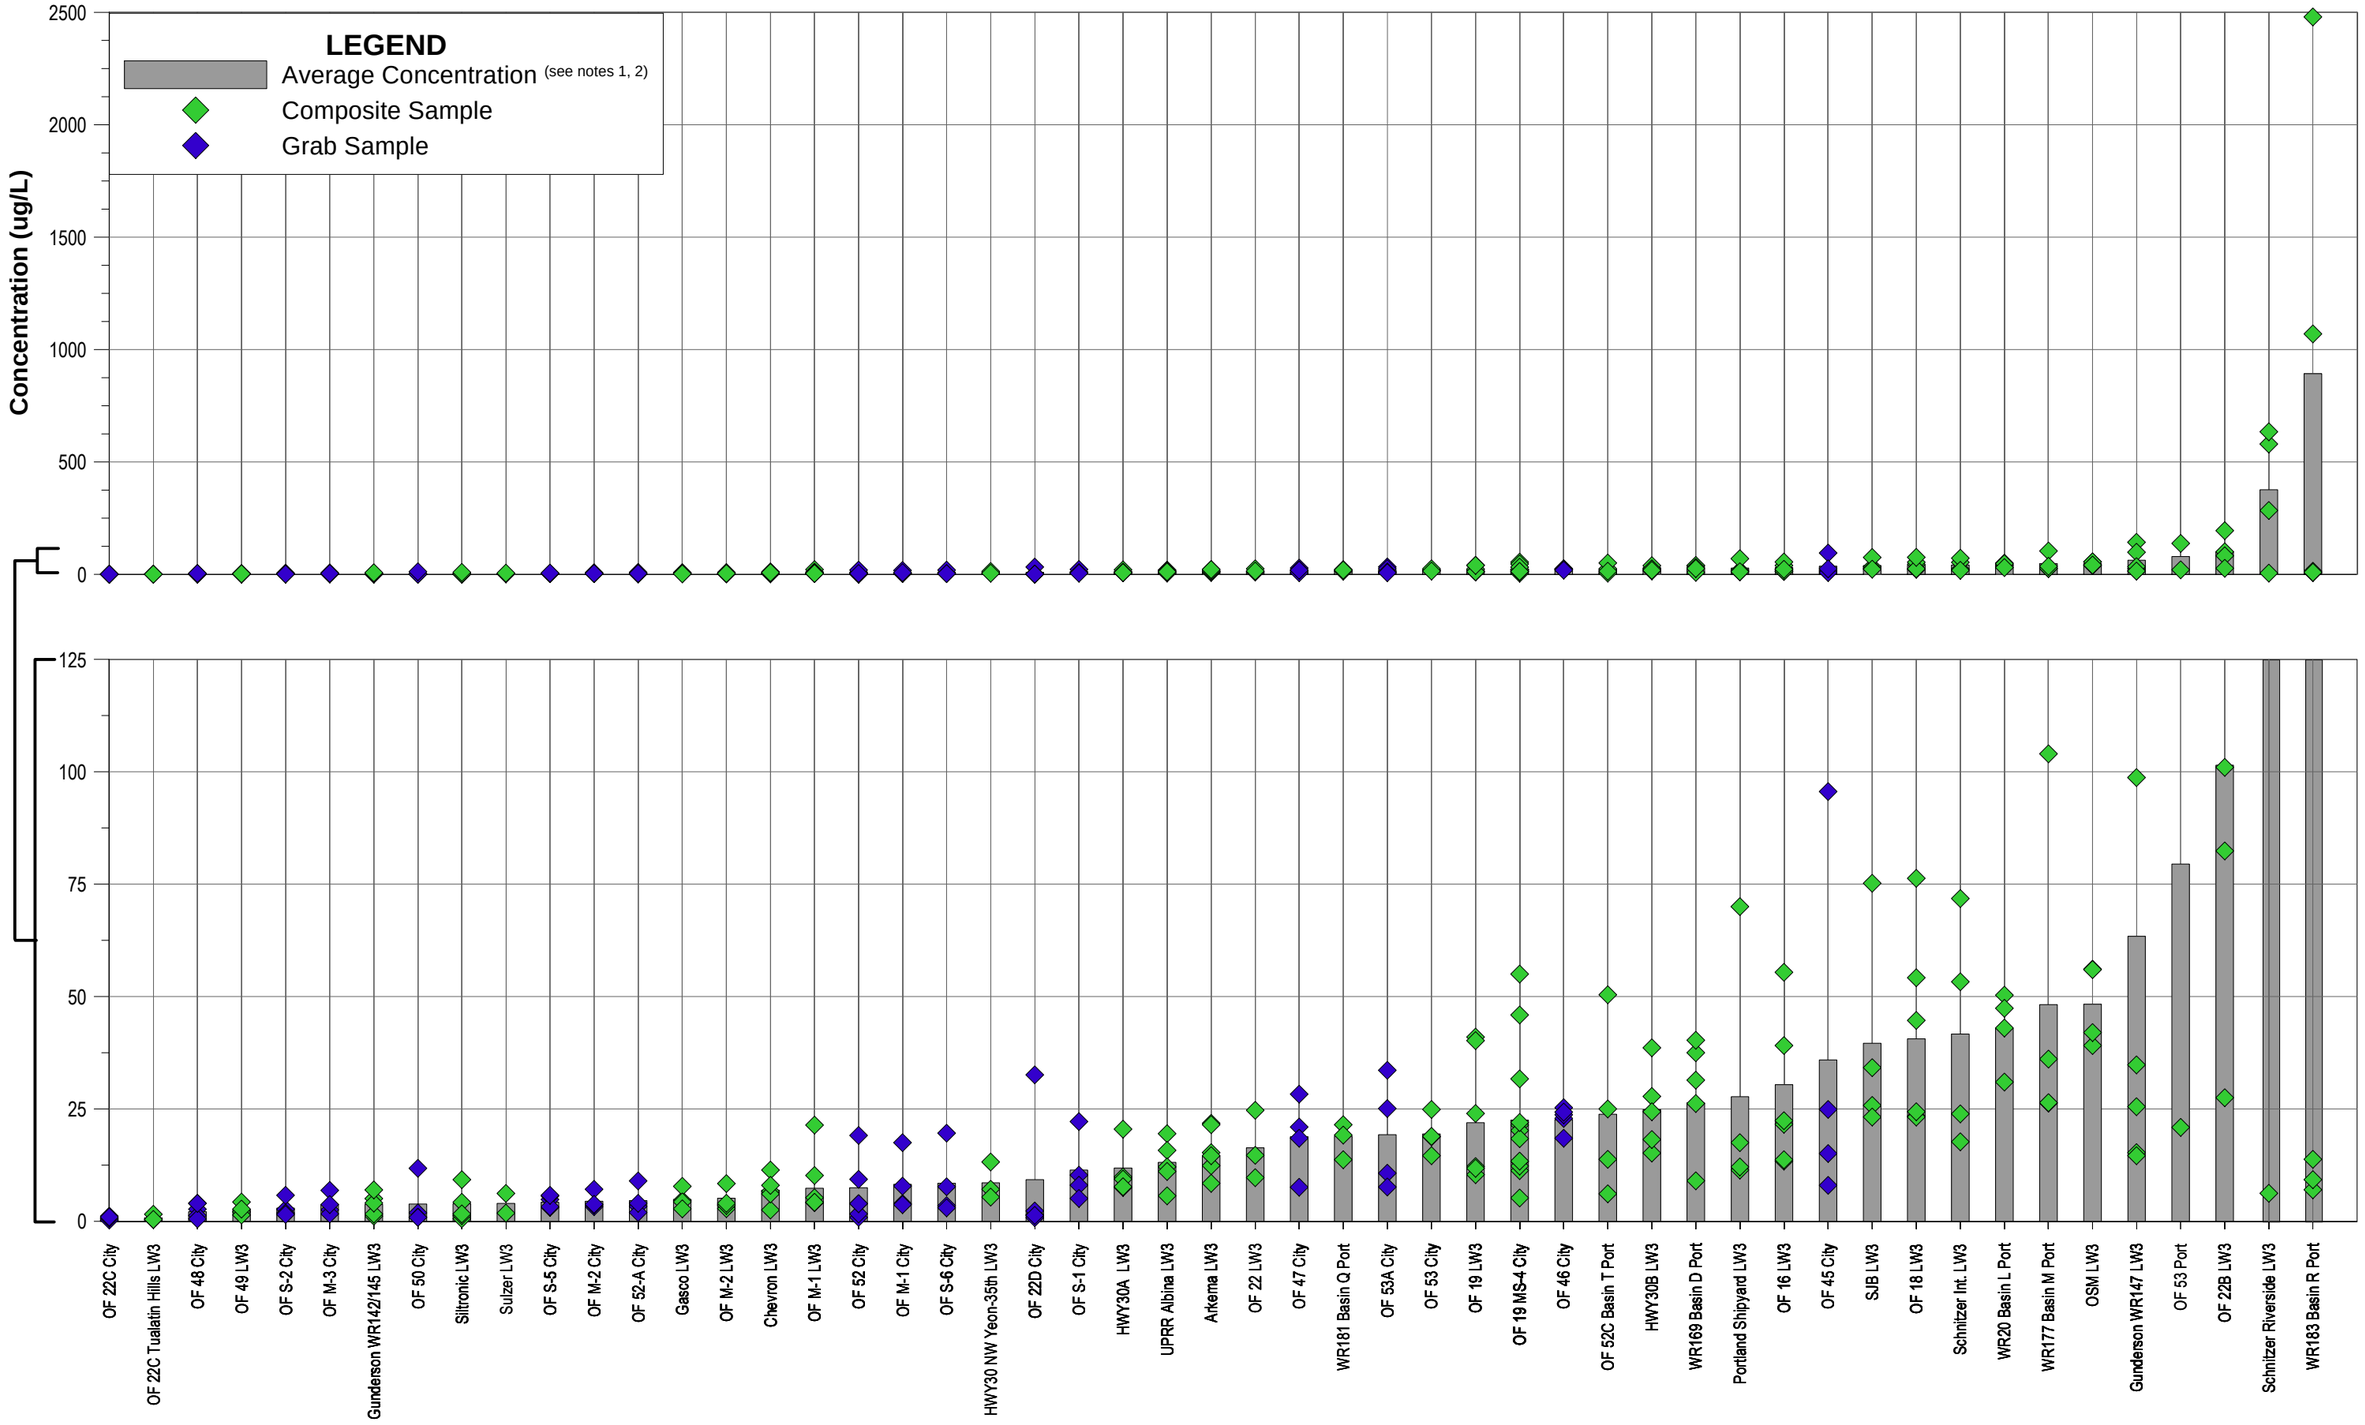
Total Copper Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



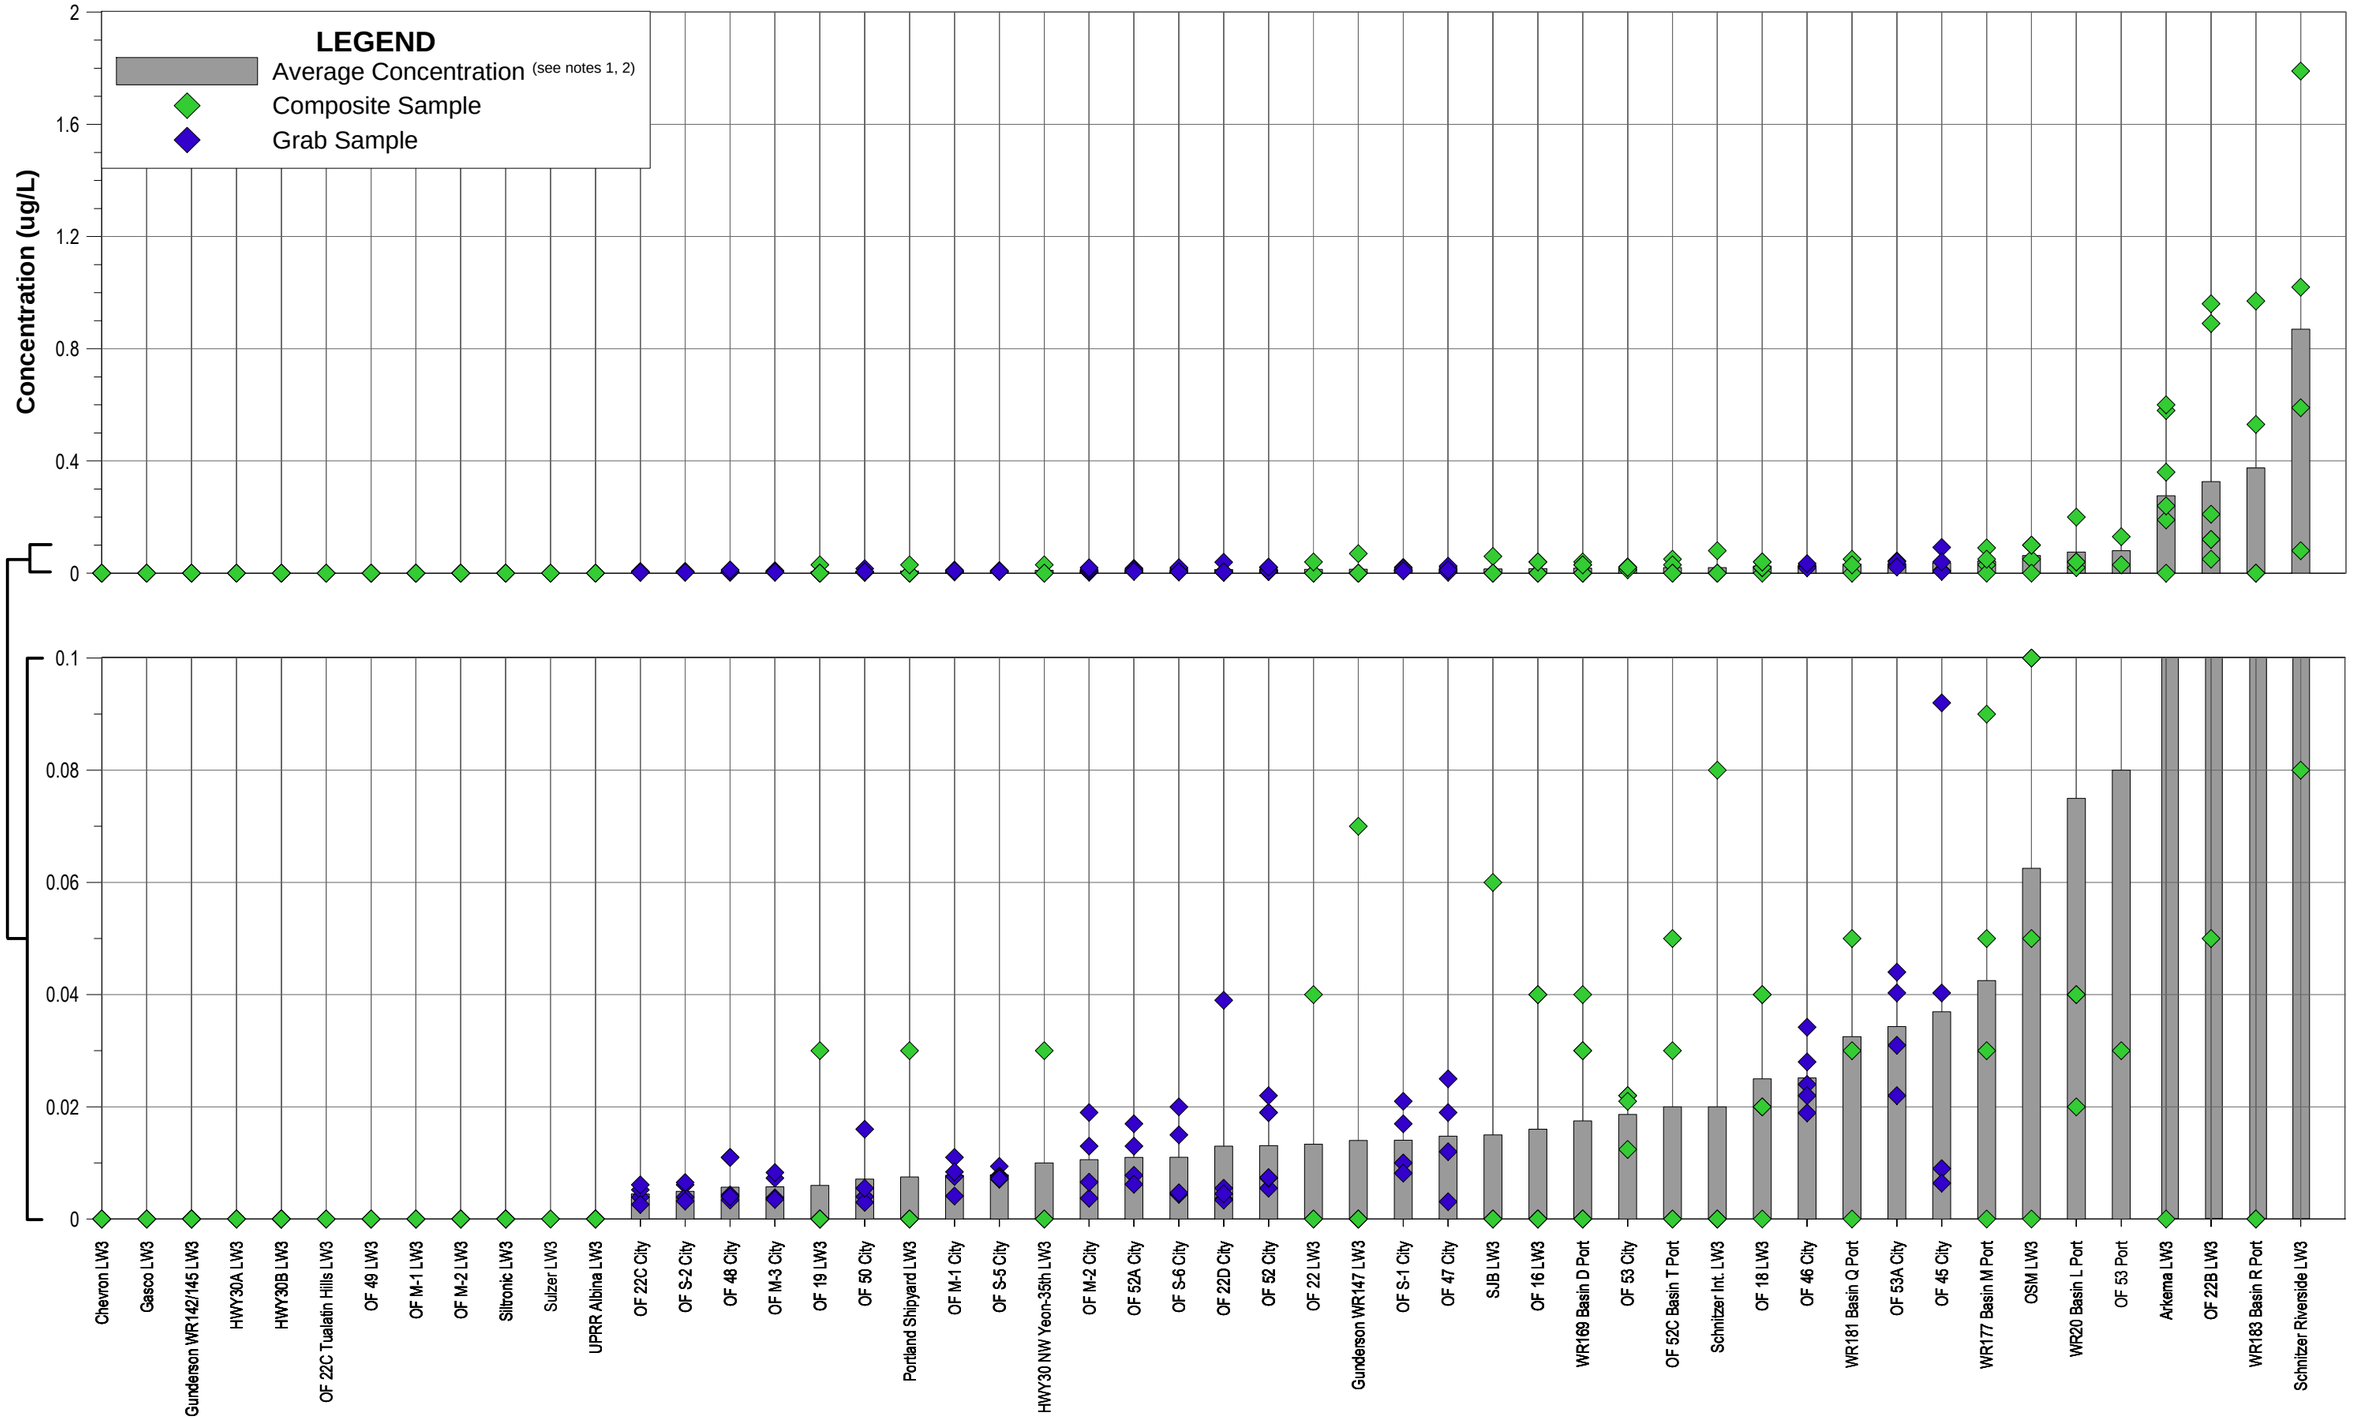
Total Lead Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



Total Mercury Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)



Total Zinc Concentrations in Stormwater Runoff Discharging to Portland Harbor Study Area*

*(See Notes and Assumptions on attached page.)

Notes:

ug/L = micrograms per liter

(1) Section 3 and Table 3-1 of the *Stormwater Evaluation Repor*t (BES, 2010) present the sources of data used in this table. Appendix C presents the assumptions and data used in calculating the mean concentrations for outfall basins included in this table. Appendix D presents the individual analyte data used in calculating the mean concentrations for City outfall basins. This table includes analytes that were identified to exceed the JSCS SLV at a concentration detected above the method reporting limit (MRL) in at least one sampling event in at least one City outfall basin.

(2) Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area. Outfall basin locations utilized by the City and the LWG in three basins (i.e. OF M-1, OF M-2, and OF 22C) represent different basins; in all three basins, the City sampling location represents a larger drainage area that includes the drainage area evaluated by LWG. City sampling locations were selected to represent stormwater discharges from the entire basin, to the extent feasible. Flow-weighted composite and grab sample results from City and LWG sampling activities are not combined in these figures. Basins with multiple sample locations include: OF M-1; OF M-2; and OF 22C.

(3) Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

(4) Qualified data are flagged with the following data qualifiers, as applicable: B = the analyte was detected in the laboratory method blank at a concentration that is significant relative to the sample result; J and Est = estimated value (method dection limit < concentration < method reporting limit); NJ = presumtive evidence of a compound, and the value is estimated; U = undetected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

(5) For the purposes of calculating the mean and geomean concentrations, non-detect results are set to the value of the MRL.

(6) Basin mean and geometric mean concentrations are typically reported to 4 decimal places. Standard rules for defining significant figures have not been applied in this table.

(7) Basin mean and geometric mean concentrations are not flagged with data qualifiers. These means often include estimated (e.g., "J" flagged) or nondected (e.g., "U" flagged) concentrations and should be flagged with the applicable data qualifier(s) if used for other purposes.

Appendix D

Stormwater Analytical Results by City Outfall Basin

Appendix D – Notes

General notes regarding Appendix D stormwater analytical results tables:

- The purpose of the tables of stormwater analytical results presented in this appendix is to:
    - Summarize individual sample results for City outfall basins for those analytes detected at concentrations greater than the corresponding Joint Source Control Strategy (DEQ/EPA 2005) screening level values (SLVs) in one or more stormwater samples from any City outfall basin;
    - Summarize the arithmetic mean and geometric mean by analyte for each City outfall basin for those analytes; and
    - Identify basin geometric means that exceed the corresponding JSCS SLVs for the purpose of selecting stormwater analytes to be evaluated in the Harborwide Statistical Analysis.
- The tables in this appendix do not include data (and corresponding mean concentrations) for private outfalls that were incorporated into the Harborwide Statistical Analysis. For the complete set of data used in the Harborwide Statistical Analysis, see Appendix C, Attachment C-3.
- Assumptions and conventions applied in the calculation of the arithmetic and geometric mean concentrations are described in Appendix C.
- Except for denoting mean concentrations that are based entirely on non-detect results (i.e., the Method Reporting Limits; see Appendix C), basin mean and geometric mean concentrations are not flagged. The mean concentrations are often based on qualified data (e.g., estimated ["J"-flagged] or non-detect ["U" or "UJ"] results) and should be flagged as appropriate if these mean values are used for other purposes.

Stormwater Analytical Results by City Outfall Basin:

Polychlorinated Biphenyls (PCBs) (Total PCB Congeners)

Stormwater Analytical Results by City Outfall Basin -- Total PCB Congeners

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for total PCB congeners = 0.000064 ug/L.
If PCBs were undetected ("U" flag) in all samples, the mean and geomean are not bolded.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for acenaphthene = 0.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for acenaphthylene = 0.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for anthracene = 0.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for benzo(a)pyrene = 0.018 ug/L.

	11/16/2007	grab		0.0321	ug/L		
	12/15/2007	grab		0.0488	ug/L		

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for benzo(b)fluoranthene = 0.018 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for benzo(k)fluoranthene = 0.018 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for dibenzo(a,h)anthracene = 0.018 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); EST = estimated value; U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for fluoranthene = 0.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for indeno(1,2,3-cd)phyrene = 0.018 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for naphthalene = 0.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] U = undetected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for 2,4'-DDD = 0.00031 ug/L.
If analyte was undetected ("U" or "UJ" flag) in all samples, the mean and geomean are not bolded.

	4/7/2007	composite		0.0017	ug/L		
	5/3/2007	composite	UJ	0.0053	ug/L		

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); NJ = presumptive evidence of a compound, and the value is estimated; U = undetected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for heptachlor = 0.000079 ug/L.
If analyte was undetected ("U" or "UJ" flag) in all samples, the mean and geomean are not bolded.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected; B = analyte was detected in the associated laboratory method blank.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for BEHP = 2.2 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for di-n-octylphthalate = 3 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = undetected.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for cadmium = 0.094 ug/L.
If analyte was undetected ("U" flag) in all samples, the mean and geomean are not bolded.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit)

[4] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for copper = 2.7 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit)

[4] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for lead = 0.54 ug/L.

Stormwater Analytical Results by City Outfall Basin -- Manganese

City Outfall Basin / Sampling Location [1]	Sample Date [2]	Sample Type	Qualifier [3]	Manganese Concentration		Basin Mean [4]	Basin Geomean [4]

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit); U = not detected; UJ = analyte was not detected, and the value is the estimated quantitation limit.

[4] For the purposes of calculating the mean and geomean, non-detect results are set to the value of the method reporting limit.

[5] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for silver = 0.12 ug/L.

Notes:

ug/L = micrograms per liter

[1] Each location listed represents discharge from the whole basin, to the extent feasible. Results for City and LWG/Port sampling are combined where sampling locations are representative of the same basin area.

[2] Results for duplicate samples are averaged with the corresponding parent sample results to achieve a mean value for that sample event that is then used to calculate the basin mean and geomean.

[3] J = estimated value (method dection limit < concentration < method reporting limit)

[4] Samples were collected at two locations within Basins 22C, M-1, and M-2. Samples collected by the City are representative of entire basin discharges; the samples collected by LWG in these basins were located upstream. For Basins M-1 and M-2 (but not Basin 22C), the LWG sampling location represented basin areas similar to those represented by the City sampling locations.

Bolded values exceed Joint Source Control Strategy (JSCS) Screening Level Value (SLV). JSCS SLV for zinc = 36 ug/L.

Notes:

J = Estimated value

N = Presumptive evidence of a compound

U = The analyte was not detected above the reported sample quantification limit

R = Rejected

T = Value is an average or selected result

NA = Not analyzed

ND = Not detected

-- = No JSCS screening level available.

ug/Kg = Micrograms per kilogram

mg/Kg = Milligrams per kilogram

(1) Results for the 1/29/08 sample from Basin 22B were listed in error under Basin 22 in the LWG database and inadvertently omitted from the data summary included in the LWG's Round 3A and 3B Stormwater Data Report (Anchor and Integral, 2008b).

(2) LWG sampling location does not represent all portions of this basin.

(3) JSCS = Portland Harbor Joint Source Control Strategy (DEQ/EPA Final December 2005, Amended July 2007)

(4) Puget Sound Estuary Program (PSEP), Recommended Protocols for Measuring Conventional Sediment Variables in Puget Sound

(5) Mercury analysis by 7471A

(6) Data obtained from Terminal 4 Recontamination Analysis (BBL, 2006). For PAHs, PCBs, and DDx, only the total values are presented in the table.

(7) The toxicity SLV represents the sum of the 2,4' and 4,4' isomers

(8) Estimated Total DDx is the sum of DDE, DDD and DDT

(9) Alpha-Chlordane also is known as cis-Chlordane. Beta-Chlordane is also known as trans-Chlordane.

(10) Total Chlordane is the sum of alpha-, and beta-isomers.

(11) Total PCBs and PAHs are calculated by assigning "0" to undetected constituents.

= concentration exceeds JSCS Toxicity Screening Level Value.

bold = concentration exceeds JSCS Bioaccumulation Screening Level Value.

Appendix E. Summary of Polychlorinated Biphenyl Congener Analytical Results, LWG and Port of Portland Sediment Trap Solids Samples

Notes:
MoCB = Monochlorobiphenyl
DiCB = Dichlorobiphenyl
TriCB = Trichlorobiphenyl
TeCB = Tetrachlorobiphenyl
PeCB = Pentachlorobiphenyl
HeCB = Hexachlorobiphenyl
HpCB = Heptachlorobiphenyl
OcCB = Octachlorobiphenyl
NoCB = Nonachlorobiphenyl
J = Estimated Result
T = Value is an average or selected result
U = The analyte was not detected above the reported sample quantification limit
-- = No JSCS screening level available
NA = Not analyzed
ug/Kg = Micrograms per kilogram
[1] IUPAC - International Union of Pure and Applied Chemistry
[2] LWG sampling location does not represent all portions of this basin
[3] JSCS - Portland Harbor Joint Source Control Strategy (DEQ/EPA Final December 2005, Amended July 2007)
[4] Data obtained from Terminal 4 Recontamination Analysis (BBL, 2006).
[5] For the purposes of calculation of total PCBs, not detected results were assigned a value of 0.
bold = concentration exceeds JSCS Bioaccumulation Screening Level Value
= concentration exceeds JSCS Toxicity Screening Level Value
