10.0 APPENDIX A: BUILDING DATABASE DEVELOPMENT

10.1 Building Database Data Sources

Table 10.1 lists the several data sources used for constructing the building asset database. The table is organized as follows: the most general data source for a particular attribute is listed first, then, where available, the source of more specific and accurate data. For example, the Regional Land Information System tax lot database had an Oregon Department of Revenue-based Property Class designation assigned to each tax lot. A lookup table provided a Hazus-based occupancy class mapping for most Property Class values. All buildings on the tax lot are given that occupancy class assignment. If better information on occupancy class was available, such as the Metro Fire/Police/School/Hospital spatial dataset, we updated the attribute with that information. More detailed datasets are typically restricted to a small subset of the buildings.

The Year Built attribute is not directly consumed by Hazus AEBM, but this attribute is used to establish the seismic design level (Section **10.2**).

Table 10-1. Data sources used in construction of the building database. Table uses Hazus occupancy class names (FEMA, 2011, Table 3.2).

Dataset Owner/Distributor	Dataset	Date of Publication or Acquisition	Occupancy Class	Year Built	Square Footage	Number of Stories	Building Type	Summarization Unit	Notes
Metro, Portland, Oregon	Regional Land Information System: Tax Lots	February 2016	✓						Spatial association of building footprint with assessor tabular information.
Clackamas County Assessor, Oregon City, Oregon	Clackamas County Assessor Database (tabular)	June 2016	✓	✓	✓	✓	(RES2)[+]		Detailed information on individual structures. Square footage available only for residential properties.
Multnomah County Assessor, Portland, Oregon	Multnomah County Assessor Database (tabular)	March 2016	✓	✓	✓	✓	(RES2)[+]		Detailed information on individual structures.
Washington County Assessor, Hillsboro, Oregon	Washington County Assessor Database (tabular)	March 2016	✓	✓	✓	✓	(RES2)[+]		Detailed information on individual structures. Square footage not available for governmental or institutional buildings. Year Built information variable.
Oregon Dept. of Geology and Mineral Industries	Building footprint digitization	December 2016	✓						Assigned occupancy class during heads-up digitization with NAIP and oblique imagery. Limited to building footprint digitized for this project.
Metro, Portland, Oregon	Metro Area Disaster GIS (MADGIS) Database	1999					✓		Building construction type based on field visits and identification for ~40,000 non-single family residential buildings.
Metro, Portland, Oregon	Multi-family housing inventory	February 2017	✓				✓		Refined the distinction between single-family and multi-family residential buildings.
City of Portland	Unreinforced Masonry Building Database	January 2017		✓			✓		Includes information on seismic retrofits to URMs. Limited to City of Portland. https://www.portlandoregon.gov/bds/70767
Oregon Employment Department	North American Industry Classification System (NAICS)	September 2016	✓						Refinement of occupancy class designation for commercial and industrial buildings, building on methods described by Wein and others (2013). Data obtained under terms of a confidentiality agreement; information from dataset can be shared only in aggregate, non-individually identifiable, form.
Metro, Portland, Oregon	Regional Land Information System: Fire, Police, School, Hospital Buildings	February 2016	✓						Refinement of occupancy class designation for educational and certain governmental buildings.
Oregon Dept. of Geology and Mineral Industries	Oregon Statewide Seismic Needs Assessment (Lewis, 2007)	2007	✓	✓	✓	✓	✓		Most detailed information; limited to 777 public schools and government agency buildings.
Metro, Portland, Oregon	Regional Land Information System: Building footprints	February 2016			✓				Combined with other building footprint databases; see Section 2.1.1.
Oregon Dept. of Geology and Mineral Industries	Building footprints (Burns and others, 2011, 2013)	2011, 2013			✓				Previously digitized building footprints for portions of Multnomah and Clackamas counties.
City of Portland	Development Capacity Analysis GIS Model (City of Portland, 2012)	October 2012				✓			Established number of stories attribute for buildings in City of Portland. Used to establish building height to number of stories relationship for buildings where number of stories data were not available.
Oregon Dept. of Geology and Mineral Industries	Lidar compilation: bare earth and highest hit models	2009–2014			✓	✓			Used for building footprint (BF) development in areas where no BFs existed, and to refine existing BF database. Building height derived from lidar elevation models (highest_hit minus the bare_earth) and converted to Number of Stories using relationships established by analysis of data from City of Portland Development Capacity Analysis GIS Model. Lidar acquisition dates vary, depending on area. https://gis.dogami.oregon.gov/lidarviewer/
Metro, Portland, Oregon	Regional Land Information System: County and City Boundaries	February 2016						✓	Building spatial associations with particular jurisdictions and counties, including county unincorporated areas.
Tetra Tech, Portland, Oregon	City of Portland Risk Reporting Areas (Tetra Tech, 2016a)	September 2016						✓	Building spatial associations with one of nine Risk Reporting Areas within the City of Portland.
U.S. Census Bureau	2010 Census Block Groups	April 2010						✓	U.S. Census Block Group (CBG) 2010 boundaries, with contiguous CBGs combined by DOGAMI where needed, to establish neighborhood units. Buildings spatially associated with neighborhood units. Population numbers used to assign residential building population. https://www.census.gov/geo/reference/gtc/gtc_bg.html

[+]RES2 (Single-Family Manufactured Housing) available from Assessor records and, by definition, a Manufactured House building type.

10.2 Seismic Design Level Assignments

We assigned a Hazus seismic design level based on the building's construction year and type. Seismic design codes have evolved with time, with more stringent requirements developing as the natural hazard threat is better understood. We interpreted the relevant state building code histories as described by Judson (2012), Oregon Building Code Division (2002, 2010), and Business Oregon (2015) and developed a seismic design level categorization table (**Table 10-2**). The design level assignment is one of the parameters used by the Hazus tool to derive a damage estimate. Once the seismic design level was assigned to each building, we summarized the number of buildings, square footage, and replacement cost per seismic design level (**Table 10-3**). We did not have sufficient information to further classify buildings into the Hazus-supported Low-Special, Moderate-Special, and High-Special seismic design levels.

Table 10-2. Oregon seismic design level benchmark years.

Building Type	Year Built	Design Level	Basis
Single Family Dwelling (includes Duplexes)	prior to 1976	Pre Code	Interpretation of Judson (2012)
	1976–1991	Low Code	
	1992–2003	Moderate Code	
	2004–present	High Code	
Manufactured Housing	prior to 2003	Pre Code	Interpretation of Oregon Manufactured Dwelling Special Codes (Oregon Building Codes Division, 2002)
	2003–2010	Low Code	
	2011–present	Moderate Code	Interpretation of Oregon Manufactured Dwelling Special Codes Update (Oregon Building Codes Division, 2010)
All other buildings	prior to 1976	Pre Code	Interpretation of Oregon Benefit-Cost Analysis Tool (Business Oregon, 2015, p. 24)
	1976–1990	Low Code	
	1991–present	Moderate Code	

Table 10-3. Building statistics by seismic design level, per county.

County	Seismic Design Level	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Cost Percent
Clackamas	Pre Code	89,647	50%	202,323	42%	24,922	40%
	Low Code	43,530	24%	146,754	30%	19,523	31%
	Moderate Code	30,638	17%	88,682	18%	11,550	19%
	High Code	15,349	9%	48,363	10%	6,394	10%
Multnomah	Pre Code	184,704	72%	489,280	60%	67,497	59%
	Low Code	28,280	11%	111,783	14%	15,884	14%
	Moderate Code	26,383	10%	101,405	13%	14,248	12%
	High Code	16,210	6%	107,620	13%	16,418	14%
Washington	Pre Code	55,806	31%	145,812	24%	19,341	23%
	Low Code	46,556	26%	215,049	36%	31,128	38%
	Moderate Code	55,092	30%	147,174	24%	18,728	23%
	High Code	23,657	13%	94,936	16%	13,534	16%
Total Study Area	Pre Code	330,157	54%	837,415	44%	111,760	43%
	Low Code	118,366	19%	473,586	25%	66,535	26%
	Moderate Code	112,113	18%	337,261	18%	44,526	17%

10.3 Buildings by Geological Classification

To better understand the potential influence of local geology on the damage estimates, we summarized building information by National Earthquake Hazards Reduction Program (NEHRP) site classification and landslide and liquefaction susceptibility.

The NEHRP site classification bins a soil column's average shear wave velocity (V_{s30}), measured between 0 (surface) and 30 meters depth, into one of six categories. The site classification can be used to estimate the amplification of bedrock ground motion that may be experienced at the surface during an earthquake. Lower ratings, such as "B" and "C," minimally amplify the bedrock ground motion. Softer soil columns with lower V_{s30} values experience more surface ground motion due to the soil column's amplifying the bedrock ground motion. NEHRP site class "F" is assigned to soil columns primarily composed of fill material or certain types of clays or peat. For building seismic design purposes, such soils generally require site-specific investigations. For Hazus modeling purposes, we take a conservative approach by reclassifying NEHRP site class "F" into NEHRP site class "E"—the classification with the highest site amplification (Section **11.1**). Summary statistics in **Table 10-4** show that while a relatively small percentage of buildings are placed on NEHRP Site Classification "E" and "F" soils, their proportional building value in Multnomah County is large.

Table 10-4. Building statistics by NEHRP site classification, per county.

County	NEHRP Site Classification	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Value Percent
Clackamas	B	367	0%	746	0%	84	0%
	C	109,012	61%	278,528	57%	35,172	56%
	D	58,301	33%	178,653	37%	23,616	38%

	E, F	27,226	4%	197,202	10%	28,310	11%

The liquefaction and earthquake-induced landslide susceptibility rating is a description of a site's characteristics; it is *not* descriptive of an earthquake-induced landslide or liquefaction occurrence for a particular earthquake scenario. The susceptibility ratings are a generalization of the Hazus-based classifications, obtained from Appleby and others (in preparation), with the groupings listed at the bottom of each table (**Table 10-5** and **Table 10-6**). In all three counties, relatively few buildings are in high landslide susceptibility areas. In Washington County, at least 80% of the building value is on moderate liquefaction susceptibility soils.

Table 10-5. Building statistics by Hazus-based liquefaction susceptibility rating, per county.

County	Liquefaction Susceptibility	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Value Percent
Clackamas	None to Low	113,010	63%	288,505	59%	36,392	58%

	High to Very High	13,214	2%	45,064	2%	6,616	3%

Hazus-based landslide scale mapping: 0–5: none to low; 6–7: moderate; 8–10: high to very high.

10.4 Buildings by Primary Usage

We summarized the number of buildings on a generalized Hazus occupancy class basis, which is a classification of a building's dominant use (**Table 10-7**). In the case of mixed-use buildings, such as retail stores on the first floor and residential quarters on the upper floors, we assigned the occupancy class based on the largest square foot usage.

Table 10-7. Buildings statistics by primary usage, per county.

County	Building Use	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Value Percent
Clackamas	Agricultural	22,768	13%	52,063	11%	5,541	9%
	Commercial	4,593	3%	54,616	11%	7,929	13%
	Industrial	1,573	1%	20,621	4%	3,063	5%
	Institutional	2,558	1%	23,264	5%	3,940	6%
	Multi-family Residential	8,959	5%	40,880	8%	6,293	10%
	Single-family Residential	138,713	77%	294,677	61%	35,624	57%
Multnomah	Agricultural	2,540	1%	8,146	1%	867	1%
	Commercial	11,544	5%	210,231	26%	33,390	29%
	Industrial	1,685	1%	45,292	6%	6,874	6%
	Institutional	3,094	1%	50,145	6%	8,812	8%
	Multi-family Residential	24,197	9%	140,585	17%	22,428	20%
	Single-family Residential	212,517	83%	355,689	44%	41,675	37%
Washington	Agricultural	10,753	6%	26,823	4%	2,855	3%
	Commercial	5,863	3%	104,377	17%	15,815	19%
	Industrial	1,399	1%	50,567	8%	8,548	10%
	Institutional	1,931	1%	28,098	5%	4,856	6%
	Multi-family Residential	18,475	10%	98,385	16%	15,671	19%
	Single-family Residential	142,690	79%	294,721	49%	34,987	42%

Commercial includes the Hazus RES4 class. Institutional combines the Hazus GOV1, GOV2, EDU1, EDU2, and REL1 classes. Single-family residential combine the Hazus RES1 and RES2 classes.

10.5 Building Type by Primary Usage

We summarized the number of buildings by their generalized basic structural system (in Hazus, referred to as the building type), by generalized occupancy class (**Table 10-8**). Although several ancillary datasets informed our assignments (Section **2.1.4**), most (563,583 out of 615,852, or 92%) were based on the statistical distributions listed in the Hazus Earthquake Technical Manual (FEMA, 2011, Tables 3.A1–3.A.10).

Table 10-8. Building type by generalized building use.

Building Use	Building Type	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Cost ($ Million)	Cost Percent
Agricultural	Concrete	1,650	5%	4,032	5%	429	5%

	Reinforced Masonry	1,689	22%	21,678	21%	3,751	21%
	Steel	1,225	16%	14,277	14%	2,483	14%
	Trailers	9	0%	30	0%	5	0%
	Unreinforced Masonry	328	4%	4,861	5%	853	5%
	Wood	2,300	30%	23,279	23%	4,050	23%
Multi-Family Residential	Concrete	1,091	2%	28,476	10%	5,114	12%
	Precast Concrete	115	0%	2,801	1%	509	1%
	Reinforced Masonry	1,331	3%	16,026	6%	2,876	6%
	Steel	1,636	3%	22,913	8%	4,011	9%
	Unreinforced Masonry	403	1%	5,380	2%	947	2%
	Wood	47,055	91%	204,253	73%	30,934	70%
Single-Family Residential	Other	138	0%	377	0%	44	0%
	Reinforced Masonry	3,549	1%	7,349	1%	893	1%
	Unreinforced Masonry	1,455	0%	2,298	0%	268	0%
	Wood	471,926	99%	914,096	99%	110,199	99%
Single-Family Res. – Manuf. Housing		16,852	100%	20,966	100%	882	100%

Commercial combines all Hazus COM occupancy classes and RES4. Institutional combines Hazus occupancy classes REL1, GOV1, EDU1, and EDU2. Multi-family residential is limited to RES3, RES5, and RES6 types. Single-Family Residential – Manuf. Housing is the Hazus occupancy class RES2, and is broken out separately, given the building type's heightened sensitivity to ground shaking.

11.0 APPENDIX B: SITE GROUND MOTION AND GROUND DEFORMATION MAP DEVELOPMENT

11.1 Site Ground Motion Maps

We converted the bedrock ground motion data referenced in Section 3.1 to a 30-foot grid limited in extent to the three-county study area. For the Portland Hills fault magnitude 6.8 earthquake, we used the Nearest Neighbor tool in the Esri Spatial Analyst. For the Cascadia Subduction Zone magnitude 9.0 earthquake, we used the bedrock data published by Madin and Burns (2013). The NEHRP site classification polygons from Appleby and others (in preparation) were converted to a 30-foot grid. Sites classified as NEHRP "F" were re-assigned to NEHRP "E," a conservative and commonly implemented assumption for loss estimation purposes.

We used the revised F_a, F_v, and F_{PGA} site coefficients as published by FEMA (2015b, Tables 11.4-1, 11.4-2, 11.8-1) to derive site ground motion. For completeness, we include the NEHRP "A" class (V_{S30} > 1,500 m/s), even though such stiff material is not present in the study area. We note the coefficients are identical to what is used by the Hazus 4.0 model for probabilistic and arbitrary earthquake events available in the Hazus SQL database tables as:

[dbo].[eqPGASoilAmpFact],
[dbo].[eqPGVSoilAmpFact] ,
[dbo].[eqSa03SoilAmpFact] , and
[dbo].[eqSa10SoilAmpFact].

The coefficients applied directly will result in a non-monotonic site amplification function. To overcome the problem, we implemented the straight-line interpolation guidance given by FEMA (2015b) for intermediate values, and we added a *y*-intercept to the amplification function and adjusted the slope factor, so that the end point of the interval matches the specified amplification. We note the Hazus tool implements a similar piecewise linear function for probabilistic and arbitrary earthquakes. The functions listed in **Table 11-1** through **Table 11-4** were then implemented using the Esri Spatial Analyst raster calculator as a series of conditional statements.

For Hazus purposes, the raster data were converted to the requisite polygon data format by first discretizing the continuous site ground motion data into integer *percent g* bins, then converting the integer raster data to polygon format. The pgv was rounded to the nearest integer inches/second category, and then converted to polygon format.

Table 11-1. Site amplification coefficients for peak ground acceleration (pga, in g).

11.2 Ground Deformation Maps

We provided the liquefaction and landslide susceptibility data from Appleby and others (in preparation) and the site peak ground acceleration data for both earthquake scenarios developed in Section 3.2 as input to the tool developed by Sharifi-Mood and others (in preparation). The tool implements the methods for permanent ground deformation (PGD) estimation described by Madin and Burns (2013, Section 4), which implemented the Hazus ground failure models described in the Hazus Earthquake Technical Manual (FEMA, 2011). The tool generates raster grids describing the amount and probability of PGD resulting from liquefaction lateral spreading and earthquake-induced landslides. The tool is currently limited to modeling lateral spread from liquefaction in "wet" (saturated) soil conditions. For earthquake-induced landslide modeling, it implements the WET portion of Table 4.15 in the Hazus Earthquake Technical Manual (FEMA, 2011). For liquefaction, it assumes a water depth of 5.0 feet. The tool provides PGD and probability of occurrence estimates for liquefaction lateral spreading and for earthquake-induced landslides. The data are provided in the accompanying geodatabase for the CSZ and the Portland Hills fault simulated earthquakes.

To aid in interpretation, Appendix E, Plates 8 and 9 combine the PGD and probability occurrence from the two mechanisms (earthquake-induced landslides and lateral spread resulting from liquefaction). For a given raster cell, the plates represent the maximum PGD and maximum probability from the two mechanisms.

Our "dry" soil conditions scenario assumes non-saturated soils, thus ground failure due to liquefaction does not occur. However, earthquake-induced landslides may still occur, depending on the ground shaking intensity and local geologic conditions (FEMA, 2011, Table 4.15(A)). To overcome the current limitation of the tool, we developed a "dry" soil conditions scenario ground failure model due to earthquake-induced landslides as follows. As part of a statewide multi-hazard risk assessment effort for Oregon, we developed a lookup table method for rapid loss estimation from a Cascadia Subduction Zone earthquake (Bauer, 2016). All combinations of ground motion, at discrete intervals, and all combinations of liquefaction and landslide susceptibility values, were run through the Hazus model. Building loss ratios, along with ground failure probabilities and lateral spread amount, were captured in a lookup table. Of the four site ground motion parameters (Section **11.1**), the Hazus ground failure model uses only the site peak ground acceleration. A Hazus-based ground failure layer can then be created by associating the local landslide susceptibility rating and the site peak ground acceleration with the lookup table. We repeated the lookup table process for the Portland Hills fault "dry" soil conditions scenario.

The "dry" soil conditions scenario ground failure and probability values are included in the accompanying geodatabase. The lookup table method used the discretized peak ground acceleration (pga) intervals described in Section **11.1** and while it is not as continuous as what is available via the tool developed by Sharifi-Mood and others (in preparation), we determined it is a reasonable representation of the Hazus ground failure model for earthquake-induced landslides in the "dry" soil conditions scenario.

12.0 APPENDIX C: BUILDING DAMAGE ASSESSMENT AND IMPACTS TO OCCUPANTS

12.1 Number of Buildings by Damage State

We summarized the number of buildings in each damage state, by county (**Table 12-1**), using the structural damage states (StrPDS) obtained from the Hazus AEBM output. The quantification of buildings in each damage state follows the methods discussed by FEMA (2017a). The information can inform the planning process for post-earthquake building inspection needs.

Table 12-1. Number of buildings per damage state, by county and by earthquake and soil moisture scenario. Numbers for buildings in the None damage state are not included.

		Cascadia Subduction Zone Magnitude 9.0 Earthquake				Portland Hills Fault Magnitude 6.8 Earthquake

12.2 Number of Collapsed Buildings

We used the collapse percentage rates listed in the Hazus Earthquake Technical Manual (FEMA, 2011, Table 13.8), together with probability of Complete structural damage state from the Hazus AEBM output, to estimate the number of collapsed buildings by county and earthquake scenario (**Table 12-2**). The casualty calculations built into Hazus AEBM factor in an assumption that a percentage of completely damaged buildings will collapse, which varies based on building type. For example, the Hazus methods estimate 15% of completely damaged unreinforced masonry buildings will collapse, whereas completely damaged manufactured housing and single family wood frame construction buildings have only a 3% chance of collapse.

Table 12-2. Collapsed buildings by county and by earthquake and soil moisture conditions

		Cascadia Subduction Zone Magnitude 9.0 Earthquake		Portland Hills Fault Magnitude 6.8 Earthquake	
County	Total Number of Buildings	"Dry" Soils	"Wet" (Saturated) Soils	"Dry" Soil	"Wet" (Saturated) Soils
Clackamas	179,164	158	313	666	1,066
Multnomah	255,577	302	677	1,001	1,876
Washington	181,111	209	619	387	1,155
Total	615,852	668	1,609	2,054	4,097

12.3 Permanent Residents by Building Damage State

We assigned permanent residents to individual residential buildings based on the building's square footage, the total square footage of residential buildings for a census block group, and the U.S. Census 2010 population amount for that census block group (Section **2.1.7**). Using the Hazus AEBM output, we multiplied the individual building's permanent residential population by each structural probability of damage state. Summary statistics by county and earthquake scenario are provided in **Table 12-3**. Note the figures in the Complete state are the same as the long-term displaced population figures in **Table 12-4** through **Table 12-7**. The Hazus Complete damage state equates to the ATC-20 red-tag designation (ATC, 1989), and the Extensive damage state equates to the ATC-20 yellow-tag designation. All other building damage states are considered green-tagged (FEMA, 2010, Table 6.1). Qualitative descriptions of the building damage states as relates to the characteristics of the building, per building type (such as Steel Moment Frame), are provided by FEMA (2011, Section 5.3).

Table 12-3. Permanent residents per building damage state, by county and by earthquake and soil moisture conditions scenario.Numbers for permanent residents occupying buildings in the None damage state are not included.

		Cascadia Subduction Zone Magnitude 9.0 Earthquake		Portland Hills Fault Magnitude 6.8 Earthquake

	Complete	16,852	85,211	95,577	256,936

We recognize that planning for short-term and long-term shelter needs throughout the response and recovery phases is a complex task requiring many assumptions, but at its base the planning requires underlying data on demographics as relates to predicted building damage. **Table 12-4** through **Table 12-7** quantify the number of buildings and permanent residents by generalized occupancy, per county and per building damage state, for the four earthquake scenarios.

Table 12-4. Buildings and permanent residents per building damage state for Cascadia Subduction Zone magnitude 9.0 earthquake, "dry" soil conditions. Dash (—): not applicable

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

Table 12-6. Buildings and permanent residents per building damage state for Portland Hills fault magnitude 6.8 earthquake, "dry" soil conditions. Dash (—): not applicable

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

12.4 Loss Estimates by Jurisdiction

Table 12-8 through **Table 12-11** provide county-level and jurisdictional level building inventory and building loss estimates, along with casualty estimate for the daytime and nighttime earthquake scenarios. The jurisdictional data are available electronically in the accompanying geodatabase. Casualty and displaced population estimates are based on 2010 U.S. Census data and Hazus population distribution models across business types (Section **2.1.7**). The estimates for jurisdictions include all buildings within their 2016 jurisdictional boundaries, as defined by the Metro (2016) Regional Land Information System city boundary layer, dated February 2016.

Table 12-8. Loss estimates by jurisdiction, Cascadia Subduction Zone magnitude 9.0 earthquake, "dry" soil conditions.

[+] The jurisdiction is associated with the county it occupies most by area. Figures are for the entire jurisdiction and may include building data from neighboring counties. Summaries by all jurisdictions and unincorporated area for a given county will vary slightly with the county total.

[*] Gaston census numbers are for entire jurisdiction. Gaston loss figures limited to buildings and residences in Washington County and do not include buildings, casualties, debris, and displaced population in Yamhill County.

Casualty level definitions are provided in **Table 4-1** and are based on U.S. Census 2010 population figures.

Table 12-9. Loss estimates by jurisdiction, Cascadia Subduction Zone magnitude 9.0 earthquake, "wet" (saturated) soil conditions.

[+] The jurisdiction is associated with the county it occupies most by area. Figures are for the entire jurisdiction and may include building data from neighboring counties. Summaries by all jurisdictions and unincorporated area for a given county will vary slightly with the county total.

[*] Gaston census numbers are for entire jurisdiction. Gaston loss figures limited to buildings and residences in Washington County and do not include buildings, casualties, debris, and displaced population in Yamhill County.

Casualty level definitions are provided in **Table 4-1** and are based on U.S. Census 2010 population figures.

13.0 APPENDIX D: GEOGRAPHIC INFORMATION SYSTEM (GIS) DATABASE

The GIS data included with this publication are partitioned into two ArcGIS version 10.1 file geodatabases. Earthquake loss estimates and impact assessment data are contained in RDPO_Earthquake_Impact_Analysis_Phase1.gdb. Loss estimates for a particular earthquake scenario are contained in independent tables and can be joined to the appropriate polygon dataset to graphically represent impacts. Ground motion and ground deformation data are contained in RDPO_GroundMotion_GroundFailure_Phase1.gdb.

RDPO_Earthquake_Impact_Analysis_Phase1.gdb:

Feature Dataset Phase1:

Building_Footprints	Outlines of buildings and other non-building structures.
Electrical_Transmission_Structures	Pointfile containing locations of electrical transmission poles and towers, and an estimate of permanent ground deformation at the location for all four earthquake scenarios.
Emergency_Transportation_Routes	Buffered and segmented version of the Metro area Emergency Transportation Routes, and a categorization, per segment, of the impact of permanent ground deformation on the segment, for all four earthquake scenarios.
Jurisdictions	Cities, villages, hamlets, and unincorporated areas, and summary statistics for number of buildings, square footage, replacement cost, and population estimates. Contains **Jurisdiction** attribute for joining to loss estimate tables.
Neighborhood_Units	Neighborhood units (876 total), and summary statistics for number of buildings, square footage, replacement cost, and population estimates. Contains **NUID** attribute for joining to loss estimate tables.
Population_and_Building_Density	20-acre hexagonal grid with summary statistics for number of buildings, number of residential buildings, and permanent residents per hexagonal cell. All cells contain at least one building.

Tables with building loss, casualty, and displaced population estimates for a given scenario

Loss estimates by jurisdiction

Tables can be joined to the Jurisdictions *feature class using* **Jurisdiction** *attribute*

Loss_Jurisdiction_CSZ_M9p0_dry	Scenario: Cascadia Subduction Zone M 9.0, “dry” soil conditions
Loss_Jurisdiction_CSZ_M9p0_wet	Scenario: Cascadia Subduction Zone M 9.0, “wet” (saturated) soil conditions
Loss_Jurisdiction_PHF_M6p8_dry	Scenario: Portland Hills fault M 6.8, “dry” soil conditions
Loss_Jurisdiction_PHF_M6p8_wet	Scenario: Portland Hills fault M 6.8, “wet” (saturated) soil conditions

Loss estimates by neighborhood unit

Tables can be joined to the Neighborhood_Units *feature class using the* **NUID** *attribute*

Loss_Neighborhood_Unit_CSZ_M9p0_dry	Scenario: Cascadia Subduction Zone M 9.0, “dry” soil conditions
Loss_Neighborhood_Unit_CSZ_M9p0_wet	Scenario: Cascadia Subduction Zone M 9.0, “wet” (saturated) soil conditions
Loss_Neighborhood_Unit_PHF_M6p8_dry	Scenario: Portland Hills fault M 6.8, “dry” soil conditions
Loss_Neighborhood_Unit_PHF_M6p8_wet	Scenario: Portland Hills fault M 6.8, “wet” (saturated) soil conditions

RDPO_GroundMotion_GroundFailure_Phase1.gdb:

Synthetic Cascadia Subduction Zone magnitude 9.0 earthquake

Site ground motion (rasters)

CSZ_M9p0_pga_site	Site peak ground acceleration, in g (standard gravity).
CSZ_M9p0_pgv_site	Site peak ground velocity, in centimeters per second.
CSZ_M9p0_sa03_site	Site spectral acceleration at 0.3 sec, in g (standard gravity).
CSZ_M9p0_sa10_site	Site spectral acceleration at 1.0 sec, in g (standard gravity).

Permanent Ground Deformation (PGD) (rasters)

Each PGD raster is accompanied with a probability (Prob) raster

CSZ_M9p0_PGD_landslide_dry	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_landslide_dry	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
CSZ_M9p0_PGD_landslide_wet	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_landslide_wet	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
CSZ_M9p0_PGD_liquefaction_wet	Permanent ground deformation due to liquefaction lateral spreading. Liquefaction assumes wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_liquefaction_wet	Probability of liquefaction under wet (or saturated) soil conditions. In percent.

Synthetic Portland Hills fault magnitude 6.8 earthquake

Bedrock ground motion

PHF_M6p8_bedrock_groundmotion	Pointfile with descriptors of bedrock ground motion (pga, pgv, sa03, sa10)

Site ground motion (rasters)

PHF_M6p8_pga_site	Site peak ground acceleration, in g (standard gravity).
PHF_M6p8_pgv_site	Site peak ground velocity, in centimeters per second.
PHF_M6p8_sa03_site	Site spectral acceleration at 0.3 sec, in g (standard gravity).
PHF_M6p8_sa10_site	Site spectral acceleration at 1.0 sec, in g (standard gravity).

Permanent Ground Deformation (PGD) (rasters)

Each PGD raster is accompanied with a probability (Prob) raster

PHF_M6p8_PGD_landslide_dry	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_landslide_dry	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
PHF_M6p8_PGD_landslide_wet	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_landslide_wet	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
PHF_M6p8_PGD_liquefaction_wet	Permanent ground deformation due to liquefaction lateral spreading. Liquefaction assumes wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_liquefaction_wet	Probability of liquefaction under wet (or saturated) soil conditions. In percent.

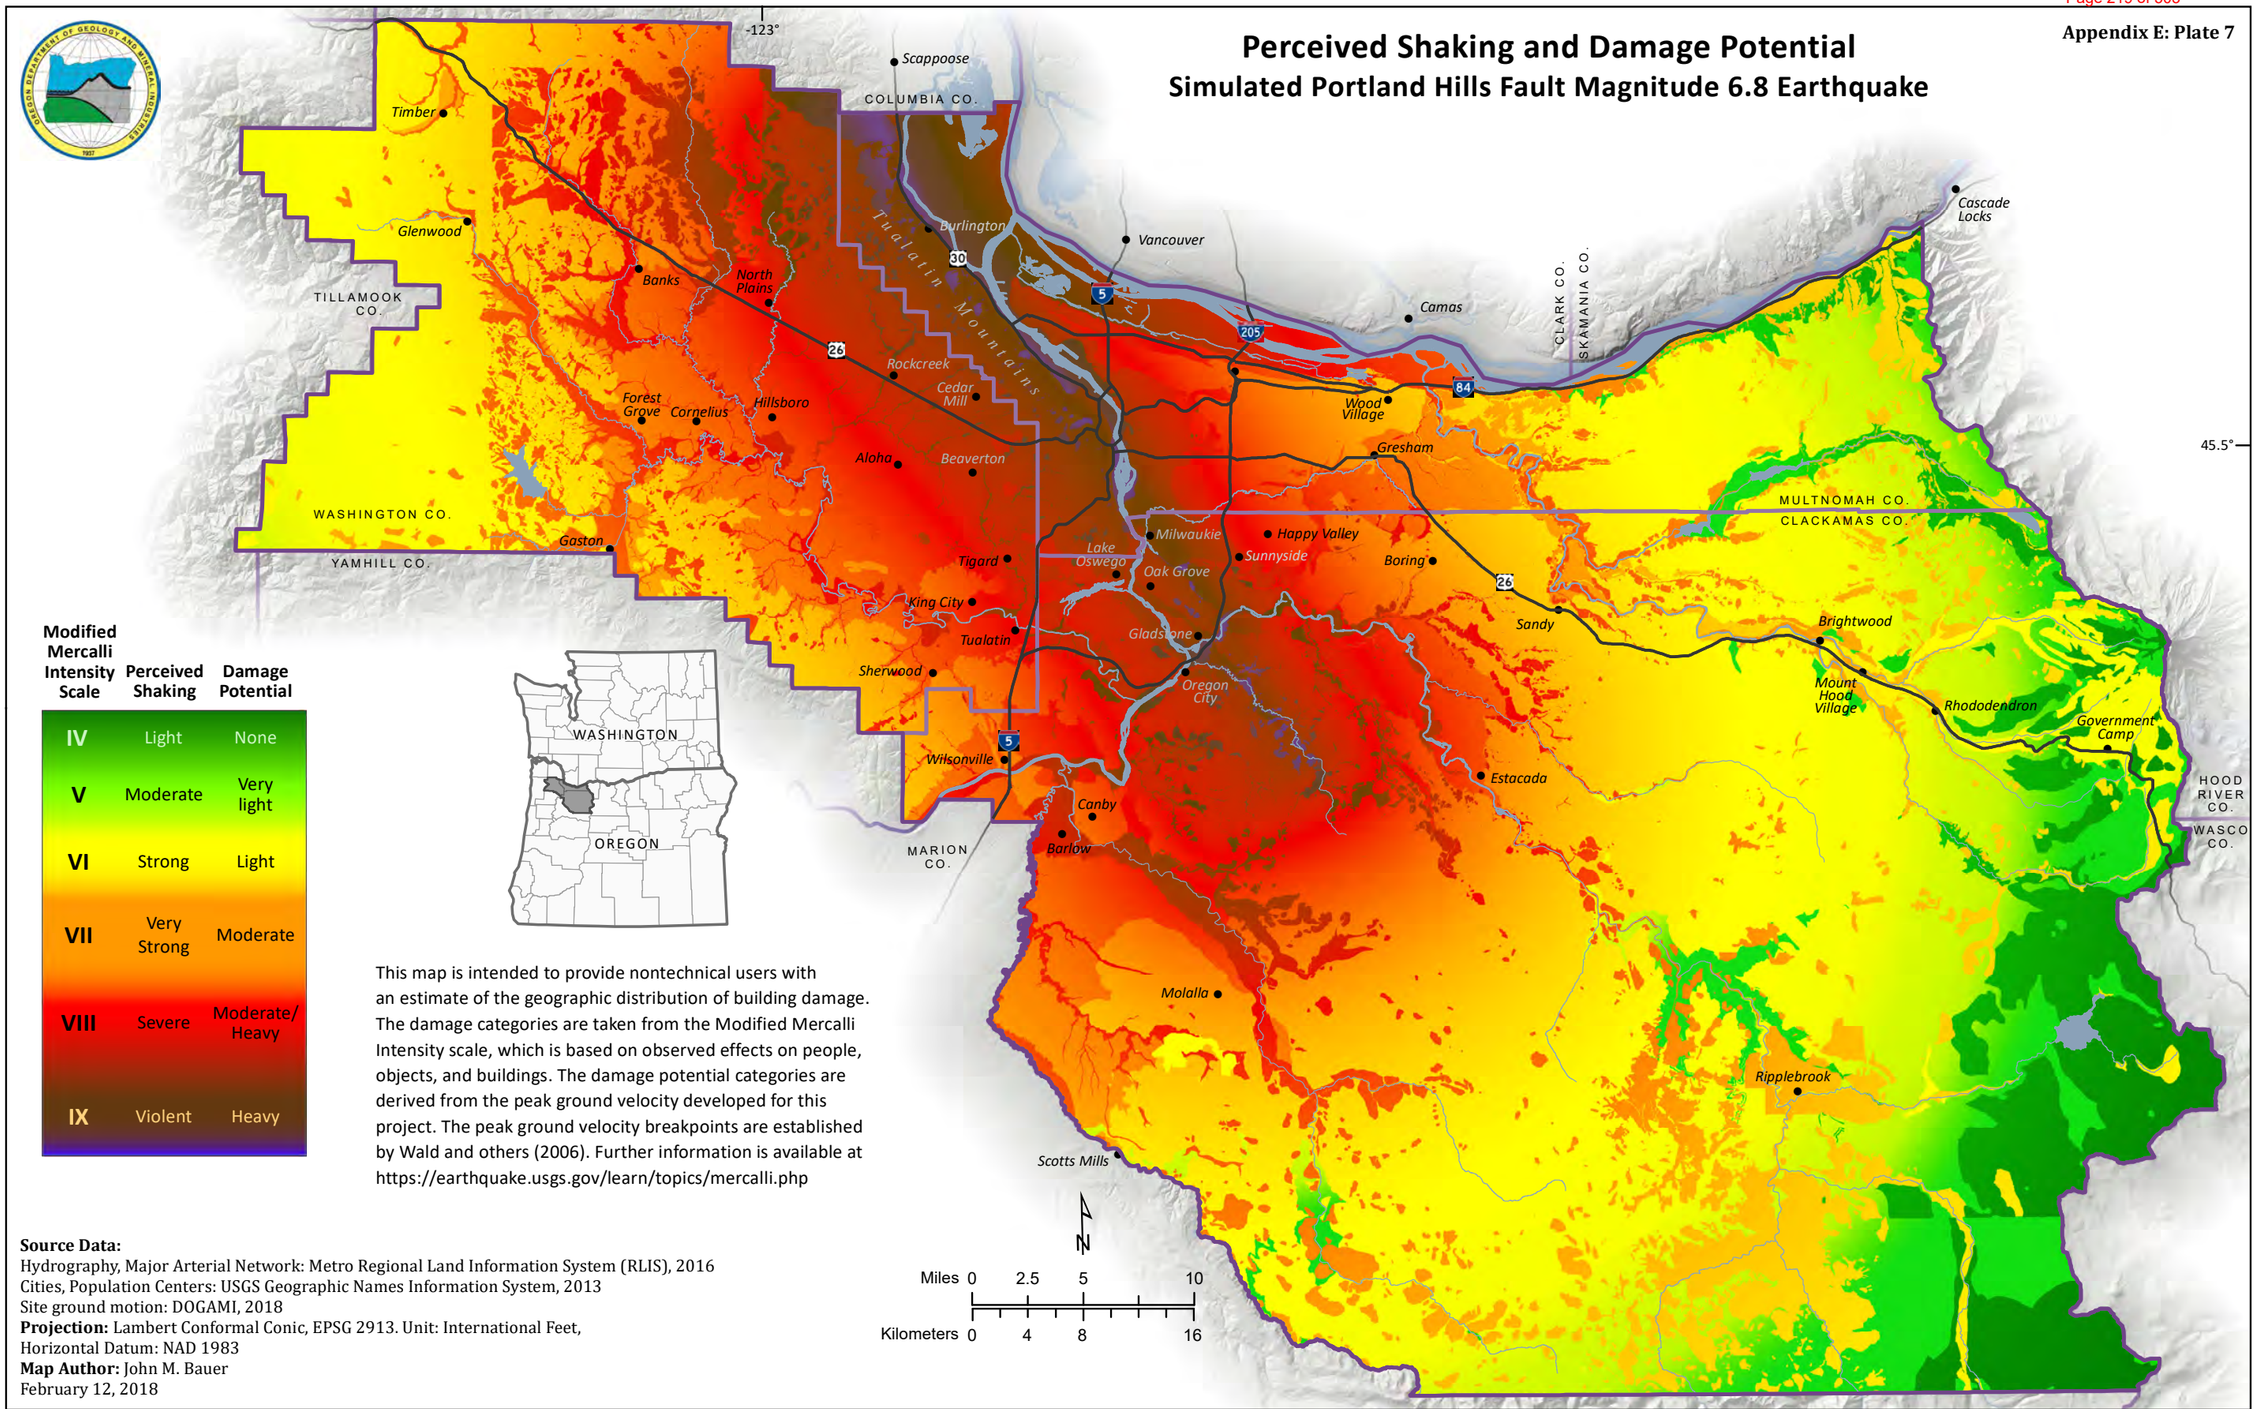
Perceived Shaking and Damage Potential

Simulated Cascadia Subduction Zone Magnitude 9.0 Earthquake

Modified Mercalli Intensity Scale	Perceived Shaking	Damage Potential
IV	Light	None
V	Moderate	Very light
VI	Strong	Light
VII	Very Strong	Moderate
VIII	Severe	Moderate/ Heavy
IX	Violent	Heavy



This map is intended to provide nontechnical users with an estimate of the geographic distribution of building damage. The damage categories are taken from the Modified Mercalli Intensity scale, which is based on observed effects on people, objects, and buildings. The damage potential categories are derived from the peak ground velocity developed for this project. The peak ground velocity breakpoints are established by Wald and others (2006). Further information is available at https://earthquake.usgs.gov/learn/topics/mercalli.php

Submitted via Map App portal

RE: Testimony in Support of Re-Adopting Fossil Fuel Terminal Zoning Amendments

Dear Mayor Wheeler and Portland City Council Commissioners,

Thank you for the opportunity to offer our comments on the proposed re-adoption of the City of Portland's Fossil Fuel Terminal Zoning Amendments ("amendments"). These comments are submitted on behalf of Columbia Riverkeeper, Center for Sustainable Economy, Oregon Physicians for Social Responsibility, Portland Audubon Society, 350PDX, Friends of the Columbia Gorge, Willamette Riverkeeper, Climate Action Coalition, Northwest Environmental Defense Center, Oregon Conservancy Foundation, and Human Access Project. We appreciate and support the City's commitment to address the issues identified by the Land Use Board of Appeals and re-adopt the amendments as they were originally adopted in December 2016, with the minor adjustments as proposed in the Remand Report. We offer the following comments as general support for the proposed amendments and to provide additional evidence that we believe is relevant to the Council's decision.

I. Re-adopting the Amendments is Consistent with Council Resolutions and the City's Commitments.

The City Council has adopted several policies aimed at reducing the risks associated with bulk fossil fuel infrastructure and climate change impacts associated with fossil fuel consumption. The amendments further these policies by designating bulk fossil fuel terminals as a limited use in the city. In November 2015, Council adopted Resolution 37168, where it resolved to "actively oppose expansion of infrastructure whose primary purpose is transporting or storing fossil fuels in or through Portland or adjacent waterways[.]" The amendments directly advance the resolution by prohibiting new bulk fossil fuel terminals and limiting the expansion of existing terminals within the city.

With respect to specific fossil fuel developments, in adopting Resolutions 36959 and 36962 in 2012, Council expressed opposition to coal trains travelling through Portland until a programmatic, comprehensive environmental impact statement and health impact assessment are completed. Similarly, in November 2015, Council adopted its Oil Train Policy through Resolution 37164, which called for the City to oppose any project that would increase oil train traffic through Portland. The amendments are an important first step in advancing these policies by prohibiting new or expanded bulk fossil fuel storage and transloading within the city in order to address existing health and safety risks associated with these facilities.

Portland's 2015 Climate Action Plan sets a goal to reduce local carbon emissions by 80 percent from 1990 levels by 2050. In June 2017, Council adopted Resolution 37289, which established a goal to transition to 100% renewable energy community-wide by 2050. The amendments are consistent with these policies because they restrict new bulk fossil fuel developments and provide flexibility for existing terminals to reconfigure and transition storage capacity to non-fossil fuels to meet shifting energy demands.

Additionally, the amendments are consistent with and support each of the five Guiding Principles of the 2035 Comprehensive Plan. Specifically, the amendments support economic prosperity and a low-carbon economy by prioritizing growth in non-fossil and renewable fuels over additional fossil fuel development on Portland's limited available industrial land. The amendments support human and environmental health by seeking to avoid and minimize the potentially catastrophic health, safety, and environmental risks associated with the existing bulk fossil fuels infrastructure. Finally, the amendments support equity and resilience by halting continued development that concentrates risk in communities disproportionately impacted by fossil fuel infrastructure and in areas that have significant seismic vulnerabilities.

II. The Amendments are Necessary to Address Serious Health and Safety Risks Associated with Existing Fossil Fuel Terminals.

Portland is at risk of a catastrophic earthquake from the Cascadia Subduction Zone, which has a 15–20 percent chance of rupture in the next 50 years and could be similar in impact to the Magnitude 9 earthquake that hit Japan in 2011. Additionally, the Portland Hills fault line, which runs underneath downtown Portland, is considered an active crustal fault line and could have significant impacts on the Portland Metropolitan Region.[1]

All of Portland's existing bulk fossil fuel terminals are located within the Critical Energy Infrastructure ("CEI") Hub. The Portland Bureau of Emergency Management's ("PBEM") 2019 CEI Hub study found that the majority of the facilities in the CEI Hub are constructed to no or low seismic standards and are mostly located on soft liquefiable soils that are typically associated with increased seismic vulnerability. Specifically, the study states, "the permanent ground deformations due to liquefaction and lateral spreading is expected to be very high at all fuel storage tank locations."[2]

Bulk fossil fuel terminals pose serious health and safety risks from explosions and fire as a result of seismic vulnerabilities. The CEI Hub Study evaluated impacts to fossil fuel storage tanks from various earthquakes in recent history. In each instance, tanks of similar design and age to those in the CEI Hub experienced tank buckling and cracking, roof collapse, uplift, and damage to connecting piping causing leakage, spills, and fire. The CEI Hub facilities are located in close proximity to residential neighborhoods, important transportation corridors, and the

Willamette River, which provides important habitat, economic, recreational, subsistence, and aesthetic values to residents of Portland and surrounding communities.

A recent example of the potential risks of fossil fuel storage tanks in the CEI Hub is the October 2019 explosion at the NuStar Energy fuel storage facility in Crockett, CA after a 4.5 magnitude earthquake struck near the facility.[3] The tanks erupted in flames for several hours and an explosion blew the roof off one of the storage tanks. Thousands of local residents were forced to stay in their homes to avoid dangerous air pollution, the nearby interstate I-80 was closed for several hours,[4] and it is estimated that thousands of barrels of industrial chemicals were released from the tanks.[5] According to local officials who investigated the incident, the tanks were only at 1% of their storage capacity, indicating that the impacts could have been much worse had the tanks been filled.[6]

Tanks at NuStar Energy facility in Crockett, CA are consumed with flames. Photo: Contra Costa County

In addition to risks with storage tanks, bulk fossil fuel terminals also involve high-risk transport of volatile liquids through communities. Oil trains associated with bulk fossil fuel storage have an estimated risk of derailment as high as one in every 30 months. In 2016, an oil train derailed in the Columbia River Gorge in Mosier, spilling 1,000-barrels of oil and affecting local drinking water facilities. In August 2018, a train carrying tar sands crude oil derailed in Doon, Iowa and released 230,000 gallons of tar sands crude into a local river.[7] Earlier this year, a Union Pacific train carrying liquified petroleum gas (LPG) derailed in Portland and struck a support beam for the Going Street overpass bridge, causing a main access point to Swan Island to close.[8] Thankfully, none of the tank cars leaked, which likely would have caused significantly

more damage to the bridge and surrounding area and prolonged disruption of access to the Swan Island industrial area.

Without the amendments, Portland's zoning code would allow for new bulk fossil fuel terminals to be located within the high-risk liquefaction areas without any restrictions on size or format and would allow for the unlimited expansion of the existing terminals. The City's 2035 Comprehensive Plan recognizes the importance of limiting the potential catastrophic risks to health, safety and the environment associated with bulk fossil fuel terminals (Goal 4.B) and of ensuring long-term resilience of development to withstand natural disasters (Goal 4.D). The amendments are consistent with these goals.

On October 16, 2019, Council adopted an amendment to the City's budget to allocate $50,000 of funding to partner with Multnomah County and Portland State University to study and mitigate the risks of fossil fuel infrastructure in the CEI Hub. During the City Council meeting to adopt the amended budget, Mayor Wheeler stated that this study is a "foundational piece to the city strategy to transition to a clean, secure, and safe energy future." The amendments are the necessary first step to confronting the serious risks posed by Portland's existing bulk fossil fuel infrastructure. The City must first ensure that these risks are not made worse through continued and unlimited development of fossil fuel infrastructure, then it must turn to developing and implementing policy to reduce those risks and improve safety and resilience in the CEI Hub.

III. The Amendments are Consistent with Local and State Efforts to Transition Away from Fossil Fuels.

Greenhouse gas emissions from burning fossil fuels are a major contributor to climate change and pollution. As climate change accelerates, Portland will experience greater incidence of drought, high temperatures and increased risk of wildfire, damaging floods and landslides. The amendments are an important action towards encouraging and facilitating local and state efforts to transition away from reliance on fossil fuels towards renewable and non-fossil fuel alternatives by restricting unlimited growth of fossil fuel storage while providing flexibility for growth in storage of non-fossil fuels.

As discussed above, the City has committed to significantly reduce its greenhouse gas emissions below 1990 levels and to transition to 100% renewable energy by 2050. Multnomah County is a partner in the City's Climate Action Plan and has also committed to numerous actions to reduce carbon emissions by 2020. The State of Oregon has a goal to reduce climate emissions levels 75% below 1990 levels by 2050.

As of 2017, per-capita carbon emissions in Portland had reduced 38% below 1990 levels, despite increases in population and job growth. Total carbon emissions in Multnomah County are down 15% from 1990 levels due to growth in renewable energy sources, investments in transit and bike infrastructure, dense and walkable neighborhoods, renewable transportation fuels and other measures. Continued efforts toward meeting local, statewide and regional goals to transition away from fossil fuels will result in further declines in carbon emissions and in the demand for fossil fuels.

The City has adopted multiple other policies aimed at reducing fossil fuel consumption, increasing reliance on renewable energy and reducing greenhouse gas emission. In Resolution 37255, the City adopted the 2017 Portland Electric Vehicle Strategy to shift from gasoline and diesel to lower-carbon transportation fuels with the specific goal of replacing at least 10,000 fossil fuel-powered vehicles in Multnomah County by 2020.[9] In December 2018, the City adopted rules to incentivize property owners and developers to design highly energy efficient buildings in planned development.[10] In May 2018, Portland voters passed Measure 26-101, which created the Portland Clean Energy Community Benefits Fund (PCEF).[11] The measure imposes a 1% surcharge on certain retail sales in Portland in order to fund clean energy projects, clean energy jobs training, and other programs to reduce greenhouse gas emissions. The City is expected to begin issuing funding awards for these projects in July 2020.

There are also statewide efforts to reduce fossil fuel consumption and the corresponding greenhouse gas emissions. Oregon's electric grid is moving toward becoming one of the cleanest in the country. In signing SB 1547, Governor Brown doubled Oregon's renewable portfolio standard to 50% by 2040. The Oregon Clean Fuels Program requires a 10 percent reduction in average carbon intensity from 2015 levels by 2025.[12] Oregon's 2020 Clean Fuels Forecast predicts a less than 0.5% increase in conventional gasoline and a 2.5% reduction in fossil diesel consumption as compared to 2018 levels.[13] Meanwhile, consumption of electricity for on-road plug-in hybrid and battery electric vehicles is projected to increase 25% over 2018 levels.[14] In Executive Order 17-21, Governor Brown set a target to reach 50,000 electric vehicles in Oregon by 2020–more than double the number of actively registered EVs in 2018.[15]

Several recent studies evaluate various pathways to decarbonization in Oregon and the Pacific Northwest. One report prepared for Portland General Electric, projects that even under the reference case with a continuation of current and planned policy, end-use demand for liquid transportation fuels, such as gasoline and diesel, will decrease by 2050.[16] With additional changes in policy to move towards greater electrification of the energy system, demand for fossil fuels would sharply decline.[17] Another report projects that under the most flexible path to decarbonization, fossil fuels in liquid and gaseous fuel supply mix for diesel and jet fuel will be entirely replaced by biofuels by 2050.[18]

The amendments are narrowly tailored to focus on one aspect of fossil fuel infrastructure developments–bulk storage. The amendments do not regulate fossil fuel transport or the docks, pipelines, or rail infrastructure used for fossil fuel transport in or through Portland. The amendments leave flexibility for growth in non-fossil and renewable fuels storage and distribution in order to meet local and regional commitments to transition away from fossil fuels.

IV. Council Should Commit to Future Action to Address Fossil Fuel Infrastructure Risks and Foster a Clean, Safe Energy Economy and Stable Climate.

As noted above, the amendments are an important first step to addressing the serious health, safety, and climate change risks associated with the existing bulk fossil fuel terminals in Portland. We strongly support the Council's action to re-adopt the amendments as drafted and move towards full implementation as soon as possible. Nonetheless, the amendments are far from a complete solution to the risks facing our city and we strongly encourage the Council and City staff to continue to develop and adopt policies and regulations to fully address these risks.

PBEM's 2019 CEI Hub Study recommends that the City develop seismic performance criteria for storage tanks at the CEI Hub.[19] Thus, as directed by Council when it first adopted these amendments, the City should move forward on its commitment to identify policy and regulatory options to require seismic updates of storage tanks in the CEI Hub with a firm deadline for replacement of older, unsafe tanks.

Additionally, we fully support Council's decision to participate in the PSU CEI Hub risk assessment and we encourage the City to analyze and develop a mechanism that places the financial burden of the health and safety risks associated with existing fossil fuel infrastructure on the owners of those facilities. A catastrophic event at the CEI Hub could cause billions of dollars in damage to infrastructure, the Willamette River, and the surrounding Portland community. The owners of the fossil fuel terminals—rather than Portland residents—should bear the burden of the expense for emergency response and clean up from such a disaster.

Finally, while the amendments provide the necessary mechanism to stop continued expansion of bulk fossil fuel storage within the city, it is only a partial solution to the ongoing risks facing our community. As we have witnessed with the Zenith Energy facility over the past few years, existing facilities have the capability to shift their operations and add new infrastructure to intensify fossil fuel transport and storage. Beginning in 2014, the Zenith facility (formerly owned by Arc Logistics) quietly transitioned from an asphalt batch plant into a crude oil storage and transport terminal.[20] Earlier this year, Zenith completed construction on three new rail platforms that nearly quadrupled the facility's capacity for unloading tanks cars carrying tar sands crude oil.[21] With this expansion, Zenith is capable of receiving multiple mile-long oil trains per week—trains which must travel through the Columbia Gorge and Portland neighborhoods to reach the facility in the CEI Hub.

[19] CEI Hub Study, p.18.
[20] https://www.opb.org/news/article/crude-oil-terminal-planned-in-nw-portland/
[21] https://www.opb.org/news/article/more-oil-trains-willamette-columbia-portland/

The amendments do not prohibit this type of expansion or change in operations at existing bulk fossil fuel terminals. Thus, we encourage Council to take further steps to implement Resolution 37168 to oppose the "expansion of infrastructure whose primary purpose is transporting or storing fossil fuels in or through Portland or adjacent waterways." Specifically, Council should consider regulations on fossil fuel off-loading and transloading facilities and restrictions on the storage of particular fossil fuels such as dangerous tar sands crude oil. With these additional actions, the City can continue its work towards improving safety of Portland neighborhoods while supporting the managed decline of fossil fuel use throughout the region.

We look forward to the Council's vote to readopt the Fossil Fuel Terminal Zoning Amendments as written and to put this important policy into effect. We also look forward to working with the City to continue to develop proactive policies to address the health, safety, and environmental risks associated with fossil fuel infrastructure.

Oregon Climate Agenda:

A Strong, Innovative, Inclusive Economy While Achieving State Climate Emissions Goals

Kate Brown, Governor
Kristen Sheeran, Ph.D., Director, Carbon Policy Office and Governor's Climate and Energy Policy Advisor

November 28, 2018

STATE OF OREGON
Office of the Governor
KATE BROWN

Vision

Oregon has a strong, innovative, and inclusive economy that achieves the state's climate emissions goals through a complementary set of policies, including a least-cost, market-based greenhouse gas emissions pricing program.

Executive Summary

Climate change threatens our communities, our economy, our ecosystems, and our way of life in Oregon. We see the effects of climate change in record temperatures, declining snowpack, reduced summer streamflow, water scarcity, increased wildfires, and elevated public health risks. Climate change impacts every Oregonian, but our rural communities, our low-income communities, communities of color, and Tribes are especially vulnerable. Climate change also poses serious risks for many of Oregon's natural resource-based industries. Meeting the challenge of climate change and growing our economy are not mutually exclusive goals: we must do both.

Oregon has long been a national and world leader in demonstrating the Oregon Way: policies that preserve our natural environment while also supporting long-term economic competitiveness and business growth. The world is at a crossroads on climate policy, and Oregon must continue to pursue solutions that reduce emissions while creating good jobs and building a clean energy economy. The Governor's strategies for achieving her vision are:

1. Implement a well-designed market-based program to achieve our state climate emissions reduction goals at the least possible cost, while protecting our manufacturing sector and mitigating impacts and providing opportunities for low-income and rural communities, communities of color, and Tribes.

2. Hasten the pace of electrification of vehicles in Oregon by expanding electric vehicle infrastructure and incentives to support 50,000 electric vehicles on Oregon roads by 2020.

3. Decarbonize the electricity sector by achieving the state's renewable energy targets and encouraging grid modernization, while maintaining affordable and competitive electricity rates.

4. Expand opportunities for residential, municipal, and commercial customers to access clean energy services from their utilities while ensuring utility regulation supports the utility system and does not preference new customers over existing ones.

5. Maintain and strengthen strong energy efficiency investments in residential, commercial, industrial and agricultural sectors, expand the reach of energy efficiency programs to ensure all communities benefit, and improve the energy efficiency of state building codes.

6. Support world-leading industrial efficiency initiatives by Oregon's large industrial utility customers.

7. Pursue climate solutions that benefit rural communities and Tribes, support working lands, and foster resilience to climate change.

8. Create the new Oregon Climate Authority to better align state programs and expertise to achieve the state's climate policy goals.

The Governor's strategies will create new clean energy jobs across Oregon over the next five years and put Oregon on a trajectory to achieve the state's greenhouse gas reduction goals.

Background

Science

There is no doubt that the Earth's climate is warming, and Oregon is also experiencing that trend. The last three decades have been the warmest decades on record, and the five warmest years in the global record have all occurred since 2010.[1] Oregon's summers have become hotter and drier with record numbers of 90+ degree days. The Oregon Climate Change Research Institute projects average temperatures in Oregon will climb an additional 3-7 degrees Fahrenheit by mid-century under current emissions trends, or 2-5 degrees Fahrenheit if emissions level off.[2] The scientific consensus attributes the observed warming trend to increased greenhouse gas concentrations in the atmosphere from human activities, especially the combustion of fossil fuels.[3] In Oregon, transportation is the largest single source of greenhouse gas emissions, followed by electricity and natural gas.[4]

While some impacts of warming are now inevitable, every degree of additional warming we can avoid increases the livability of the planet for future generations. The international community's goal, reflected in commitments made by nearly every country in the 2015 Paris Climate Agreement[5], is to prevent the world from warming by more than 2 degrees Celsius (3.6 degrees Fahrenheit). This is the critical threshold beyond which the most serious consequences of climate change may become unavoidable.[6] Though the U.S. pulled out of the Paris Agreement[7], Oregon and 15 other states and Puerto Rico have committed to meeting their respective shares of global emissions reduction through the U.S. Climate Alliance. Together, Alliance jurisdictions represent 40% of the U.S. population and a $9 trillion economy – larger than every economy in the world except for the U.S. and China.[8]

> "Average temperatures in Oregon will climb an additional 3-7 degrees by mid-century under current emissions trends"

Oregon-Specific Impacts

Climate change threatens our communities, our economy, our ecosystems, and our way of life in Oregon. We see the effects of climate change in declining snowpack, reduced summer streamflow, and water scarcity.[9] We're witnessing larger and more damaging wildfires, insect outbreaks, heat waves, floods, acidic oceans[10], and algal blooms. Rising sea levels place homes and coastal infrastructure at risk[11], while changing ocean conditions compromise the health of fisheries and marine ecosystems.[12]

Climate change is already exacting significant costs on Oregon's economy. Our tourism and natural resource-based industries, including thousands of Oregon farmers, fishermen, and shellfish growers, are already experiencing significant negative effects.[13] The state spent $100 million this year fighting wildfires, a figure which does not include the value of lost timber, infrastructure, or economic activity.[14] The closure of trails due to wildfire, cancellation of outdoor events due to heat and smoke, diminished skiing and rafting due to lack of snowfall and summer streamflow, and fishing and shellfish closures threaten Oregon's $11.8 billion tourism industry.[15]

The impacts of climate change, while experienced by nearly every

7. Originally signed by 200 counties, there were only three countries in 2017 who had not signed the Paris Agreement: Nicaragua, Syria, and the United States. Syria and Nicaragua have since signed.

8. U.S. Climate Alliance, https://www.usclimatealliance.org/

Oregonian, pose even greater risks to vulnerable populations: rural communities, low-income communities, communities of color, and Tribes.[16] These populations may rely heavily on climate-impacted industries and natural resources, may be the least able to afford required adaptations, have fewer resources to plan for and recover from extreme weather events, and often suffer disproportionately from exposure to other pollutants.[17] Communities of color and low-income households already bear a disproportionate burden of disease and may experience cumulative health effects as climate-related disruptions increase in frequency. Climate disruptions may affect resources and habitats important to the cultural, community, medicinal, and economic health of Tribes.[18]

Particulate levels from wildfires may increase 160 percent in our region by mid-century, exacerbating risks to those with asthma, heart and lung disease.[19] When air quality deteriorates from smoke, it is children, the elderly, and those with pre-existing conditions who suffer first and most. The good news is that actions to reduce greenhouse gas emissions can produce other public health co-benefits, including improved air and water quality. The conversion to electric vehicles or biofuels, for example, can reduce exposure to diesel pollution, a known carcinogen and respiratory health risk.

Oregon's Leadership and Legacy

Reducing greenhouse gas emissions, creating climate-resilient communities and growing our economy are not mutually exclusive goals. We have a strong legacy of environmental stewardship in Oregon, and this history has shown us that well-designed programs can deliver public health and environmental benefits while facilitating a strong economy. Oregon has already taken important steps to reduce climate emissions and build a clean energy economy. Some of the foundational legislation addressing climate change in Oregon includes:

- Land use: Oregon's nationally renowned land use planning program (SB100) laid the groundwork for mitigation and adaptation in

Oregon for 45 years by creating dense, livable communities and protecting farms, forests, and natural areas from development.

- Energy Efficiency: The Northwest Power Act (1980) established energy efficiency as a cost-effective priority for the region, establishing Oregon's legacy as an energy efficiency leader nationwide. SB 1149 (1999) required Oregon's largest utilities to consistently invest in energy efficiency, using utility revenues collected through a public purpose charge.

- Renewable Energy: Oregon was one of the early states to adopt a renewable portfolio standard in 2007 (SB 838), when only two percent of Oregon's electricity came from renewable energy.

- CO2 Standard: In 1997, HB 3283 became the first U.S. law to specifically reduce levels of CO2 by requiring new power plants in Oregon to either reduce or offset some of their carbon dioxide emissions.

In 2007, HB 3543 established the Oregon Climate Change Research Institute (OCCRI) to advance regional understanding of climate change science, impacts, adaptation, and mitigation. HB 3543 also set specific, science-based climate emissions reduction goals for Oregon:

- Arrest the growth of emissions by 2010 (achieved)
- Achieve climate emissions levels that are 10 percent below 1990 levels by 2020 (not on track)
- Achieve climate emissions levels that are at least 75 percent below 1990 levels by 2050 (not on track)

Oregon Department of Environmental Quality produces an annual inventory of human-caused greenhouse gas emissions produced by economic sectors within Oregon. The inventory also includes emissions associated

with electricity imports that serve Oregon utility customers.[20] The Oregon Global Warming Commission uses this emissions inventory to track progress towards the state's emissions goals.[21] In its latest biennial report to the Legislature in 2017, the Oregon Global Warming Commission concluded that, despite Oregon's successes, current programs and policies are not sufficient and additional measures are needed to achieve the state's statutory emissions goals.[22]

Clean Energy Progress

Oregon has long been recognized as a national and global leader in energy efficiency. Energy efficiency reduces energy use, lowers utility system costs, saves customers' money on their utility bills, and avoids greenhouse gas emissions. Weatherization and energy efficiency improvements can also increase comfort, livability, improve public health, and lower health care expenditures, especially for low-income and rural communities. Energy efficiency is the lowest-cost energy resource available to Oregon utilities; for example, for every $1 the Energy Trust invests in energy efficiency, customers across Oregon save nearly $3.[23] Since 2002, the Energy Trust of Oregon has delivered $7.6 billion in savings on customer utility bills, while avoiding 22.8 million tons of carbon emissions. [24] Public utilities across Oregon

21. According to DEQ data, total emissions in Oregon in 2016 were 62 million metric tons of carbon dioxide equivalent. To achieve our 2050 goal, emissions need to fall to 14 million metric tons.

also administer their own energy efficiency programs, which contribute additional monetary savings and avoided carbon emissions.

Oregon's electrical grid is progressing toward becoming one of the cleanest in the country. A natural abundance of clean, zero-emissions hydropower provides about forty-percent of our state's electricity needs.[25] In 2010, Portland General Electric became the first utility in the country to commit to closing a modern baseload coal plant when it agreed to shut Oregon's only in-state coal plant in Boardman twenty years ahead of schedule in 2020.[26] When Governor Brown signed SB 1547, she committed Portland General Electric and PacifiCorp, our state's largest utilities, to eliminating all imported coal from Oregon electricity rates by date-certain, while doubling the amount of renewable energy required to serve Oregon customers to fifty-percent by 2040.

Recent changes in technology and the marketplace have placed a clean electricity system firmly within reach. The costs of wind and solar power have fallen dramatically over the last decade; for example, utility-scale solar costs have fallen more than seventy-percent since 2010. Onshore wind, solar, hydropower, and bioenergy-for-power are very cost-competitive, and in many markets, beating the generation costs for fossil-based electricity.[27] At the same time, the emerging energy storage technologies needed to balance intermittent resources – batteries and smart grid advancements – are rapidly improving in efficiency and price.[28] Our region also shows strong potential for hydroelectric "pumped" energy storage project. Utilities are increasingly using techniques such as demand response and direct load control to shift energy use from peak times in order to reduce the amount of needed generation. The growth and expansion of organized regional electricity markets will further lower costs and risks to customers while enabling greater integration of a diversity of energy resources. There are also opportunities to further decarbonize the natural gas grid through the addition of renewable natural gas.[29]

Economic Opportunity for Oregon

Oregon's emissions reduction goals reflect the state's share of global reduction efforts. But they are also an important signpost of the readiness of Oregon's economy and industries to compete in a climate-changed future. At the World Economic Forum in 2018, global business leaders identified climate change as this century's biggest business opportunity.[30] Led by China, global annual investment in clean energy exceeded $335 billion last year.[31] If positioned on the right side of this growing technological divide, Oregon can benefit from the investment fueling this global transformation. The world's economies are rapidly transitioning away from fossil fuels. Seventy jurisdictions worldwide have carbon pricing programs implemented or scheduled, representing twenty-percent of global greenhouse gas emissions. This list includes eleven U.S. states, Canada, Mexico, China, and Europe. The total value of the carbon priced under these initiatives exceeds $81 billion.[32]

The jurisdictions leading on climate change are building long-term competitiveness, creating good jobs, and improving access to affordable energy, while creating public health and environmental benefits. The clean energy sector worldwide now employs more than ten million people.[33] Nationally, the fastest growing occupations are in solar and wind power.[34] There are now more people employed in the U.S. in solar than in oil, coal, and gas combined.[35] The Pacific Coast jurisdictions of British Columbia, Washington, Oregon, and California – a region representing the world's fifth largest economy – witnessed regional economic growth of thirty-two percent since 2008, while emissions fell by six percent, demonstrating that it is possible to decouple economic growth from emissions growth. Clean economy jobs in these jurisdictions grew more than twice as fast as regional job growth overall.[36]

Recent Accomplishments

In the past three years under Governor Brown's leadership, Oregon has become a leader in the U.S. and globally on reducing climate pollution and building a clean economy:

Coal to Clean Energy in SB1547 (2016)

- SB 1547 removes coal from Oregon electricity rates, effectively divesting Oregon from out-of-state coal plants.
- SB 1547 doubled Oregon's Renewable Portfolio Standard to 50%.
- SB 1547 reaffirms Oregon's commitment to pursuing all cost-effective energy efficiency and demand response.
- SB 1547 authorized community solar programs and utility investments in electric vehicle charging infrastructure.

Transit, Clean Fuels and EV Rebates in HB2017 (2017)

- The Clean Fuels Program will lower the carbon intensity of transportation fuels by 10% over 10 years. Last year alone, the program reduced emissions by nearly 1 million tons.[37]
- HB 2017 helps modernize our transportation infrastructure, including new investments in public transit, pedestrian and bike lanes.
- A new Zero Emissions Vehicles Rebate Program will accelerate the adoption of electric cars, including specific incentives for low and moderate income households.

Executive Orders: EVs and Building Efficiency

- The Governor's Executive Order on Electric Vehicles established a goal of 50,000 zero-emissions vehicles in Oregon by 2020 (18,000 today).
- The Governor's Executive Order on Efficiency calls for new state-owned buildings to be carbon neutral in 2022; all new buildings to be solar ready by 2022; and new residential buildings to "zero energy ready" starting in 2023.

37. https://www.oregon.gov/deq/aq/programs/Pages/Clean-Fuels-Data.aspx

> "Oregon can no longer wait for federal action to address carbon emissions. States must act to protect their communities and grow their economies"

These efforts are contributing to a thriving clean energy jobs economy in Oregon. There are 50,000 people employed in energy efficiency, clean fuels and clean power generation in Oregon.[38] More than 130 wind and solar companies call Oregon home. Governor Brown is committed to growing the low-carbon economy and achieving our state emissions goals through smart policies and initiatives, including a least-cost, market-based greenhouse gas emissions pricing program that aligns economic incentives in favor of clean energy solutions. Oregon can no longer wait for federal action to address carbon emissions. States and local jurisdictions must act to protect their communities and grow their economies.

Why Oregon? Why Now?

The international scientific consensus on the human causes of climate change is clear. But climate change is a global phenomenon, leading some to question the value of state action to address a global problem of this scale. While it is true that Oregon contributes only a small portion of global greenhouse gas emissions, so too does any single jurisdiction. This is why governments worldwide are pulling together to provide leadership. As discussed above, the world is rapidly transitioning away from fossil fuels and every country in the world except for the United States has signed on to the Paris Agreement to keep the increase in global temperature to below 2 degrees Celsius.

38. U.S. Energy and Employment Report, May 2018. www.usenergyjobs.org

Governor Brown believes that state and local actions to address climate change are justified on both ethical and economic grounds. As the Governor says: "Future generations will judge us not by the fact of climate change, but by how we respond to it." Oregon has a responsibility to address its share of global emissions and the economic evidence strongly suggests our economy will be better for it. Two different economic analyses commissioned by the Legislature, each examining a different approach to carbon pricing in Oregon[39], both found negligible to positive impacts on Oregon's economy under reasonable scenarios.[40] These studies correspond to findings in the economics literature broadly, which demonstrate that well designed carbon pricing programs will not adversely impact the economy.[41]

The Governor's Strategies to Achieving Our Climate and Economic Goals

ONE: Implement a Market-Based Program to Reduce Emissions

Achieve our state climate emissions reduction goals, while protecting our manufacturing sector and mitigating impacts on low-income and rural communities, communities of color, and Tribes

TWO: Add 50,000 Electric Vehicles to Oregon Roads by 2020

Expand electric vehicle infrastructure and incentives to support 50,000 electric vehicles on Oregon roads by 2020

THREE: Decarbonize the Electricity System

Achieve the state's renewable energy targets and encourage grid modernization while maintaining affordable and competitive electricity rates

FOUR: Expand Access to Clean Energy Services

Expand opportunities for residential, municipal, and commercial customers to access clean energy services from their utilities

FIVE: Strengthen Energy Efficiency Investments

Maintain and strengthen energy efficiency investments in residential, commercial, industrial and agricultural sectors, expand the reach of energy efficiency programs to ensure all communities benefit

SIX: Increase Industrial Energy Savings and Competitiveness

Support world-leading industrial efficiency initiatives by Oregon's large industrial utility customers

SEVEN: Invest in Climate Solutions That Foster Resilience

Pursue climate solutions that benefit rural communities and Tribes, support working lands, and foster resilience to climate change

EIGHT: Create the New Oregon Climate Authority

Align state programs and expertise to acheive the state's climate policy goals

The Governor's strategies will create new clean energy jobs and put Oregon on a trajectory to achieve the state's greenhouse gas reduction goals.

ONE: Implement a Market Based-Program to Reduce Emissions

Implement a well-designed market-based program to achieve our state climate emissions reduction goals at the least possible cost, while protecting our manufacturing industry and mitigating impacts on low-income and rural communities, communities of color, and Tribes.

The state must set a gradually declining cap on emissions to achieve the state's emissions reduction goals with certainty. A market-based, cap-and-trade program will allow the state to achieve those emissions reductions at the least possible cost.

The basic construct of cap-and-trade is straightforward: large emitters either adopt technology to reduce emissions on-site or they purchase an emission allowance. The state caps the total amount of allowances economy-wide and gradually lowers the number of allowances over-time. Entities that can't reduce emissions cost-effectively will purchase allowances from entities that can attain reductions at a lower cost. The state sets the total cap on emissions at levels consistent with its goals, while the market determines where the actual reductions take place.

Cap-and-trade is an approach for reducing emissions widely supported

by economists because it aligns market incentives in favor of clean technologies, while providing regulated sectors flexibility in how they choose to comply. A federal cap-and-trade program in the 1990s reduced sulfur dioxide emissions from power plants and the associated acid rain at considerable savings.[42] Cap-and-trade programs have been adopted by many jurisdictions worldwide to address climate pollution, including Europe, China, California, Quebec, and ten Northeast states in the U.S. Oregon has the opportunity to connect its cap-and-trade program to existing programs, achieving administrative efficiencies and providing regulated sectors access to larger, established carbon markets.

Unlike a carbon tax, the goal of a cap-and-trade program is least-cost emissions reduction with certainty. A carbon tax can also reduce emissions cost-effectively, but may need to be continuously adjusted upward to drive the behavioral and technological change required to hit state emissions goals. Whereas with cap-and-trade, the cap sets a carbon budget across the economy and the cap is slowly and gradually reduced over time to achieve an emissions goal. The cap provides emissions reduction with certainty, and lets the market determine where the lowest cost reduction opportunities are. There is typically more flexibility for regulated industries under cap-and-trade unlike with with a carbon tax, where they pay the tax for every ton of emissions, or adopt technologies to reduce emissions on-site. With a cap-and-trade program, industries can reduce emissions on-site, purchase allowances from other regulated entities, purchase allowances at auction, or receive a distribution of allowances from the state. Moreover, if a jurisdiction links its cap-and-trade program to established carbon markets, its regulated sectors may access a larger market of allowances, offsets, and emissions reduction opportunities.

42. The SO2 Allowance Trading System and the Clean Air Act Amendments of 1990: Reflections on Twenty Years of Policy Innovation, Harvard Kennedy School, 2012. https://www.belfercenter.org/sites/default/files/legacy/files/so2-brief_digital4_final.pdf

A well-designed cap-and-trade program will take preventative measures to protect manufacturers in certain trade-exposed industries from competition in markets where climate emissions are not currently regulated. Once identified, sectors such as cement, pulp-and-paper, and steel could receive some free allowances to level the playing field with their competitors. Some utilities could also receive allowances to maintain competitive and affordable rates for customers. The distribution of allowances from within the state's allowance budget does not change the cap and the level of emissions reduction required economy-wide; it simply eases compliance while maintaining economic incentives to innovate and find ways to lower emissions. If the state auctions allowances, it can redirect proceeds to activities that further reduce emissions or help communities adapt to climate change impacts.

Governor Brown has identified the following priorities for a cap-and-trade program in Oregon:

• Science-based targets and innovation: The program goals should reflect the best available science and incentivize best-in-class technologies and carbon sequestration on natural and working landscapes.

•Protect vulnerable Oregonians: Protect vulnerable Oregonians from increased costs, especially low-income families, communities of color, Tribes, and people in rural areas.

•Maintain adequate cost-controls, certainty and transparency: The program must protect existing jobs and industries and provide certainty and transparency for covered sectors, including workers in those industries.

• Complement existing policies: Work alongside existing state policies to reduce emissions, transition to clean energy, and modernize our transportation infrastructure without duplicating costs.

• Link to the Western Climate Initiative (WCI): Oregon should seek to link its program to the larger, established WCI carbon market. This option could ensure greater price stability, certainty, access to wider range of emission reduction opportunities and administrative

TWO: Add 50,000 Electrical Vehicles to Oregon Roads by 2020

Hasten the pace of electrification of vehicles in Oregon by expanding electric vehicle infrastructure and incentives to support 50,000 electric vehicles on Oregon roads by 2020.

As EVs have entered the mainstream over the past several years, Oregon has consistently been a national leader in EV market share, boasting some of the highest rates of EV sales in the country. There are currently nearly 18,000 electric vehicles in Oregon[43], and in November 2017, Governor Brown established an ambitious target to reach 50,000 EVs by the end of 2020.[44] Executive Order 17-21 outlines a range of state actions to provide additional support to this growing market for clean cars. The executive order deploys more EVs in public fleets, establishes recognition programs for EV champions, helps school and transit districts deploy clean buses, and provides support to many other state programs around low-carbon transportation. The 2017 transportation package (HB2017) created one of the nation's leading rebate programs to incentivize EV purchases.

43. As of 6/30/18, there were 17,893 actively registered electric vehicles in the Oregon Department of Motor Vehicles database.

44. State of Oregon Office of the Governor, 2017. "Executive Order 17-21: Accelerating Zero Emission Vehicle Adoption in Oregon to Reduce Greenhouse Gas Emissions and Address Climate Change." Available at: https://www.oregon.gov/gov/Documents/executive_orders/eo_17-21.pdf

Fossil Fuel Terminal Zoning Amendments Testimony
Ordinance #189807
LUBA No. 2020-009
Page 4366

Governor Brown is committed to seeking innovative ways to reduce transportation emissions. The state will continue to be a national leader in EVs through successful implementation of the components of Executive Order 17-21, successful marketing of the EV rebate, collaboration with utilities, dealerships, auto manufacturers, and other private sector entities, and successful implementation of the Clean Fuels Program. Electric vehicles may play the biggest role in the near term, but hydrogen fuel cell vehicles and vehicles powered by renewable biofuels are also an important part of the Governor's vision for a low-carbon transportation system.

THREE: Decarbonize the Electricity System

Achieve the state's renewable energy targets and encourage grid modernization while maintaining affordable and competitive electricity rates.

For decades, Oregon utilities have served Oregon customers well with reliable, affordable electricity. Looking ahead, our utilities are well-positioned to deliver a wider range of clean energy services and emissions reductions to help the state meet its emissions goals. Utilities are actively investing in clean energy, energy efficiency, grid modernization, and electric charging in response to market demand and existing state policies. To hasten this transition while maintaining low rates for customers, Governor Brown supports:

• Complementing existing policies without duplicating costs: Oregon's energy efficiency programs, the renewable portfolio standard, and coal-to-

clean requirements have set utilities along a path to significant emissions reductions. Customers pay for these investments in their electricity rates. A market-based emissions trading program provides the flexibility to incentivize a faster transition to clean energy without duplicating costs, by allocating carbon allowances to utilities on behalf of their customers to account for emissions reductions already reflected in customer rates. This approach maintains market incentives, while maintaining affordable electricity rates. The cap-and-trade program also provides clear direction to the Public Utility Commission to consider regulated-climate emissions as part of its role as economic regulator of investor-owned utilities.

•Regionalization: Oregon must actively coordinate with neighboring states and utilities to ensure regulatory alignment and safeguard the emergence of regional power markets as it transitions to clean energy and implements a cap-and-trade program. The goal is to ensure that regional electricity markets can continue to enhance reliability, reduce costs, and facilitate greater integration of renewable energy resources, while providing new market opportunities for the low-carbon and hydropower resources abundant in our region.

FOUR: Expand Access to Clean Energy Services

Expand opportunities for residential, municipal, and commercial customers to access clean energy services from their utilities while ensuring utility regulation is designed to support the utility system and does not preference new customers over existing ones.

As technologies improve, residential, municipal, and commercial customers of natural gas and electric utilities increasingly seek more choices in clean energy services from their utility, including options such as rooftop solar, electric vehicle charging, renewable natural gas, carbon offsets and renewable power. These emerging green power options provide utility customers the flexibility they seek to meet their own sustainability and renewable energy goals.

Governor Brown supports expanding green power options and tariffs for residential, municipal, and commercial utility customers, provided these options do not compromise the efficiency and reliability of the utility system or impose costs on existing customers. Designed well, utility green power options can enhance the quality of utility services, continue to attract sustainability-minded businesses to Oregon, create good jobs in the clean power sector, and reduce Oregon's emissions.

FIVE: Strengthen Energy Efficiency Investments

Maintain and strengthen energy efficiency investments in residential, commercial, industrial and agricultural sectors, expand the reach of energy efficiency programs to ensure all communities benefit, and improve the energy efficiency of state building codes.

Energy efficiency is the cornerstone of a low-carbon economic development strategy and Oregon should continue aggressive efforts to acquire energy efficiency in all sectors. At the same time, Oregon needs to expand energy efficiency and weatherization programs to reach traditionally under-served communities by identifying and overcoming barriers to serving these communities. Oregon also needs to capture a wider range of energy efficiency improvements beyond the lowest cost, "low hanging fruit" measures that have already been picked. Carbon pricing can help level the playing field for energy efficiency, just as it does for renewable energy resources, by better accounting for the climate and public health costs of fossil fuels in resource decisions by utilities and other actors in the economy.

Buildings are large consumers of electricity and natural gas. In addition to increasing our efforts to update our existing buildings with energy efficiency improvements, Oregon needs stronger building codes for new construction. By adopting state-of-the-art building codes, Oregon can lock in energy savings and avoided emissions from new residential and commercial buildings for decades to come. Governor Brown's Executive Order No. 17-20 focused specifically on the built environment - residential, commercial, and public buildings across the state. Specifically, the Governor's Executive Order directs:

• Solar-ready buildings. New residential buildings should be ready for solar panel installation by 2020 for residential buildings and 2022 for commercial buildings.

• Zero-energy homes. For new residential construction, structures will need to achieve at least equivalent performance levels with the U.S. Department of Energy "Zero Energy Ready Standard" by 2023.

• High performance buildings. For new commercial construction, buildings will exceed national model energy codes and meet energy efficiency levels of high-performance standards by 2022.

• High efficiency H20. For new construction, the commercial code will require high-efficiency water fixtures by 2020, and the ability to capture and safely reuse water for irrigation or other uses by 2025.

• Building Retrofits: Calls for coordinated agency action to increase energy efficiency in existing buildings, with emphasis on affordable housing, multi-family dwellings, and buildings that are well below current building code requirements.

In these efforts, the state will demonstrate leadership by leading by example, ensuring that existing state-owned buildings operate efficiently and that new buildings operate as carbon-neutral by 2022.

SIX: Increase Industrial Energy Savings and Competitiveness

Support world-leading industrial efficiency initiatives by Oregon's large industrial utility customers.

Oregon's large industrial utility customers have pursued a variety of energy saving measures, including waste heat utilization, lighting modifications, energy management systems, energy efficient pumps, and industrial process modifications. But there is more potential to capture industrial energy efficiency savings in the market. Governor Brown supports a focused effort to reduce the energy intensity of Oregon's industries through creative partnerships and innovative approaches to identify and overcome barriers preventing the acquisition of all cost-effective energy efficiency in the industrial sector. This could include dedicating proceeds from Oregon's cap-and-trade program to help Oregon industries adopt more efficient technologies and equipment. These efforts can help Oregon industries maintain global competitiveness while reducing emissions at the same time.

In addition, Oregon should leverage existing efforts to become a global leader in industrial energy efficiency technologies. Collaborations between industry, universities, and government, such as the Oregon Manufacturing and Innovation Center, can lead to world-class innovations in advanced manufacturing, as well as new jobs and career pathways for Oregonians. Oregon's climate policy should support these and related efforts to build centers-of-excellence in green technologies here in Oregon.

SEVEN: Invest in Climate Solutions That Foster Resilience

Pursue climate solutions that benefit rural communities and Tribes, support working lands, and foster resilience to climate change.

Natural and working lands, including Oregon's farms, forests, ranchlands, grasslands, and wetlands, are vital to the health and resilience of rural communities but are threatened by the impacts of climate change. Working and natural lands also sequester and store carbon emissions at significant levels and play an important role in addressing climate change. Governor Brown is committed to maintaining and enhancing the health and viability of our working and natural lands in the face of climate change. This includes:

• Protecting the resources and habitats threatened by climate change that are important to the cultural, community, medicinal, and economic health of Tribes.

• Working with landownders, producers, and stakeholders to keep agricultural lands in production and avoid the conversion to more emissions-intensive uses.

• Providing technical and other assistance to producers looking to implement practices and technologies that improve soil health, increase productivity, and sequester carbon.

• Exploring innovative investments in working and natural lands that address water scarcity, reduce energy use, foster resilience to climate change, and increase carbon sequestration and storage.

EIGHT: Create the Oregon Climate Authority

Align state programs and expertise to achieve the state's climate policy goals.

In response to the urgency of the climate crisis and the need to better align state programs and expertise to achieve the state's climate goals, Governor Brown proposes a new Oregon Climate Authority and ceasing the operations of the Department of Energy and Carbon Policy Office. The Governor's vision is for a new entity, transparent and responsive to stakeholders and the regulated community, with exceptional domain and market expertise that is responsible for implementing the state's climate and clean energy strategies and tracking progress toward the state's climate goals. This would include the new carbon marketplace, greenhouse gas emissions reporting and accounting, energy markets data collection and analysis, as well as energy programs central to the state's climate and clean energy goals. The Governor would appoint a Director, subject to Senate approval, and work with the Legislature to appoint an advisory board and move existing energy programs to the new entity or other state agencies. By aligning state programs in this new capacity, the state can significantly reduce the Energy Supplier Assessment currently paid by utility rate payers.

2020 Clean Fuels Forecast

Background

Oregon Revised Statutes (2017) Chapter 750, Section 163[1] authorizes the Office of Economic Analysis (OEA), in coordination with the Department of Environmental Quality, to assess the availability of fossil and alternative fuels in Oregon. In particular, the forecast is to determine whether fuel supply will be sufficient to generate alternative fuel credits (on ethanol, electricity, and diesel substitutes - including biodiesel, renewable diesel, natural gas, and propane) to meet the scheduled low carbon fuel standards for the compliance period. The forecast report is required to include an assessment of total deficits and banked credits at the beginning of the compliance period.

In preparing the forecast, the Office of Economic Analysis has formed a Clean Fuels Forecast Advisory Committee comprised of relevant experts and stakeholders to assist in reviewing methodological considerations and various data sources. A membership list can be found in Appendix A.

Data Sources

The forecast uses available public and program data to develop the estimates of low-carbon fuels available to Oregon and estimated consumption of fossil and alternative fuels in Oregon. The sources of this data include:

- Oregon Clean Fuels Program (CFP) Online System
- Fuel Pathway Codes (carbon intensity values) approved in Oregon and California
- Oregon Department of Transportation's (ODOT) Revenue Forecast
- Oregon DMV vehicle registration data
- Annual Energy Outlook and other resources from the US Energy Information Administration
- Trade associations (Renewable Fuels Association and the National Biodiesel Board) on their members' production capacity

Clean Fuels Program 2020 Consumption Forecast

To determine the amount of deficits that will be generated in 2020, and thus the amount of credits needed for compliance, a forecast for consumption of all relevant fuels must be made. The following are the volume projections for each fuel type.

Gasoline Consumption

1,708 million gallons of gasoline, including ethanol, were consumed in 2018, the most recent year of data collected. Growth projections exhibited in the Oregon Department of Transportation's December 2018 forecast equal an annualized 0.8 percent from 2018 to 2020. There were two factors considered in making adjustments to these initial growth parameters: ODOT observed gasoline consumption coming in lower than projected through the first two quarters of 2019. Secondly, the mandated decreases in the carbon intensity targets for fossil fuels incentivize reporting parties to record supplies of fuel in the earliest year

[1] https://olis.leg.state.or.us/liz/2017R1/Downloads/MeasureDocument/HB2017/Enrolled

possible to minimize the deficits generated. For the first factor, growth was adjusted down to 0.4 percentage points. Given that the reduction in the carbon intensity target is the same in percentage terms for 2020 and 2021, ultimately no adjustment was made for potential pull forward in reporting. The final annualized growth in motor gasoline from the 2018 base year through 2020 is 0.4 percent annually, resulting in a projected 1,720.4 million gallons for the total gasoline pool. To determine the amount of conventional gasoline represented, ethanol must be subtracted. The blend rate assumed for 2020 is 10.1 percent, equal to that observed for 2018. The final forecast for conventional gasoline is 1,546.3 million gallons.

Diesel Consumption

According to CFP reported data, 771.2 million gallons of diesel, including bio- and renewable diesel, were consumed in 2018, the most recent year of data collected. Growth projections exhibited in the Oregon Department of Transportation's December 2018 forecast equal an annualized 1.4 percent from 2018 to 2020. The same add-factor considerations noted under the gasoline section were made for diesel as well, particularly the fact that diesel consumption fell far below projections through the first two quarters of 2019. The final annualized growth in total diesel from the 2018 base year through 2020 is -0.6 percent, resulting in a projected 762.5 million gallons of total diesel. To determine the amount of conventional diesel, biodiesel and renewable diesel must be subtracted. The blend rate for these biofuels are assumed to be 6.9 percent and 3.5 percent, respectively. The final forecast for the consumption of conventional diesel in 2020 is 683.2 million gallons.

Ethanol Consumption

The amount of ethanol reported for 2018 equaled 172.2 million gallons. As described above, the amount of ethanol projected for 2020 is based on a blend rate assumption driven by historical observations and trends, as well as blend rates observed in California. Given that the last actual blend rate observation, (for the 2018 compliance year), was 10.1 percent and that most gasoline consumed in Oregon is E10, the assumption for 2020 was maintained at 10.1 percent. This results in a forecast for ethanol consumption of 174.1 million gallons, which is 0.5 percent above the 2018 volume on an annualized basis. As with the fossil fuels, no adjustment was made for behavioral factors associated with the phasing in of the carbon intensity reductions given that the incentive would be similar on either end of the compliance period. This is true for the remaining alternative fuel forecasts, as well.

Electricity Consumption

Consumption of electricity for on-road vehicles is based on a projection of the number of plug-in hybrid and battery electric vehicles in use for the compliance period. DMV vehicle registration data provides actual vehicle numbers historically, from which growth projections and variances are derived to produce the number of electric vehicles projected to be in operation for the 2020 compliance period. This equaled an average of 13,050 Plug-in Hybrids and 19,772 Battery Electric vehicles. Historical volumes of electricity, including estimates for residential charging, are used to calculate average Kilowatt hours per vehicle year. For 2018, this parameter equaled 3,621 Kilowatt hours per year, which was in turn assumed for the 2020 compliance period. When converted to gasoline gallon equivalents, the forecast is 3.5 million gallons including residential charging. This is equivalent to a 25 percent increase from 2018 on an annualized basis.

Biodiesel Consumption

The reported volume of biodiesel in 2018 amounted to 51.7 million gallons. As described above, the amount of biodiesel projected for 2020 is based on a blend rate assumption driven by historical observations and trends, as well as blend rates observed in California. The highest observation in the Clean Fuels program data was 6.9 percent in 2017. This value was assumed for the 2020 forecast, resulting in a consumption projection of 52.6 million gallons. This represents growth of 0.9 percent from the 2018 actual on an annualized basis.

Renewable Diesel Consumption

The amount of renewable diesel reported in 2018 was 1.2 million gallons. Similar to biodiesel, the forecast for renewable diesel is driven by the assumption of the fraction of total diesel consumed comprised of renewable diesel. The blend rate observed for 2018 in the Clean Fuels data was 0.2 percent. In California, similarly small blend rates quickly escalated to 3.0 percent and beyond. Such an adoption schedule is assumed for Oregon, resulting in a blend rate projection for renewable diesel in 2020 of 3.5 percent. This leads to a consumption forecast of 26.7 million gallons, a substantial 369.8 percent above the 2018 value on an annualized basis.

Natural Gas and Propane Consumption

The amount of natural gas, including renewable natural gas (biogas), reported in 2018 in diesel gallon equivalents equaled 3.2 million gallons. This represented 14.7 percent growth from the prior year. Annualized growth from the 2018 base year to 2020 is assumed to be 6.9 percent, equal to the Energy Information Administration's outlook for the Pacific region. This results in a forecast of 3.6 million gallons, which is 6.9 percent annually above the 2018 level.

Propane exhibits the smallest quantity of alternative fuel reported in 2018 at 0.7 million gasoline gallon equivalents. However, this was 477.1 percent above the 2017 reported value. Annualized growth from the 2018 base year to 2020 is assumed to be 213.9 percent, resulting in a forecast of 7.3 million gallons.

The following table presents the 2020 consumption forecast in detail. Note that the percent change figures for 2020 represent annual growth from the last available actuals in 2018. To the extent that 2018 actuals were not known at the time the 2019 forecast was released, this explains the significant variance in changes related to the 2019 forecast. Presenting annualized changes from 2018 is thus more informative.

Table 1: Summary of fossil and alternative fuel consumption

(Mil. gallons, percent)	2018 Actual	2019 Forecast*	% change	2020 Forecast	annual %change vs 2018
Conventional Gasoline	1,535.4	1,437.0	-6.4%	1,546.3	0.4%
Ethanol	172.2	165.0	-4.2%	174.1	0.5%
Ethanol Blend Rate	10.1%	10.3%		10.1%	
Blendstock	1,707.6	1,602.0	-6.2%	1,720.4	0.4%
Fossil Diesel	718.2	705.0	-1.9%	683.2	-2.5%
Biodiesel	51.7	57.5	11.1%	52.6	0.9%
Biodiesel Blend Rate	6.7%	7.3%		6.9%	
Renewable Diesel	1.2	29.9	2370.6%	26.7	369.8%
Renew diesel Blend Rate	0.2%	3.8%		3.5%	
Total Diesel	771.2	792.3	2.7%	762.5	-0.6%
Electricity (on-road)	2.2	2.7	23.0%	3.5	25.0%
Electricity (off-road)	1.7	N/A		N/A	
Fossil Natural Gas	1.5	1.2	-17.8%	1.1	-13.6%
Biogas	1.7	2.8	62.9%	2.5	21.6%
Biogas Blend Rate	54.1%	70.0%		70.0%	
Total Natural Gas	3.2	4.0	25.8%	3.6	6.9%
Propane	0.7	1.3	72.2%	7.3	213.9%
*Forecast equals average of range published for 2019 forecast.					
On-road electricity include calculation of residential charging.					

Deficit and Credit Generation and Banked Credits

In order to estimate the number of deficits and credits associated with the consumption of each fuel type, the energy densities and carbon intensity differentials must be known. Most of the pertinent parameters are published here in administrative rule by the Department of Environmental Quality (see Tables 1, 2, and 4 starting on page 209). The following table presents these parameters for each fuel. Details regarding the estimation of carbon intensities for ethanol, biodiesel and renewable diesel can be found in Appendix B. Also included are the two parameters associated with electricity consumed by passenger vehicles. The carbon intensity assumption is adjusted for the energy economy ratio (EER). The actual carbon intensity of electricity is 109.3.

Table 2: Parameter values for the 2020 forecast

	Energy Density	Carbon Intensity Target	Carbon Intensity Assumption
Units	MJ/gallon	gCO2/MJ	gCO2/MJ
Gasoline	122.48	95.61	100.14
Ethanol	81.51	95.61	57.76
Diesel	134.48	96.27	100.74
Biodiesel	126.13	96.27	35.40
Reneweable Diesel	129.65	96.27	29.17
Electricity	3.6	95.61	32.15
KWh/vehicle	*3621*		
EER	*3.4*		
Natural Gas	134.48	96.27	79.98
Biogas	134.48	96.27	50.00
Liq. Petroleum Gas	89.63	95.61	80.88

Banked Credits

The number of credits is taken from the CFP Online System. The number of gross credits registered through the end of calendar year 2018 equaled 2.73 million, while the number of deficits recorded amounted to 2.23 million. The net credits banked equaled 502,608. Originally, OEA projected that another 365,348 credits will be banked during calendar year 2019. Given that another year of data are available, including actual fuel volumes (and thus blend rates for alternative fuels) for the 2018 compliance period, the 2019 estimated deficits and credits have been updated to reflect this. The total projected banked credits at the beginning of the 2020 compliance period is now expected to be 649,829.

Table 3: Summary of actual and projected net banked credits

Year	Deficits	Credits	Net Banked Credits
2016	-617,071	830,714	213,643
2017	-715,057	924,793	209,736
2018	-899,260	978,489	79,229
2019 (Proj.)	-1,015,633	1,162,854	147,221
Total	-3,247,021	3,896,850	649,829

Credit and Deficit Summary

The table below summarizes the forecast for deficit generation and credit generation. The equations for calculating the deficits and credits can be found in Appendix B.

Table 4: Summary of Deficits and Credits

Credit / Deficit Summary		
Deficits	Gasoline	-857,916
	Diesel	-410,701
Deficit Total		**-1,268,617**
Credits	Ethanol	537,140
	Biodiesel	403,946
	Renewable Diesel	232,191
	Electricity, on-road	92,317
	Electricity, off-road	25,784
	Natural Gas	17,896
	Propane	9,629
Credit Total		**1,318,903**
2020 Net Credits/Deficits		**50,286**
2019 Estimated Ending Banked Credits		**649,829**
Total Net Credits/Deficits		**700,115**

Forecasted Fuel Supply Deferral Analysis

As shown above, the forecast does not imply such an action.

Potential Supply of Alternative Fuels

Oregon Revised Statutes (2017) Chapter 750, Section 163[2] directs the Office of Economic Analysis to estimate the "potential volumes of gasoline, gasoline substitutes and gasoline alternatives and diesel, diesel fuel substitutes and diesel alternatives available to Oregon." In order to make such estimates, a number of assumptions must be made. Potential is read to mean "could be made available to Oregon under a wide range of market conditions". Currently, suppliers must be certified by the Department of Environmental Quality to receive credits for fuel delivered into Oregon. In addition, they must report volumes of fuel sold in Oregon to the Clean Fuels reporting system. It is assumed that selling fuel in Oregon implies established supply chains. Thus, the capacity of facilities that were certified and supplied fuel to Oregon for the most recent compliance period (2018) is assumed to be theoretically "available" to Oregon. The potential supply figures presented in the following sections correspond to the most recently available nameplate capacities for these facilities manufacturing the respective fuels. Where multiple values are available, the highest is presented.

[2] https://olis.leg.state.or.us/liz/2017R1/Downloads/MeasureDocument/HB2017/Enrolled

In addition to estimating potential supply, the Office of Economic Analysis is directed to consider "Constraints that may be preventing access to available and cost-effective low carbon fuels by Oregon, such as geographic and logistical factors, and alleviating factors to the constraints". Only biofuels that might pose a supply constraint that could ultimately limit the number of credits available to deficit holders to comply with the Clean Fuels program requirements are called out explicitly. Should supply issues arise for the more mature fuel markets such as conventional gasoline and diesel, as well as electricity, such issues would be added to the report. This is not anticipated for the foreseeable future.

Ethanol

As exhibited in Table 5, the potential supply of ethanol to Oregon as outlined above is 3.8 billion gallons. This compares to a projected "demand" for ethanol previously characterized of 174.2 million gallons.

Table 5: Ethanol Supply

Ethanol Supply Available to Oregon
(Existing Suppliers in 2018)

State	Nameplate Capacity (Mil. Gallons)	Number of Facilities
South Dakota	900	11
Nebraska	817	10
Iowa	650	7
Minnesota	478	6
North Dakota	300	2
Kansas	220	3
Colorado	110	2
Idaho	75	1
California	50	1
Oregon	43	1
Total Oregon Suppliers	3,643	44

Data from Energy Information Administration and Clean Fuels Program.

Biodiesel

Table 6 presents the potential supply of biodiesel to Oregon, equaling 743 million gallons in capacity for certified facilities with established supply chains in 2018. This compares to a projected demand for biodiesel in 2020 of 52.6 million gallons. Note that the Energy Information Administration is currently updating their data collection regarding biodiesel producers to match that for ethanol. When these data become available, more current estimates of nameplate capacity will be incorporated into the analysis.

Table 6: Biodiesel Supply

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Missouri	155	4
Iowa	106	2
Washington	105	2
Oregon	105	2
Nebraska	63	1
Arkansas	59	1
Korea	50	2
Oklahoma	35	1
Minnesota	30	1
Canada	22	4
Texas	15	1
Total Oregon Suppliers	743	21
Data from the Clean Fuels Program		

Renewable Diesel

As presented below, the potential supply of renewable diesel to Oregon equals 475 million gallons. This compares to a projected demand for renewable diesel in 2020 of 26.7 million gallons.

Table 7: Renewable Diesel Supply

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Singapore	291	1
Wyoming	109	1
Louisiana	75	1
Total Oregon Suppliers	475	3
Data from the Clean Fuels Program		

Renewable Natural Gas

The amount of renewable natural gas potentially available to Oregon amounts to 2.2 billion gallon equivalents. This compares to a projected demand for this biofuel of 2.5 million gallon equivalents. The

committee discussed the fact that a number of applications to supply additional renewable natural gas to Oregon are in the process of being evaluated. Given the modest volumes of natural gas currently used in transportation, incorporating these potential supplies would not alter the conclusion that there are no current constraints on the availability of natural gas in Oregon.

Table 8: Renewable Natural Gas

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Kentucky	1,179	1
Ohio	990	1
Total Oregon Suppliers	2,169	2
Data from the Clean Fuels Program		

Forecast Risks

A risk is defined as a deviation from one or more assumptions that would alter the conclusion outlined in the previous sections. There are a number of potential risks to this 2020 Clean Fuels Forecast, both positive and negative and they are:

(a) The most fundamental risk to the forecast amounts to potential deviations from the assumptions highlighted in each fuel type discussion. In particular, blend rates and carbon intensities for biofuels could be subject to significant error. In addition, this forecast contrasts with prior forecasts in that it assumes that the incentives inherent in the value of the credits generated by supplying alternative fuels will drive the carbon intensities of these fuels downward. Failure to realize these declines would result in fewer credits than currently anticipated.

(b) This forecast represents a "current law" representation of the compliance period in question. OEA's methodology does not take potential future state policy actions into account.

(c) There is a discrepancy between the diesel consumption numbers reported to the Clean Fuels Program data and the taxable gallons tabulated by ODOT. Explicitly, more gallons of diesel are reported to the former that the latter. This forecast applies projected growth of taxable diesel, at least initially, to the base year 2018 reported volumes of diesel in the CFP. To the degree that taxable gallons per ODOT is not a perfect proxy for reported gallons in the CFP, actual consumption of diesel and thereby the number of deficits generated could deviate from this forecast.

(d) House Bill 2017 (2017 Legislative Session) created a rebate for sales of electric vehicles in Oregon. The electric vehicle forecast underlying the credit projections for electricity consumption do not explicitly account for the potential impact of this rebate. To the degree that electric vehicle sales skew higher than expected herein, net credits would be even higher, constituting an upside risk to the forecast.

(e) The ethanol availability presented above is not comprehensive and does not include other potential sources, such as sugarcane ethanol imported from Brazil. Given that potential supply characterized in table 5 greatly exceeds projected demand, this is not an immediate threat to the forecast. However, it may need to be addressed as consumption increases or as carbon intensity targets are lowered.

(f) Alternative fuels used in forklifts, aviation , and certain other uses such as transport refrigeration units were recently added to the Clean Fuels Program but have not been included in the 2020 forecast These uses would generate credits in the program, constituting an upside risk to the forecast.

Accessibility

Appendix B

The estimated carbon intensities for ethanol, biodiesel and renewable diesel that are not published in rule are projected based on the historical trend in reported carbon intensities. Add factors may be employed where steeper declines are expected due to the incentives inherent in the program, as well as new information regarding potential changes in the mix of feedstocks and the composition of facilities that supply biofuels to Oregon. Currently, thirteen quarters of data are available for ethanol and biodiesel, while six quarters are available for renewable diesel. As more data become available, more advanced econometric techniques (including dynamic modeling) may be employed to provide more accurate projections. The following charts show the expected declines in all three series:

Appendix C

The following are the formulas resulting in the deficits and credits presented in Table 4.

Gasoline
$Deficit_G = CBOB * ED_G * (CIT_G - CIA_G)/1{,}000{,}000$

Diesel
$Deficit_D = V_D * ED_D * (CIT_D – CIA_D)/1{,}000{,}000$

Ethanol
$Credit_E = V_E * ED_E * (CIT_G – CIA_E)/1{,}000{,}000$

Biodiesel
$Credit_{BD} = V_{BD} * ED_{BD} * (CIT_D – CIA_{BD})/1{,}000{,}000$

Renewable Diesel
$Credit_{RD} = V_{RD} * ED_{RD} * (CIT_D – CIA_{RD})/1{,}000{,}000$

Electricity
$Credit_C = K_C * EER_E * ED_E * (CIT_G – (CIA_C/EER_E)/1{,}000{,}000$

Natural Gas

INTRODUCTION

Portland's Climate Action Plan provides a road map to reduce carbon emissions 40 percent by 2030 and 80 percent by 2050. Land use planning, transportation policies and investments are among the most important strategies to address climate change. In Portland, the transportation of goods and people accounts for nearly 40 percent of local carbon emissions. Shifting from gasoline and diesel to lower-carbon transportation fuels, like electricity, is a key strategy to achieving Portland's climate action goals.

Portland's approach to personal mobility prioritizes safety, health, affordability and environmental quality. City of Portland staff are working to encourage people movement instead of car movement by creating a healthy connected city that enables safe and convenient walking, biking and transit use (see Figure 1). This Electric Vehicle Strategy focuses on electrification of the public transit system, shared vehicles and the private automobiles that remain in use, which is one of many strategies the City is taking to reduce carbon emissions from the transportation sector. This strategy also seeks to maximize the benefits of air quality and affordability for low-income residents and parts of Portland that are the most dependent on private vehicles.

Portland's transportation hierarchy for people movement.

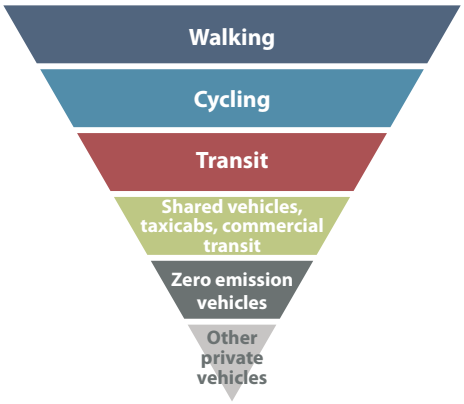

Figure 1: Portland prioritizes transportation options that reduce congestion and carbon emissions. (Source: Comprehensive Plan Policy 9.6)

In the future, significantly more people will need to travel to work and school by taking transit or biking.

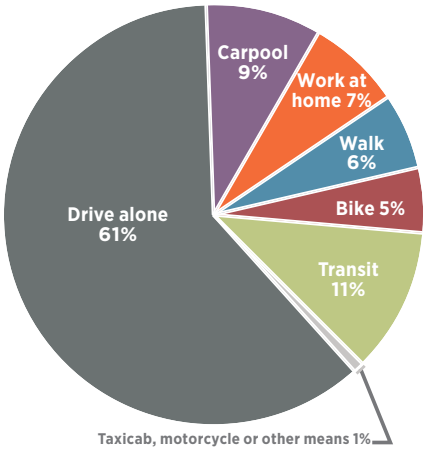

Figure 2: 2012 work commute mode share for Multnomah County (Source: American Community Survey)

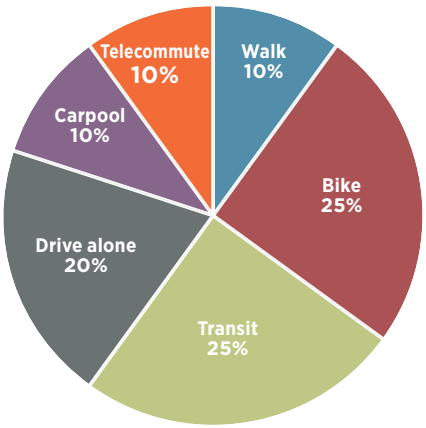

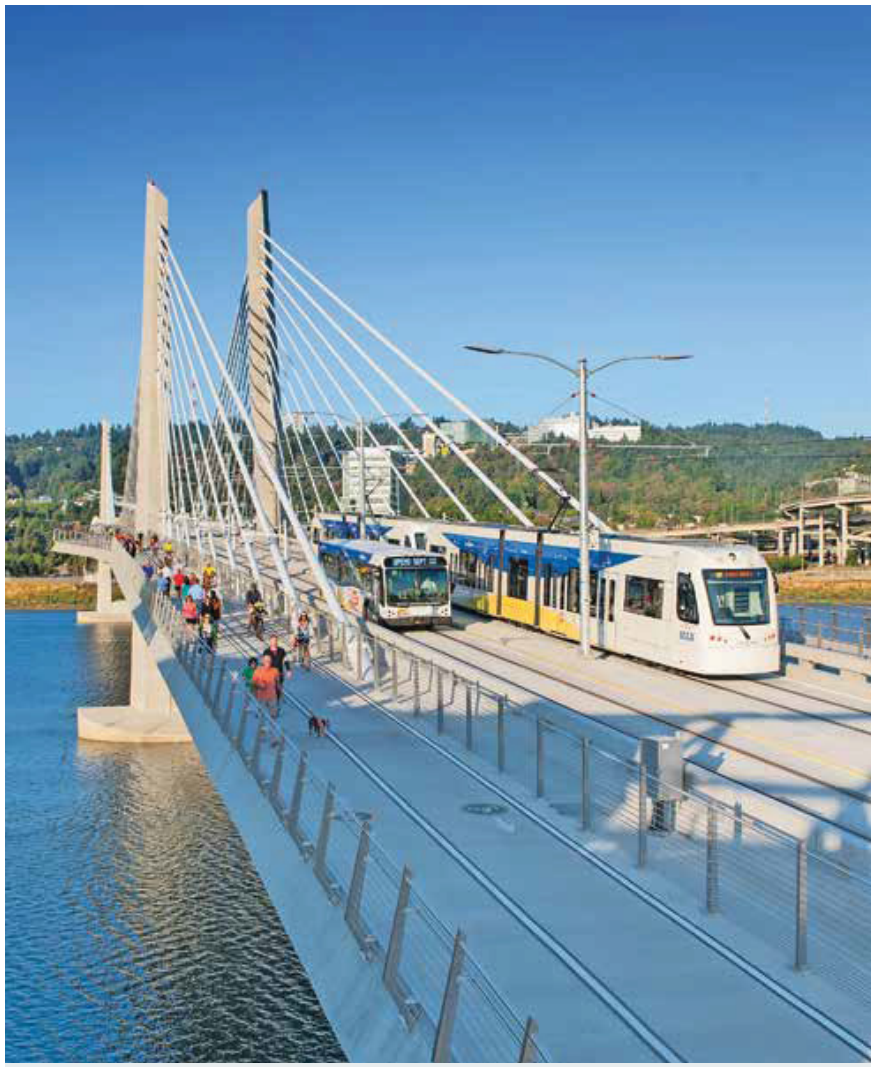

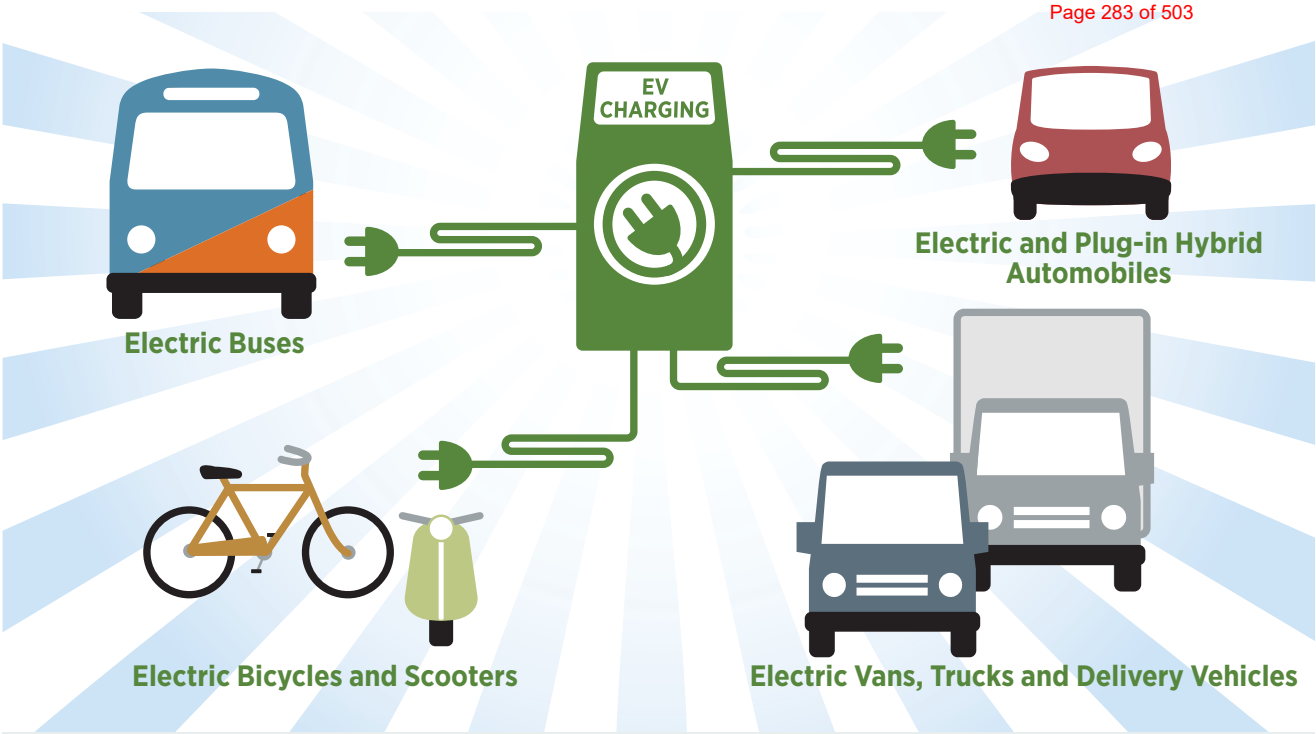

Figure 3: 2030 target work commute mode share for Multnomah County.

Portland's Climate Action Plan also includes goals to decrease the Portland's transportation-related carbon emissions 25 percent below 1990 levels by 2020, 40 percent by 2030 and 80 percent by 2050. To reach those goals, the current commute mode split will need to shift toward walking, bicycling and public transit, and the number of people commuting in single occupancy vehicles will need to decrease from 59 percent to 20 percent by 2030 (see Figures 2 and 3).

A growing proportion of the vehicles that remain on the road in 2030, including public transit and commercial vehicles, will need to be powered by electricity. Specifically, it is estimated that 10 to 15 percent of all non-commercial vehicle miles traveled on Portland's roads in 2030 will need to be in electric vehicles to achieve Portland's broader carbon emission goals. This translates into an estimated 50,000 electric vehicles in the metro area, based on average per capita vehicle miles traveled.

Tilikum Crossing: Bridge of the People, the largest car-free bridge in the United States, was completed in 2015. As the latest addition to our cityscape, Tilikum Crossing carries two of Portland's electric transit choices, the Portland Streetcar and the MAX Orange Light Rail Train, as well as TriMet buses, cyclists and pedestrians.

For the purpose of this strategy the term electric vehicle includes: electric bikes (e-bikes), electric scooters (e-scooters), and electric and plug-in hybrid cars, trucks, buses and freight vehicles.

Portland's first electric vehicle strategy, *Electric Vehicles: The Portland Way*, was developed in 2010 to prepare for the launch of the first widely available electric passenger vehicles. Almost seven years have passed and the electric vehicle market landscape has changed significantly -- for example, more than 25 electric vehicle models are available for purchase today, and many more options with significantly longer range are expected in the next few years. Similarly, the actions the City needs to prioritize to continue to support and accelerate the transition from gas- and diesel-fueled to electric vehicles has changed since the City's first electric vehicle strategy was adopted. This updated strategy establishes the City's current electric vehicle-related priorities and identifies the actions the City will take before the end of 2020 to further the electrification of the transportation sector.

ELECTRIC VEHICLES FOR ALL

The City is committed to creating mobility solutions that are equitable and empowering. Low-income populations and communities of color suffer disproportionately from vehicle-related air pollution, often drive less fuel efficient vehicles, tend to have longer commutes and spend a higher proportion of their income on fuel and transportation costs (PolicyLink/ Prevention Institute/Convergence Partnership, 2009). Improving access to affordable transportation options is critical to improving economic opportunity, wealth building and upward mobility. Electric vehicles offer many opportunities to benefit under-served communities as Portlanders transition from fossil fuels to low-carbon transportation.

Many people hear the words *electric vehicle* and *expensive* immediately comes to mind. This association contributes to the perception that electric vehicles are only accessible to wealthy people. In reality, the two-dozen electric vehicle models available on the market have diverse price and size options. Changing the perception of electric vehicles from expensive to accessible to all income levels will help bring the benefits of cleaner, lower-cost transportation to more households, as well as accelerate the transition away from fossil fuels. People of color are expected to be the majority in the U.S. by 2044 (National Equity Atlas, 2016). This increased buying power makes people of color an important segment for increasing electric vehicle adoption numbers (The Greenlining Institute, 2016). This strategy includes actions to increase access to electric vehicles and charging infrastructure for low-income populations and communities of color.

In Portland, many low-income people and communities of color live in multi-unit dwellings, such as apartment buildings. To increase access to viable electric vehicle options for these communities, charging infrastructure must be available. To begin addressing this barrier the City will explore policy options to require new buildings, especially apartments and condominiums, to be built with the necessary conduits and electrical capacity to enable cost effective installation of charging infrastructure.

Priority Electric Vehicle Charging Areas

The City prioritizes charging infrastructure in areas of Portland that have:

- Fewer existing public charging stations.
- Limited access to frequent transit and bike routes.
- Higher proportions of multifamily housing and garage-free homes.
- Large businesses with employees commuting long distances.
- Residents with higher average vehicle miles traveled.
- Destinations (recreation sites, event venues, etc.) people tend to travel longer distances to access.

ELECTRIC VEHICLE STRATEGY: 2020 GOALS

This Electric Vehicle strategy seeks to accelerate the transition to electric vehicles, including e-bikes, to achieve the people movement hierarchy (see Figure 1, page 1), and mode share and vehicle miles traveled goals of Portland's Climate Action Plan, Comprehensive Plan and Transportation System Plan. To that end, the City seeks to accomplish the following goals by the end of 2020:

- Replace at least 10,000 gas- or diesel-powered vehicles with electric vehicles in Multnomah County.
- Increase access to electric vehicle charging infrastructure by doubling the number of Level 2 and DC Fast Chargers available to the public.
- Increase access to affordable electric vehicle transportation options for low-income populations and communities of color.
- Maximize the air quality and cost savings benefits of electric vehicles for low-income populations and communities of color.
- Add 60 electric vehicles to the City's sedan fleet to increase the percentage of electric vehicles from 20 to 30 percent. Seek options to electrify other classes of vehicles in the City's fleet.
- Prioritize the electrification of shared use vehicles, bikes and buses to reduce the need for personal vehicle ownership.
- Encourage the electrification of automated vehicles to improve safety and mobility options for people who don't drive.

ELECTRIC VEHICLE STRATEGY: 2020 ACTIONS

This Electric Vehicle Strategy identifies nearly 50 actions to be completed or significantly underway by the end of 2020. To draft this strategy, City staff received input from Portland's transit agency, utilities, environmental organizations, staff from West Coast cities, the State of Oregon, Portland State University representatives, low-income Portlanders and local electric vehicle advocates and stakeholders. These groups helped to identify the near-term actions most likely to result in accelerating the transition from gas-powered to electric vehicles (EV). Going forward, the City will continue to work with interested parties and community-based organizations, and will develop a cross-bureau group to facilitate collaboration and implementation of the actions in this plan.

Reading the table of actions

This symbol appearing in the first column denotes actions where the City of Portland is a direct implementer of the action, versus actions where the City plays a supporting role.

The lead bureau for each action appears in **bold** text supporting bureaus are shown in regular text.

Bureau acronyms:

BPS – Bureau of Planning and Sustainability
BES– Bureau of Environmental Services
CBO – City Budget Office
PDC – Portland Development Commission
BDS – Bureau of Development Services
BIBS – Bureau of Information Business Systems
PBOT – Portland Bureau of Transportation
PHB – Portland Housing Bureau

Charging Infrastructure

Owning an electric vehicle is not practical without convenient, reliable access to charging. To support the growth of electric vehicles, Portland needs to have a sufficient charging infrastructure system. Providing Portlanders with a robust and reliable charging network at home, work and in public places will reduce range anxiety (the fear of running out of electricity on the road), provide access to emergency charging and enable longer trips.

Most electric vehicle drivers charge their vehicles at home (National Research Council of National Academies of Sciences, 2015), but this can be difficult for people who rent their homes, do not have a garage or live in multifamily housing. Accessing charging from multifamily residences can be especially difficult due to the complexities of negotiating costs, installation logistics and liability issues with the landlord or site host. This Electric Vehicle Strategy includes actions to increase access to charging in buildings, parking facilities and public places. The City will explore the development of EV-ready requirements for new building construction, develop clear policies and procedures to enable publicly accessible charging and work with partners to install clusters of electric vehicle charging stations in strategic areas around Portland.

	CHARGING INFRASTRUCTURE ACTIONS: BUILDINGS	LEAD BUREAU
⚡	**1. EV-Ready Multifamily and Commercial Buildings –** Explore electric vehicle (EV) parking and charging infrastructure requirements in new multi-family and commercial construction projects that include parking.	**BPS,** BDS
⚡	**2. EV-Ready for Affordable Housing –** Incorporate EV-ready provisions in the City's green building policy for affordable housing.	**PHB,** BPS
⚡	**3. Funding for EV-Ready Affordable Housing –** Seek funding to enable affordable housing projects that have parking to be EV-ready with, at a minimum, the necessary electrical capacity and conduit to enable EV chargers.	**PHB,** BPS
⚡	**4. EV-Ready for PDC-Supported Projects –** Develop EV-ready provisions for construction projects that trigger the Portland Development Commission Green Building Policy.	**PDC**
⚡	**5. Funding for City Fleet Chargers –** Develop a funding mechanism to address the upfront costs for new EV chargers for City vehicles in City-owned or -managed buildings.	**CBO,** BIBS, BPS
⚡	**6. EV-Ready and Retrofits for City Buildings –** Partner with community partners and private industry to develop a strategy to retrofit strategic existing City-owned buildings and facilities with EV chargers. Consider EV-ready construction requirements for new City buildings or major renovation projects that have parking.	**BIBS,** all bureaus
	7. Technical Assistance for Chargers – Work with utility and community partners to provide technical assistance to building managers and homeowners to install EV chargers, especially in existing buildings.	**BPS**
	8. Engage Builders and Architects – Work with partners to develop EV charging outreach and education materials and programs targeted to builders and architects.	**BPS**

Fossil Fuel Terminal Zoning Amendments Testimony Ordinance #189807
37255
LUBA No. 2020-009
Page 4397

CHARGING INFRASTRUCTURE ACTIONS: PUBLIC	LEAD BUREAU
9. Right-of-Way Charging – Develop public right of way (ROW) priorities and policies to enable installation of publicly accessible EV chargers in strategic locations, and provide clear guidelines for public and private parties. Establish a policy for addressing abandoned EV chargers in the right of way.	**PBOT**
10. EV-Ready and Retrofits for Parking Facilities – Explore the development of EV parking and charging infrastructure requirements in new and existing (public and private) parking facilities.	**BPS,** BDS, PBOT
11. Public Awareness – Work with community partners to increase the public's awareness of EV chargers through improved signage, marketing and outreach.	**BPS,** PBOT
12. City Parking Facilities – Work to increase the utilization of existing EV chargers in City-owned and/or -managed parking lots and garages (e.g., SmartPark Garages).	**PBOT**
13. E-Bike Parking – Explore opportunities to integrate e-bike charging infrastructure into the City's bike parking Title 33 code update.	**PBOT**
14. Major Public Works Projects – Identify opportunities to install EV chargers and/or conduits in conjunction with major public works projects in strategic locations and in streetscape planning.	**BPS, PBOT,** Water, BES
15. Public Charging on Private Property – Establish policies and processes that make it easier to provide publicly accessible charging on private property and encourage private property owners to do so.	**PBOT,** BPS, BDS
16. EV Signage and Parking Standards – Develop policies and standards for EV signage and parking, including parking rates, time limits and "parking while charging" restrictions.	**PBOT**
17. City-Owned and Maintained Chargers – Explore City ownership and maintenance of publicly accessible EV chargers, particularly in under-served areas.	**PBOT,** BPS
18. Streetlight Integration – Explore the integration of electric vehicle charging with streetlights in Portland.	**PBOT**
19. EV Charging Hubs – Work with public and private partners to support the installation of multi-modal EV charging pods similar to Electric Avenue around the metro area. Include e-bike charging infrastructure in these electric mobility hubs.	**PBOT,** BPS
20. Priority Areas for EV Charging – Work with community partners and utilities to install publicly accessible EV chargers in strategic locations. Prioritize EV chargers that serve low-income residences, including multi-family, single-family rental housing and garage-free homes.	**BPS,** PBOT
21. Utility Transportation Electrification Plans – Partner with local utilities to finalize and implement their transportation electrification plans.	**BPS,** PBOT
22. Park and Ride Charging – Encourage TriMet to continue installing and maintaining EV chargers at Park & Ride and Bike & Ride lots.	**PBOT**
23. Public Charging Partnerships – Work with utilities, Neighborhood Prosperity Initiative (NPI) districts and Main Street areas to install publicly accessible EV chargers.	**PDC,** BPS

Fleets

Electrifying fleet vehicles offers a key opportunity to reduce carbon emissions, improve air quality, decrease long-term maintenance and operating costs, and increase electric vehicle visibility for the general public. Many fleet managers are eager to take advantage of these benefits but also face barriers:

- Unlike gas-powered vehicles, a large portion of the costs associated with fueling electric vehicles need to be paid upfront via the installation of charging infrastructure. This contributes to increased upfront costs of buying an electric vehicle compared to a gas-powered vehicle.
- Many electric vehicles have a purchase price premium and government fleets are not able to take advantage of tax credits or rebates to help offset those increased costs.
- Medium- and heavy-duty electric vehicle models are expensive and only a few are currently available on the market.
- Many fleet managers, drivers and maintenance staff have limited awareness of electric vehicles.

To address these barriers and increase fleet electrification the City will: a) seek funding for charging infrastructure in City-owned buildings (see action A6), b) support TriMet's efforts to electrify city buses, c) encourage the electrification of medium- and heavy-duty freight vehicles, and d) partner with stakeholders to electrify car-share, taxi and bike-share fleets. Additionally, Portland will lead by example and add at least 60 additional electric vehicles to the City's sedan fleet to increase the percentage of electric vehicles from 20 to 30 percent by 2020.

	FLEET ACTIONS – TRANSIT	LEAD BUREAU
	24. Bus Electrification – Support TriMet's efforts to transition to electric buses and encourage the electrification of other people transport fleets (e.g., tour vehicles, taxis) in Portland.	**BPS**
	25. Air Quality – Work with TriMet to use new electric buses along routes through portions of the city where air quality issues have the largest impact.	**BPS**
	26. Integrated Transit and Shared EV Mobility – Explore options to integrate public transit and shared EV mobility options such as e-bikes, e-scooters and EV car-share vehicles.	**BPS,** PBOT
	27. E-Bikes on Transit Vehicles – Encourage TriMet to continue accommodating e-bikes on exterior bus bike racks and on board rail vehicles in designated areas.	**PBOT,** BPS
	FLEET ACTIONS – CITY FLEET	**LEAD BUREAU**
⚡	**28. Clean Fuels Credits –** Become a credit generator in the Oregon Clean Fuels Program for City-owned chargers. Adopt a policy to ensure that resources received from these types of credits are spent on EV-related projects.	**BPS,** BIBS
⚡	**29. City EV Purchasing –** Establish "electric first" guidelines directing City bureaus to purchase all-electric vehicles when the vehicle usage is compatible with available electric light-duty vehicles.	**City Fleet,** BPS
⚡	**30. City Employee Workplace Charging –** Explore workplace charging for City employees working in and parking personal vehicles at City-owned and -managed facilities. Encourage City staff who must drive to work to drive EVs.	**BPS,** BIBS, BHR
	FLEET ACTIONS – FREIGHT	**LEAD BUREAU**
	31. Electrifying Delivery Vehicles – Support the electrification of medium- and heavy-duty vehicles used in Portland for the delivery of goods and materials.	**PBOT**
	32. Pilot Projects – Continue to explore urban consolidation centers and support pilot projects to electrify delivery vehicles.	**PBOT,** BPS

Personal Vehicles and Shared Mobility

Key barriers to electric vehicle uptake include upfront costs, accessibility and awareness. The life-cycle costs of electric vehicles are often lower than conventional gas-powered cars, making them a promising strategy to reduce transportation costs in car-dependent areas. The upfront cost of new electric vehicles can easily be $10,000 higher, however. Most consumers need financial subsidies, such as tax credits, to overcome this cost difference. This is especially true for low-income people who often have more limited access to financing options. Used electric vehicles tend to cost less than comparable gas-powered cars and may be a great way to bring electric vehicles to low-income populations at a lower cost, as well as provide a second life for electric vehicles. This strategy includes actions to: a) increase access to used electric vehicles, b) encourage State financial incentives for electric vehicle purchases, and c) research financing options for individuals with no or damaged credit.

Another barrier to electric vehicle uptake is the lack of awareness about the performance and functionality of electric vehicles. Many Portlanders are also unfamiliar with the diversity of available models, electric vehicle purchasing incentives, or the environmental and economic benefits of electric vehicles. This strategy includes several electric vehicle-related education and outreach actions, such as supporting Drive Oregon's Northwest EV Showcase – an electric vehicle marketing and outreach initiative with a downtown Portland showroom funded by the US Department of Energy.

This strategy also calls for a community mobility assessment to ensure that electric vehicle solutions meet the needs of low-income people and communities of color. Building on the findings from that assessment, the City will work with partners to provide outreach and education programs that are targeted to under-served communities. Opportunities include: a) pop-up Northwest EV Showcase locations in East Portland, b) used electric vehicles bulk purchase programs, and c) electric vehicle car-share and e-bike pilot programs that serve these communities.

Car-share and bike-share programs offer a unique avenue for Portlanders to become familiar with electric vehicles, while at the same time reducing carbon emissions and helping to eliminate the need for personal car ownership. The City will work with partners to encourage the electrification of car-share programs (e.g., ReachNow) and ride-sourcing companies (e.g., Uber and Lyft), and seek funding to partially electrify the BIKETOWN bike-share system.

	PERSONAL VEHICLES AND SHARED MOBILITY ACTIONS	LEAD BUREAU
⚡	**33. BIKETOWN Electrification –** Continue to explore opportunities to partially electrify Portland's BIKETOWN bike-share program.	**PBOT**
	34. EV Showcase – Support Drive Oregon's Northwest EV Showcase initiative, including helping to market the EV group purchase program, seeking funding to support the initiative and collaborating to develop the physical space.	**BPS**
	35. Mobility Needs Assessment – Work with partners to leverage existing community mobility needs assessments and conduct additional engagement as necessary to ensure that EV solutions meet the needs of low-income populations and communities of color.	**BPS**
	36. EV Incentives and Pilot Projects – Work with partners to develop programs and incentives to reduce the barriers to EVs for low-income populations, communities of color and individuals with no or damaged credit, such as vouchers, instant rebates and EV car-share and e-bike pilot projects.	**BPS,** PBOT, PHB
	37. Purchasing Process Assistance – Support community partners such as Drive Oregon to help low-income Portlanders navigate the incentives, financing and decision-making process of buying or leasing new or used EVs.	**BPS**
	38. Private for Hire Vehicle Electrification – Encourage taxi, car-share and ride-sourcing companies (such as Uber and Lyft) to utilize EVs in their fleets. Explore incentives to increase shared electric mobility options, particularly in areas with limited transportation options.	**PBOT,** BPS

Innovation and Information

Electric vehicles continue to change and improve as new innovations are introduced into the market. Over the next five years, the distance that can be driven per charge (range) will increase, purchase prices will decrease and more used electric vehicles will be available. This strategy includes actions to research and track new technology, electric vehicle car sales, demographics, vehicle-miles-traveled and commute trends to inform investment and policy priorities for the electrification of the transportation system.

	INNOVATION AND INFORMATION ACTIONS	LEAD BUREAU
⚡	**39. Investment and Policy Decisions –** Develop and utilize the best available information (e.g., charger location, EV car sales, demographics, vehicle-miles-traveled) to inform investment and policy priorities for the electrification of the transportation system.	**BPS,** PBOT
	40. Data Tracking and Sharing – Work with Oregon's Department of Environmental Quality and Portland State University to track and share data on the number of zero emission vehicles registered in Oregon and Multnomah County.	**BPS**
	41. Smart Cities – Partner with public and private stakeholders to integrate EVs into Smart Cities projects.	**PBOT, BPS**
	42. Autonomous Vehicles – Seek opportunities to pilot electric autonomous vehicles (AVs).	**PBOT, BPS**

Economic Development

The electric vehicle industry provides opportunities to contribute to Portland's economy through job creation and local business development. This strategy includes actions to: a) connect local electric vehicle manufacturers, suppliers and customers to large regional and national companies, b) provide electric vehicle-related employment opportunities for underemployed or unemployed residents, and c) support Portland's leadership in clean technologies.

	ECONOMIC DEVELOPMENT ACTIONS	LEAD BUREAU
⚡	**43. Employment Opportunities –** Build resources to connect small- to medium-sized EV manufacturers with employment opportunities for qualified underemployed and unemployed residents.	**PDC**
⚡	**44. Opportunities for People of Color –** Track effectiveness of EV economic development efforts in extending business and employment opportunities to people of color.	**PDC**
⚡	**45. Marketing –** Continue to market Portland's leadership in clean technologies utilizing Portland's "We Build Green Cities" brand to drive EV business development, relocation and expansion opportunities.	**PDC**
⚡	**46. Business Development Assistance –** Prioritize business development visits and technical assistance to EV-related companies with middle-wage employment opportunities.	**PDC**
⚡	**47. Business Opportunities –** Organize supply-chain and investor matchmaking events and trade show participation opportunities for existing EV firms to increase financing, sales and export opportunities.	**PDC**
	48. EV Sector Networking – Work with Drive Oregon, TriMet, Metro and Greater Portland Inc. (GPI) to increase networking among local EV manufacturers and customers.	**PDC**
	49. EV Conferences – Support efforts to bring major EV conferences to Portland.	**PDC,** BPS

Portland Clean Energy Community Benefits Fund (PCEF)

About the Portland Clean Energy Community Benefits Fund

Purpose, goals, timeline, and frequently asked questions about PCEF.

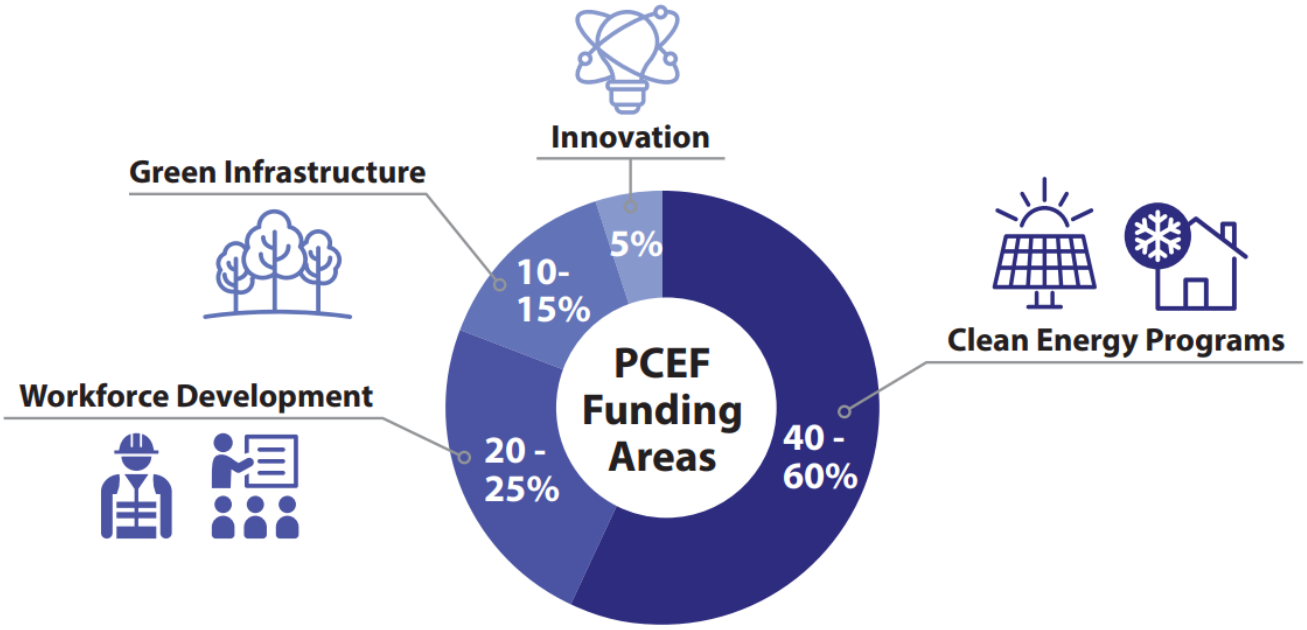
On this page

- Purpose
- Timeline
- Background
- FAQs

Purpose

The Portland Clean Energy Community Benefits Fund (PCEF) was created by a local ballot measure (#26-201) that is anticipated to bring $54 - $71 million in new revenue for green jobs and healthy homes for all Portlanders. The ballot measure passed with 65 percent of voters in support, making it Oregon's first-ever environmental initiative created and led by communities of color.

In the face of climate change and federal inaction, PCEF offers a community-led vision, grounded in justice and equity, that builds citywide resilience and opportunity. The initiative ensures that the City of Portland's Climate Action Plan is implemented in a manner that supports social, economic and environmental benefits for all Portlanders, including the development of a diverse and well-trained workforce and contractor pool in the field of clean energy.



For information on **tax filings and revenue collections** of the Clean Energy Surcharge (Portland City Code Section 7.02, Business License Law), please visit the City's Revenue Division's website.

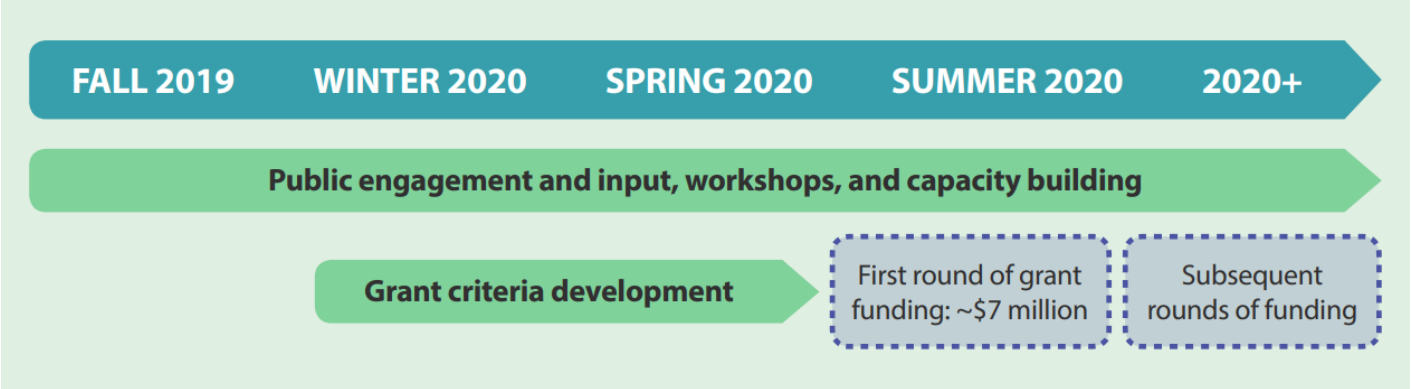
Funding a clean energy future for underserved communities

Climate change has a disproportionate impact on communities of color and low-income residents. The Fund prioritizes these communities living on the "frontlines" of climate change with clean energy funding, job training programs and green infrastructure projects. This will help ensure they are prepared for a changing climate as we move toward our goal of an 80-percent reduction in carbon emissions and transitioning to 100-percent renewable energy in Portland.

The program is funded through a 1% surcharge on the retail sales of certain large retailers within Portland. The Fund finances programs that meet the following priorities:

- Clean energy projects, including renewable energy and energy efficiency projects
- Regenerative agriculture and green infrastructure projects.
- Clean energy jobs training.
- Programs that both reduce greenhouse gases and promote economic, social and environmental benefits.

All PCEF projects prioritize Portland's underserved populations and neighborhoods, including communities of color and low-income residents. Examples of community benefits include solar panels and energy efficiency upgrades on multifamily housing, new workforce training programs in clean energy manufacturing and installation, shared food gardens, and increased tree canopy in heavily concreted neighborhoods.



Community benefits committee and City staffing

The Fund is overseen by a nine-member Portland Clean Energy Community Benefits Committee made up of experts and community members. The PCEF Committee will make funding recommendations to the Mayor and City Council and evaluate the effectiveness of the Fund achieving the goals of the initiative.

Per the initiative, membership of this committee must reflect the racial, ethnic and economic diversity of the City of Portland; include at least two residents living east of 82nd Avenue; and possess significant experience in the types of projects supported by the Fund. Project staff are housed at the City's Bureau of Planning and Sustainability.

Timeline

The community coalition that created and led the ballot measure is working together with the City of Portland to implement a successful and standard-setting grant program that faithfully reflects the will of Portland voters. Program design and development is expected to take 18 months, with a goal of launching the Fund and beginning grant awards in July 2020.

Background

Supporters of the ballot measure

The ballot measure campaign was supported by over 200 community organizations, major affordable housing and homelessness service providers and advocates, Business for a Better Portland, the Oregon Food Bank, 16 neighborhood associations, the faith community and elected officials.

The Steering Committee of the community coalition, who developed the measure and are now working with the City to implement the Fund, includes the NAACP Portland Branch, Native American Youth and Family Center, Coalition of Communities of Color, the Asian Pacific American Network of Oregon (APANO), OPAL Environmental Justice Oregon, Verde, 350 PDX, Oregon Physicians for Social Responsibility, Audubon Society of Portland, Columbia Riverkeeper and the Oregon Chapter of the Sierra Club.

FAQs

I noticed a 1% charge on grocery items. Why is this added to my bill?

After Portlanders voted to approve the Portland Clean Energy Community Benefits Initiative, a 1% surcharge ("Clean Energy Surcharge") was imposed on large retailers with $1 billion in national revenue and $500,000 in revenue in Portland. The Clean Energy Surcharge is a surcharge on large retailers and is not a sales tax imposed on customers or consumers.

These large retailers with $1 billion in national revenue and $500,000 in Portland, can choose to separately itemize its obligation to pay the surcharge on its receipts or invoices to customers or consumers. In this case, you may see an increased amount on your receipt.

How is the surcharge applied to groceries?

The 1% surcharge does not apply to certain basic goods and services such as groceries that qualify for purchase under the U.S. Department of Agriculture (USDA) Supplemental Nutritional Assistance Program (SNAP) and qualified medicines or drugs.

Qualified medicines or drugs that are exempt from the surcharge include any medicine, drugs or medical devices that are regulated by the U.S. Food and Drug Administration (FDA) as a medicine or drug. Examples include over-the-counter drugs, prescription drugs, certain pet drugs and medical devices.

Examples of groceries that are not subject to the surcharge based on USDA SNAP guidance include:

- Fruits and vegetables
- Meat, poultry and fish
- Dairy products
- Breads and cereals
- Other foods such as snack foods and non-alcoholic beverages
- Seeds and plants, which produce food for the household to eat

Examples of groceries that are subject to the surcharge include:

- Beer, wine, liquor, cigarettes or tobacco
- Vitamins and supplements (if an item has a Supplement Facts label, it is considered a supplement and is not eligible for SNAP purchase)
- Live animals (except shellfish, fish removed from water, and animals slaughtered prior to pick-up from the store)
- Prepared foods fit for immediate consumption
- Hot foods
- Any nonfood items such as:
    - Pet foods
    - Cleaning supplies, paper products and other household supplies
    - Hygiene items, cosmetics

Is my business subject to the 1% surcharge?

The Clean Energy Surcharge applies to large retailers with annual tax-year total gross revenue from retail sales of $1 billion or more in the U.S. and $500,000 or more within the City of Portland, excluding utilities, co-ops, credit unions, as well as sales of qualified groceries, medicine or drugs and health care services. For more information on the definition of a “large retailer,” tax filings and revenue collections of the Clean Energy Surcharge (Amendments to the Portland City Code Section 7.02, Business License Law), please visit the City’s Revenue Division’s website.

How much will the surcharge raise?

The City of Portland's Revenue Division currently estimates annual tax receipts of $54 million to $71 million. Because of timing differences between tax and fiscal years and an option for taxpayers to extend their filing deadlines for an additional six months, the Revenue Division will not have a final accounting of first year (tax year 2019) revenues until late 2020/early 2021. Actual collections will vary based on economic conditions, the proportion of sales that are classified by taxpayers as retail or wholesale, and the definition of taxpayers and their tax liability.

Where will the money generated through the surcharge go?

Revenues from the Clean Energy Surcharge on large retailers will be deposited into the Portland Clean Energy Community Benefits Fund and disbursed as grants for programs and projects that meet the requirements and priorities of the ballot measure. Nonprofit organizations, including community centers and rental housing providers, will be eligible to apply either solely or in partnership with other nonprofit entities, government entities or for-profit businesses.

How do I apply for a PCEF grant?

Qualified nonprofit organizations will be eligible to apply for grants. Applicants are encouraged to partner with other nonprofits, governmental organizations, and for-profit businesses in developing projects and program proposals. More details about project eligibility will be available and released in Spring 2020 as grant criteria are developed.

How can I be sure the dollars will be spent wisely?

A nine-person oversight committee of experts and community members — modeled after the successful Portland Children's Levy — will recommend which projects get funded and ensure accountability. The Committee's funding recommendations will be approved by City Council in a transparent and public process before funds are awarded. The Committee will also evaluate and report on the effectiveness of the funded programs in meeting their stated objectives and the overall goals of the initiative. In addition, the Fund will be subject to an annual financial audit and a performance audit every two years.

How will the Fund help people with low incomes?

The Fund will directly benefit people with low incomes. It will prioritize creating family-wage jobs, healthier homes and reduced utility costs for underserved communities. Landlords who agree to improve properties through the Fund's energy efficiency

upgrade programs will be required to limit rent increases. Robust contracting standards will also ensure that historically disadvantaged people are trained, and minority- and women-owned businesses are performing the work.

How is this different from the work of Energy Trust of Oregon and State of Oregon clean energy programs?

The Portland Clean Energy Community Benefits Fund is unique because it supports community-driven clean energy solutions and jobs to help Portlanders that need them the most. It also provides resources for families that do not have the disposable income to qualify for energy efficiency rebates and tax credits.

Energy Trust of Oregon provides support and incentives for residential energy efficiency and solar energy to the maximum level governed by the Oregon Public Utilities Commission, whose mission does not include climate change or social justice. The Portland Clean Energy Community Benefits Fund will add much-needed dollars on top of Energy Trust incentives. In addition, the Fund will provide a stable source of long-term funding for energy efficiency projects since the Oregon Department of Energy's Residential Energy Tax Credit (RETC) program expired in 2017.

We are testing the beta release of Portland.gov. See something we could improve? Give feedback.

Petroleum Terminal Expands To Allow More Oil Trains Into Portland

by **Tony Schick** (https://www.opb.org/contributor/tony-schick/) Follow () OPB Feb. 7, 2019 8:15 p.m. | Updated: Feb. 11, 2019 8:10 p.m. | Portland, Ore.

Download (https://api.spreaker.com/download/episode/17016652/17016652.mp3)

A Portland petroleum terminal is significantly expanding its capacity to unload rail cars, a move that sets the stage to more than double the number of oil trains along the Columbia and Willamette rivers into Oregon's biggest city, OPB has learned.

Related Content

Zenith Energy, sandwiched between the river and Forest Park in the city's northwest industrial district, began receiving train shipments of crude from Canada's oil sands last year (https://www.opb.org/news/article/crude-oil-rail-portland-oregon-canada-ship-china/), records show, which it stored in tanks and later pumped onto ocean-going vessels.

Zenith's outpost in Portland now has visible construction underway on a project to build three new rail platforms that will nearly quadruple the site's previous capacity for offloading oil from tank cars, according to building plans filed with the City of Portland in 2014, which the city's Bureau of Development Services confirmed Wednesday.

()

Construction continues at the Zenith Terminals site in Northwest Portland in early February, 2019.

When operational, a terminal with such a capacity could handle multiple oil trains per week — a sizeable increase over Zenith's 2018 operations. According to Oregon Department of Environmental Quality estimates, the site handled fewer than 30 full oil trains throughout last year.

Public Resistance To Oil Projects

The site's expansion of crude-by-rail infrastructure comes despite much public resistance in the Northwest for new oil projects. That includes a vote by Portland's City Council in 2016 (https://www.portlandoregon.gov/citycode/article/557499) to oppose any new fossil fuel infrastructure. That same year the Northwest experienced firsthand one of the oil-train mishaps (https://www.opb.org/news/series/oil-trains/oil-train-bills-in-oregon-legislature/)that have occurred across North America as more and more oil has been moved by what critics have dubbed "rolling pipelines" and "bombs trains."

(https://www.opb.org/support/partners/)

Public records and interviews with state officials indicate those trains would carry a kind of heavy oil that presents a new risk for Northwest communities and rivers, and one the state's emergency spill responders say they are ill-equipped to contain if it spills.

RELATED COVERAGE

(https://www.opb.org/news/article/vancouver-washington-oil-terminal-grassroots-

"It greatly complicates the spill. It's going to take a lot more money and time and cause a lot more harm to the environment probably," said Scott Smith, who regulates the Zenith terminal's oil spill preparedness as part of the Oregon DEQ emergency response program.

He said the increased oil-by-rail traffic creates a risk in Portland of an environmental disaster like the one in Michigan in 2010, when heavy Canadian oil spilled from a pipeline into the Kalamazoo River. It took more than five years (https://www.mlive.com/news/index.ssf/2016/07/kalamazoo_river_oil_spill_time.htm and $1 billion to clean up.

"It's really among the most challenging spills we have out there, and if it was a large spill, it would cause quite a bit of damage," Smith said.

Zenith declined to comment on how the project would affect its ability to unload more crude oil, saying only that the project would allow it to fit additional railcars on site and minimize the need to shuffle cars around.

community-oil-companies/)

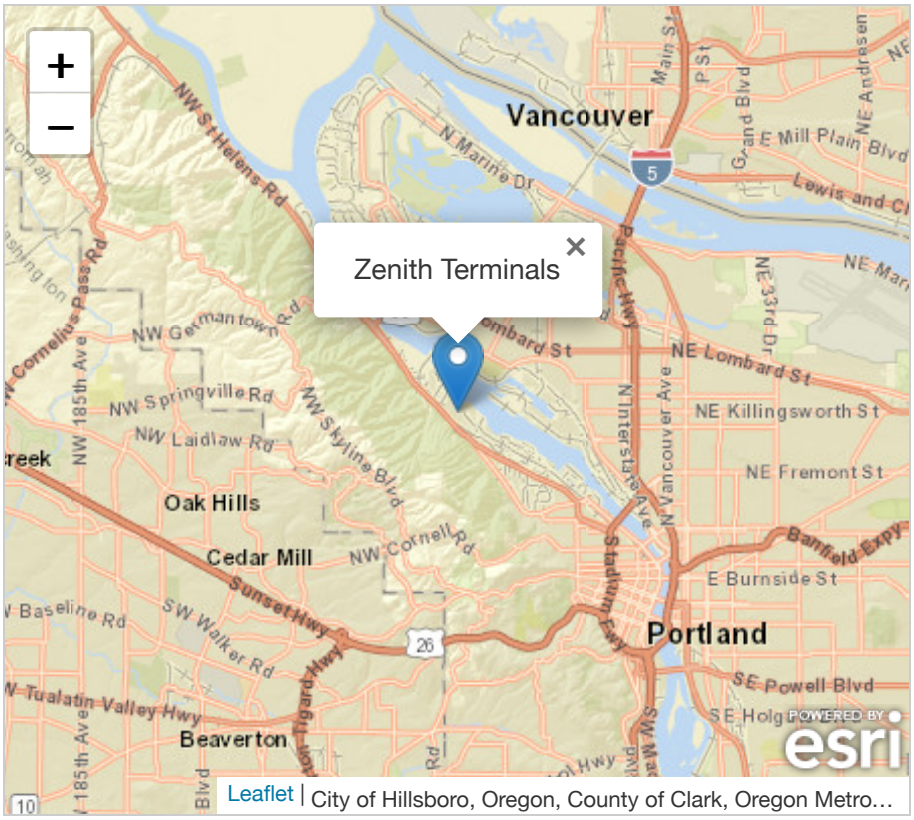
How A Grassroots Effort In Vancouver Fought Big Oil — And Won (https://www.opb.org/news/article/vanco washington-oil-terminal-grassroots-community-oil-companies/)

"The multi-million-dollar project will provide an even safer and more efficient operation," Megan Mastal, a public-relations representative for Zenith Energy, said in an emailed statement.

The company also declined to say what products it would handle. Mastal disputed that Zenith would be handling what's known as bitumen, which is a type of petroleum extracted from Canada's oil sands. It is thick like peanut butter and often diluted with other petroleum products before it is transported.

"We are not handling bitumen crude through our terminal," Mastal said.

Records show the facility did handle diluted bitumen in 2018, and Oregon's Department of Environmental Quality said it anticipates the facility will be handling heavy crude from Canada's oil sands.



Recent site inspections from Oregon's Department of Transportation found railcars with the placard UN 1267 (Petroleum Crude Oil) on the tracks outside the Zenith facility, and that the cars were from Canada. Photographs of cars at the terminal from earlier this month also show cars with the 1267 placard, along with a placard warning of toxic inhalation.

From Asphalt To Canadian Crude

Five years ago, the site was an asphalt plant in limited operation when a company called Arc Logistics Partners LP, later acquired by Zenith Energy, purchased it and

shifted operations to crude (https://www.opb.org/news/article/crude-oil-terminal-planned-in-nw-portland/). That transition coincided with the North American oil boom and subsequent spike in oil moving by rail. While those shipments have declined since their peak nationally, data from the Energy Information Administration show oil by rail has reached its highest level in three years (https://twitter.com/tatecurtis/status/1079797472812249088), driven largely by Canadian oil.

The Zenith site spans 39 acres with a storage capacity of nearly 1.5 million barrels and access to a nearby dock. Trains can reach it crossing the Willamette over the BNSF Railway bridge south of St. Johns or on Union Pacific tracks across the Steel Bridge.

Its main constraint has been rail capacity. When construction began, the terminal had space to unload 12 cars at a time, records show.

Plans for the facility upgrade of Arc Terminals filed in 2014 with the City of Portland depict a system capable of unloading 44 cars (https://www.documentcloud.org/documents/5732053-Eggers4700BPlans.html).

The company's storage tanks are not getting any larger, but unloading more train cars simultaneously can expedite the process of transferring oil to ships, bound for export or other domestic markets.

Mastal said the work includes new emissions-control technology, which is required by regulations, as well as a state-of-the-art fire suppression system and barrier along the street. The Portland Bureau of Development Services confirmed the work includes numerous safety upgrades, many of which are now required by code.

Mastal said the terminal employs 18 people full time, all of whom are "trained and certified to maintain the highest environmental and operational standards."

"Since Zenith purchased the terminal, we have added full-time staff positions. These jobs pay a family wage with benefits," Mastal said. "In addition, the multi-million-dollar construction project uses local vendors and suppliers – currently averaging 125 individuals on site per day – providing significant economic stimulus for the area."

The city issued permits for the work in 2014 (https://www.portlandmaps.com/detail/permit/2014-251964-000-00-CO/3558079_did/?p=R315845), two years before its leaders voted to oppose new fossil fuel infrastructure.

'These Trains Present A Significant Risk'

Eileen Park, spokeswoman for Portland Mayor Ted Wheeler, said the mayor "supports further action to prohibit the construction of new fossil fuel infrastructure like the site in question."

"These trains present a significant risk to Portlanders, most especially those residents close to railroads and routes through the city," Park said. "On a larger scale, the threat of climate change depends on the bold and decisive actions of governments and leaders. The Mayor's administration will not be supportive of any action that threatens the health and well-being of our city's residents or our natural resources and environment."

Mastal said Zenith's Portland terminal meets all local, state and federal standards, including Portland's 2016 ordinance.

"We are committed to delivering safe, reliable, efficient and flexible service to our customers while maintaining the highest environmental and operational safety standards," she said.

Environmentalists say they fear a “rolling pipeline” of trains through Portland.

“To us, it seems like it’s another quiet effort to increase the capacity of that terminal to handle tar sands crude,” said Travis Williams of the Willamette Riverkeeper. “The vast majority of people in the City of Portland don’t want the risk — they don’t want the potential safety risk, the risk to the Willamette River, the risk to air quality in that area.”

Williams said he fears a repeat of the 2016 oil train derailment in Mosier, Oregon, only with a type of oil that is more difficult to contain and in an area like the Willamette, with a dense population and already a problem with existing pollution.

OPB’s Amelia Templeton contributed reporting.

PORTLAND — A national fuel storage company has plans to turn an asphalt plant near the Willamette River into a rail and marine terminal for crude oil.

The former Paramount Petroleum plant in Northwest Portland has become part of Arc Logistics Partners LP, which operates four crude oil plants in Alabama and methanol, ethanol and other fuel plants throughout the East Coast and Midwestern United States. Arc Logistics entered into a lease in January with CorEnergy, an infrastructure investment company that purchased the plant for $40 million, according to the company's financial reports. (https://www.documentcloud.org/documents/1018089-arc-logistics-8k-2014-01-14.html)

The Arc Logistics website lists the Portland site (http://arcxlp.com/terminal/portland-terminal/) among its terminals and describes it as "capable of receiving, storing, and delivering heavy and light petroleum products," by both rail lines and marine vessels.

The project is the latest of several potential crude oil terminals in the Pacific Northwest, a region receiving unprecedented amounts of oil by rail shipments because of a surge in North American oil production. Currently, Port Westward on the Columbia River near Clatskanie is the only crude oil terminal in Oregon. In Washington, terminals have been proposed in Grays Harbor,

Vancouver and Tacoma, and expansions to accommodate more Bakken crude shipments have been proposed at refineries in Anacortes and near Bellingham.

Arc Logistics, funded by the investment group Lightfoot Capital, became a public company in November. It describes itself as "principally engaged in the terminalling, storage, throughput and transloading of crude oil and petroleum products," listing production of both U.S. and Canadian crude as factors affecting its business.

The Portland site spans 39 acres and has 84 tanks for a total capacity of 1,466,000 barrels — several times that of Port Westward. At one time, the plant also had a refining operation of nearly 12,000 barrels per day. That portion of the plant ceased operation in 2006.

Arc Logistics did not return calls for comment. In a release on the company's website (http://arcxlp.com/arc-logistics-partners-lp-announces-entrance-into-west-coast-terminalling-market/), CEO Vince Cubbage called the Portland terminal an important addition to the company's asset base, supported by a long-term contract with a major oil company: "We expect the Portland Terminal to provide the opportunity for significant incremental growth as additional customers or terminal capabilities are developed," he said.

The shipment of crude oil through the Northwest has raised concerns over safety and environmental health from environmental groups, state agencies and

emergency responders. A dramatic increase in the shipment of oil by rail has included a string of fiery derailments, and federal data show more oil spilled from rail lines in 2013 than in the previous 40 years combined (http://earthfix.info/energy/article/do-999977-percent-of-crude-oil-rail-shipments-reac/).

“It’s a big threat to our communities and to water quality,” Brett VandenHeuvel, executive director of the Columbia Riverkeeper, said. “We’ve seen that these trains carrying Bakken crude have regularly been exploding. A federal safety board said that this Bakken crude should route around urban areas and the thought of putting one in the heart of Portland is a big problem.”

Another environmental consideration raised in the company’s financial report is the Portland Harbor, designated as an Environmental Protection Agency superfund site in 2002 to cleanup uncontrolled hazardous waste. The boundaries of the superfund site are not yet finalized, but if they were to include the facility, its new owner would become a responsible party.

Matt McClincy, the state’s project manager for the Portland Harbor cleanup, said the EPA occasionally includes upland facilities that do not sit directly on the river, but that state evaluations (http://www.deq.state.or.us/Webdocs/Forms/Output/FPController.ashx?SourceId=1281&SourceIdType=11) haven’t indicated it will be included.

"The hope would be that short of unforeseen accidents they wouldn't be a concern for the river," McClincy said.

Arc Terminals, the operating subsidiary of Arc Logistics, runs 17 facilities throughout the country. Federal data (http://echo.epa.gov/?redirect=echo) show one third of those facilities have been found out of compliance with EPA regulations in the past three years, ranging from minor violations to a $101,500 fine in Alabama in 2012. Arc Terminals facilities have been involved in only a handful of small spills, none larger than 200 gallons, according to National Response Center reports (http://www.nrc.uscg.mil/).

Scott Smith, spill contingency planner for the Oregon Department of Environmental Quality, said the agency typically doesn't judge a facility based on its company's performance in other states. The individual plant's past performance, even under a different owner, is much more telling.

The facility opened in 1947, and since then "numerous releases have occurred, resulting in localized impacts to soil and groundwater at the site by petroleum hydrocarbons, volatile organic compounds (" VOCs "), polycyclic aromatic hydrocarbons (" PAHs "), and metals," according to the Arc Logistics report. One of the

plant's largest spills was in 2011, when corrosion caused a spill of nearly 21,000 gallons of Naphtha, a liquid hydrocarbon that petroleum plants use as a solvent and diluent. Paramount Petroleum, which has owned the facility since 2005, had it in limited operation at the time of the purchase, according to DEQ.

> *"It looks like a fixer-upper to me," Smith said of the plant. "A lot of those terminals are very old, and this is one of them. I'll be looking forward to any infrastructure investment that Arc makes in it."*

The lease agreement between Arc Logistics and CorEnergy includes $10 million worth of additional investments to clean, inspect and upgrade the facility's storage and to enhance the terminal's infrastructure.

Correction: *An earlier version of this story understated the capacity of the facility. The correct capacity is 1,466,000 barrels.*

Train with liquefied gas derails, strikes overpass support beam in Portland

Updated Sep 08, 2019;
Posted Sep 07, 2019

Oil tank cars pictured at a rail yard near in Northwest Portland on Saturday, March 30, 2019. Mark Graves/staff

73 379 shares

By The Associated Press

Update: Swan Island traffic could be backed up for months after train slams into vital Going Street bridge

Union Pacific says two locomotives and three tank cars containing liquefied petroleum gas derailed in Portland, striking and cracking a support beam to an overpass providing access to a major industrial area.

The company says there are no injuries and none of the tanks leaked in the derailment that happened at about 9:20 a.m. Saturday. Crews are working to get the locomotives and tank cars back on the tracks.

Portland Bureau of Transportation spokesman Dylan Rivera says North Going Street is closed until city engineers determine how much damage the overpass sustained. It's not clear when the road might reopen.

The road provides access to Swan Island, a major industrial area of the city with many workers.

Rivera says a small private road is being used to access Swan Island.

Officials Investigating If Earthquake Triggered Explosion, Fire at Bay Area Fuel Storage Facili

POSTED 9:02 AM, OCTOBER 16, 2019, BY ASSOCIATED PRESS

This video is no longer available

Officials were trying to determine Wednesday if a 4.5 magnitude earthquake triggered an explosion at a fuel storage facility in the San Francisco Bay Area that started a fire and trapped thousands in their homes for hours because of potentially unhealthy air.

The earthquake struck about 15 miles southeast from the NuStar Energy fuel storage facility in the Bay Area community of Crockett 15 hours before the Tuesday fire that consumed thousands of gallons of fuel. Aftershocks in the same area were still being felt Wednesday, including one with a 3.4 magnitude.

State and local inspectors were investigating the fire that shut down the facility, which according to the company has 24 tanks capable of holding more than 3 million barrels of different kinds of fuels.

The seven-hour blaze erupted in towering, stubborn flames Tuesday afternoon at the facility in Crockett, about 30 miles northeast of downtown San Francisco.

A firefighter was injured and was treated at a hospital, said Contra Costa Fire Department spokesman Steve Hill, who had no details about the firefighter's injuries.

Randy Sawyer, Contra Costa County's chief environmental health and hazardous materials officer, told KQED News that Tuesday's earthquake caused malfunctions at two nearby oil refineries operated by Shell and Marathon oil.

Emergency sirens blared and a column of thick black smoke that could be seen for miles prompted Contra Costa County public health officials to order people in Crockett, neighboring Rodeo and part of Hercules to stay inside with fans and air conditioners off and to seal their windows and doors with tape or wet towels.

The concern was that hazardous particulates might be spewing from the fire.

County health officials late Tuesday lifted a shelter in place order affecting about 12,000 people. But at least four schools in the area closed on Wednesday as a precaution.

Contra Costa County health department spokesman Karl Fischer did not immediately return a phone message seeking comment.

The fire began at about 2 p.m. at the tank farm, one of several refining and fuel storage facilities in the Carquinez Strait, a major shipping thoroughfare and a key oil hub.

Video footage of the fire showed flames leading up to an explosion so strong it blew the lid of one of the tanks high into the air.

The fire badly damaged or destroyed two tanks containing about 250,000 gallons of ethanol, a gasoline additive. The facility also stores gasoline, diesel and aviation fuels, according to NuStar Energy LP.

About 200 firefighters fought the flames with foam and water, trying to prevent it from spreading to other tanks containing jet fuel and ethanol. They would knock down the flames but they kept reigniting in the spilled fuel.

THE LATEST, Oct. 15, 9:28 p.m.: The CHP is reopening Interstate 80 in both directions after fire crews extinguished a blaze at the NuStar Energy facility in Crockett.

A massive fire that erupted at a NuStar Energy facility in Crockett prompted Caltrans to shut down Interstate 80 near the Carquinez Bridge on Tuesday afternoon. Closures were predicted to last until at least midnight, according to the California Highway Patrol.

The fire broke out before 2 p.m. at NuStar's storage tanks on San Pablo Avenue, about a mile from the Contra Costa County side of the Carquinez Bridge.

At 2:30 p.m., Caltrans requested the CHP start diverting traffic, according to CHP's traffic log.

By about 3 p.m., I-80 was fully closed between the intersection with Highway 4 (in Hercules) and the Carquinez Bridge toll plaza (on the Vallejo side). At 4 p.m., the CHP log warned the closure could last "six hours to all night," and the agency confirmed just after 5:30 p.m. **via Twitter** that I-80 would remain closed until midnight.

POWERED BY CONCERT FEEDBACK

Eastbound traffic was being diverted onto Highway 4, while westbound traffic was being diverted onto Interstate 780. The Benicia Bridge was the alternate crossing between Contra Costa and Solano counties.

The fire and resulting road closures were

already starting to cause a traffic nightmare for afternoon and evening commuters through the East Bay. By 3 p.m., eastbound traffic already appeared to be backed up to El Cerrito.

Railroad: Northwest Iowa oil train derailment was related to flooding

Associated Press Published 10:53 a.m. CT Aug. 10, 2018 | **Updated 11:55 a.m. CT Aug. 10, 2018**

(Photo: Bryon Houlgrave/The Register)

DOON, Ia. — BNSF Railway acknowledged Friday that flooding played a role in a derailment that loosed thousands of gallons of oil into northwest Iowa floodwaters.

Railroad spokesman Andy Williams wouldn't say whether the train engineer knew or should have known about washed-out tracks mentioned in a preliminary federal report released Thursday (https://www.ntsb.gov/investigations/AccidentReports/Pages/HMD18LR002-preliminary-report.aspx).

"The train was operating within its authority," Williams told the Associated Press.

"The cause of the derailment is flood related," he said, declining to comment further.

The National Transportation Safety Board report cited heavy rainfall in the area 48 hours before the June 22 derailment just south of Doon, near Rock Valley. The report said the water washed out track and flooded a tributary of the nearby Little Rock River. The report stopped short of saying the flooding caused the 32-car derailment.

PREVIOUS COVERAGE: ***Railroad track reopened at site of train derailment, oil leak (/story/news/2018/06/26/doon-oil-spill-train-derailment-track-reopened-rock-valley-bnsf/737087002/)***

PREVIOUS COVERAGE: ***Seven cars removed after train derailment, oil spill (/story/news/2018/06/24/train-derailment-doon-oil-spill-rock-river-leaked-crude-oil-into-rock-river-flooding-bnsf/729417002/)***

Ten of the oil tank cars were breached, the report said, releasing about 230,000 gallons of tar sands oil from Canada that was headed to a Texas refinery. Last month BNSF updated its similar spill estimate, saying that 160,000 gallons had leaked.

Regarding the differing figures, safety board spokesman Keith Holloway said preliminary data "is subject to change as more information is known." He also said that it could be 12 to 18 months before his agency issues a final report that reviews the cause of the derailment.

Much of the spilled oil was contained to an area east of the tracks then recovered. Floating barriers were installed downstream to keep oil from reaching the riverfronts and polluting the water supplies of larger communities, including Sioux City and Omaha in Nebraska.

The derailment site cleanup is expected to take several months.

The federal report also said the train was moving at 48 mph — just below the authorized speed for that stretch.

About the Clean Energy Transition Institute

The Clean Energy Transition Institute is an independent, nonpartisan Northwest research and analysis nonprofit organization with a mission to accelerate the transition to a clean energy economy by identifying deep decarbonization strategies, advancing urban clean energy, and building a clean energy workforce. The Institute provides information about the pathways to a clean energy economy and convenes stakeholders to accelerate the shift to a low-carbon economy.

Caleb Smith, Digital Communications

In-Kind Support

The Institute gratefully acknowledges ongoing in-kind support for meeting space, printing and copying, and notary services provided by **Barnard Iglitzin & Lavitt** (Genipher Owens); **Davis Wright Tremaine** (Jim Greenfield, Megan Huffman, Crespin Rodriguez); **Lane Powell** (Sarah MacLeod, Taryn Grant, Jonelle James); and **Madrona Venture Group** (Tom Alberg, Kelly Bidlingmaier, Jennifer Chambers, Cindy Petek, Lauren Olson).

Technical Consultant

Evolved Energy Research (EER) conducted the Northwest deep decarbonization pathways study—Jamil Farbes, Ben Haley, Jeremy Hargreaves, Ryan Jones, and Gabe Kwok. EER has been involved in numerous global and domestic deep decarbonization studies, including those for California, Washington, the U.S. Northeast, and Portland General Electric.

EER brings tried and tested expertise in planning for least-cost decarbonization, using a tool kit built to answer technical and economic questions about deep decarbonization, including the EnergyPATHWAYS and RIO models. EER's integrated approach to holistic energy planning finds the lowest-cost pathways to future policy goals by co-optimizing investments in the electric and non-electric energy sectors, which is essential for finding realistic and least-cost solutions for a clean energy future.

Decarbonization Pathways Work Group

The Clean Energy Transition Institute convened a work group from February to November 2017 to determine whether to conduct a Northwest deep decarbonization pathways study. The Institute gratefully acknowledges the critical input of the following Decarbonization Pathways Work Group members:

Jabe Blumenthal, Clean Energy Transition Institute Board

Rod Brown, Cascadia Law Group; Portland General Electric Board

Robert Cromwell, Seattle City Light Director, Power Contracts and Resource Acquisition

Marc Daudon, Clean Energy Transition Board; Energy Northwest Board

Philip B. Jones, Executive Director, Alliance for Transportation Electrification; former Washington State Utilities and Transportation Commissioner; Climate Solutions Board

Vlad Gutman-Britten, Washington Director, Climate Solutions

Nancy Hirsh, Executive Director, Northwest Energy Coalition

Michael Lazarus, Center Director and Senior Scientist, Stockholm Environment Institute–US

Ross Macfarlane, Clean Energy Transition Institute Board; Sierra Club Board; Climate Solutions Board

John McGarry, Clean Energy Transition Institute Board; Sightline Board; Rocky Mountain Institute Advisory Board

Eric Redman, CEO, Thunderbolt Clean Energy; Senior Policy Fellow for energy system decarbonization, University of California, San Diego, School of Global Policy and Strategy

Virinder Singh, Director of Regulatory and Legislative Affairs, EDF Renewable Energy; Climate Solutions Board

Gregg Small, Executive Director, Climate Solutions

Chris Stolte, Co-Founder, Stolte Family Foundation

Technical Advisory Group

The Northwest deep decarbonization pathways study was informed by a Technical Advisory Group that worked with the Clean Energy Transition Institute and Evolved Energy Research to develop the scope and assumptions that defined the deep decarbonization cases. The Clean Energy Transition Institute thanks the following members of the Technical Advisory Group for their many substantive contributions along the way:

Zach Baker, Oregon Policy Manager, Climate Solutions

Angela Becker-Dippmann, Principal, Glacier Creek Road, LLC

Jabe Blumenthal, Board Member, Clean Energy Transition Institute

Marc Daudon, Board Member, Clean Energy Transition Institute

Wendy Gerlitz, Policy Director, Northwest Energy Coalition

Fred Heutte, Senior Policy Associate, Northwest Energy Coalition

Kelly Hall, Washington Policy Manager, Climate Solutions

Phil Jones, Executive Director, Alliance for Transportation Electrification

Michael Lazarus, Center Director and Senior Scientist, Stockholm Environment Institute–US

Chris Stolte, Co-Founder, Stolte Family Foundation

David Van't Hof, Energy Policy Consultant

Cameron Yourkowski, Senior Policy Manager, Renewable Northwest

Design Firm

One Visual Mind designed *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest*. Founded in 2004, One Visual Mind has offices in Boston, MA, and in Portland, OR, and aims to provide functional design solutions that have an impact.

Terms and Definitions

100% Clean Electricity: Electricity infrastructure that produces no greenhouse gas emissions during the production, transmission, and distribution of electricity.

Bioenergy Potential: A measure of the energy stored within organic materials, such as wood, crops, or solid waste, and their usefulness as fuel sources.

Biofuel/Biomass Feedstocks and Infrastructure: A biofuel/biomass feedstock is a renewable source of organic matter, such as sugarcane, cornstarch, woody plants, crop residues, etc., that can be either used as fuel or converted into fuel. Biofuels require distinct infrastructure: equipment that converts feedstocks into fuel, as well as specialized storage facilities, transportation methods, and pumps.

Biogas: A combustible gas composed predominantly of methane that is collected from waste streams, such as landfills and manure lagoons, for use as fuel. As a fuel, it is virtually identical to conventional natural gas.

Biomass Resources: Sources of organic materials that can be converted into fuel, including dedicated energy crops, agricultural crop residues, forestry residues, algae, wood processing residues, municipal waste, industrial waste, and food waste.

Built Environment: Human-made surroundings, especially buildings.

Capacity Factor: A measure of an electricity resource's utilization; the ratio of actual electrical energy output to maximum possible output.

Carbon-Beneficial Biomass: Sources of biomass that when used for fuel result in net reductions of carbon dioxide emissions.

Carbon Capture: Technology that prevents carbon emissions from escaping into the atmosphere from power plant or industrial waste gas streams and stores it in geological formations or in biological material such as forests, or that converts the carbon into fuel for reuse and recapture. Also called carbon capture and sequestration, carbon capture and storage, carbon capture sequestration and utilization.

Carbon Feedstock: The reservoir of available carbon dioxide in the atmosphere or produced by burning fossil or biofuels that can be captured and converted back into useful fuels and products.

Compressed Natural Gas: A fuel produced by compressing natural gas into a liquid form so that it can be used in place of other liquid fuels such as gasoline.

Cross-Sectoral Decarbonization/ Cross-Sectoral Integrated Energy Economy: In the case of deep decarbonization, integrating low-carbon solutions across the transportation, built environment, and electricity.

Demand-Side Scenario: Decarbonization strategies that involve decisions and technologies that affect energy demand.

Diesel Hybrid Vehicle: Much like gasoline hybrid vehicles, a diesel hybrid vehicle is powered by both a diesel engine and a rechargeable electric battery.

Direct Air Capture: Technology that removes carbon dioxide from the atmosphere.

Electric Boiler: A water tank containing electrical heating elements that heat water.

Electricity System Reliability: The ability for utility operators to deliver electricity to consumers with adequate generation and available operating capacity even after outages or equipment failure. Reliability is measured by frequency, duration, and magnitude of adverse effects on service.

Electrolysis, Power-to-X: Power-to-X is a term that describes a variety of different technologies and processes that enable production of fuels using electric power. See Appendix B for detailed description.

Energy Crops: Plants grown specifically for use in producing biofuels.

Energy Density: Energy density is a measure of how much energy a fuel can store in a given amount of space. Energy-dense fuels include most liquid petroleum fuels such as gasoline, jet fuel, and diesel.

EnergyPATHWAYS Model: Evolved Energy Research's analysis tool that evaluates energy consumption across all end-use sectors and models final energy demand for fuels (electricity, pipeline gas, diesel fuels, gasoline, etc.), as well as the hourly demand for electricity.

Energy-Related Carbon Dioxide Emissions: Carbon dioxide produced from burning carbon-based fuels for energy.

Energy Resource: A source of energy; something that can be burned, harvested, extracted, or processed in order to generate energy.

Flexible Loads/Controllable Loads: A flexible load is an appliance or device with power consumption that can be directly controlled or varied.

Fuel-Switching: In the case of deep decarbonization, substituting fuels with cleaner, less carbon-intense alternatives (e.g., replacing gasoline with electricity).

Gaseous Fuel: Fuel that is stored as a vapor, rather than as a liquid or a solid, such as methane, propane, or hydrogen. Gaseous fuels take up more space but weigh less per unit of energy than liquid or solid fuels.

Generation Mix: The proportion of energy sources used to generate electricity in a given geography or jurisdiction (e.g., coal, natural gas, hydropower, wind, solar, etc.).

Grid Flexibility: The ability for an electrical system to balance power supply and demand under changing or uncertain conditions.

Grid Integration: The process of introducing and connecting new energy resources into an existing power system. Often used in reference to renewable energy, as renewables must be added into an existing grid powered by coal, natural gas, etc.

Grid Reliability: The ability of the power system to deliver electricity to consumers without interruption.

Heavy-Duty Vehicle (HDV): Usually used in reference to non-passenger vehicles, heavy-duty vehicles are freight vehicles, such as large trucks and trains, that weigh more than 8,501 pounds and are powered by diesel.

High-Capacity Factor: A highly utilized electricity resource; an electricity resource that produces almost as much energy during operation as its maximum theoretical energy output.

Hurdle Rates: Costs applied to imports and exports between transmission zones. These represent the transaction costs of trading between regions, wheeling charges, GHG charges associated with California imports, and any additional frictions of trading across borders.

Installed Capacity/Nameplate Capacity/ Maximum Effect: Installed capacity is the intended, maximum, sustained output of a power plant or electrical generator.

Interties: Connections that allow the flow of electricity between two balancing areas or transmission zones.

Least-Cost Optimization Framework: Method used in this study to determine the most cost-effective strategies for maximum carbon emissions reductions.

Light-Duty Vehicles (LDV): Vehicles that weigh less than 8,500 pounds; for example, standard passenger automobiles.

Liquefied Natural Gas: Natural gas that has been cooled to -260°F to compress it into a liquid state for storage and transportation. As a liquid, natural gas takes up 600 times less space than as a vapor.

Lithium-Ion Batteries: Energy storage method that provides a way to generate electricity and save it for use later. Lithium-ion batteries contain solid metal electrodes and allow charged lithium atoms to move in order to generate electricity.

Load: The amount of electricity drawn from the electrical grid.

Load Balancing: Matching supply to demand of electricity, including increasing and decreasing production of power plants, storing electrical power when demand is low and releasing it when demand rises, and adjusting loads through flexible load technologies.

Low-Quality Solar: Electricity produced in areas with relatively low levels of annual sunlight, or on rooftops that are shaded or at a poor angle.

Medium-Duty Vehicle (MDV): A passenger vehicle weighing between 8,501 and 10,000 pounds.

Natural Gas–Fired Generation: Producing electricity by burning natural gas. Combustion of the gas turns a turbine. The hot exhaust (carbon dioxide and water vapor) is redirected to heat water, producing steam, which also turns a turbine.

Non-Energy-Related Carbon Dioxide Emissions: Carbon dioxide emitted from sources other than the burning of fossil fuels, such as deforestation, methane from livestock, soil carbon, landfills and wastewater, and permafrost.

Optimal Electricity Supply Mix: The mixture of energy resources that produce the most efficient, lowest-cost energy with minimal carbon emissions.

Operational Integration: Integration of system dispatch activities across currently separated or only partially integrated balancing areas, lowering costs by using resources and transmission more efficiently.

Overall End-Use Energy Demand: The energy needed by all consumers on the grid.

Overgeneration: When power supply exceeds power demand, resulting in excess or wasted power. Typically, this manifests as curtailed renewable resource output.

Pipeline Gas: Gaseous fuel transported to consumers via pipelines. Today, the vast majority of pipeline gas is fossil natural gas, but in a decarbonized future it may also consist of large quantities of biogas or synthetic gas.

Regional Investment and Operations Model (RIO): Evolved Energy Research's computational tool that finds least-cost resource investments and operations for all energy-supply options and fuel types, including electricity, pipeline gas, gasoline, diesel, jet fuel, hydrogen, and other fuels. The model decides which technologies will be used over time to meet annual emissions targets and other constraints.

Regional Integration/Regional Grid Integration: Strengthening interconnection between transmission zones; a key strategy to resolve issues of overgeneration, undergeneration, or high electricity demand.

Renewable Diversity: Using varied sources of renewable energy to meet electricity demand.

Resource Adequacy: A regulatory construct developed to ensure that there will be sufficient resources to serve electric demand under all but the most extreme conditions.

Residual Fuels: The by-products of crude oil after gasoline and other fuels have been extracted during the refining process; used in thermal power plants and large engines, such as marine vessels.

Scenario-Based Pathways Approach: One of the methodologies used in a pathways study, involving specific sets of economic and policy conditions in order to determine the optimal route and tools to accomplish emissions reduction goals.

Sensitivities/Sensitivity Analyses: A measure of how changes in one resource or condition will impact other resources and conditions in an energy modeling analysis.

Sustainable Biomass: Biomass harvested from renewable resources, such as from forestry and agricultural residues, where waste products are reused to fertilize future biomass feedstocks.

Thermal Power Plants: A power station in which heat energy is converted into electricity, usually using coal or natural gas.

Undergeneration: The production of less electricity than is needed; when the load (demand) exceeds the production (supply).

Waste and Wood Feedstocks: Sources of organic material that can be converted into biofuels derived from waste (e.g., landfills) and wood (e.g., forestry residues).

Vanadium Flow Batteries: Vanadium flow batteries contain salt solutions that interact through a membrane. Flow batteries use both an electrochemical cell and a liquid electrolyte stored in separate tanks, which flow through the cell when the battery is operating. Vanadium flow battery capacity and power can be scaled independently.

Zero-Carbon Electricity/Zero-Carbon Sources: Electricity production that emits no carbon dioxide.

Executive Summary

The Clean Energy Transition Institute commissioned this economy-wide deep decarbonization pathways study to serve as a blueprint for how Idaho, Montana, Oregon, and Washington might achieve a low-carbon, clean energy economy over the next three decades. The study, *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest*, examines alternative pathways to achieving an 86% reduction of carbon emissions below 1990 levels in the built environment, transport sector, and electricity grid by 2050. A pathways approach enables an understanding of the most economically and technically efficient means of realizing this mid-century decarbonization goal.

The study models the energy systems in each of the four Northwest states to identify the interdependencies, efficiencies, and trade-offs that must be considered when pursuing deep decarbonization. The study's purpose is to provide guidance to policymakers, advocates, leaders, and investors as decisions are made to catalyze the clean energy transition in the Northwest over the coming three decades.

Since the fall of 2017, several regional studies have been conducted for different stakeholders and with varying assumptions that offer insights into different aspects of the Northwest's decarbonization puzzle. *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* is the first economy-wide analysis to examine the most likely decarbonization scenarios mapped to the region's economic and institutional realities. Prior studies looked only at the electricity grid, at one state or one utility service territory, or at the role of one fuel in specific sectors or subsectors of the economy as Figure 1 shows.

FIGURE 1. This study is the only four-state and sector-wide decarbonization analysis of the Northwest.

Each of these studies had a narrower purpose and answered questions of more limited scope than those posed by *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest*. For example, none has looked at the impact of constraining biomass, the use of natural gas in transport, limited electrification, or greater integration of the Northwest and California electric grids. This study is unique in offering a blueprint that broadly frames the opportunities and trade-offs for the Northwest to achieve economy-wide deep decarbonization between 2020 and 2050.

Key Findings

The study demonstrates how the Northwest can rapidly deploy strategies to reduce carbon emissions in the energy sector efficiently and at least cost for the electricity grid, the built environment, and transportation. The region's relatively clean electricity grid and proximity to California, where climate policies aim to achieve a massive transition to clean energy within the coming three decades, are key assets.

Consistent with prior decarbonization pathways efforts, this study demonstrates that the low-carbon system of the future must have four primary features: (1) energy must be used more efficiently than it is today; (2) electricity generation must be as clean as possible; (3) liquid fuels must be as low-carbon as technically and economically feasible; and (4) clean electricity must be used for as many purposes as possible.

The study's key findings include:

- **Deep decarbonization is achievable in the Northwest.** Multiple strategies exist to achieve a deeply decarbonized energy system in the Northwest using today's technologies. Policymakers must decide how to achieve a low-carbon energy system at an acceptable cost.
- **Energy efficiency is a key strategy to reduce costs and meet goals.** Decreasing the demand for energy through efficiency reduces the need for new energy supply and associated infrastructure, and therefore also reduces the cost of decarbonization.

"Clean electricity is the backbone for deep decarbonization and the cross-sectoral role that electricity will play in the coming decades is key to the low-carbon future."

- **A nearly 100% clean electricity grid is needed.** A Northwest electric grid nearly free of fossil fuels efficiently achieves mid-century climate targets. Carbon emissions from electricity generation were reduced by 96% in the study's Central Case, the core decarbonization pathway. While coal is eliminated in a deep decarbonized future, a small amount of natural gas–generated electricity (just 3.7% of annual energy in the study's Central Case by 2050) ensures that the grid can reliably deliver power during periods of low generation from hydroelectricity and other renewable sources.
- **Demand for clean electricity will continue to grow.** A low-carbon future hinges on an integrated energy economy where power sources—and electricity in particular—play a cross-sectoral role in transportation and the built environment. Widespread transportation electrification (100% of light-duty, 60% of medium-duty, and 40% of heavy-duty vehicles in the study's Central Case) will be crucial to reduce emissions at least cost and avoid using either scarce biofuel supplies or relatively expensive electric fuels for transport. Clean electricity also

Fossil Fuel Terminal Zoning Amendments Testimony
Ordinance #189807
LUBA No. 2020-009
Page 4447

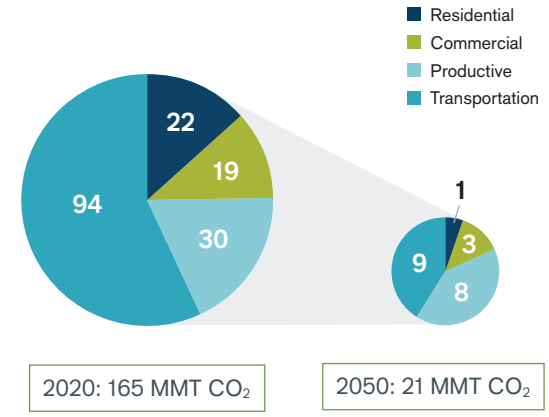
needs to replace oil and gas to heat and cool buildings in a low-carbon future. Finally, clean electricity will be used to produce synthetic gas and liquids as additional energy sources.

- **Increased grid integration and transmission between the Northwest and California is cost-effective.** Significant cost savings can be realized if the Northwest and California electric grids are expanded and operations are better integrated. Building additional transmission lines between the Northwest and California electricity grids could reduce the costs of decarbonization by an estimated $11.1 billion in net present value over the 30-year study period accrued to the combined California and Northwest region.
- **Sustainable biomass is best used for jet and diesel fuel.** The best use for sustainable biomass is creating liquid fuels to power the hardest-to-electrify subsectors within transportation, namely aviation and long-distance freight shipping.
- **Emerging technologies will play a critical decarbonizing role.** With the correct mix of regulatory guidance, investment, and research it is likely that a range of technological developments will emerge to solve some of the most challenging deep decarbonization problems in the years beyond 2030. These technologies, which include electrolysis, direct air capture, hybrid boilers, hydrogen, synthetic fuels, and carbon capture, will provide economic value for excess renewables, displace conventional gas and liquid fuels, and help balance the grid.

This study is designed to show the trade-offs between different deep decarbonization pathways, but it does not take into account equity considerations for different communities. The study demonstrates that we can decarbonize our economy, but the critical work ahead must focus on how to do so equitably.

Pathway Scenarios

The study examined eight cases, starting with:



- **Business as Usual Case** based on existing policies and the scenario against which the seven deep decarbonization cases are compared; and
- **Central Case** that represents the study's core optimal deep decarbonization pathway.

The Central Case is the most flexible pathway to achieve emissions reductions because it is technology neutral. Six additional scenarios representing demand and supply variables relevant to current discussions in the Northwest energy community were modeled off the Central Case to understand the energy system trade-offs that occur as a result of different constraints or policies.

- **100% Clean Electricity Grid Case**, where all electricity generation must be zero-carbon in 2045.
- **Limited Electrification and Efficiency Achieved Case**, in which the aggressive electrification and energy efficiency assumptions in the Central Case do not materialize.
- **No New Gas Plants for Electricity Case**, which prohibits any new gas-fired power plants from being built across the region after 2020 and retires existing gas plants at the end of their economic lifespan.
- **Increased Northwest-California Transmission Case**, where unconstrained construction of additional transmission is allowed between the Northwest and California for better grid integration.
- **Limited Biomass Available for Liquid Fuels Case**, where each state's bioenergy potential is limited to only waste and wood feedstocks, and no energy crops or biomass resources outside of the region are permitted.
- **Pipeline Gas Used for Freight Vehicles Case**, where compressed and liquefied pipeline gas replace renewable diesel fuel for freight vehicles in the Central Case.

Northwest CO_2 emissions decrease in the Central Case from 165 million metric tons (MMT) in 2020 to 20.8 MMT in 2050.

FIGURE 2. Comparison by sector of Northwest CO_2 emissions decrease from 2020 to 2050 in the Central Case.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 63.

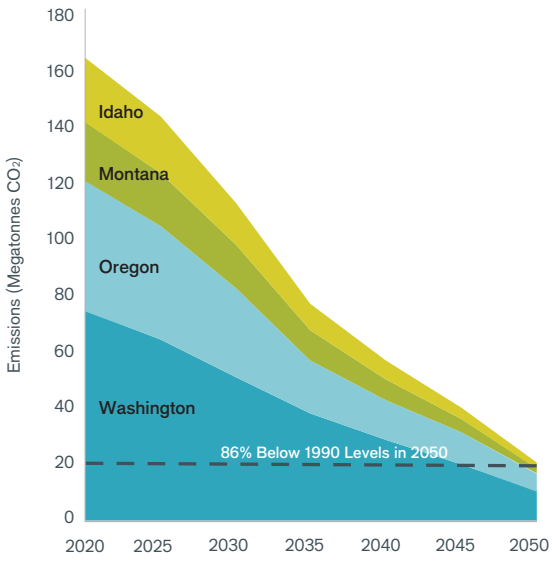


Figure 2 shows that Northwest CO_2 emissions decrease in the Central Case from 165 million metric tons (MMT) in 2020 to 21 MMT in 2050. Emissions in the residential sector decline by 95%; in the commercial sector by 86%; in the productive (industrial) sector by 72%; and in the transportation sector by 91%.

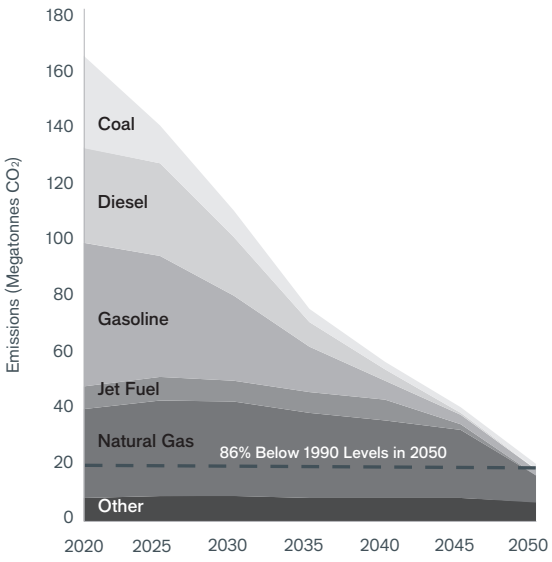
Figure 3 shows the emissions decline from 2020 to 2050 by each state, as well as by fossil fuel type. These emission reductions are achieved through five key decarbonization strategies: energy efficiency; decarbonizing electricity; decarbonizing gas and liquid fuels; fuel-switching in industry, transportation, and buildings; and carbon capture. The cost of achieving these reductions is offset by avoided fossil fuel purchases.



This study is unique in offering a blueprint that broadly frames the opportunities and trade-offs for the Northwest to achieve economy-wide deep decarbonization between today and 2050.

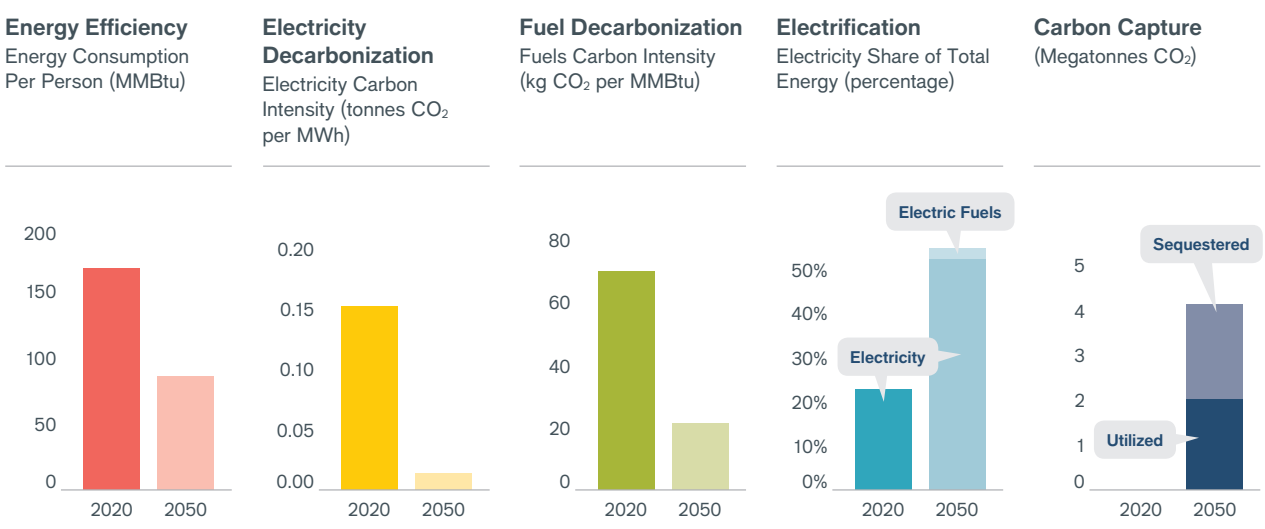
Five Key Decarbonization Strategies

Transitioning the Northwest to a low-carbon energy system relies on five decarbonization strategies:



1. **Energy Efficiency:** reducing energy consumed to provide an energy service
2. **Electricity Decarbonization:** reducing the emissions intensity of electricity generation
3. **Fuel Decarbonization:** reducing the emissions intensity of liquid and gaseous fuels
4. **Electrification:** switching end uses from fuel to electricity
5. **Carbon Capture:** capturing CO_2 from a facility or removing CO_2 from the atmosphere

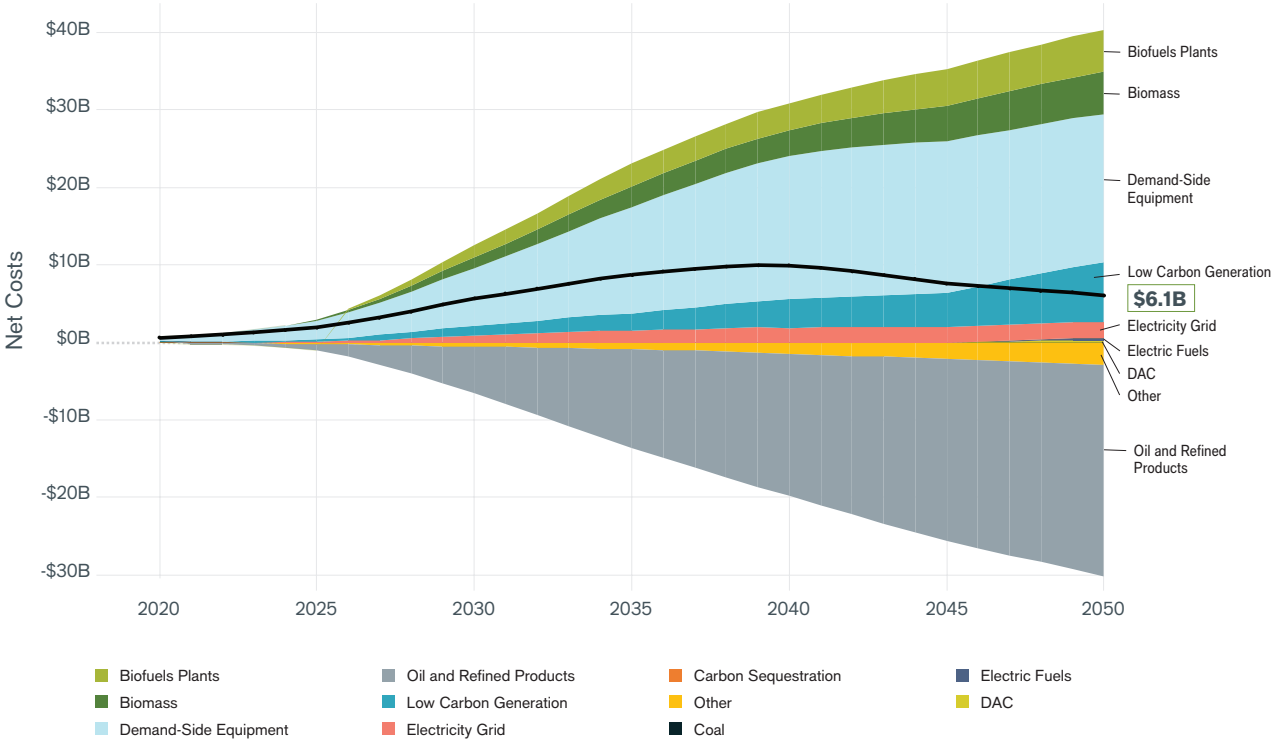
The purpose of the fifth strategy, carbon capture, is twofold: the captured CO_2 can either be used as a carbon feedstock for electric fuel production or sequestered.

Figure 4 shows metrics for the five strategies in the Central Case. Per capita energy consumption decreases from approximately 170 MMBtu per person today to 85 MMBtu per person in 2050, a 50% decrease. The average carbon intensity of electricity generation, which is already relatively low in the Northwest due to the hydroelectric system, decreases to near-zero by 2050.

The carbon intensity of fuels (liquid and gas) decreases by 70% primarily using biofuels. The share of total final energy served by electricity or electrically produced fuels (e.g., hydrogen and synthetic natural gas) more than doubles from approximately 23% today to 55% in 2050. Four million metric tons of CO_2 are captured in 2050, with about half of the CO_2 being utilized to produce synthetic fuels and the other half being sequestered (e.g., in saline aquifers in Montana).

FIGURE 4. Five decarbonization strategies.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 65.



Costs

The study models the annual energy system costs of producing, distributing, and consuming energy, comparing the annual costs of the Business as Usual Case and the Central Case from 2020 to 2050. Net annual costs of the Central Case vary over the modeled period based on the timing of infrastructure investments, peaking at 16.1% ($9.8 billion) above the Business as Usual Case in 2038 and decreasing to 8.3% ($6.1 billion) higher than the Business as Usual Case in 2050. The cumulative costs of decarbonizing the energy system in the Central Case are 9.5% higher than the capital and operating expenses of the Business as Usual Case's energy system, roughly 1% of the region's total GDP in 2017 of more than $870 billion.[1] (See Figure 5.)

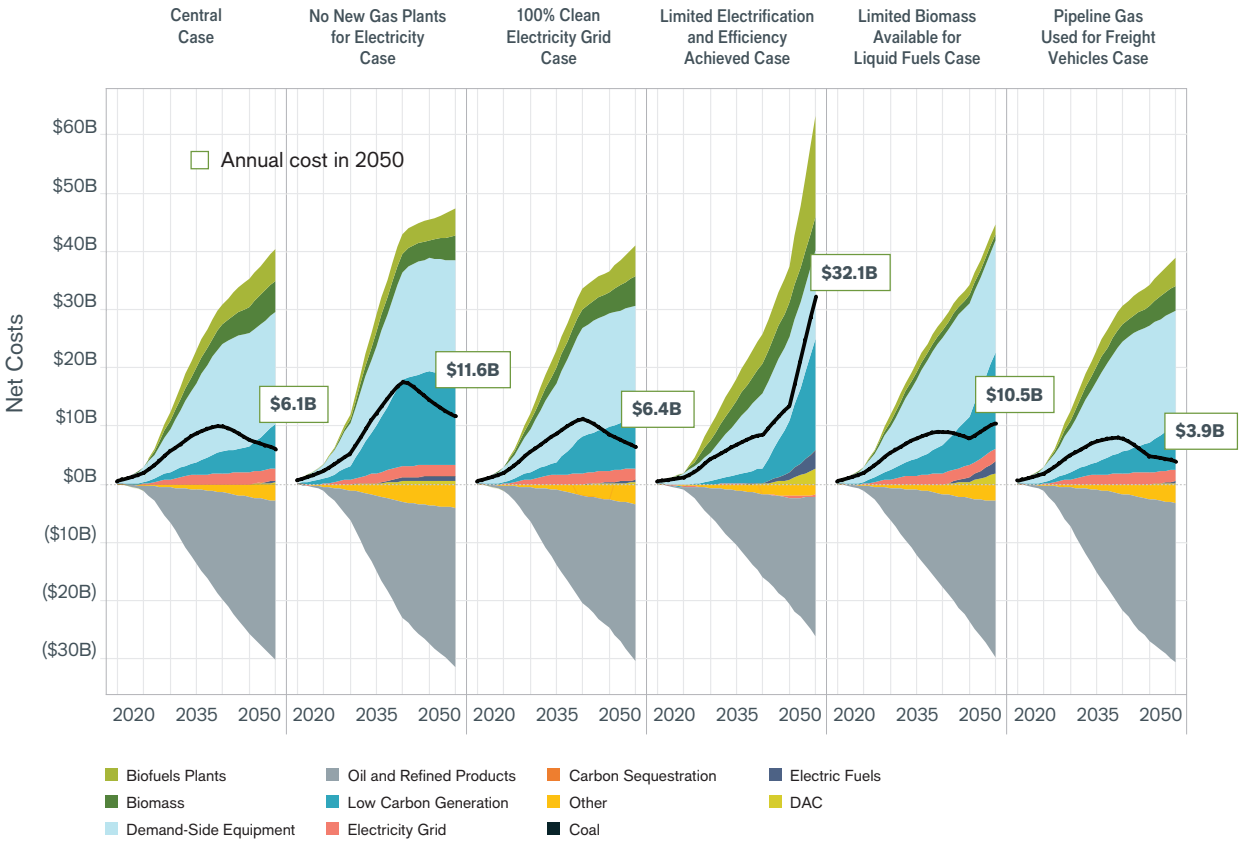
Ordinance #189807
LUBA No. 2020-009
Page 4451



Increased costs in a decarbonized system consist primarily of biofuel feedstocks and infrastructure, demand-side electrification and efficiency investments, and renewable power plants and supporting electricity infrastructure. These costs are mitigated by the savings from reduced spending on fossil fuels, primarily liquid petroleum products such as gasoline, diesel, and jet fuel.

Costs for each scenario were modeled and compared to the Business as Usual Case. All cases performed worse than the Central Case, with the exception of the 100% Clean Electricity Grid scenario, which was only a marginal change from the Central Case and therefore has only a minimal impact on costs. The Pipeline Gas for Transport Case was $2 billion less than the Central Case. While this is a more cost-effective result, there are two issues that must be considered: (1) the model does not take into account the upstream emissions of pipeline gas production, and (2) there are significant technical challenges with using gas in the transport sector.

The Limited Electrification and Efficiency Achieved, No New Gas Plants for Electricity, and Limited Biomass Available for Liquid Fuels scenarios differ the most from the Central Case in terms of an increase in net systems costs. (See Figure 6.)

In 2050, the average cost of avoided carbon is $48/tonne and declining. The model makes conservative assumptions about the costs and scalability trends of clean energy technologies. A future report will explore in greater depth details on costs and emissions reductions, the assumptions that returned these results, and what these results mean for how the Northwest should consider investing in transitioning the region to a low-carbon economy.

FIGURE 6. Annual net energy system costs for six cases compared to the Business as Usual Case.

Next Steps for the Northwest

Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest aims to represent potential energy futures in enough technical detail to be used as blueprints to develop a future of the Northwest's choosing. While this analysis offers a functional technical representation of low-cost deep decarbonization pathways, successful implementation is more uncertain. Implementation challenges include the following:

- A nearly 100% clean grid is a key feature of low-cost decarbonization in the region. Policymakers and utilities must focus on overcoming the policy, technical, business model, and economic barriers to cleaning the grid well in advance of 2050.
- The level of transportation electrification called for by 2050 requires immediate attention to accelerating the widespread adoption of electric vehicles, investing in the essential charging infrastructure, and determining how the grid will handle the additional load required to serve this new demand. Not only must we move quickly to electrify transportation, we also need to invest in solutions that promote greater equity, especially for people historically least served or most impacted by fossil fuel–based transportation systems.
- New grid infrastructure and operational integration are needed to leverage renewable development efficiently and cost-effectively in California and across the West. Achieving this integration and installing the needed grid capacity is complicated politically and technically, so planning must get underway now to ensure successful integration of these markets.

Further work is needed to develop the policies that will accelerate a deep decarbonization path in the Northwest that is affordable, equitable, and meets reliability standards.

There are several areas of additional examination that the study suggests pursuing, including changing assumptions about hydroelectricity and nuclear availability, coal plant retirement dates, and natural gas pricing and carbon intensity. Further examination is needed of the role of natural gas and the decentralization of the electricity grid, as is work on the key policy drivers that are needed to accelerate decarbonization in the Northwest.

This study is designed to show the trade-offs between different deep decarbonization pathways, but it does not take into account equity considerations for different communities. The study demonstrates that we can decarbonize our economy, but the critical work ahead must focus on how to do so equitably.

Meeting the Challenge of Our Time: Pathways to a Clean Energy Future in the Northwest is the only independent and rigorous deep decarbonization analysis framing the choices we must make in the coming decade to achieve a deeply decarbonized future in the next 30 years. Stakeholders can use the results of this and other decarbonization studies to formulate policies and make investments and operational decisions to accelerate the clean energy transition and put the Northwest on a deep decarbonization path that is sustainable, affordable, equitable, and meets reliability and security needs.

Introduction

Humanity has a small window in which to reduce greenhouse gas emissions. According to the October 2018 UN Intergovernmental Panel on Climate Change (IPCC) report,[2] "rapid and far-reaching" transitions in worldwide land use, energy, industry, building, transport, and cities are required to keep global warming temperatures to a maximum of 1.5 degrees Celsius (1.5°C) above pre-industrial global temperatures. Scientific consensus indicates that there is a critical 12-year window in which to bring global net human-caused carbon dioxide (CO_2) emissions down by approximately 45% below 2010 levels by 2030, and that the world must be net-zero emitting by 2050.

Just 11 days after the IPCC report was released, an International Energy Agency (IEA) analysis concluded that the world is on a path to build so many fossil fuel power plants and energy-inefficient factories and buildings in the next five years that it will become impossible to hold global warming to safe levels.[3] "The chances of meeting [a 1.5°C target] are becoming weaker and weaker every year, every month,"[4] IEA's executive director Fatih Birol declared to an audience gathered in Paris in late 2018.

The Northwest region of the United States is uniquely suited to lead the country in accelerating a path to deep decarbonization with its longstanding environmental ethic, abundant supply of clean hydroelectricity, and decades-long investment in energy efficiency. The region's built-in advantages suggest that the Pacific Northwest could take the lead in achieving a nearly 100% clean electricity grid by piloting the technologies and strategies required to decarbonize the transportation sector and buildings.

Northwest residents believe that global warming is happening by overwhelming majorities and express concern about climate change impacts.[5] The Northwest's close economic and historical energy linkages to California, as well as that state's ambitious carbon emission reduction policies, offer an opportunity to embrace new technologies that could drive change in Western energy markets, with an eye toward capturing additional efficiency and deeper carbon reductions.

Grand Coulee Dam. Photo credit: U.S. Bureau of Reclamation

According to the Yale Program on Climate Communication, 73% of Washington, 72% of Oregon, 65% of Montana, and 63% of Idaho believe that global warming is happening; 63% of Washington, 62% of Oregon, 55% of Montana, and 56% of Idaho are worried about global warning.

Now is the time for the Northwest to determine the path to a low-carbon future. The Clean Energy Transition Institute, a Northwest research and analysis nonprofit organization, developed *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* to offer a roadmap for how to achieve deep greenhouse gas emission reductions across the economy at a reasonable cost.

Study Objective

An analytical blueprint for decarbonizing the Northwest's economy offers a common set of assumptions to guide the region in making informed decisions about how the clean energy transition could unfold regionally over the coming three decades.

The study aims to provide unbiased analysis of decarbonization strategies for the region and, by doing so, demonstrate a variety of pathways to lower carbon emissions in the Northwest. The study also serves to illuminate the practical implications of achieving mid-century climate targets and broaden conversations about the actions we need to take to get there.

Study Differentiation

The study is an economy-wide analysis that models the technical and economic implications of different decarbonization choices for the Northwest from now through 2050 for Washington, Oregon, Montana, and Idaho's energy systems—the network of all infrastructure that produces, converts, delivers, and consumes energy. This analysis contributes to an existing body of technical work related to decarbonization in the Northwest but is the first to optimize energy supply decisions for all four Northwest states, revealing new low-cost pathways to decarbonization.

The study includes a detailed representation of residential and commercial buildings and stocks, electricity demand, industrial energy demand, and vehicle fleets and transportation demand for freight and passenger transport to provide a full picture of the Northwest's energy systems. The study does not account for emissions from agriculture nor from industrial processes that are separate from the energy directly consumed by these sectors of the economy, due to data limitations associated with these sectors.

Several studies of decarbonization for the Northwest have been conducted since November 2016 and each of them provides slices of the decarbonization picture for the Northwest. (See Figure 1.)

FIGURE 1. This study is the only four-state and sector-wide decarbonization analysis of the Northwest.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 9.

The five key differentiators between this study and prior studies are:

Scope: Each of the prior studies had a narrower purpose and answered questions of more limited scope than those that this study poses. None looked at the impact of constraining biomass, the use of natural gas in transport, limited electrification, or greater integration of the Northwest and California electric grids.

Economy-Wide: Looking economy-wide at all energy systems—not just at the electricity grid—yields a better understanding of how the whole energy system could work together to decarbonize and how the sectors interconnect. Evaluating only one source of emissions at a time provides an incomplete assessment of decarbonization. For example: should biomass be used to produce biogas for gas-fired power plants or for renewable jet fuel for aviation? Approaching deep decarbonization holistically provides an understanding of cross-sectoral advantages, impacts, and trade-offs.

Geography: Of the seven studies, only this study and the Public Generating Pool's 2019 study consider all four states in the region, while the other five include only parts of each state.

Energy Sectors: Four of the seven studies are electricity-sector focused only, while the other three, including this study, look at all energy sectors.

Models: The study combines detailed demand-side scenario development using a bottom-up energy system model called EnergyPATHWAYS, with optimal decision-making of the supply side done by an optimal-capacity expansion tool called the Regional Investment and Operations (RIO) model. Prior studies either optimized only for the electricity grid or only used a scenario-based pathways approach. (See Appendix A for a detailed description of the modeling approach.)

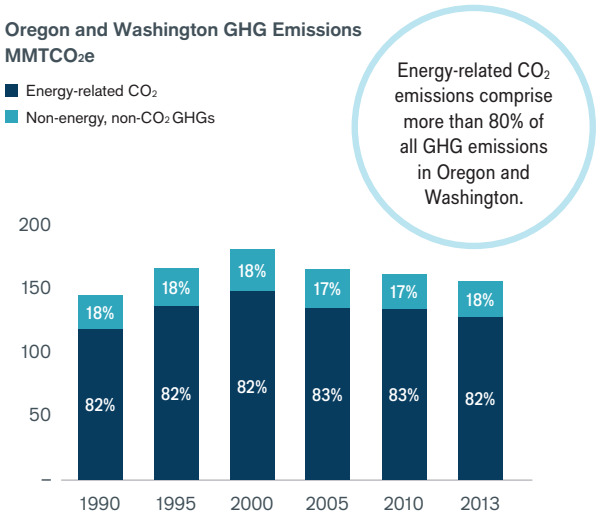
Greenhouse Gas Emissions Context

Energy-related CO_2 emissions have historically dominated greenhouse gas emissions in the Northwest, including emissions from fossil fuel combustion in buildings, industry, transportation, and electricity consumption. As Figure 2 shows, energy-related CO_2 emissions comprise more than 80% of all GHG emissions in Oregon and Washington.[6]



The remaining GHG emissions, colored light blue on the chart, include non-energy CO_2 and non-CO_2 greenhouse gas emissions from agriculture and industrial processes, such as methane from agriculture and waste, as well as hydrofluorocarbons and other high-intensity industrial emissions.

Energy CO_2 emissions are spread across three major sectors: electricity, transportation, and buildings and industry. The transport sector accounts for nearly half of all energy-related CO_2 emissions in Washington and Oregon primarily because of liquid fuel consumption: gasoline in passenger vehicles, diesel fuel in freight transport, fuel for marine transport, and jet fuel for aviation. Figure 3 depicts the breakdown of emissions by sector.

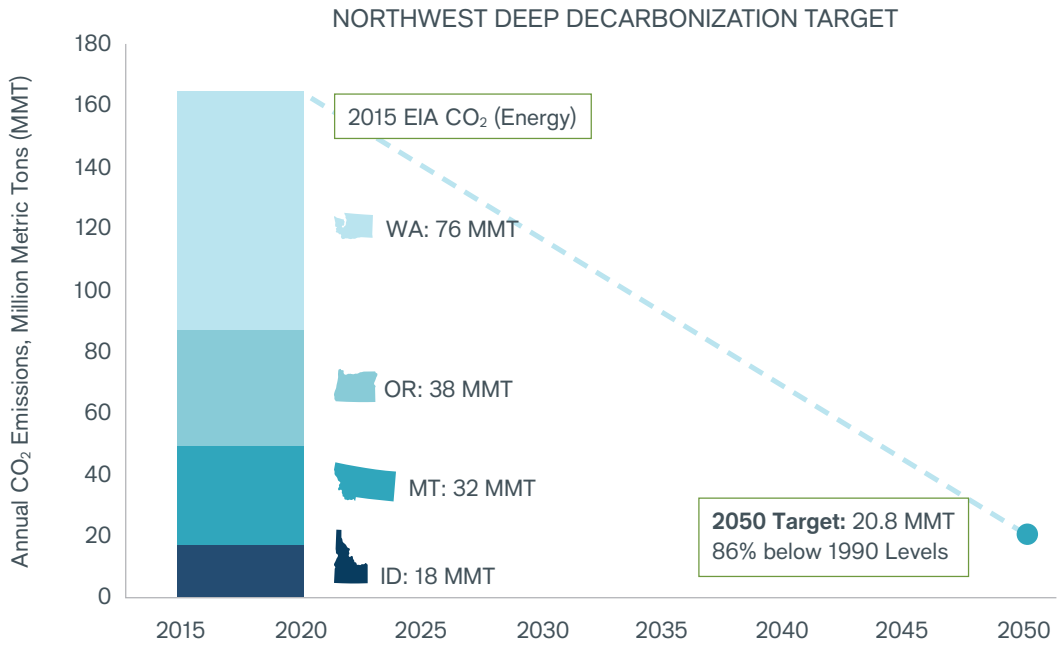
Study Emissions Target



Two of the four Northwest states have set mid-century greenhouse gas emissions reduction targets. Washington established limits on emissions in 2008, including a 50% reduction below 1990 levels by 2050, which the Department of Ecology has recommended strengthening to 80%. Since 2007, Oregon has had the goal of reducing GHG emissions by 75% below 1990 levels by 2050.

This study's analysis uses the carbon emissions reduction target of 80% below 1990 levels by 2050 for all emissions (the global target established by scientific consensus) and assumes that the energy system will need to achieve reductions of 86% in energy-related CO_2 emissions below 1990 by 2050 to achieve the overall target that includes other sources of carbon emissions, such as forestry, agriculture, waste management practices, and others. This target was applied to each Northwest state independently. Targeting an 86% reduction in energy-related CO_2 emissions allows for fewer reductions of non-energy CO_2 emissions and non-CO_2 GHG emissions, where reduction strategies are less well understood.

While achieving the economy-wide target of 80% below 1990 levels by 2050 does not put the Northwest on track to do its part to limit the rise of global temperatures to 1.5°C, it is the standard target that most deep decarbonization pathways studies have modeled to date. An 80% reduction target provides a baseline against which deeper reductions could be measured in future studies.

This study, therefore, represents a floor and not a ceiling for responsible climate action, and while it develops an important pathway, further analysis should be conducted to achieve the targets that scientists recommend for the world to address global warming. Figure 4 depicts the deep decarbonization target for the Northwest energy system to attain.

FIGURE 4. An 86% reduction in energy-related CO_2 emissions below 1990 levels by 2050 is required to achieve an overall Northwest deep decarbonization target.

Deep Decarbonization Pathways Framework

To decarbonize energy supply—electricity, pipeline gas, liquid fuels—the study applies a least-cost optimization framework that chooses the most cost-effective investment in resources to develop low-carbon energy supply portfolios. The model determines the fuel and energy supply-side infrastructure simultaneously while also considering constraints, such as the need to maintain electricity system reliability, or how much of a given resource, such as biomass, is available.

The deep decarbonization pathways framework for energy includes these strategies:

1. Use Less Energy

Energy efficiency and conservation reduce energy so fewer resources are needed, less carbon is emitted, and consumers pay less. Buildings, appliances, and vehicles all must become far more efficient to dramatically reduce energy consumption.

2. Decarbonize Electricity

By 2050, low-carbon technologies must replace nearly all fossil fuel electricity generation. A nearly 100% clean electric grid is essential to achieving required emission reductions.

3. Decarbonize Liquid Fuels and Gas

For energy-dense transportation, such as aviation, long-haul trucking, and some industrial heat processes, carbon-beneficial biomass and synthetic fuels may be used.

4. Fuel-Switch

Transportation is currently powered by petroleum, while buildings and industry are currently fueled by a mix of natural gas, petroleum, and electricity. All must switch to cleaner fuels, principally clean electricity.

Study Methodology

Prior to commissioning *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest*, the Clean Energy Transition Institute convened a Deep Decarbonization Pathways Working Group (see page 4 for the list of participants) and conducted numerous interviews with Northwest stakeholders about the value of conducting an economy-wide pathways study.

This stakeholder process revealed a clear need for a common set of facts about the decarbonization pathways for the Northwest that legislators and the advocacy community could agree to. (See Appendix E for the questions that stakeholders developed.) The Clean Energy Transition Institute commissioned Evolved Energy Research (EER) to develop the pathways to deep decarbonization for the four Northwest states with the following study parameters:

- Explore how energy sectors and energy supply need to transform in the most technologically and economically efficient way.
- Examine the extent to which electricity generation needs to be decarbonized to achieve economy-wide carbon reduction goals.
- Estimate the most cost-effective use of biomass for decarbonizing fuels.
- Assess the impacts of alternative assumptions and constraints, such as the limits of available biomass or the failure to achieve a high rate of electrification.
- Explore the value of increased electricity grid transmission between the Northwest and California.

The modeling process began by creating representations of each of the four state energy systems, incorporating state-specific energy infrastructure data and existing policies and creating benchmarks against historical energy use and emissions. The modelers then defined the deep decarbonization pathways by identifying plausible technologies for energy supply and demand and creating multiple scenarios that were designed to address the specific regional decarbonization questions, cases, and sensitivities that the Clean Energy Transition Institute wanted to explore.

King County Cities Climate Collaboration summit, January 2015.
Photo credit: Clean Energy Transition Institute

The model ran scenarios for each pathway through 2050, optimizing energy supply-side decisions within the constraints of the scenario being run and producing outputs of energy, emissions, cost, and infrastructure for different pathways to achieve steep reductions in energy-related CO_2 emissions by 2050. Modeling involved two different models that Evolved Energy Research developed: EnergyPATHWAYS (EP) and the Regional Investment and Operations model (RIO). (See Appendix A for detailed discussion of the modeling approach.)

The deep decarbonization target was applied to each Northwest state independently and assumes that each state complies with the target individually, although each can also use regional energy resources by importing or exporting clean energy to achieve compliance. One advantage of this study methodology is that it produces deep decarbonization pathways for each state individually.

Overview of Study Cases

The study explores multiple pathways for decarbonizing the region's energy system, while addressing policy questions and potential implementation challenges in the context of economy-wide carbon limits. The modeling exercise involved eight cases: the Business as Usual Case and the Central Case, two cases that examine different levels of energy demand, and four cases that assume varying sources of energy supply.

The Business as Usual Case is based on existing policies and is the scenario against which the seven deep decarbonization cases are compared. The Central Case represents the optimal deep decarbonization pathway, and the remaining six pathways cases are developed off the Central Case to draw out insights from alternative assumptions and policies. (See Appendix C for a list of all study assumptions and Appendix D for a list of key references.)

Wind turbine technicians. Photo credit: Pinnacle Career Institute

This approach allows for a better understanding of the trade-offs across the energy system when we assume alternative levels of electrification, mandates to use 100% clean electricity generation or prohibit new gas power plants, constraints on the use of biomass, and further electricity sector integration between the Northwest and California.

FIGURE 5. Overview and descriptions of the eight cases in this study.

Case	Description
Business as Usual Case	• A continuation of current and planned policy • Provides a benchmark against the deep decarbonization pathways
Central Case	• Represents the core pathway to achieve deep decarbonization • Flexible pathway to achieve emissions reductions (e.g., technology agnostic in the electricity sector)
100% Clean Electricity Grid Case	• 100% of electricity generation in the Northwest must come from zero-carbon sources in 2045 • Allows gas-fired generation to burn biogas and synthetic electric fuels
Limited Electrification and Efficiency Achieved Case	• Aggressive electrification fails to materialize • Adoption of electrification is half of the Central Case
No New Gas Plants for Electricity Case	• Pathway prohibits any new gas-fired power plants across the region throughout the study horizon • Existing gas plants retire at the end of their natural life, which effectively results in zero gas plants by 2050
Increased Northwest-California Transmission Case	• NW and CA power systems are currently connected by approximately 8,000 MW of interties • Pathway allows for transmission interties to be expanded as both regions strive to achieve decarbonization
Limited Biomass Available for Liquid Fuels Case	• Each state's bioenergy potential is limited to waste and wood feedstocks without access to energy crops or resources outside of the region • Biomass supply is 60% less than Central Case
Pipeline Gas Used for Freight Vehicles Case	• Freight vehicle fleet has a large composition of compressed and liquefied pipeline gas trucks • Increased pipeline gas use in freight transportation supplants diesel fuel demand in the Central Case

Page 4463

The eight cases studied are as follows:

Business as Usual Case

The Business as Usual Case assumes the continuation of current and planned policy for the four Northwest states, serves as the benchmark case, and demonstrates that existing policies are not enough to attain the deep decarbonization target.

Central Case

The Central Case is the optimal low-carbon pathway for the Northwest and shows that a diverse set of unconstrained technologies and strategies (including significant energy efficiency and electrification) will achieve deep decarbonization. It is structured to answer multiple questions: How clean must electricity generation be to realize a deep decarbonization target? What is the cost-optimal allocation of biomass? How quickly must we electrify transportation? What is the role of natural gas for electric power generation in 2050?

100% Clean Electricity Grid Case

The 100% Clean Electricity Grid Case puts the grid on a trajectory to zero-carbon sources for all electricity generation starting in 2020, and constrains electricity generation to be 100% clean in 2045 and beyond to align with California's clean energy mandate. Gas-fired power plants are allowed to burn biogas and synthetic electric fuels to meet the target. This case demonstrates how more aggressive decarbonization in the electricity sector can make up the balance with harder-to-mitigate sectors.

Limited Electrification and Efficiency Achieved Case

In this case, the aggressive electrification and efficiency assumed in the Central Case fail to materialize. It explores the strategies needed to achieve deep decarbonization if electrification is only half of that achieved in the Central Case.

No New Gas Plants for Electricity Case

This case prohibits any new gas-fired power plants in the region after 2020 and has existing gas plants retire at the end of their economic lives, which means no gas plants operate on the grid by 2050. This case reveals the options that electric grid managers have for maintaining resource adequacy and flexibility as renewables are added, as well as the role that storage would need to play in maintaining grid reliability.

Increased Northwest-California Transmission Case

In this case, unconstrained construction of additional transmission between the Northwest and California electric grids allows better integration than currently exists. This case reveals how a more efficient use of electricity sector infrastructure can reduce costs and grid-balancing challenges.

Limited Biomass Available for Liquid Fuels Case

For this case, each state's bioenergy potential is limited to waste and wood feedstocks with no access to energy crops or to biomass resources outside of the region, which means 60% less biomass than in the Central Case. This case tests the impact of limiting biomass to see what other strategies would be required to meet deep decarbonization if a sustainable biomass supply fails to materialize.

Pipeline Gas Used for Freight Vehicles Case

Here hybrid diesel vehicles in the Central Case are powered by compressed natural gas for medium-duty vehicles and liquefied pipeline gas for heavy-duty vehicles. The total vehicle fleet has the same proportion of battery electric vehicle fleets as in the Central Case, which helps illuminate the potential role for pipeline gas in transportation.

Page 4465

Case Assumptions and Results

Central Case

The Central Case was designed to probe how clean the electric grid must be to achieve the economy-wide carbon reduction target and how biomass would be cost-optimally allocated. On the demand side, the Central Case incorporates aggressive levels of efficiency and electrification across all sectors.

On the supply side, the Central Case allows for cost-optimal decarbonization of energy supply without explicitly constraining which fuels are decarbonized. In other words, in the Central Case there is no explicit requirement that all electricity must be 100% clean or an explicit prohibition on building new gas plants.

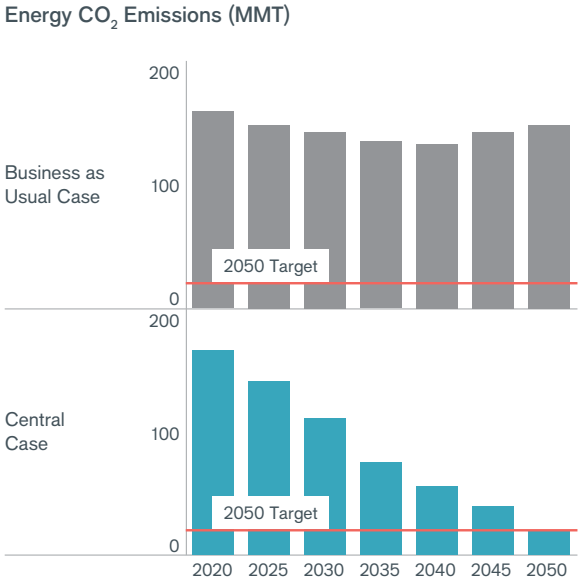
Figure 6 below shows the demand-side assumptions that the modelers chose for transportation, buildings, and industry.

Electric smart car. Photo credit: Green Energy Futures, David Dodge

FIGURE 6. The assumptions for demand in the Central Case.

Sector	Subsector	Assumption
Transportation	Light-duty vehicles	90% battery electric 10% plug-in hybrid electric
	Medium-duty trucks	60% battery electric 40% hybrid diesel
	Heavy-duty trucks	40% battery electric 60% hybrid diesel
	Aviation	48% reduction in energy intensity
Buildings	Space conditioning	Primarily air source heat pump
	Water heating	Primarily heat pump water heater
	Lighting	LED
	Appliances	Best available technology
Industry	Industrial curing, processing, boilers, machine drives, and process heat	Electrification adoption similar to NREL Electrification Futures Study "High scenario"
	Other subsectors	20% reduction from baseline

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 49.



As Figure 7 shows, the Business as Usual Case's emission trajectory falls far short of the 2050 reduction goal, while in the Central Case, electrification, energy efficiency, and decarbonizing the energy supply enable each Northwest state to meet the mid-century energy CO_2 emission target of 86% below 1990 levels.

As Figure 8 demonstrates, overall end-use energy demand in 2050 is more than one-third less than today, in spite of population increase and economic growth; electricity consumption increases by more than 50% and comprises one-half of all end-use demand by 2050; and liquid fuels decrease from one-half of today's demand to one-fifth by 2050 as on-road vehicles transition to electricity.

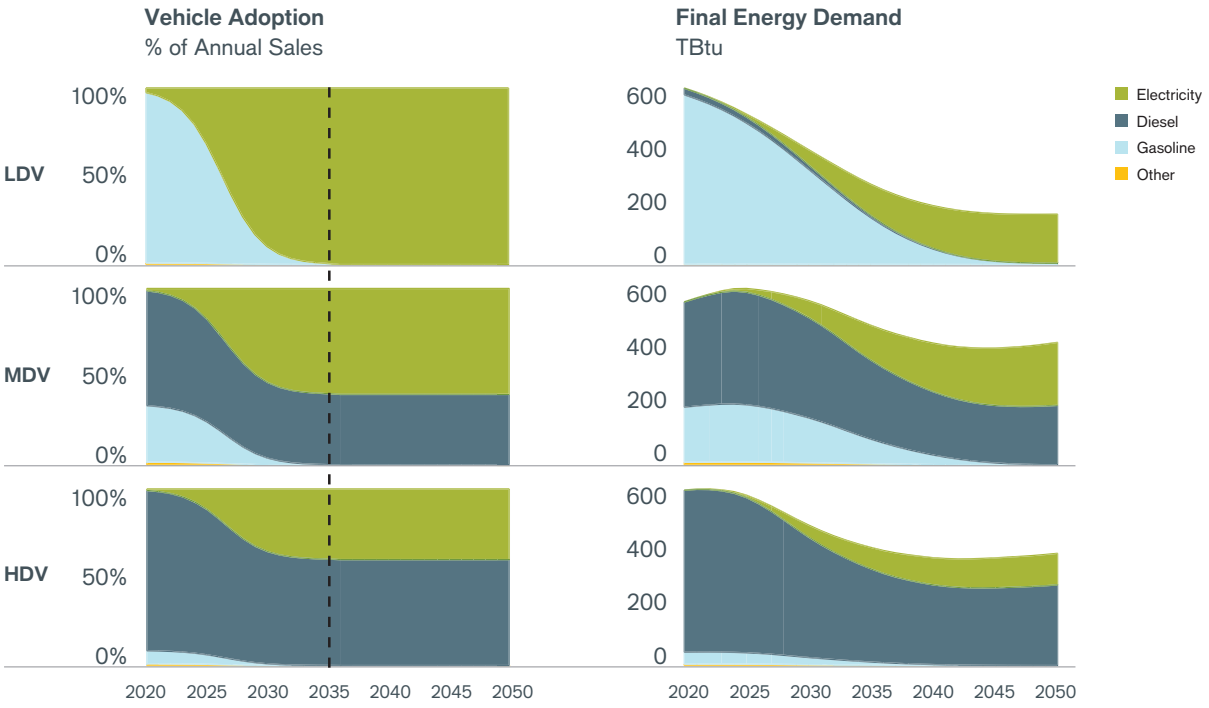
LUBA No. 2020-009
Page 4467

The primary reason for the net increase in electricity consumption in the Central Case is that by 2050 all passenger vehicles (LDVs), 60% of medium-duty vehicles (MDVs), and nearly half of all freight trucks (HDVs) are electric. The freight trucks that continue to use liquid fuels mostly consume renewable diesel in 2050. Figure 9 shows the increasing proportion of electric to liquid fuels for the three vehicle classes in 2020, 2040, and 2050.



As Figure 10 shows, in the Central Case all LDV (passenger car) sales are electric by 2035 (note the dotted line in the Vehicle Adoption graph). The figure also shows the proportion of electric versus renewable diesel versus gasoline to meet energy demand over the 30-year span. Gasoline is out of the fuel mix in the Central Case. The significant decrease in energy demand for LDVs is all met with clean electricity in 2050 and the freight truck fleet uses a combination of electricity and renewable diesel by 2050.

FIGURE 9. The increasing proportion of electric to liquid fuels for vehicles from 2020 to 2050.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 69.

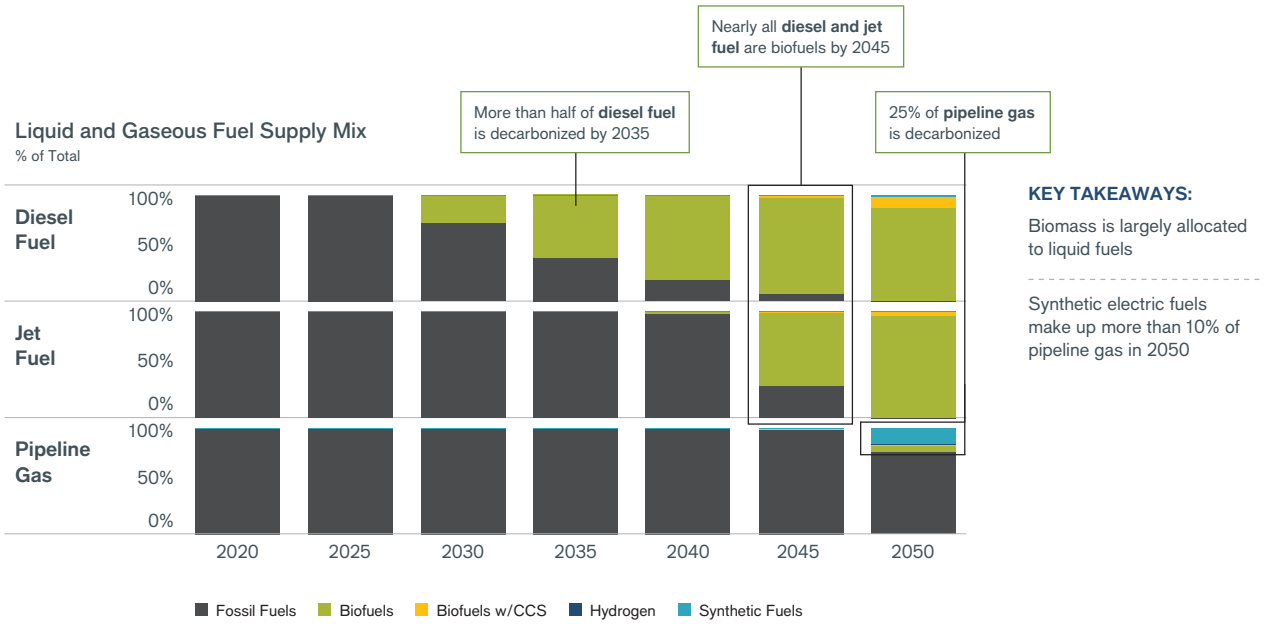

Figure 11 shows the composition of the liquid and gaseous fuel supply mix from 2020 to 2050 in five-year increments, divided among fossil fuels, biofuels and biofuels with carbon capture and sequestration (CCS), hydrogen, and synthetic fuels. Biofuels begin replacing fossil fuels for diesel fuel in 2030, and by 2035 more than half of diesel fuel is decarbonized.

In 2050, biofuels begin decarbonizing jet fuels and nearly all diesel and jet fuel are biofuels by 2045. By 2050, diesel and jet fuel are decarbonized, largely by biofuels, but synthetic electric fuels also make up more than 10% of pipeline gas in 2050, and 25% of pipeline gas is decarbonized, mostly with synthetic electric fuels.

Electricity sector load increases by more than 60% between 2020 and 2050, largely due to the net increase of higher fixed loads from transportation and building electrification. However, producing hydrogen, capturing CO_2, and using electric boilers to produce steam also create significant new load.

Incremental wind and solar photovoltaics (PV) are the principal sources of supply to decarbonize electricity generation and meet the growing demand for electricity in the Central Case from 2020 to 2050. Wind generation is nearly the same as hydroelectricity generation by 2050, while the share of gas-fired generation is only 3.7%, and coal-fired generation is completely eliminated by 2050. The model extends Columbia Generating Station (CGS)'s nuclear power beyond its current 2043 end date through 2050, the study's time horizon.

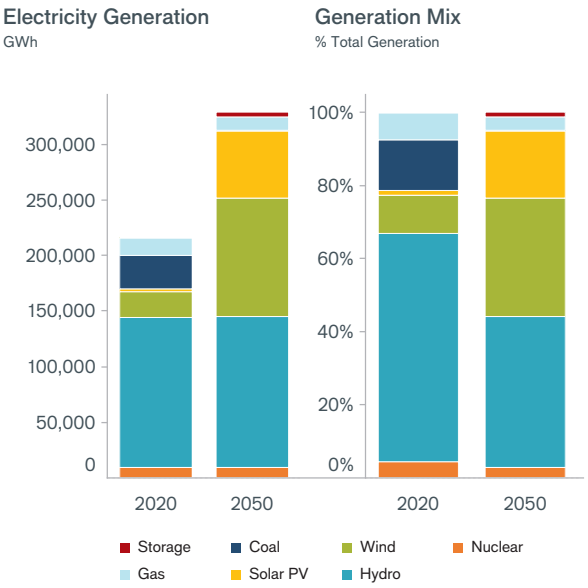
Page 4469

Figure 12 shows electricity generation in gigawatt hours on the left, and the generation mix as a percentage of total generation on the right.

New electricity power generation to be built in the Central Case is significant: nearly 100 gigawatts of new electricity supply resources by 2050, shown in Figure 13. Renewable energy dominates the new capacity, with more than 40 gigawatts of new onshore wind and 35 gigawatts of solar photovoltaic.



Gas and storage resources are added primarily to ensure that the grid has adequate resources to serve demand for energy and that different power sources are balanced; however, the share of gas-fired generation is 3.7% in 2050.

The large percentage of wind and solar resources is non-dispatchable generation, which creates electricity balancing challenges. In many low-carbon electricity systems studies, thermal and energy storage resources are used for balancing the grid. But these are either not able or too expensive to address grid imbalances that persist over days or weeks. This study expands the portfolio of options available to address balancing challenges by including flexible electric fuel production (electrolysis) as a resource.

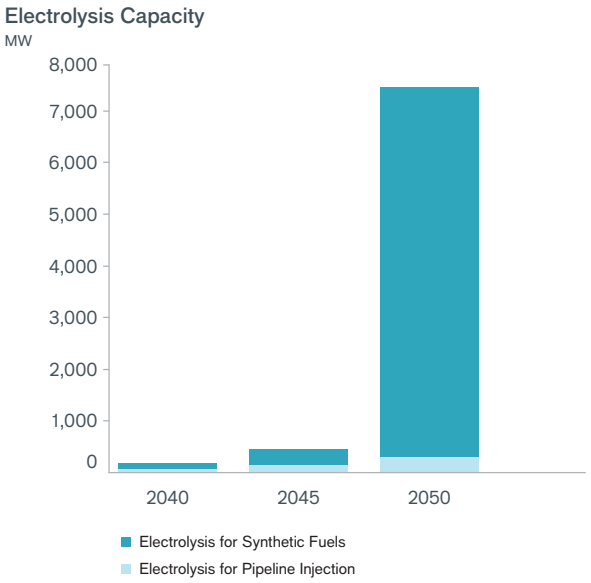
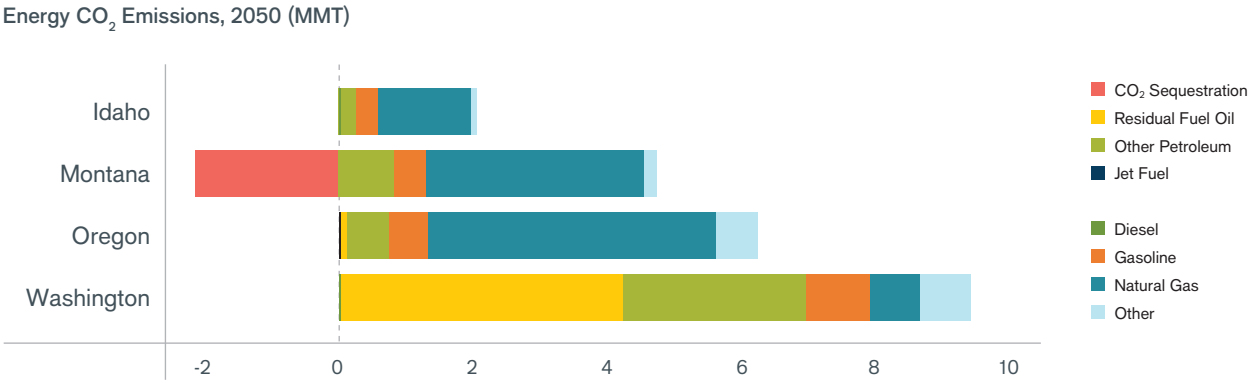
FIGURE 13. The Northwest region would build 95 gigawatts of new electric generation in the Central Case.



Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 73.

Electrolysis produces hydrogen that can be used in two principal ways: (1) as a feedstock to combine with a source of CO_2 to produce synthetic electric fuels; and (2) to be used as synthetic gas to inject directly into the gas pipeline. In the Central Case, 7,500 megawatts of electrolysis capacity is added in the Northwest by 2050, most of which is used to produce synthetic gas and uses existing gas delivery mechanisms, thereby avoiding new infrastructure expense. This electrolysis capacity is mostly added in 2050, as Figure 14 shows. (See Appendix B for a description of power-to-X, hydrogen electrolysis, and direct air capture.)



Jet fuel and diesel are almost completely displaced by biofuels and therefore barely register in Figure 15 below, which shows the remaining emissions in 2050 in the Central Case. In three of the four states, the majority of remaining emissions in 2050 are from natural gas combustion. The exception is Washington State, which is home to 75 ports and where residual fuel oil used in shipping is the largest remaining source of emissions. Montana is the only state with enough geological CO_2 sequestration potential to allow for the CO_2 capture and storage in saline aquifers.

FIGURE 16. Decline in building energy intensity for commercial and residential buildings from 2020 to 2050.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 70.

In terms of energy efficiency, residential and commercial energy intensity drop significantly over time (See Figure 16.) This means that even as the number of households and commercial square footage grow over time, total energy use in the built environment declines and contributes to the Central Case's 34% decrease in overall energy use.

The decline in energy intensity is due to aggressive efficiency in electricity end-uses, such as lighting, clothes washers, and ventilation. The efficiency of heat pump technology relative to the best-in-class combustion equipment also translates into deep energy-use reductions in electrification of space and water heating.

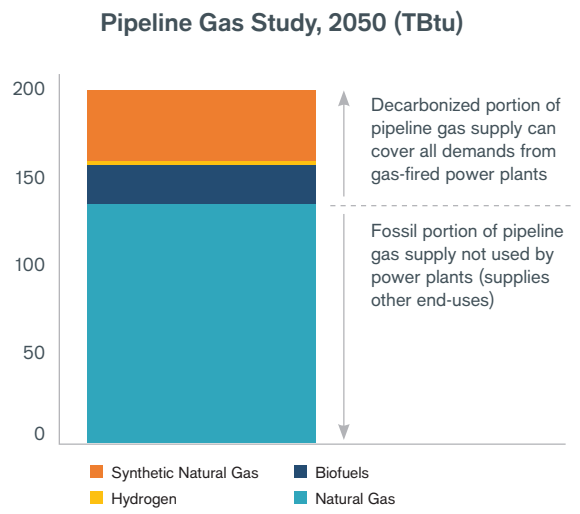
100% Clean Electricity Grid Case

In the 100% Clean Electricity Grid Case, the Northwest states achieve economy-wide deep decarbonization with the mandate that all electricity generation must be zero-carbon by 2045, permitting no fossil fuel combustion in electricity generation. Thermal power plants can continue to operate, but pipeline gas consumption must be 100% decarbonized with either biogas or synthetic gas.

Requiring 100% of electricity generation in the Northwest to come from zero-carbon sources produces marginally different results from the Central Case. The share of gas-fired generation decreases from 3.7% to 1.7% due to incremental renewables and energy storage deployment and, by 2050, all of the gas burned for electricity is either clean synthetic or biofuels in the 100% Clean Electricity Grid Case.

Even though biofuels and synthetic gas are expensive, it is still cost-effective to burn them during times when it is challenging to supply adequate power, such as when low renewable generation coincides with periods of high load and low hydro.



Seen in Figure 17, decarbonized pipeline gas supply (biofuels [dark blue], hydrogen [yellow], and synthetic natural gas [orange]) covers all demand from power generation in 2050. The majority of incremental decarbonized pipeline gas is from synthetic gas.

To achieve deep decarbonization of the energy system, the Central Case is 96% (nearly 100%) clean without a specific mandate, so a relatively small quantity of additional synthetic fuels and biofuels are needed to bridge the gap between 96% and 100% clean electricity in the Northwest. It is easier to obtain 100% clean electricity when the electricity sector is integrated with other parts of the supply-side energy economy that serve fuel demands. Producing fuels from electricity decarbonizes fuel supplies, replacing fossil fuels for transportation, industry, and buildings.

Producing fuels from electricity also provides valuable benefits that reduce investment costs in the electricity sector at high renewable penetrations in two ways: 1) producing flexible electric fuels increases load flexibility and makes it easier to balance the electricity system; and 2) clean synthetic gas can be used to generate electricity during challenging system-balancing conditions.

Furthermore, there are economic benefits with 100% clean electricity that come from sharing a border with California and the resulting renewable resource diversity: The Northwest has excellent wind, California has excellent solar, and both regions benefit economically from running clean electrons through the interties between them. (See the description of the Increased Northwest-California Transmission Case on page 40 for additional discussion of the technical and economic benefits of 100% clean electricity.) By sharing the same clean energy standard, the two regions could more easily take advantage of these resource diversity benefits.

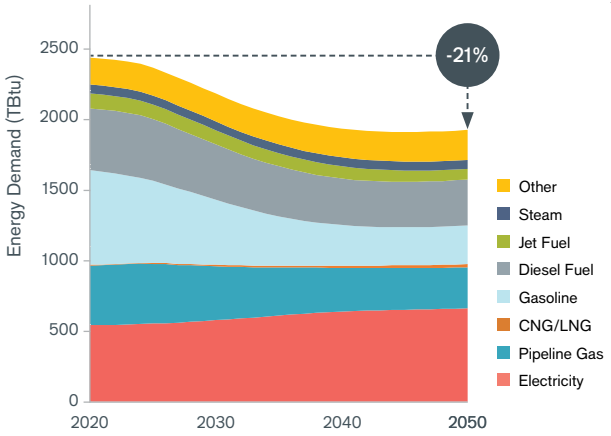
Limited Electrification and Efficiency Achieved Case

The Central Case relies almost completely on clean, efficient electricity replacing gasoline in vehicles, and biofuels replacing diesel and jet fuel, with a very small amount of synthetic fuels providing the remaining decarbonized source for the transportation sector. The Limited Electrification and Efficiency Achieved Case assumes that aggressive electrification fails to materialize and shows that removing clean electricity as a replacement for liquid and gaseous fuels requires using more of the other fuel sources in varying degrees, which results in significant added cost as discussed in the Cost section. (See page 45.)

In the Limited Electrification and Efficiency Achieved Case, adoption of electrification is one-half that of the Central Case (only 50% of passenger cars, 30% percent of medium-duty vehicles, and 20% of trucks are electric) and half of the electrification is achieved for buildings and industry. The demand for fuels shifts from 49% of the final energy demand in the Central Case to 66% in the Limited Electrification and Efficiency Achieved Case, as Figure 18 shows.

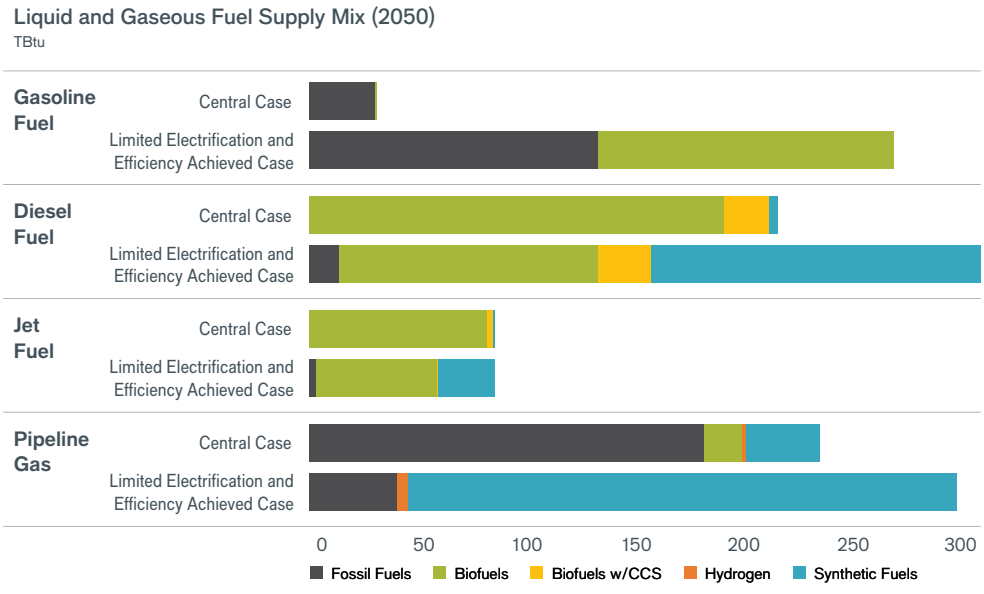


The lower levels of electrification also translate into higher overall final energy demand in the Limited Electrification and Efficiency Achieved Case. Overall end-use energy is 21% less than today's levels but 7% more than in the Central Case, as Figure 19 shows. With more energy demand to meet than in the Central Case, the supply side faces a higher mitigation burden to achieve the emission reduction target.

FIGURE 18. Assumptions for final energy demand in the Central Case vs. the Limited Electrification and Efficiency Achieved Case.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 52.

FIGURE 19. Energy demand declines by 21% in the Limited Electrification and Efficiency Achieved Case vs. 34% in the Central Case.



Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 83.

Achieving lower electrification, particularly in the transportation sector, means that large volumes of diesel fuel, jet fuel, and gasoline remain in the energy system during the 30-year study period, unlike in the Central Case where we saw that biofuels largely decarbonize these fuels.

Here, biofuels replace gasoline (which electricity replaced in the Central Case, thus saving biofuels for the harder fuels to decarbonize) and significantly more expensive synthetic fuels are required to decarbonize diesel fuels, jet fuels, and pipeline gas. Figure 20 shows the changes to fuel supply and biomass allocation in the Limited Electrification and Efficiency Achieved Case compared to the Central Case.

FIGURE 20. Changes to fuel supply and biomass allocation in the Limited Electrification and Efficiency Achieved Case.

Biomass is allocated to **gasoline fuel** as cellulosic ethanol, but fossil fuels still account for a large quantity of supply

As a result of the biomass reallocation, power-to-fuels is needed for liquid and gaseous fuels to decarbonize supply

Pipeline gas contains less natural gas to offset higher refined fossil gasoline emissions

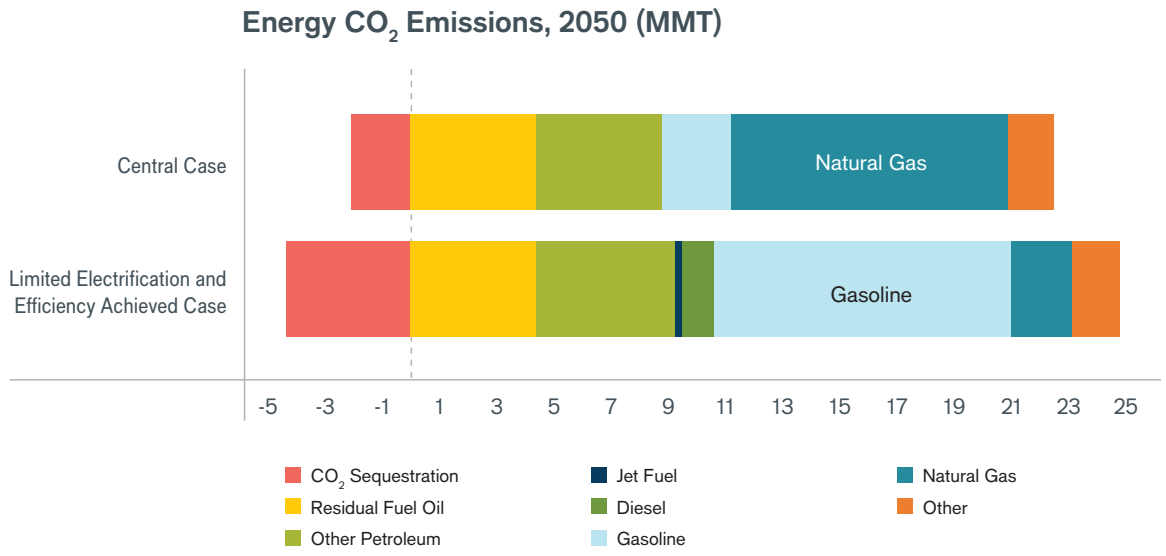
LUBA No. 2020-009
Page 4475



With lower levels of end-use electrification, the Limited Electrification and Efficiency Achieved Case has significantly higher emissions in the transportation fleet, primarily from gasoline, than in the Central Case. To compensate for these higher emissions, pipeline gas must be decarbonized to a greater extent than in the Central Case.

With all available biofuels being used to displace transportation fuels in the Limited Electrification and Efficiency Achieved Case, pipeline gas largely consists of synthetic gas and some hydrogen. Figure 21 shows that the remaining emissions in the Limited Electrification and Efficiency Achieved Case compared to the Central Case are largely in gasoline, jet and diesel fuel, and other petroleum, which includes kerosene, liquefied petroleum gas, and other petroleum products used in industry.

The large quantity of additional synthetic fuels required in the Limited Electrification and Efficiency Achieved Case to decarbonize pipeline gas, diesel, and jet fuel increases the need for CO_2 feedstocks, thus increasing investment in direct air capture (DAC) technology to provide them. In the Central Case, DAC technology captures approximately 2 million metric tons (MMT) of carbon in 2050, whereas in the Limited Electrification and Efficiency Achieved Case, 27 MMT must be captured in 2050.

The bottom line: not replacing gasoline with electricity means both that significantly more fuel is needed with the Limited Electrification and Efficiency Achieved Case than the Central Case and that there are not enough biofuels for jet and diesel fuels, so expensive synthetic fuels are required to decarbonize the fuel supply. In general, the study shows that achieving deep decarbonization in the transportation sector requires either widespread electrification or substantial increases in DAC-produced synthetic fuels.

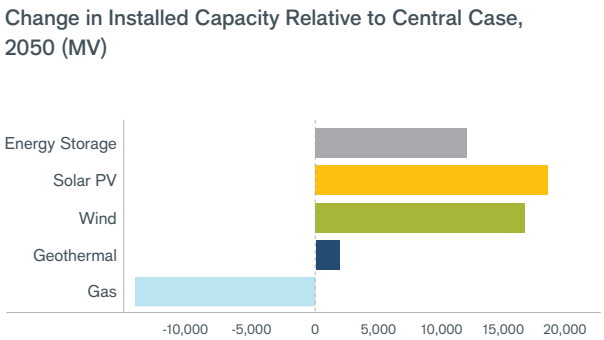
No New Gas Plants for Electricity Case

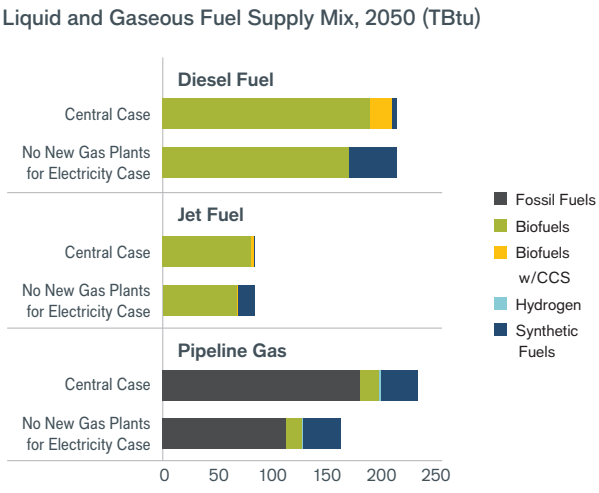
For the No New Gas Case, new gas-fired resources cannot be developed anywhere in the Northwest from 2020 to 2050. Existing gas resources retire at the end of their economic lives and cannot be extended or replaced, which means that there are no gas-fired resources online in 2050 in the region. There are no constraints on pipeline gas outside of the electricity sector.

Even though gas-fired resources comprise a small portion of generation in 2050 in the Central Case (3.7%), the resource adequacy value they provide to the system is significant and expensive to replace with other resources. Prohibiting the development of new gas-fired generating resources in the electricity sector results in 12 gigawatts of additional energy storage resources—dominated by lithium-ion batteries—to maintain resource adequacy. In addition to the 75 gigawatts of new renewables required in the Central Case, the No New Gas Case requires an additional 35 gigawatts of wind, solar, or geothermal resources. Figure 22 shows the change in installed capacity in the No New Gas Case relative to the Central Case in 2050.



Electrical apprentice works on solar reference array. Photo credit: Northern Alberta Institute of Technology

The constraint on gas-fired resources in the electricity sector also has spillover effects on the rest of the energy system. Higher penetrations of renewables—and resulting overgeneration—incentivize the production of additional electric fuels, notably power-to-diesel and power-to-jet-fuel.



As a result, fewer biofuels are used. In fact, the No New Gas Case is the only case that does not fully use available biomass (biomass use is 30% below the Central Case). Figure 23 shows the impact on the liquid and gaseous fuel supply mix in 2050 when gas is constrained.

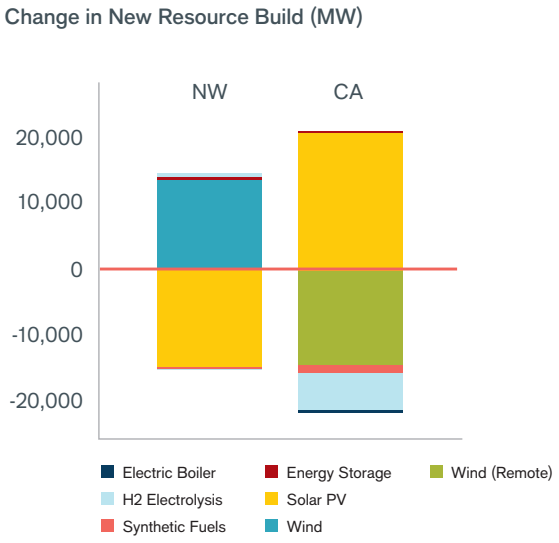
Increased Northwest-California Transmission Case

The Increased Northwest-California Transmission Case explores how increased transmission between the Northwest and California could allow both regions to achieve deep decarbonization at potentially lower costs. The Northwest's and California's electricity systems are currently connected by approximately 8,000 MW of interties, including the California-Oregon Intertie (COI) and Pacific Direct Current Intertie (PDCI). The model economically expands transmission, relaxes California's net export limit over time, and removes hurdle rates between the two regions starting in 2030.

Approximately 4,500 MW of incremental transmission capacity is developed between the Northwest's and California's power systems. With this infrastructure in place, there are increased exports from California to the Northwest during daylight hours, while the Northwest increases exports to California during traditionally off-peak hours. Net exports from the Northwest increase by approximately 7,000 GWh in 2050.



Expanded interties change the optimal electricity supply mix, with each region avoiding the development of local, low-quality renewables and expanding the development of high-quality resources that are more efficiently shared across both areas. Figure 24 shows the difference in resource build between the Central Case and the Increased Northwest-California Transmission Case by region. Those resources shown with positive megawatt changes increase in capacity versus the Central Case, whereas those on the negative side of the scale decrease in capacity.

By allowing greater transfer between regions, the Northwest and California can focus on building their best-quality resources. The Northwest avoids developing low-quality solar and increases wind development, and California avoids procuring remote wind generation from other Western states (New Mexico and Wyoming) and develops additional high-quality solar. In total, it is estimated that increased integration between California and the Northwest could save $11.1 billion in net present value over the 30-year study period (accrued to the combined California and Northwest region), with resource cost savings offsetting higher transmission investment costs.

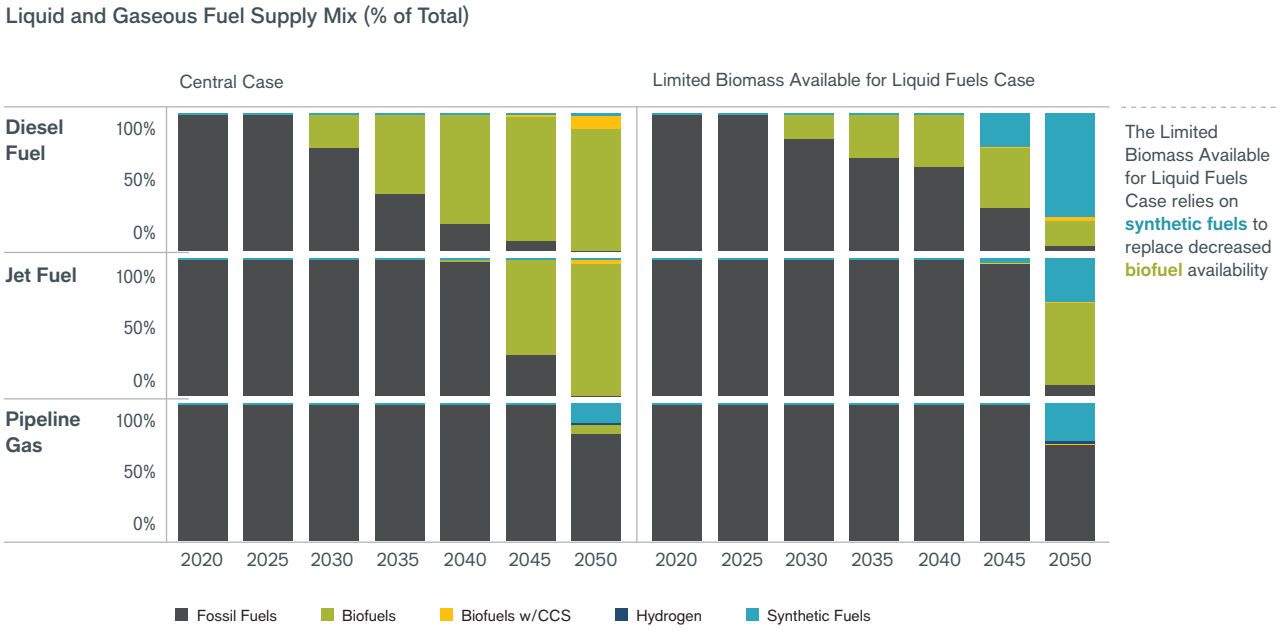
Limited Biomass Available for Liquid Fuels Case



The Limited Biomass Available for Liquid Fuels Case addresses concerns about biomass availability, particularly crops grown expressly for energy. In this case, each state's bioenergy potential is restricted to in-state waste and its population-weighted share of regional wood. This constraint results in an overall biomass supply that is 60% less than the Central Case biomass assumptions.

Figure 25 shows how the fuel supply mix evolves over time for diesel fuel, jet fuel, and pipeline gas. The Limited Biomass Available for Liquid Fuels Case relies on synthetic fuels (seen in teal) to replace the lost biofuels (seen in green) present in the Central Case. The diesel fuel supply mix is impacted the most, shifting from almost 100% biofuels in the Central Case to predominantly synthetic fuels in the Limited Biomass Available for Liquid Fuels Case, which are more expensive.

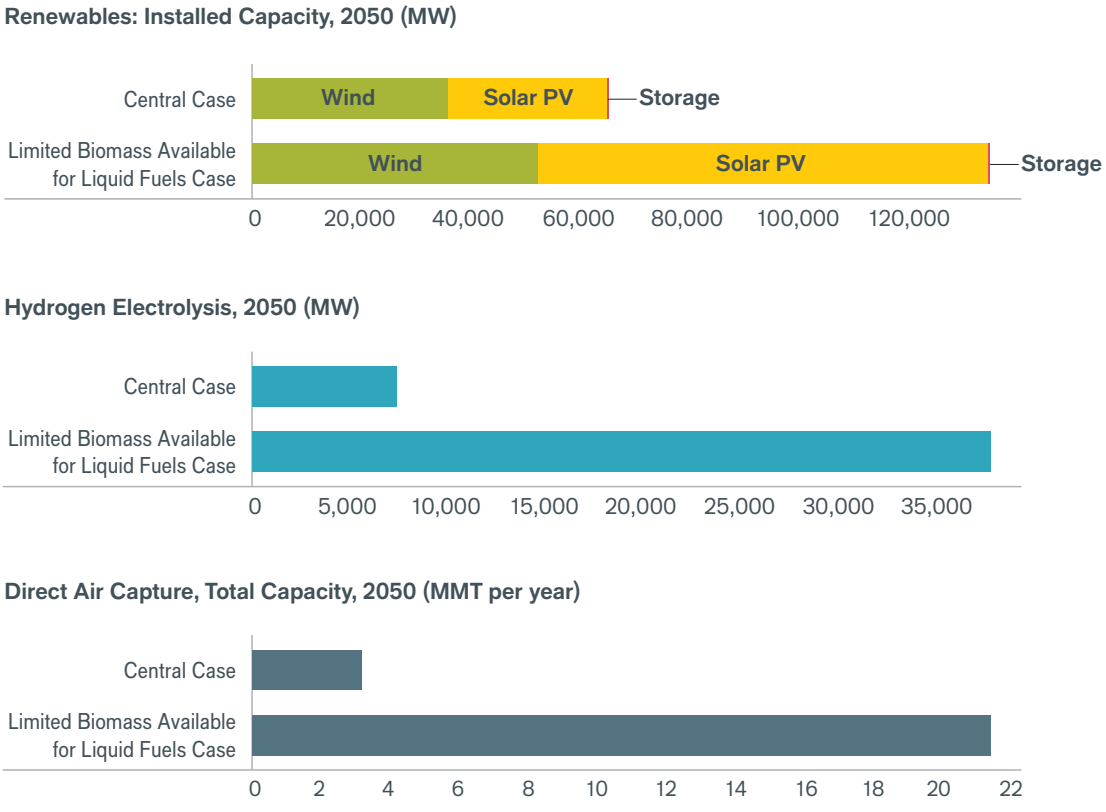
Page 4479



Producing high volumes of synthetic electric fuels to replace biofuels means building considerably more infrastructure, including two times the installed capacity of wind and solar resources, five times the requirement for electrolysis capacity, and six times the direct air capture capacity.

Hence, on top of the 40 gigawatts of new onshore wind and 35 gigawatts of solar PV already built in the Central Case, substantial investments in generation to power synthetic gas production would be required to offset the lack of biofuels. (See Figure 26 to understand the infrastructure implications of a constrained biomass supply.)

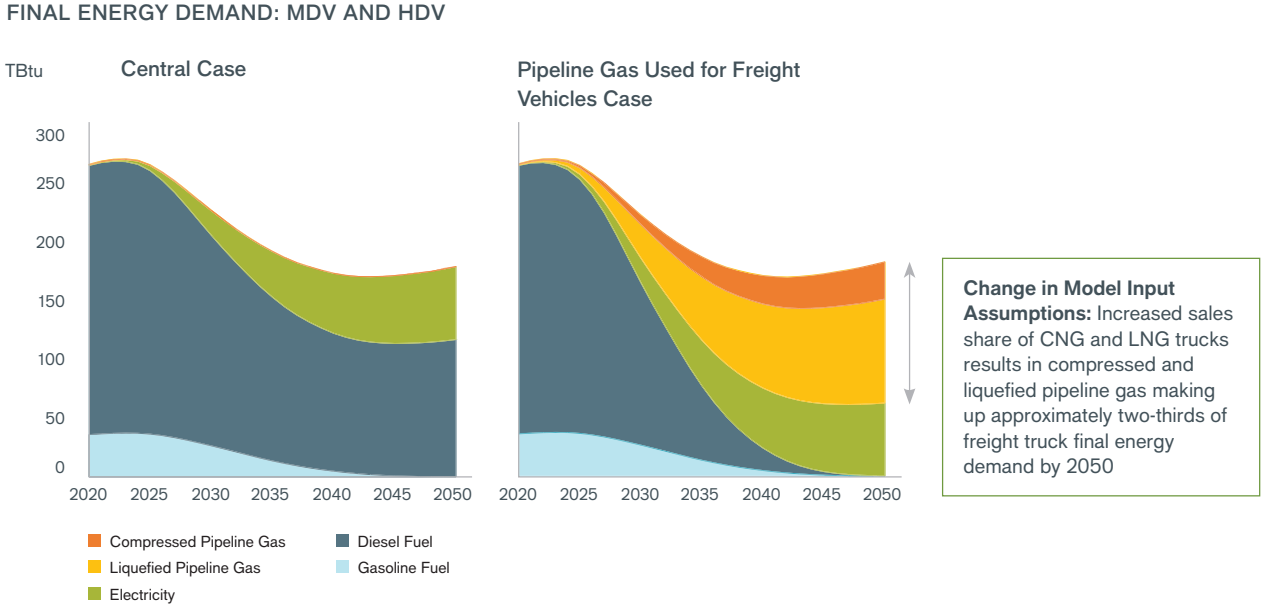
Pipeline Gas Used for Freight Vehicles Case



The freight vehicles in the Central Case that are not electric are diesel hybrid vehicles and in the Pipeline Gas Used for Freight Vehicles Case, compressed and liquefied pipeline gas substitute for diesel hybrid vehicles. Specifically, the Central Case assumes that medium-duty vehicles (MDVs) are 60% battery electric and 40% are diesel hybrid vehicles. In the Pipeline Gas Used for Freight Vehicles Case, the same number of MDVs are electric, but the remaining 40% of MDVs are powered by compressed natural gas.

Similarly, the 40% of heavy-duty trucks (HDVs) in the Central Case that are electric remain electric in the Pipeline Gas Used for Freight Vehicles Case, while the remaining 60% of HDVs are fueled by liquefied natural gas. Compressed and liquefied pipeline gas make up approximately two-thirds of freight truck final energy demand by 2050 as Figure 27 shows.

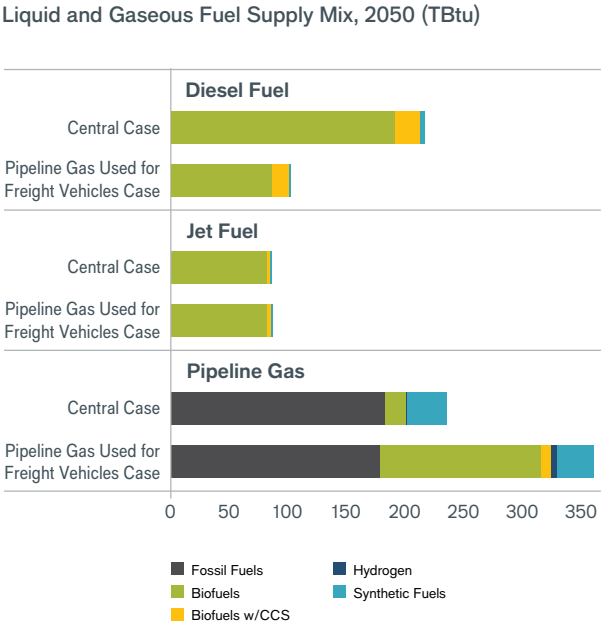
Fossil Fuel Terminal Zoning Amendments Testimony
Ordinance #189807
LUBA No. 2020-009
Page 4481

Compressed and liquefied pipeline gas are nearly 10% of end-use demand by 2050 in the Pipeline Gas Used for Freight Vehicles Case, with half of freight trucks consuming compressed or liquefied gas. Demand for diesel fuel is further reduced relative to the Central Case. (See Figure 28.)

As Figure 29 shows, freight trucks in the Pipeline Gas Used for Freight Vehicles Case consume more pipeline gas, which is supplied by increasing biofuels to pipeline gas and decreasing biofuels to diesel fuel. The main impact across energy systems in the Pipeline Gas Used for Freight Vehicles Case is the reallocation from liquid fuels to gaseous biofuels, as Figure 29 indicates.



Important Note: The study does not take into account the carbon emissions from methane leakage or upstream emissions in the production of natural gas. Hence, the carbon benefit in the Pipeline Gas Used for Freight Vehicles Case is likely over-estimated and further study is required to investigate higher carbon emissions in the production and transport of pipeline gas.

FIGURE 28. Final energy demand in the Pipeline Gas Used for Freight Vehicles Case is down 33%, with compressed and liquefied pipeline gas constituting 9% of end-use demand in 2050.

Costs

The scope of costs in this study is limited to energy system costs, which represent the annual cost of producing, distributing, and consuming energy. This study considered the annualized capital costs of equipment (both supply and demand), fixed and variable operations and maintenance (O&M) costs, and fuel costs. (See Appendix C for details on the cost assumptions used in this study.) The study excludes costs outside of the energy system or benefits from avoiding climate change and air pollution.

The study compares the annual costs of the Business as Usual Case and the Central Case from 2020 to 2050. Net annual costs of the Central Case vary over the modeled period based on the timing of infrastructure investments, peaking at 16.1% ($9.8 billion) above the Business as Usual Case in 2038 and decreasing to 8.3% ($6.1 billion) higher than the Business as Usual Case in 2050. The cumulative costs of decarbonizing the energy system in the Central Case are 9.5% higher than the capital and operating expenses of the Business as Usual Case's energy system, roughly 1% of the region's total GDP in 2017 of more than $870 billion. (See Figure 30.)

The increased costs in a decarbonized system consist primarily of biofuel feedstocks and infrastructure, demand-side electrification and efficiency investments, and renewable power plants and supporting electricity infrastructure. These increased costs are mitigated by the savings from decreased fossil fuel use, primarily expensive liquid petroleum products.

FIGURE 30. Annual net energy system costs for the Central Case relative to the Business as Usual Case 2020–2050.

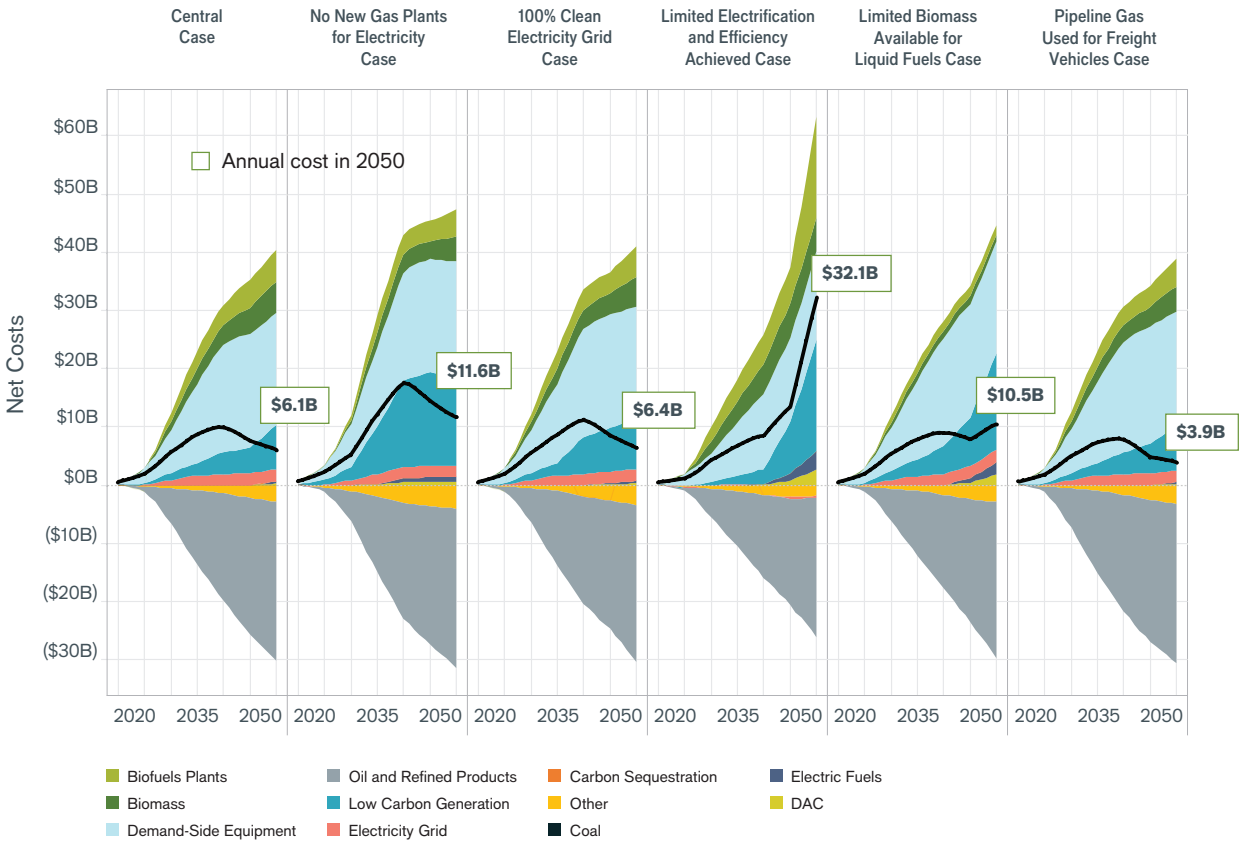
LUBA No. 2020-009
Page 4483



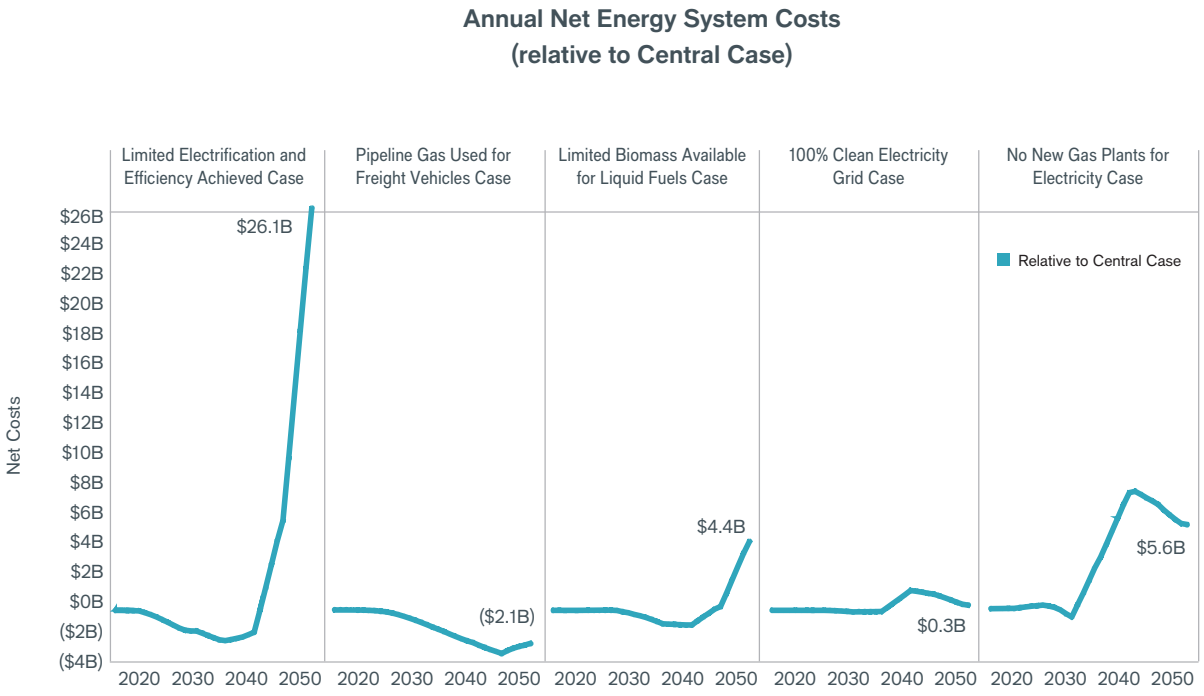
In Figure 31, the black line shows the net annual energy system costs as the difference in cost between each of the cases (except the Increased Northwest-California Transmission Case) and the Business as Usual Case. The stacked areas show the differences in investment by category between each case and the Business as Usual Case. Investments in additional clean energy measures (positive cost differences) are offset by avoided fuel purchases (negative cost differences).

The most impactful sensitivities in terms of net system costs include prohibiting new gas assets, not achieving demand-side transformation, and constrained biomass. Because 100% clean electricity has only a marginal change from the Central Case, it has minimal impact on costs.

City of Eugene, Oregon, transit service. Photo credit: City of Eugene, Oregon

FIGURE 31. Annual net energy system costs for six cases compared to the Business as Usual Case.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 107



Increased gas in transportation allows access to a lower-emissions/lower-cost fossil fuel than diesel, but as previously noted, this result does not consider the carbon emissions of methane leakage, so its lower cost must be viewed in light of its uncounted higher carbon emissions. Further, there are technical challenges with using pipeline gas for heavy-duty trucks. (See Figure 32.)

Most cases show a slight increase in household expenditures in the 2030 time frame—roughly $25 per month. But by 2050, most cases show small monthly savings, due to the increasing cost-effectiveness of electric vehicles and the elimination of gas costs.

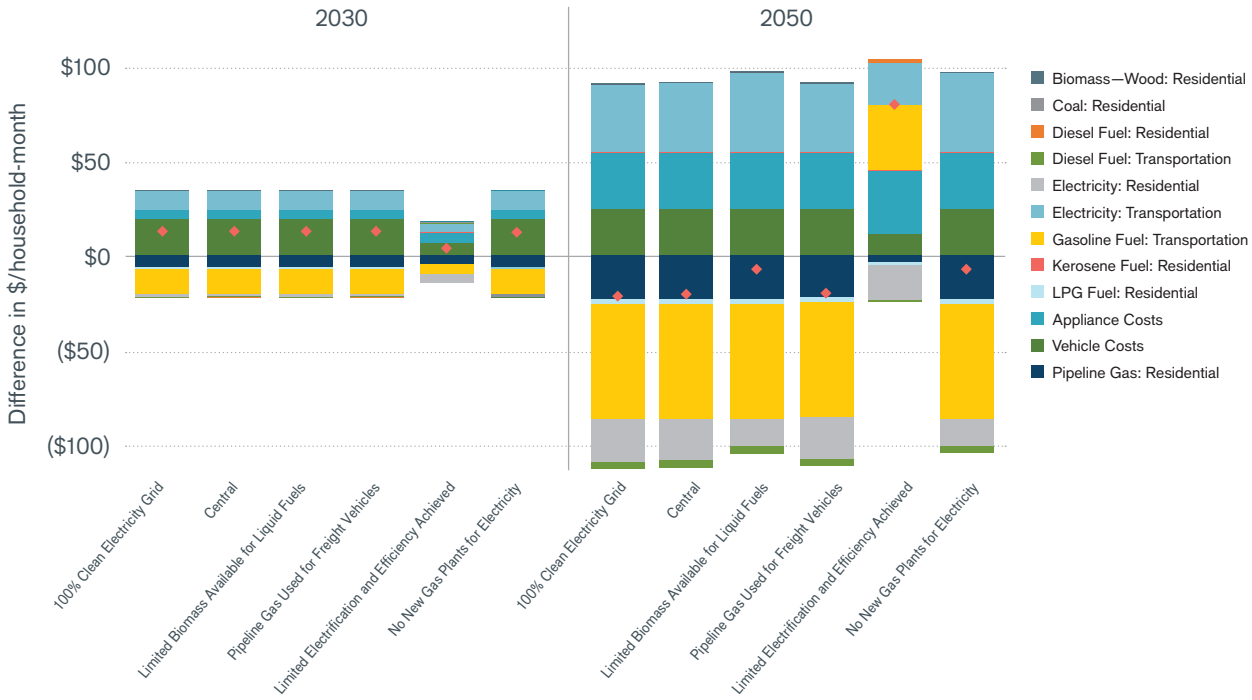
Fossil Fuel Terminal Zoning Amendments Testimony
Ordinance #189807
LUBA No. 2020-009
Page 4485



The Limited Electrification and Efficiency Achieved Case has the lowest cost in the 2030 time frame as it does not have to incur as much in incremental costs for electric vehicles and other electrified appliances. But by 2050, limited electrification necessitates huge investments in electric sector infrastructure for electrolysis and direct air capture to produce electric fuels and biofuels to offset the increased fuel usage, driving up costs. (See Figure 33.)

In 2050, the average cost of avoided carbon in the Central Case is $48/tonne and declining. The model makes conservative assumptions about the costs and scalability trends of clean energy technologies. A future report will explore in greater depth details on costs and emissions reductions, the assumptions that returned these results, and what these results mean for how the Northwest should consider investing in transitioning the region to a low-carbon economy.

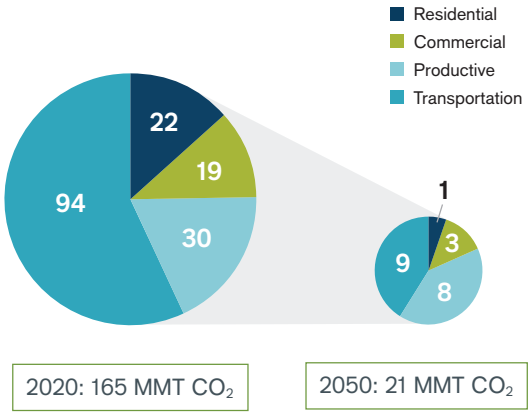
Study Conclusions and Case Comparisons



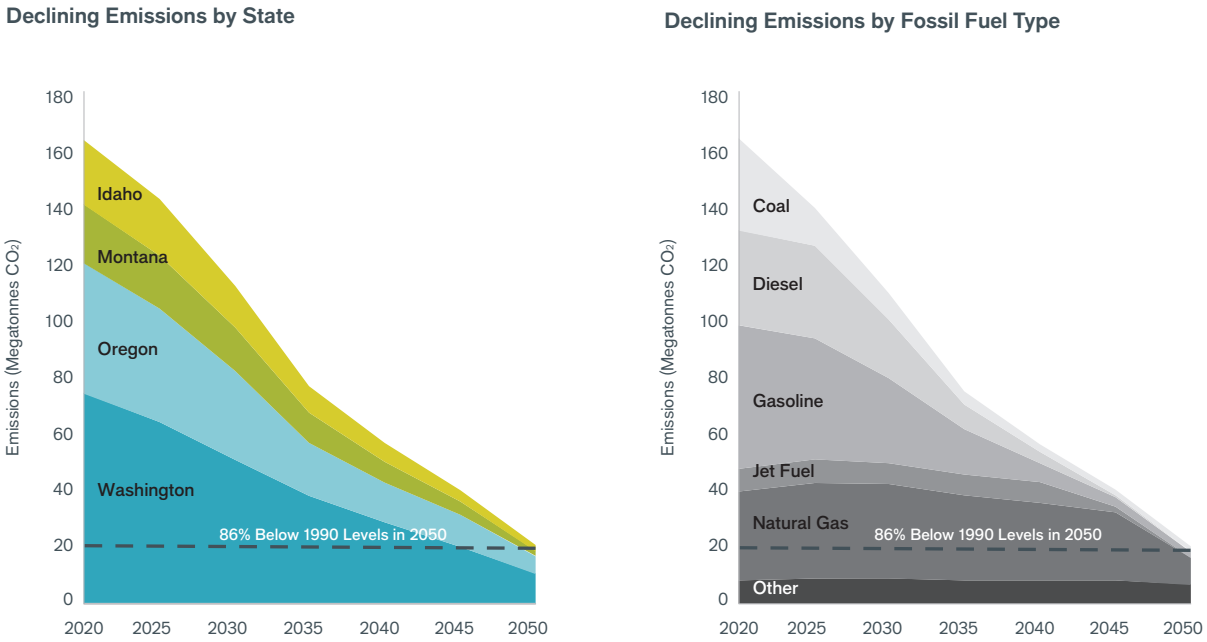
The results of *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* demonstrate the feasibility of Northwest states to achieve deep decarbonization by mid-century, even if we postulate several potential implementation challenges, such as lower levels of electrification and constraints on biomass availability.

This study incorporates several new and unique analytical approaches to assess deep decarbonization in the Northwest, including developing cost-optimal energy supply portfolios, incorporating new electric loads (direct air capture, fuel production, steam production), and accounting for changing dynamics outside of the region (California energy policy).

The study's Central Case is a flexible pathway to achieve emissions reductions, and highlights several key findings:

- Electricity generation approaches 100% clean.
- Aggressive electrification on the demand side is required, particularly in the transportation and building sectors. All passenger transportation is electric by 2050.
- Biomass is primarily allocated to jet fuel and diesel fuel even after partial electrification of freight trucks.
- Flexible electricity demand, notably from facilities that produce hydrogen and synthetic gas, plays a large role in electricity balancing and energy system–wide carbon mitigation.

FIGURE 34. Comparison by sector of Northwest CO_2 emissions decrease from 2020 to 2050 in the Central Case.



Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 63.

Northwest CO_2 emissions decrease in the Central Case from 165 million metric tons (MMT) in 2020 to 21 MMT in 2050. Emissions in the residential sector decline by 95%; in the commercial sector by 86%; in the productive (industrial) sector by 72%; and in the transportation sector by 91%. Relatively inexpensive abatement measures for the built environment (residential and commercial sectors) and transportation enable a greater percentage of emission decreases for those sectors. The difficulty and expense of decarbonizing industrial end uses explains the increase in the productive sector. (See Figure 34.)

Figure 35 shows the emissions decline from 2020 to 2050 by each state, as well as by fossil fuel type. These emission reductions are achieved through five key decarbonization strategies: energy efficiency; decarbonizing electricity; decarbonizing gas and liquid fuels; fuel-switching in industry, transportation, and buildings; and carbon capture. The cost of achieving these reductions is offset by avoided fossil fuel purchases.

FIGURE 35. Declining emissions by state and by fossil fuel type 2020–2050.

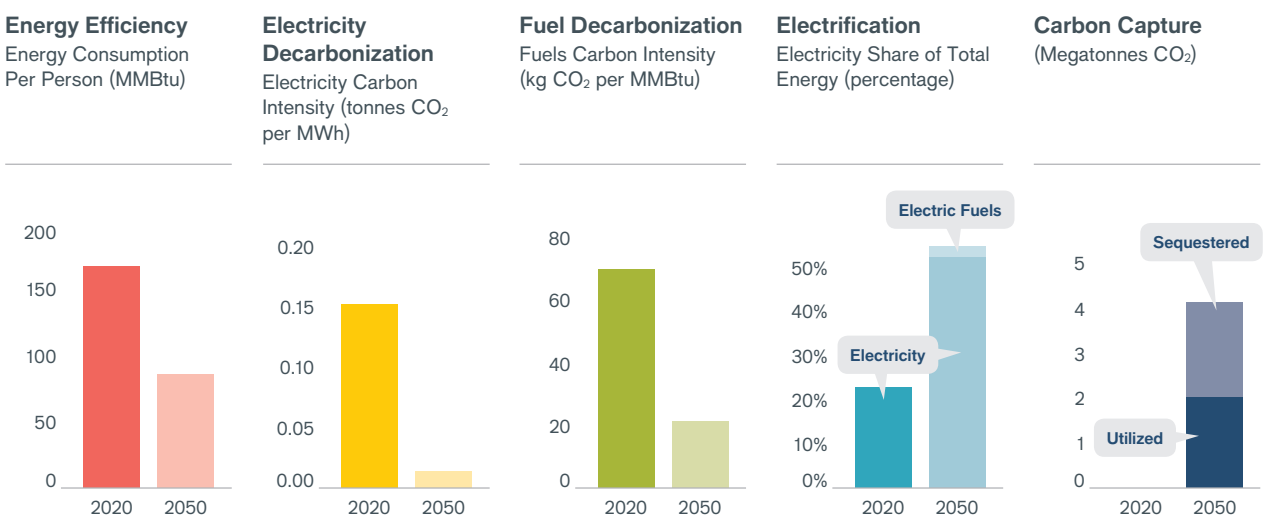
Five Key Decarbonization Strategies

Transitioning the Northwest to a low-carbon energy system relies on five decarbonization strategies:



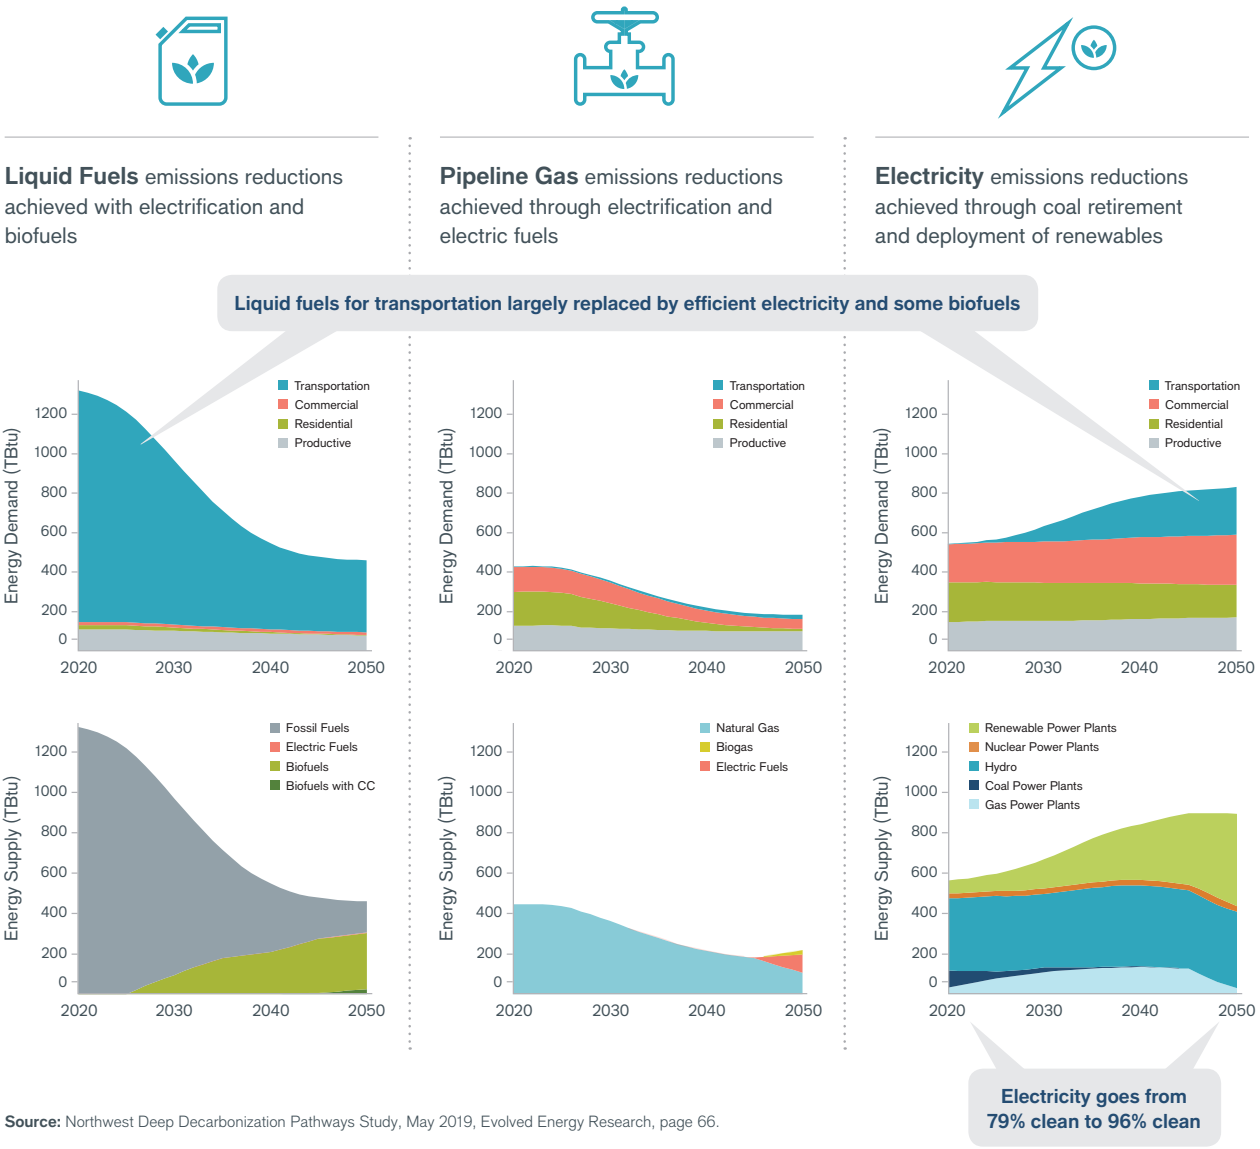
1. **Energy Efficiency:** reducing energy consumed to provide an energy service
2. **Electricity Decarbonization:** reducing the emissions intensity of electricity generation
3. **Fuel Decarbonization:** reducing the emissions intensity of liquid and gaseous fuels
4. **Electrification:** switching end uses from fuel to electricity
5. **Carbon Capture:** capturing CO_2 from a facility or removing CO_2 from the atmosphere

The purpose of the fifth strategy, carbon capture, is twofold: the captured CO_2 can either be used as a carbon feedstock for electric fuel production or sequestered.

Figure 36 shows metrics for the five strategies in the Central Case. Per capita energy consumption decreases from approximately 170 MMBtu per person today to 85 MMBtu per person in 2050, a 50% decrease. The average carbon intensity of electricity generation, which is already relatively low in the Northwest due to the hydroelectric system, decreases to near-zero by 2050.

The carbon intensity of fuels (liquid and gas) decreases by 70% primarily using biofuels. The share of total final energy served by electricity or electrically produced fuels (e.g., hydrogen and synthetic natural gas) more than doubles from approximately 23% today to 55% in 2050. Four million metric tons of CO_2 are captured in 2050, with about half of the CO_2 being utilized to produce synthetic fuels and the other half being sequestered (e.g., in saline aquifers in Montana).

FIGURE 36. Five decarbonization strategies.



Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 65.

Figure 37 combines all of the results of the Central Case in one graphic to show the changes in energy demand and supply for the three energy sources—liquids, gas, and electricity—from 2020 to 2050 by sector. The right-hand side of the graphic shows the overall emissions decrease by energy source over the 30-year period of the study, demonstrating the significant drop in the carbon intensity of liquid fuels.

The graphic clearly shows the critical role of electrification for all three sources. Electrification decreases liquid fuel and gas demand for the transport, building, and productive (industrial) sectors. The increased demand for electricity across the sectors is also displayed.

On the supply side, biofuels, along with synthetic liquids produced with clean electricity, significantly reduce the carbon intensity of liquid fuels, while synthetic gas decarbonizes pipeline gas. Coal retirement and renewable deployments decarbonize the electricity supply. Overall demand and supply for clean electricity increase substantially.

Study Highlights

Critical Role of Electricity

Clean electricity is the backbone for deep decarbonization, and the cross-sectoral role that electricity will play in the coming decades is vital to achieving a low-carbon future. A clean grid decarbonizes all existing electricity uses, including industrial processes powered by electricity and buildings heated and cooled by electricity in the years to come.

In the low-carbon energy future, clean electricity must include electrifying as many transportation operations as possible to replace petroleum-generated liquid fuels, as well as substitute for the oil and natural gas that heats and cools buildings.

Electrifying the Northwest transportation sector is critical to achieving deep decarbonization and provides the least-cost path to reducing fossil fuels in transportation. Hence, the interactions between the fuel and electricity sectors in long-term planning processes is paramount.

Electricity Sector Insights

The difference between the 100% Clean Electricity Grid Case and the Central Case is much smaller than anticipated, where a nominal quantity of additional synthetic fuels and biofuels is needed to bridge the gap. Economy-wide decarbonization involving the fuel supply sectors and not just the electricity grid brings two benefits that make it easier to attain 100% clean electricity. First, flexible electric fuels increase load flexibility and make balancing the electricity system easier, and second, the clean synthetic gas that is produced can be used to generate electricity during challenging system-balancing conditions.

In addition, California's 100% clean electricity requirement encourages the Northwest to export power to California that would otherwise be curtailed, thus giving that resource economic value, and makes it possible for there to be fewer requirements for California to build storage or additional resources to balance its California grid.

Significant cost savings ($11.1 billion in net present value from 2020 to 2050 accrued to the combined California and Northwest region) could be realized if interties between the Northwest and California were expanded (Northwest-California Transmission Case). But further investigation is required to understand the benefits fully.

Prohibiting new gas plants (No New Gas Case) would require additional energy storage and renewable generation facilities to provide reliable supply. Electric fuels using excess renewables implement this pathway, which would otherwise involve a large amount of curtailment, but at a significantly higher cost than the Central Case.

New Sources of Clean Electric Fuel

Emerging technologies that can deploy hydrogen, carbon capture, and synthetic gas to create very low-carbon fuels will be important in the out-years. Clean electric fuels can be produced using renewable electricity. Splitting water molecules through electrolysis produces hydrogen that can constitute up to 7% of the gas in pipeline gas or be used as a feedstock in other processes. Combining that feedstock with carbon dioxide can create synthetic gas or liquid fuels that are as clean as the energy used to produce them.

Carbon dioxide as a feedstock can be captured via industrial waste streams, direct air capture, or from biorefineries that use carbon capture. Synthetic gas can be used for either heating or cooling instead of natural gas, or for powering transport as compressed liquefied gas, while synthetic liquid fuels can substitute for conventional transportation fuels.

Flexible Electric Loads

The study highlights the important cross-sectoral role that new technologies and flexible electric loads could play in making economic use of renewable overgeneration and with balancing the grid in two key ways. First, the Northwest's reliance on hydroelectric and wind resources means that periods of sustained overgeneration may become common. This is a component of a least-cost decarbonized energy economy. However, when considering all possible system-balancing options, it is important to limit costs. Electric storage solutions, outside of limited pumped hydro, do not yet economically address long-duration balancing and system reliability when renewable energy production is low.

The mismatch between load and intermittent supply and the subsequent curtailment of generation is a lost opportunity to use that energy to decarbonize the economy. Hence a key challenge is how to minimize the costs of a deeply decarbonized, intermittent, renewable-dominant system, recognizing the many cross-sectoral opportunities that exist at high levels of decarbonization.

Transmission lines. Photo credit: Mike Wilson

Electricity that would otherwise be curtailed is put to good use when the electricity system is integrated with fuels production for the rest of the energy economy, and electric loads can more flexibly respond to levels of renewable production. Gas and liquid transportation fuels can be stored far more cheaply than energy in electrochemical storage and large quantities of storage for these fuels exist today.

The lowest-cost pathways to deep decarbonization include electric fuels production, moderating the variability in intermittent renewables by increasing production in periods with high renewable and hydro output, and decreasing production during periods of low output.

Second, Northwest grid planners need to address the challenge of interannual variability in hydroelectric and wind resources. Achieving high percentages of renewables is a fundamentally different challenge in years of low hydro and wind production than in high hydro and high wind years.

Several nontraditional solutions exist for electricity balancing: electrolysis that uses renewable overgeneration to produce hydrogen, steam production with electric boilers, and direct air capture technologies that supply energy or feedstocks for synthetic gas. Models and approaches that don't incorporate this sectoral integration and the potential for this portfolio of solutions tend to be suboptimal, as they result in higher cost for renewables systems and large amounts of unused energy.

Limited Thermal Generation Needed

The inverse of overgeneration in high-renewables systems is rare periods of undergeneration, when hydro and other renewable energy production is diminished, typically during the winter. Renewable diversity and regional integration could help address this issue, while storage can be used for short (4- to 8-hour) periods of undergeneration.

These rare undergeneration events are most economically served by thermal generators that operate only for a very limited number of hours each year and can be fueled by biofuels, electric fuels, or fossil gas depending on policy design. In the study, gas and storage are added as new resources to provide resource adequacy and balancing, and the share of gas-fired generation is 3.7% in 2050.

Role for Carbon Capture

In modeling regional 80% of 1990 levels by 2050 emissions targets, it is important to note the long-term role of carbon capture, either for high-capacity factor biofuels facilities or in the use of direct air capture facilities. This captured carbon may be used to provide a feedstock for power-to-fuels production or directly sequestered.

The study does not project a significant use of carbon capture and sequestration in the Northwest's power sector (where the role of carbon capture has traditionally been most closely examined), due to the low-capacity factors at which thermal generators would operate in highly renewable systems.

Carbon capture and sequestration infrastructure is expensive, and low utilization makes it too costly to be part of a least-cost resource solution. As carbon reduction targets become even more stringent—with some even contemplating net-zero emissions futures—developing this technology will become more important.

Regional Electricity Collaboration

Understanding California's electricity policy landscape is critical for cost-effective electricity planning in the Northwest. California lacks non-solar renewable resources and requires off-peak renewable energy to meet its 100% clean electricity goal, which is driving renewables development across the Western grid.

The Northwest has an opportunity to create a complementary resource portfolio to meet California's clean energy needs. Expanding interconnection capacity to California would allow greater integration of resources, relieving California's overgeneration conditions and enabling the Northwest access to higher-quality California solar than what can be produced regionally.

Demand-Side Electrification and Biomass

Failure to electrify on the consumer side has enormous implications for energy supply, as depicted in the Limited Electrification and Efficiency Achieved Case. The scale of new wind, solar, direct air capture, electrolysis, and power-to-X facilities in this case (see Appendix B for a description and graphic of power-to-X) could be considered prohibitive in implementation and may ultimately require imports of electric fuels produced elsewhere.

Restricted availability of net-zero-carbon biomass as in the Limited Biomass Available for Liquid Fuels Case results in similar energy system impacts. If consumers don't electrify or biofuels are not available, then the "backstop" resource to decarbonize is synthetic electric fuels, which may face implementation challenges to develop at the necessary scale and are expensive.

Power County wind farm, Idaho. Photo credit: U.S. Department of Energy

Cross-Case Comparisons

Significant Positive Benefit Case

Expanded interties between the Northwest and California change the optimal electricity supply mix, with each region avoiding the development of local, low-quality renewables and expanding the development of high-quality resources that are more efficiently shared across both areas. The Northwest avoids developing low-quality solar and increases wind development, while California develops additional high-quality solar and avoids procuring remote wind generation from other Western states. Savings are estimated as $11.1 billion net present value over the 30 years of the study (accrued to the combined California and Northwest region).

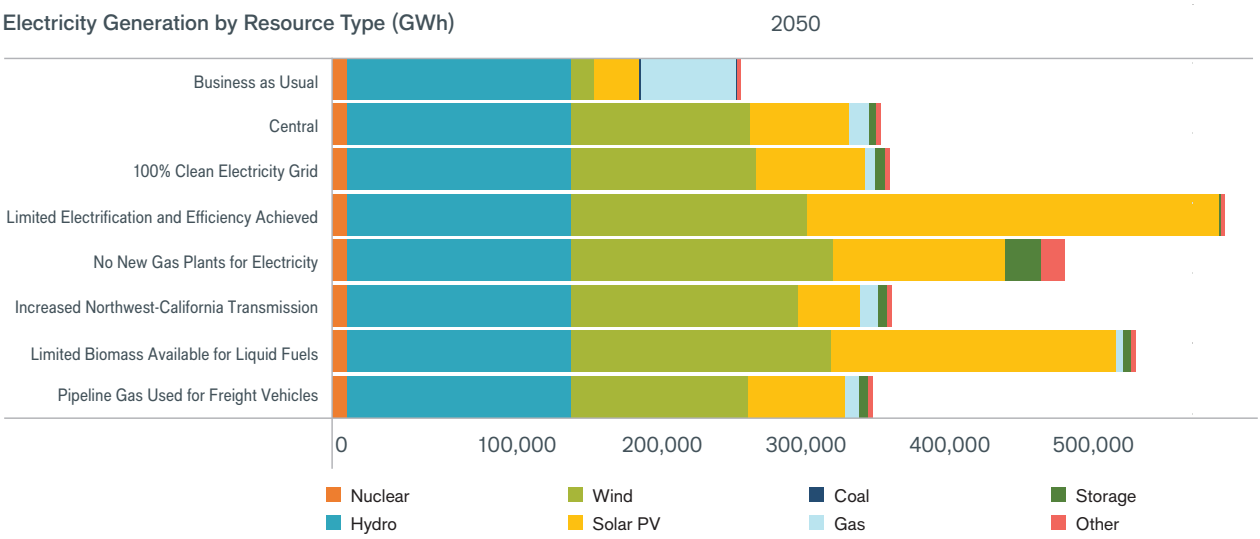
Significant Negative Impact Cases

In the Limited Electrification and Efficiency Achieved Case, where deep electrification of building, transport, and industry does not occur, there are large volumes of residual liquid fuel demand for diesel fuel, jet fuel, and gasoline in the system. This necessitates squeezing the use of gas-fired resources out of electricity generation to reduce emissions as much as possible in non-transportation sectors, and substantially ramps up direct air capture. While 2 million metric tons (MMT) are captured in 2050 in the Central Case, the Limited Electrification and Efficiency Achieved Case requires 27 MMT of carbon to be captured in 2050.

In the No New Gas Plants for Electricity Case, more than 35 gigawatts of additional wind, solar, and geothermal resources are required—on top of the 75 gigawatts of new renewables built in the Central Case. In addition, 12 gigawatts of additional energy storage resources are needed to maintain resource adequacy. This higher penetration of renewables and associated overgeneration incentivizes the production of additional electric fuels, in the form of power-to-diesel and power-to-jet-fuel.

When biomass is constrained, high volumes of synthetic electric fuels must be produced to replace biofuels. This has considerable infrastructure implications, including two times the installed capacity of wind and solar resources, five times the electrolysis capacity, and six times the direct air capture capacity than what is needed in the Central Case.

Poplar harvest and swallows. Photo credit: Marcus Kaufman



Marginal Impact Cases

The 100% Clean Energy case produces marginally different results from the Central Case. The share of gas-fired generation decreases from 3.7% to 1.7%, due to incremental renewables and energy storage deployment. Decarbonized pipeline gas supply (biofuels, hydrogen, and synthetic natural gas) covers all gas demand from power generation, and most of the incremental decarbonized pipeline gas is from synthetic gas.

Increasing gas in transport also has limited impact, but the study did not account for upstream methane leakage, so this result comes with a significant caveat. Freight trucks consuming higher pipeline gas means biofuels are not used to substitute for diesel fuel and are available for pipeline gas. This means minimal impacts across the energy system other than that reallocation from liquid biofuels to gaseous biofuels. But this case would be far less salutary if the full carbon accounting for methane leakage were considered.

Figure 38 combines all eight cases in one graphic to show the quantity and type of electricity generation (in GWh) required to achieve deep decarbonization in 2050.

FIGURE 38. There are significant impacts on total electricity generation for the Limited Electrification and Efficiency Achieved Case, Limited Biomass Available for Liquid Fuels Case, and No New Gas Plants for Electricity Case.

Conclusion

A principal goal of this deep decarbonization pathways study was to represent potential energy futures in enough technical detail to be used as blueprints to develop a future of the Northwest's choosing. There are several areas of additional examination that the study suggests pursuing.

Focus on Equity. This study is designed to show the trade-offs between different deep decarbonization pathways, but it does not take into account equity considerations for different communities. The study demonstrates we can decarbonize our economy, but the critical work ahead must focus on how to do so equitably.

Areas for Further Study. Understanding the dynamics of alternative fuel development on refinery activity and relative fuel prices is important for the Northwest. While it might be possible to predict the decline of certain fuels as electrification increases in buildings and transportation, the development of biofuels or electric fuels that also displace fossil fuels may be more challenging to foresee. This is an unanswered question in almost all deep decarbonization transformations and developing long-term strategies today could mitigate the clean energy transition's disruptive impacts and avoid unnecessary investments.

This study examined low, normal, and high hydro years; however, it held the likelihood of experiencing these hydro conditions constant through 2050 and did not consider even lower future water years, assumptions that require examination. Follow-on work should involve a scenario in which lower snowpack occurs more frequently, and seasonal dynamics are altered due to climate change.

Sensitivity analyses are needed to understand how a 10% to 20% lower hydro resource would impact other resources, as well as how removing the Lower Snake River dams and retiring the nuclear Columbia Generating Station before 2043 would affect clean power supply. Finally, a combination of all three of these changes in low-carbon resources should be modeled together.

Modeling the retirement of all coal-fired electricity generation by 2030 is an additional area for study, as is modeling natural gas at higher prices than the study assumed and, if possible, modeling natural gas with a higher emissions level to account for upstream emissions and methane leakage.

Focus on Implementation. While this study offers a functional technical representation of low-cost deep decarbonization pathways, successful implementation is more uncertain. Some implementation challenges include:

- A nearly 100% clean grid is a feature of low-cost decarbonization in the region. Policymakers and utilities must overcome the technical and economic barriers to cleaning the grid well in advance of 2050.
- The level of transportation electrification called for by 2050 requires immediate attention to overcoming barriers to massive adoption of electric vehicles, and to determining how the electric grid will handle the additional load required to serve new electricity needs.
- Grid infrastructure development and operational integration are needed to most efficiently leverage renewable development in California and across the West; this is complicated politically and technically and will take time. Planning must get underway now to ensure successful integration of these markets.

With several recent international and national reports clearly establishing that there is a small window of time within which to massively reduce fossil fuel dependence, and a U.S. federal government currently focused on increasing, not decreasing, the use of fossil fuels, it is imperative that states and regions in the United States step up to the decarbonization challenge.

Initiatives such as the Green New Deal, the Keep it in the Ground Movement, and 100% Clean Energy campaigns set forth a range of goals and strategies to reduce carbon emissions. Achieving these goals requires technology investment, smart policies, innovation, and regulatory reform to shape the low-carbon energy system of the future.

Solutions need time to be developed and implemented, so policymakers must anticipate them now. *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* provides support and direction for policy-makers, advocates, businesses, government leaders, and investors to begin implementing effective solutions for a deeply decarbonized future in the Northwest.

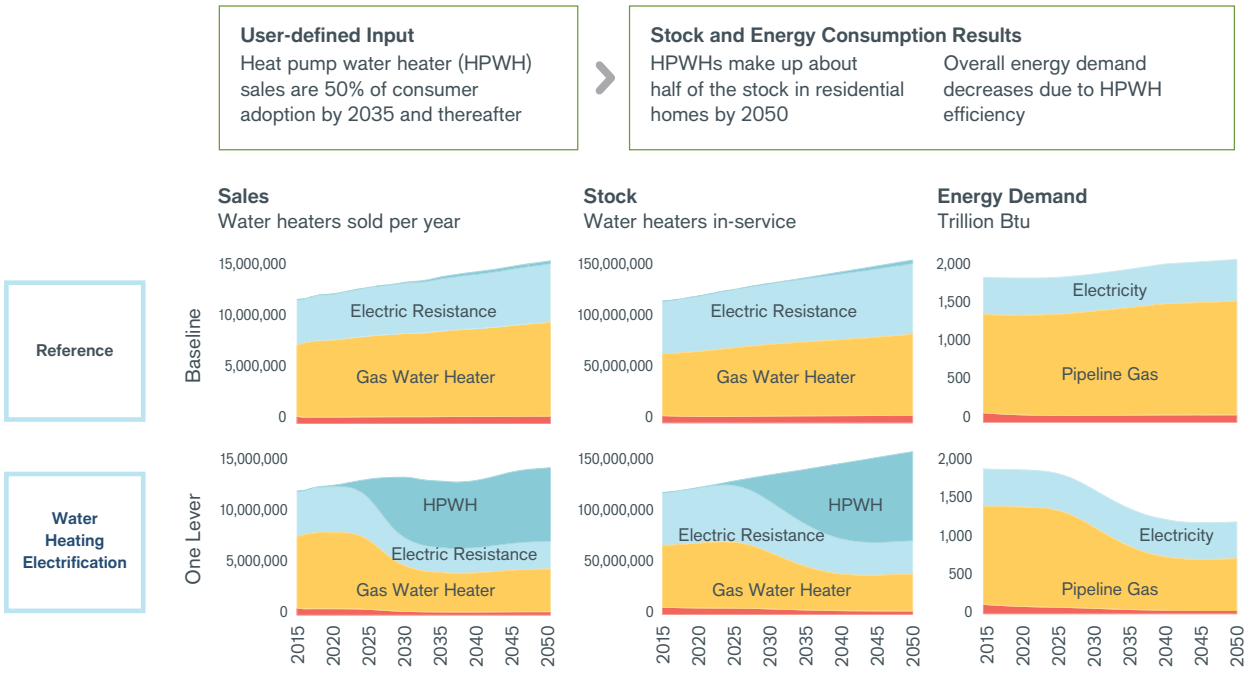
Appendix A: Modeling Approach

Modeling involved two different models that Evolved Energy Research has created: (1) EnergyPATHWAYS, and (2) the Regional Investment and Operations model (RIO).



EnergyPATHWAYS

The EnergyPATHWAYS (EP) model is a bottom-up energy system scenario analysis tool that tracks energy infrastructure, including stocks for building, industry, and transportation infrastructure.

EP develops demand-side scenarios across all end-use sectors and produces annual final energy demand for electricity, pipeline gas, diesel fuels, gasoline, etc., as well as hourly electricity load shape demand.

User-defined measures specify low-carbon and efficient technologies to replace energy infrastructure over time. Specifically, modelers choose the scale and rate of adoption for new technologies for different sectors (e.g., the percent of light-duty car sales that are battery electric vehicles in each year). Figure 39 demonstrates how user-defined decisions for residential water heaters generate the stock and energy demand for heaters over time from now until 2050.

FIGURE 39. EnergyPATHWAYS: residential water heating example.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 23.

EP represents approximately 80 demand subsectors for the residential, commercial, industrial, and transportation sectors, the major energy-consuming subsectors of which are displayed in Figure 40 below.

Regional Investment and Operations (RIO)

The Regional Investment and Operations (RIO) model is a capacity expansion tool that produces cost-optimal resource portfolios for all energy supply options and fuel types, including electricity, pipeline gas, gasoline, diesel, jet fuel, hydrogen, and other fuels. The model decides the suite of technologies that will be used over time to meet annual emissions targets and other constraints. RIO's optimization allows for trade-offs of limited resources across the energy system (like biomass) to be determined simultaneously.

For the electricity sector, RIO simulates sequential hourly system operations for every modeled year from now until 2050, incorporating long-duration energy storage logic that optimizes investment and operations of all types of energy storage, which is required to manage high renewable penetrations. RIO simulates operations and investment across the energy supply side, including electricity and fuels, while accounting for dynamically changing inputs and constraints across the energy system.

The model incorporated load, wind, solar, and hydro profiles from multiple weather years to capture a range of electricity system operating conditions because weather-driven or seasonal trends in load, hydro availability, and renewable production cause operational challenges that can persist over long periods. For load, wind, and solar, the modelers used hourly profiles from 2010, 2011, and 2012, and for hydro, the modelers represented conditions from three historical years—2001 (dry), 2005 (normal), and 2011 (wet).

RIO invests across a range of thermal, renewable, and energy storage technologies to satisfy energy, capacity, balancing, and environmental needs, as Figure 41 below demonstrates. RIO can select from three gas-fired resource alternatives.

FIGURE 42. Conversion technology options.

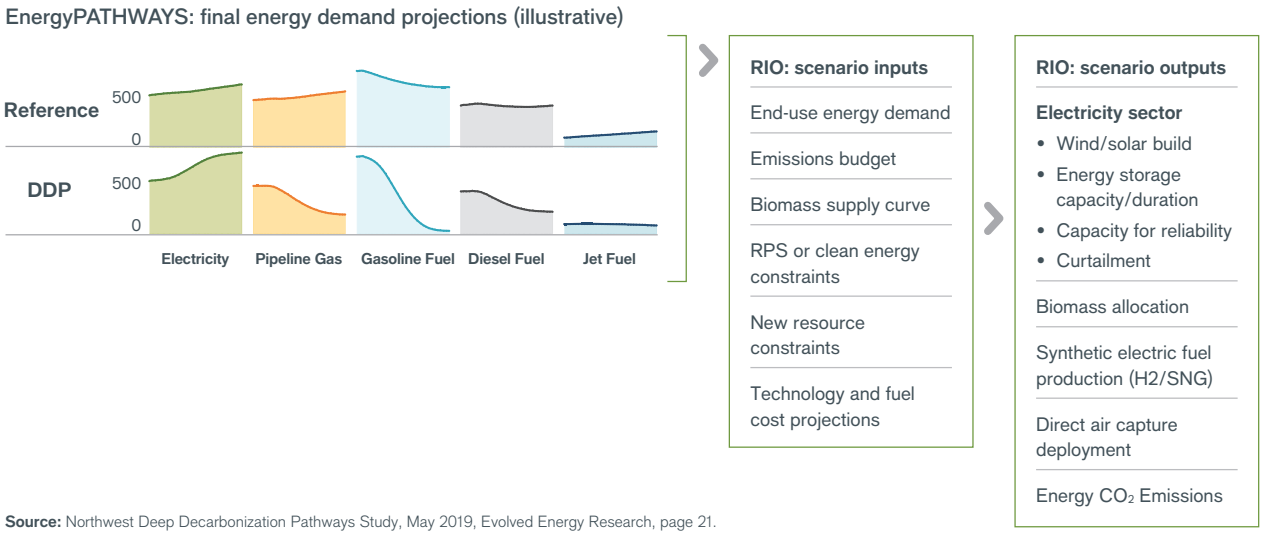
BIOMASS-BASED

- Biomass feedstock can be converted into liquid or gaseous fuels using a variety of conversion technologies
- Biomass gasification technology can produce biogas
- Fischer-Tropsch can produce renewable diesel and renewable jet fuel

ELECTRIC-BASED

- **Power-to-X** processes convert carbon-free electricity into synthetic fuels (e.g., power-to-gas, power-to-liquids)
- Processes rely on:
  - Electrolysis to produce hydrogen
  - Carbon feedstocks either from CO_2 embodied in biomass or direct air capture

RIO represents a suite of conversion technologies to produce useful low-carbon fuels that depend on biomass- or electric-based feedstocks



Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 40.

RIO represents a suite of conversion technologies to produce useful low-carbon fuels that depend on either biomass- or electric-based feedstocks, as Figure 42 shows.

Pairing EnergyPATHWAYS and RIO

The energy demand parameters that EP produces are then fed into RIO. Taking the demand projections aggregated from subsector loads that the EP model produced, RIO provides cost-optimal energy supply investments and operations for the electricity sector, biomass allocation for fuels, synthetic electric fuels, and direct air capture. Figure 43 below illustrates how EP and RIO are paired together.

FIGURE 43. Modeling framework: pairing EnergyPATHWAYS and RIO.

Source: Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 21.

Appendix B. Emerging Technologies

Power-to-X

A major finding of *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* is the crucial role that power-to-X (either fuels or liquids) will play in the later years of this study. Power-to-X is a term that describes a variety of different technologies and processes that enable surplus electric power to be stored or used to produce fuels.

In this study, power-to-X is primarily referring to electrolysis that converts surplus electricity captured by power-to-X technology into hydrogen and then further converts it to methane gas or ammonia (e.g., power-to-gas). Carbon that is captured from power plants can also be recycled into synthetic fuels, which can replace the oil and gas that have been the traditional feedstocks for fuels used in transport.

Emmanouil Kakaras, senior vice president and the head of the department of innovation and new products at Mitsubishi Hitachi Power Systems Europe, told *Forbes* magazine in June 2018[10] that "gasoline produced by combining the captured carbon and hydrogen produced by renewable energy emits 90% less carbon than gasoline produced by conventional means."

Hydrogen Electrolysis

Using electricity to produce hydrogen by electrolyzing water plays a key role in balancing the electricity system during periods of renewable energy overgeneration. The hydrogen produced is used to create synthetic fuels that can be used for difficult-to-electrify applications. Electrically produced hydrogen is used as a feedstock to produce renewable liquid and gaseous fuels that already have existing delivery mechanisms.

Hydrogen can be combined with captured CO_2 to produce methane (the main component of natural gas). Chemical synthesis using the Fischer-Tropsch process can produce synthetic liquid fuels that are interchangeable with refined petroleum products, including diesel, gasoline, and jet fuel. Produced hydrogen can be injected into a natural gas pipeline directly, limited to 7% by energy, which research has shown can be blended with fossil-based or synthetic natural gas without damaging end-use equipment or the delivery infrastructure.

Electrical power lines. Photo credit: Public Domain

Producing electrolytic hydrogen and synthetic fuels provides a primary method of long-duration storage for systems with high penetrations of renewable generation. When peak electricity generation exceeds demand, the extra electricity is used to synthesize the hydrogen and synthetic fuels. These fuels in turn can be used directly to meet liquid and gaseous fuel demand and—to a limited extent—to produce electricity during times when renewable energy is not created.

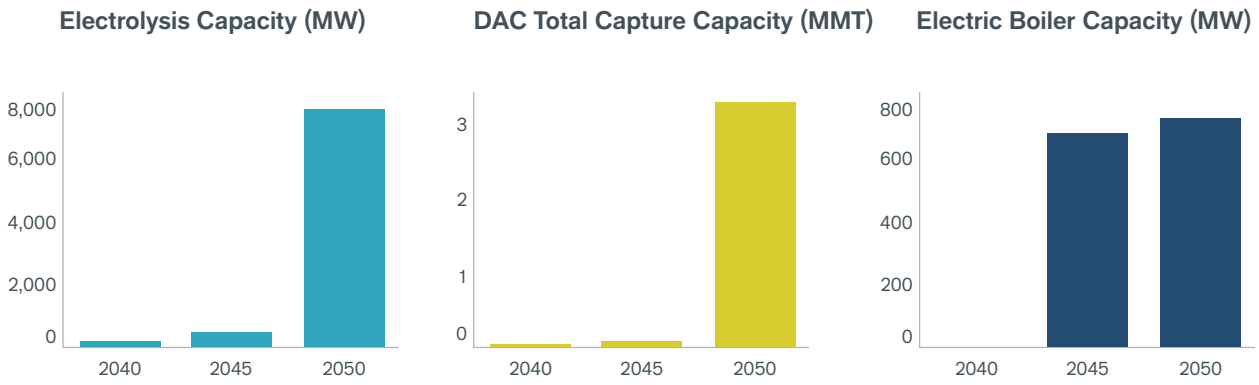
The principal mechanism by which electric fuels balance the electricity system is not "round-trip" electricity storage in which energy is stored in one time period and discharged back to the electricity grid in another. Instead, the dominant economic means of balancing with electric fuels involves producing fuels that will be used to meet demand from hard-to-decarbonize end uses.[11]

Electric fuel production utilizes otherwise curtailed renewable energy, which means that electric fuels create value for electricity overgeneration. In doing so, electric fuels increase loads during times of renewable abundance and decrease them during low production periods. Because fuels can be stored far more cheaply than electrical energy, this method of balancing is the economic option for long-term balancing challenges.

Fossil Fuel Terminal Zoning Amendments Testimony
Ordinance #189807
LUBA No. 2020-009
Page 4503

Direct Air Capture

Direct air capture (DAC) removes CO_2 directly from the atmosphere. In this study, DAC created a carbon feedstock to be used for electric fuel production. Heightened emphasis on early commercialization of DAC is needed, as DAC can accelerate overall decarbonization and also serve as a technological backstop if widespread electrification does not take place or biomass for biofuels is constrained.



While there are legitimate concerns that DAC can be used to justify the continued development and combustion of fossil fuels, there is increasing understanding that DAC could play an important and complementary role in deep decarbonization. DAC pairs best economically with low-cost zero-carbon resources, such as wind or solar, because CO_2 feedstock (like hydrogen) can be stored and therefore DAC can operate flexibly to take advantage of periods of renewable overgeneration. Carbon capture scenarios where fossil fuels provide the grid electricity do not offer the same economic benefit.[12] Figure 45 illustrates how synthetic gas is produced from renewably generated hydrogen when methanated with captured CO_2.

Electric Boilers

Electric boilers produce steam for commercial and industrial activity. When used in conjunction with a fuel boiler at the same location, they can provide electric load flexibility. In periods of excess renewable energy, the electric boiler produces steam and the fuel boiler sits idle. In periods short of renewable energy, i.e., when the wind is not blowing, the fuel boiler takes over and the electric boiler sits idle, reducing electric loads. This functionality helps balance the electricity grid.

In the 2040s, new sources of electric load play essential roles for both the electricity system and the energy system as a whole. First, the new loads are flexible and can manage electricity imbalances across the year. Second, these new electric loads produce co-products that assist with energy system–wide decarbonization in the form of (1) hydrogen from electrolysis and CO_2 from DAC to produce synthetic natural gas, and (2) electric boilers that produce steam for commercial and industrial activity. Figure 44 shows the builds for each of these new sources of electric load in the Central Case.

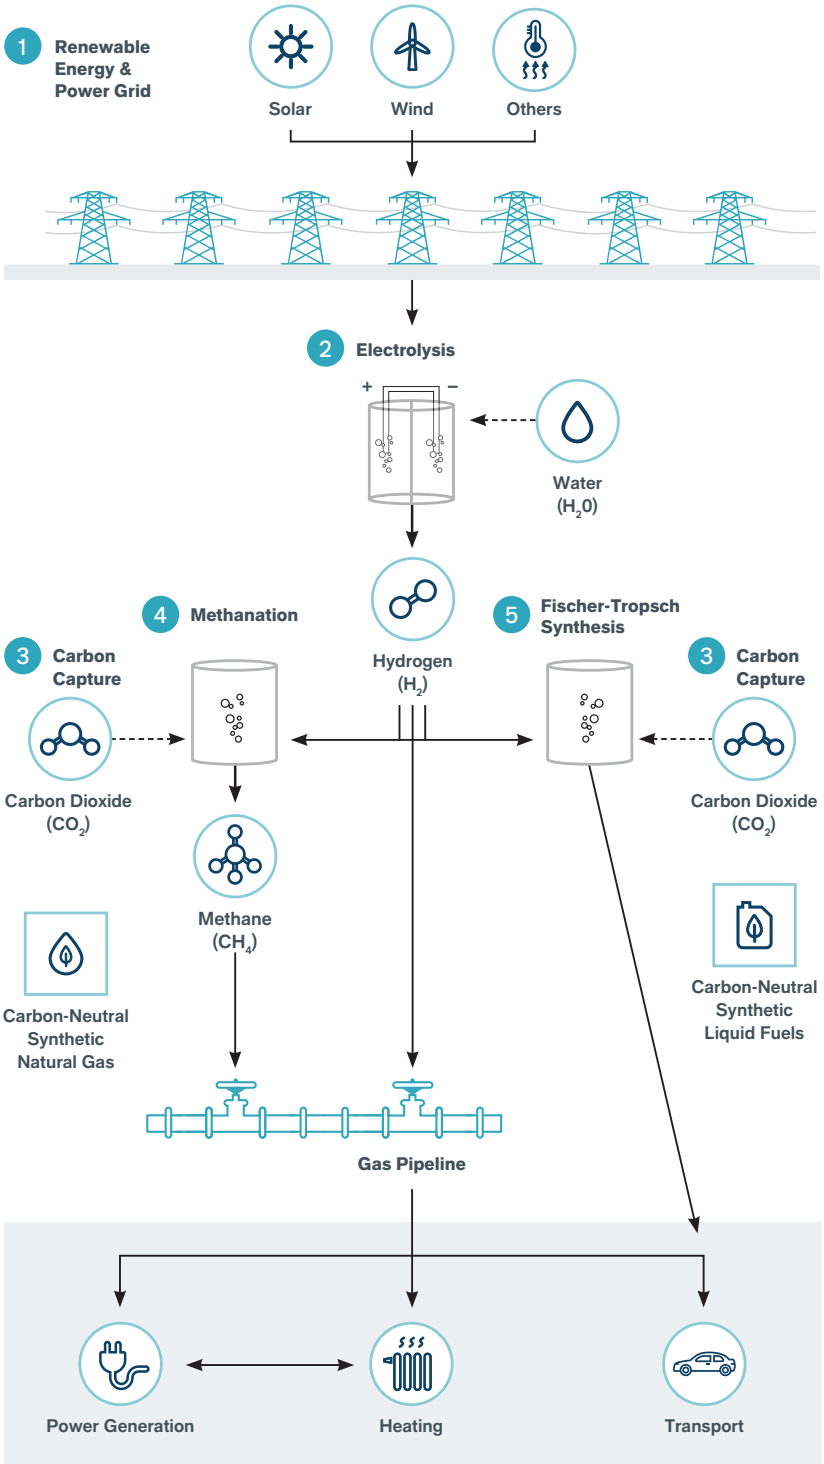


FIGURE 44. New sources of electric load.

FIGURE 45. Illustration of power-to-gas and power-to-liquids (P2X).

A major finding of *Meeting the Challenge of Our Time: Pathways to a Clean Energy Future for the Northwest* is the crucial role that power-to-X will play in 2040–50 to create synthetic gas or synthetic liquid fuels. Power-to-X is a term that describes a variety of different technologies and processes that enable surplus electric power to be stored or used to produce fuels.

In the study, power-to-X refers to electrolysis that converts surplus electricity into hydrogen, which then is combined with carbon dioxide, captured either through direct air capture powered by carbon-free electricity, or from biorefineries to produce methane gas (power-to-gas). The Fischer-Tropsch synthesis process can also be used to create synthetic liquid fuels to replace conventional oil based transport fuels (power-to-liquids).

1. **Renewable Energy & Power Grid:** Clean electricity powered by sources such as solar, wind, and hydroelectricity supplies the power grid.

2. **Electrolysis:** The process of using electricity, in this case carbon-free, to split water into hydrogen and oxygen.

3. **Carbon Capture:** Carbon dioxide is captured either through direct air capture powered by carbon-free electricity or from biorefineries.

4. **Methanation:** Combines hydrogen with carbon dioxide to produce methane that can be injected into the gas pipeline as carbon-neutral synthetic gas.

5. **Fischer-Tropsch Synthesis:** Chemical reactions that change a mixture of carbon dioxide gas and hydrogen gas into liquid hydrocarbons, such as gasoline or kerosene, that can be used for transportation.

Appendix C. Assumptions

Deep decarbonization analyses require a wide variety of inputs and data sources to characterize current and future energy systems. This study relies on state and regional data sources where available, and leverages public sources primarily from federal government reports, including the U.S. Energy Information Administration (EIA), U.S. Department of Energy (DOE), and National Renewable Energy Laboratory (NREL).

This section describes how various assumptions were derived and the way the models incorporated those assumptions. The list of key references and data sources is provided in Appendix D. These sources tend to be conservative about the projected cost and performance of low-carbon technologies.

End-Use Stocks and Technologies Assumptions

Regional building stock assessments from Northwest Energy Efficiency Alliance (NEEA)[13] were used to characterize the existing building stocks in each of the four states.

Cost and performance for new end-use technologies were primarily derived from the NREL Electrification Futures Study,[14] which includes projections for:

- **Buildings Sector:** Air source heat pumps and heat pump water heaters
- **Transportation Sector:** Battery electric vehicles for light-duty cars and trucks, medium-duty battery electric trucks, heavy-duty battery electric trucks, and battery electric buses
- **Industrial Sector:** Air source heat pumps, electric machine drives, industrial heat pumps, electric boilers, and electric process heating

The Annual Energy Outlook (AEO) produced from the U.S. Energy Information Administration (EIA)'s National Energy Modeling System[15] was used to develop the demand-side database, including baseline and projected cost and performance for residential and commercial equipment, such as residential clothes dryers and commercial ventilation systems.

Link light rail train pulls into SoDo Station. Photo credit: Joe A. Kunzler

Electric Topology

Electricity sector operations and investment were modeled across the four Northwest states, California, and the rest of the Western Electric Coordination Council (WECC). Transfer capability between zones is based on major WECC paths and their line ratings. The capacity of Colstrip's major remote generation resources is allocated to the four states based on utility ownership.

Existing Generation Resources

The model derived the installed capacity of generation resources in each state from the U.S. Energy Information Administration's Form EIA-860.[16] Capacity from the existing hydroelectric system was assumed to remain constant through 2050.

Existing Coal Resources

The study incorporates planned retirement of coal-fired resources as the table below demonstrates.

Plants without a planned retirement year are assumed to retire at the end of their economic lifetimes.

Existing Nuclear Resources

The Columbia Generating Station (CGS) is the only operating nuclear power plant in the Northwest and its current license expires at the end of 2043. RIO allows CGS to retire or continue operations after 2043 to maintain dependable capacity and carbon-free energy.

The going-forward fixed costs of maintaining CGS are derived from Energy Northwest's Fiscal Year 2019 Long-Range Plan:[17]

- Fixed capital costs are assumed to equal $85/kW-yr
- Fixed operations and maintenance costs are assumed to equal $238/kW-yr
- Total going-forward fixed costs are equal to $323/kW-yr

Thermal Resource Options

Capital, fixed operations and maintenance (O&M), variable O&M, and heat rate characteristics are from NREL's 2018 Annual Technology Baseline (ATB).[18]

Fuel costs vary depending on the pipeline gas composition. Natural gas fuel costs are from the Annual Energy Outlook 2017[19] and the cost of decarbonized pipeline gas is solved for endogenously in RIO.

New coal and advanced nuclear resources were not considered.

Renewables Resource Options

Various state-level inputs characterizing renewable resources (potential, performance/capacity factor, transmission costs) are derived from NREL's Regional Energy Deployment System (ReEDS).[20]

Capital cost projections for wind, solar, and geothermal are from NREL's 2018 Annual Technology Baseline (ATB).[21]

Energy Storage Resource Options

Cost and efficiency inputs are derived from the International Renewable Energy Agency (IRENA) "Electricity Storage and Renewables: Costs and Markets to 2030" report. Costs are portioned into capacity ($/kW) and energy ($/kWh) components, where RIO selects the optimal duration of new resources over time.

New pumped hydro storage potential is limited to 2,000 MW in the Northwest based on a review of existing projects under development, which reflects the Gordon Butte, Goldendale, and Swan Lake pumped storage projects.

Table 1. Washington and Oregon coal plant retirement schedule.

Unit	Assumed Retirement Year (First Year Offline)
Boardman	2021
Centralia 1	2021
Centralia 2	2026
Colstrip 1 and 2	2022
Colstrip 3 and 4	▪ Avista and PSE share: 2028 (reflects accelerated depreciation schedule) ▪ PACW share: 2030 ▪ PGE share: 2035

Supply-Side Resource Options

The model assumes the following supply-side energy resource options:

TABLE 2. Supply-side resource options.

Diesel Fuel	Jet Fuel	Pipeline Gas	Liquid Hydrogen	Gasoline Fuel
Power-to-Diesel	Power-to-Jet-Fuel	Power-to-Gas	Electrolysis	Corn Ethanol

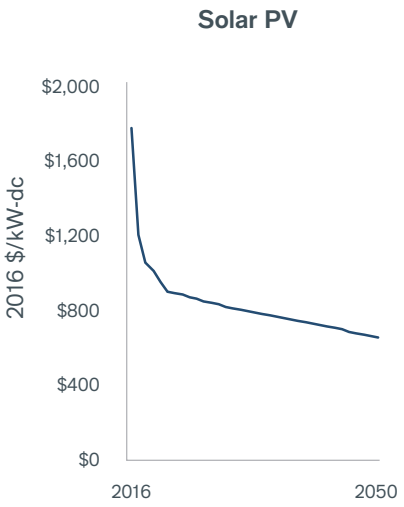
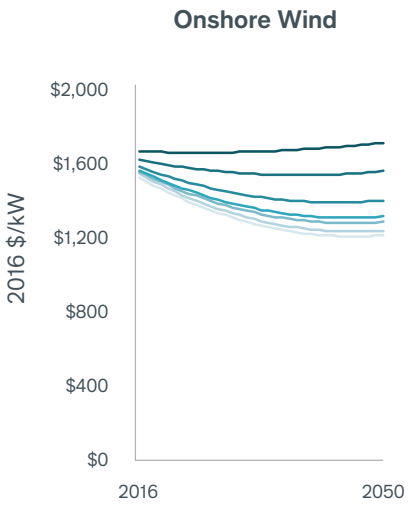
Biomass Availability and Costs



Prior deep decarbonization pathways studies have relied on the Department of Energy (DOE) Billion-Ton Study[22] for estimates of biomass availability and costs. This study includes feedstock potential by U.S. county at different price points for agricultural residues, forest residues, purpose-grown energy crops, and waste stream.

The Washington State and Portland General Electric deep decarbonization pathways studies assumed an allocation of biomass to the jurisdiction that is equal to its population-weighted share of national supply. This study follows the same approach as earlier work, where each state in the Northwest is allocated a share of national supply based on its relative population. RIO determines the application of biomass for the energy system by allocating limited supply to the most cost-optimal fuel type.

Electricity Supply Technology Cost Projections



Onshore wind and solar PV cost projections were sourced from the NREL 2018 Annual Technology Baseline (ATB).[23] The different trajectories of onshore wind cost represent NREL resource bins that differ in wind speed. These map to the wind resource potential within the Northwest states and are derived from the NREL Regional Energy Deployment System (ReEDS) model database.[24]

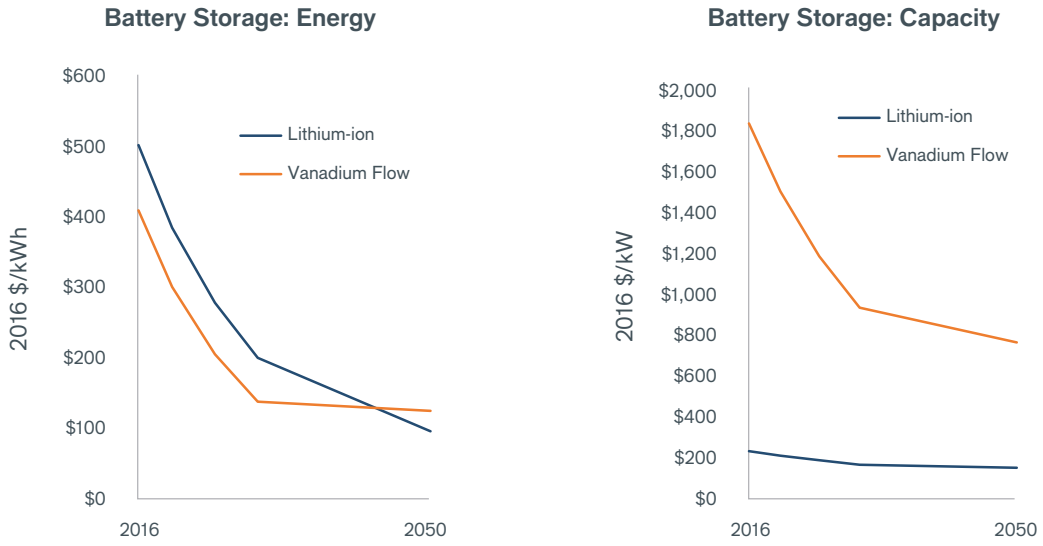
FIGURE 47. Onshore wind technology cost projections.

Note: Lines represent separate resource bins. **Source:** Northwest Deep Decarbonization Pathways Study, May 2019, Evolved Energy Research, page 121.

Battery Electric Vehicles Technology Cost Projections

The energy storage costs used in the study were sourced from the International Renewable Energy Agency (IRENA) "2017 Electricity Storage and Renewables: Costs and Markets to 2030" report. IRENA projects battery costs only to 2030. We therefore assumed battery prices follow the IRENA baseline projection through 2030, then drop to the IRENA 2030 Low Cost Case projection by 2050.



This assumes that the additional price declines due to various factors assumed in the IRENA Low Cost Case projection happen post-2030 and may be conservative depending on whether new battery chemistries become more competitive than the current market leaders.

Battery costs are separated by energy (kWh of storage) and capacity (kW of power) components. For example, the total kilowatt hours stored in a flow battery are driven by the quantity of electrolyte, whereas a flow battery's maximum discharge is driven by its membrane. Separation of the energy and capacity components allows the RIO model to optimally size new battery build.

The cost evolution of electric vehicles in each of the categories modeled in the study is shown in the figures below. These are sourced from the NREL Electrification Futures Study that provides price projections by vehicle class out to 2050.[26]

Appendix E: Stakeholder Process

Prior to commissioning *Meeting the Challenge of Our Time: Achieving a Low-Carbon Future in the Northwest*, the Clean Energy Transition Institute convened a Deep Decarbonization Pathways Working Group (see page 4 for the list of participants) and conducted numerous interviews with Northwest stakeholders about the value of conducting an economy-wide pathways study.

This stakeholder process revealed a clear need for a common set of facts about the decarbonization pathways for the Northwest that legislators and the advocacy community could agree to. Stakeholders' questions were summarized as:

1. **What is the likely trajectory by which we will clean the electricity grid in the Northwest by 2030, 2040, and 2050?**
   - When looking at economy-wide decarbonization in the Northwest, how close to 100% clean does the electricity sector have to be, by when?
   - How quickly can we remove coal from the Northwest grid?
   - How realistic is it that we will not replace coal with natural gas to power the grid?

2. **How will electrification of the transportation and buildings sectors contribute to deep decarbonization in the Northwest?**
   - How will energy efficiency help in decreasing load and therefore contribute to decarbonization?
   - How much decarbonization can we achieve through electrifying the transport sector with a nearly 100% clean electricity grid?
   - How does demand management contribute to peak load reduction and decarbonization?
   - How does transportation electrification impact load in Washington and Oregon?

3. **What is the role of natural gas for power generation and other end uses, including transportation?**
   - How do trade-offs in natural gas infrastructure impact emission reductions? From a carbon emissions reduction point of view, should we replace old natural gas plants with peakers if storage prices are high?
   - Absent policy changes, how soon do we expect storage to directly compete with natural gas for peaking?
   - What is the role of compressed natural gas/liquefied natural gas in reducing emissions in the transport sector over the next 20–30 years? Are there transportation subsectors (maritime, freight) where the role may be more prominent, given technology trajectories? How would knowing the answer to this question inform our policy choices and our approach to this sector and to natural gas?

4. **What is the cross-sector role of biomass?**
   - What are the highest value allocations of biomass among fuels, electricity, and gas?
   - What is the role of renewable natural gas derived from biomass and used for power generation or transportation?

5. **How would greater integration between the Northwest and California contribute to deep decarbonization?**
   - How much could Northwest-California integration reduce energy infrastructure needs and costs?

Executive Summary

Background

Portland General Electric (PGE) retained Evolved Energy Research to undertake an independent study exploring pathways to deep decarbonization for its service territory. This study comes amidst a broad interest in decarbonization from customers and stakeholders, as well as policies and goals to promote clean energy and emissions reductions.

Since 2007, Oregon has had a goal of reducing statewide greenhouse gas (GHG) emissions by 75 percent below 1990 levels by 2050. Recently proposed legislation seeking to establish a cap-and-trade program in Oregon also proposes to tighten the statewide GHG reduction goal to 80 percent below 1990 levels by 2050. At the local level, the City of Portland and Multnomah County passed resolutions in June 2017 committing to 100 percent renewable electricity by 2035 and a complete transition to carbon-free energy by 2050.

These drivers to deeply decarbonize the economy would require a transformation of the energy system, and major choices will need to be made about which technologies play a role and how aggressively to pursue carbon reductions across different sectors. A substantial body of existing technical work shows that the electricity sector plays a pivotal role in a low-carbon transition, but the extent and type of role depends on choices made in other sectors.[1] For example, the level of electrification pursued in buildings and the decision to produce fuels from electricity, such as hydrogen from electrolysis, will have implications for electricity demand and the quantity of renewable electricity generation that will need to be developed.

Due to the potential impact on long-term planning, PGE sponsored this study to inform its Integrated Resource Planning (IRP) efforts. This study is intended to provide an understanding of: (1) the opportunities and challenges of achieving economy-wide deep decarbonization; and (2) the resulting implications for electricity system operations and planning.

Approach

The overarching emissions target for this study is an 80 percent reduction below 1990 levels by 2050 in energy-related CO_2 emissions. CO_2 emissions from fossil fuel combustion have been the predominant source of Oregon's historical GHG emissions, and, since 1990, they have accounted for approximately four-fifths of total GHG emissions in the state. This target would allow for fossil fuel combustion emissions of no more than 9.2 $MMTCO_2$ in 2050 for the state of Oregon. We allocate the statewide carbon budget to PGE's service territory using its projected share of Oregon's population, which is estimated to be 47 percent in 2050.[2] This results in a carbon budget of 4.3 $MMTCO_2$ in 2050 for the PGE service territory.

We designed three future energy scenarios that reduce emissions to comply with the 4.3 $MMTCO_2$ target. These scenarios are referred to as "deep decarbonization pathways" or "pathways", and they provide alternative blueprints for achieving deep decarbonization of the energy system.

[1] For example, see Williams, et al. (2014) and Haley, et al. (2016).
[2] Population growth rate projections from OEA (2013).

For each sector of the energy economy, we developed a range of measures to replace today's energy infrastructure with efficient and low-carbon technologies over the next three decades. For example, passenger travel currently provided by a gasoline vehicle is replaced by an electric vehicle, and a compact fluorescent (CFL) light bulb is replaced by a light emitting diode (LED) light bulb. Each pathway combines measures across sectors at the scale and rate necessary to meet the study's emissions target.

We use EnergyPATHWAYS, a bottom-up energy systems model, to estimate energy demand, emissions and costs for each pathway. Our analysis starts with the same model and approach we have previously used to evaluate deep decarbonization for the United States, the State of Washington and other jurisdictions. We developed a detailed representation of the PGE service territory energy system, including infrastructure stocks and energy demands for buildings, industry, and transportation. Our analysis incorporates an hourly dispatch of PGE's electricity system, which allows us to better understand fundamental changes to electricity supply and demand, such as how to balance very high levels of intermittent renewables and the impact of electrification on hourly electricity demand.

Pathways

Our study aims to provide an understanding of the broad choices available to achieve deep decarbonization across the economy and the potential implications on the electricity sector. To inform this understanding, we develop three plausible energy futures for PGE's service territory that achieve steep reductions in energy-related CO_2 emissions between now and 2050. These future energy scenarios outline: (1) potential sources and demands for energy types over time; and (2) the scale and timing of change over the next three decades.

Table 1 provides a high-level summary of the three pathways included in this study, where each scenario incorporates alternative emissions reduction strategies and technologies. One of the primary objectives of our scenario design was to reflect a broad range of outcomes for the electricity sector. The High Electrification pathway relies on electrifying space and water heating in buildings and deploying bulk energy storage to balance high levels of renewable generation. Passenger transportation is characterized by high levels of battery electric vehicles (BEV), while freight transportation includes both battery electric and hybrid diesel trucks. The Low Electrification pathway decarbonizes energy supply with a variety of renewable fuels, and electrolysis and power-to-gas facilities provide both electricity balancing services and decarbonized pipeline gas. Passenger transportation is primarily BEV, while compressed and liquefied natural gas trucks are incorporated in the freight transportation sector. The High DER pathway is highly electrified and distributed, with increased rooftop solar PV and distributed energy storage in buildings and industry. The Reference Case projects business-as-usual conditions, including the Oregon Clean Electricity and Coal Transition (OCEP) and Clean Fuels Program (CFP).

Table 1 Scenario Summary

Scenario	Description
High Electrification	Fossil fuel consumption is reduced by electrifying end-uses to the extent possible and increasing renewable electricity generation
Low Electrification	Greater use of renewable fuels, notably biofuels and synthetic electric fuels, to satisfy energy demand and reduce emissions
High DER	Distributed energy resources proliferate in homes and businesses, which also realize higher levels of electrification
Reference	A continuation of current and planned policy, and provides a benchmark against the deep decarbonization pathways

We are not choosing or recommending a pathway to 2050, and the scenarios presented above are not exhaustive. However, the pathways we have included in this study illustrate possible routes to a deeply decarbonized energy system and provide an understanding of trade-offs between complex decisions made by consumers and producers across the energy economy.

Key Findings

The three pathways evaluated in this study demonstrate that achieving deep decarbonization is both possible and there are multiple ways of doing so. Through this analytical exercise, we have identified a number of key findings, which we describe in detail below.

Common Elements to Achieve Deep Decarbonization

Although our pathways demonstrate that a variety of technologies and approaches are possible to realize a low-carbon economy, they also share common strategies, including: energy efficiency, decarbonization of electricity generation and electrification. These *three pillars* are common themes in all pathways, and the energy transformation from today to 2050 reflects: (1) a decline in per capita final energy consumption by approximately 40 percent; (2) a decrease in the carbon intensity of electricity generation to near zero; and (3) an increase in the share of energy coming from electricity or fuels produced from electricity from approximately one-quarter today to at least half by 2050. All three strategies are required and pursuing only one is insufficient.

Planning for a 2050 Energy System

In order to facilitate a pathway to 2050, new energy infrastructure will be required that is low-carbon and efficient. Transformation is required across all sectors with consumers and energy suppliers both playing a key role. The analysis identifies the scale and rate of change for each pathway, and highlights trade-offs between choices made to achieve deep decarbonization. One example is the choice of decarbonizing heat in buildings. Electrification of heat with heat pumps may require electricity distribution network upgrades to allow for growth in electricity demand, but they also provide a source of flexibility and efficient cooling services during the summer. The alternative is decarbonized pipeline gas that requires new central-station fuel production facilities, additional renewable generation and

transmission network upgrades. *Both* choices require new infrastructure and highlight how long-term planning will need to address several uncertainties.

Energy Demand and Electricity Demand

Energy efficiency plays a crucial role in all pathways, and *total energy demand* in 2050 is approximately 10 to 20 percent below today's level, while the population grows by more than 40 percent. Despite overall energy demand decreasing, *electricity consumption* increases in all pathways. By 2050, retail electricity sales are projected to increase by 60 to 75 percent relative to today's level. As a result, electricity's share of overall energy demand is projected to increase in a deeply decarbonized future.

Transportation Electrification

Electrification of passenger transportation is a critical component of decarbonizing the energy system, and passenger vehicles are at least 90 percent BEV by 2050 across all pathways. To ensure these vehicles are on the road by 2050 requires consumer adoption to be near 100 percent of vehicle sales during the mid-2030s. Delays in adoption increase the likelihood of missing the 2050 target.

Widespread adoption of electric vehicles (EVs) is projected to be the largest source of increased electricity consumption, and, left unmanaged, would increase peak demand. However, the fleet of EVs across PGE's service territory can employ smart charging by shifting their demand to more efficient times of day. Charging off peak, such as when renewable generation is high or during the middle of the night can mitigate peak load impacts while ensuring that passengers complete all of their intended trips.

Scale of Renewable Resources

Oregon's existing renewable portfolio standard (RPS) requires half of the energy PGE delivers to its customers to come from qualifying renewable resources by 2040. Deep decarbonization extends that ambition in two ways. First, the overall electricity generation mix is more than 90 percent carbon-free by 2050, including onshore wind, solar PV, hydro and geothermal resources. Second, the total quantity that must be generated (in average megawatts) increases due to: (a) electrification of end-use demand, such as heating and transportation; and (b) producing fuels from electricity, such as hydrogen and synthetic natural gas. As a result, the installed capacity of renewables is substantially higher than what's anticipated in any current planning proceedings and is more than double the quantity we would expect under current RPS policy.

Rooftop solar PV can play a key role in electricity supply, but its share of the overall electricity generation mix in a deeply decarbonized energy system is limited by the resource quality in Northwest Oregon (i.e., low capacity factors) and growth in electricity consumption. Distributed solar reduces the need for, but does not completely replace, transmission-connected renewables. Although the Low Electrification pathway has the lowest retail energy deliveries by 2050, the pathway requires the highest level of transmission-connected renewable generation due to electric loads from producing hydrogen and synthetic natural gas.

The scale of renewable resource development present in all scenarios highlights the need for proactive planning to ensure that these resources are available to come online in a timely fashion. This includes identifying promising areas for resource development, possible transmission network upgrades to

ensure renewable generation is delivered to load, and operational considerations to balance a highly renewable electricity grid.

Balancing the Electricity System

Electricity systems must be continually balanced across several timescales, from seconds to daily, weekly and seasonal changes. Today, generation from thermal and hydro resources is varied to meet changes in demand. However, balancing electricity supply and demand becomes more challenging when inflexible, variable renewable generation is the principal source of electricity supply. For example, renewable generation exceeds load in approximately half of all hours in 2050 in our pathways.

This operational paradigm necessitates a transition to new forms of balancing resources to integrate renewables and avoid curtailment. New sources of flexibility, including energy storage and flexible demand, can complement traditional sources of flexibility. Flexible demand includes both: (a) flexible end-use loads, such as smart EV charging and water heating; and (b) flexible transmission-connected loads, such as electrolysis and power-to-gas facilities that produce low-carbon fuels. The portfolio of available balancing options depends on choices made across the energy economy.

I. Background

Portland General Electric (PGE) retained Evolved Energy Research to undertake an independent study exploring pathways to deep decarbonization for its service territory. This study comes amidst a broad interest in decarbonization from customers and stakeholders, as well as policies and goals to promote clean energy and emissions reductions at the state and local level. Transitioning towards a low-carbon energy economy will have significant implications for electricity supply and demand, and the various technologies and strategies deployed during this transformation can result in broad outcomes for the electricity sector. Due to the potential impact on long-term planning, PGE sponsored this study to inform its Integrated Resource Planning (IRP) efforts and provide an understanding of: (1) the opportunities and challenges of achieving economy-wide deep decarbonization across its service territory; and (2) the resulting implications for electricity system operations and planning.

A. Motivation and Context

Oregon has long been at the forefront of recognizing the risks imposed by climate change. In 2007, the Oregon legislature passed House Bill 3543 (HB 3543), which established GHG reduction goals, including: (a) 10 percent reduction below 1990 levels by 2020; and (b) 75 percent reduction below 1990 levels by 2050. The Oregon Global Warming Commission (OGWC) was established through the same bill, and later recommended an interim goal of a 40 percent reduction below 1990 levels by 2035.

Recently proposed legislation seeking to establish a cap-and-trade program in Oregon also proposes to tighten the statewide GHG reduction goal. The proposed legislation would require a reduction in statewide GHG emissions to: (a) a goal of 20 percent below 1990 levels by 2025; (b) a limit of 45 percent below 1990 levels by 2035; and (c) a limit of 80 percent below 1990 levels by 2050.

Oregon has existing climate policies targeting specific sectors. The Clean Fuels Program requires the average carbon intensity of transportation fuels to be reduced by 10 percent between 2015 and 2025. The state adopted a Renewable Portfolio Standard (RPS) in 2007, which requires a percentage of retail electricity sales to be met by qualifying renewable electricity generation. This policy originally required 25 percent of load to be met by renewables by 2025. Senate Bill 1547 (SB 1547), also known as the Oregon Clean Electricity and Coal Transition (OCEP), was passed in March 2016 and requires: (1) an increase in the RPS to 50 percent renewables by 2040; and (2) removing coal-fired electricity generation from the state's electricity supply by 2035.

PGE's 2016 IRP reflected the increase in renewable energy requirements and transition from coal generation called for in the OCEP. Throughout the IRP process, stakeholders and customers have expressed interest in low-carbon portfolios and exploring deep emissions reductions. In addition, the City of Portland and Multnomah County passed resolutions committing to ambitious clean energy goals shortly after, including: (a) 100 percent renewable electricity by 2035; and (b) a complete transition to carbon-free energy by 2050.

These drivers to deeply decarbonize the economy would require ambitious energy system transformation. Prior studies examining similar levels of GHG reductions for the states of Washington and California, the United States and countries representing more than 75 percent of global GHG emissions have all identified the following required changes to their future energy systems: (1) highly efficient use of energy; (2) generating electricity with low- and zero-carbon resources; and (3)

substituting fossil fuels with electricity and electricity-derived fuel.[3] Pursuing only one change, such as decarbonizing electricity generation, is insufficient to meet economy-wide goals and all three strategies are needed.

In addition to these common themes, there are a range of alternative strategies that make it possible to achieve the same GHG goal. Different technologies and fuels can be deployed to decarbonize energy supply and demand, and the extent of decarbonization by end-use sector may vary. Key differences between pathways identified in prior studies include the level of end-use electrification and the allocation of limited bioenergy resources to decarbonize gaseous and liquid fuels.

As a result, long-term planning for the electricity sector will need to account for decarbonization efforts in other sectors and the complex mix of choices that may be pursued. Examples of actions that would affect long-term electricity planning include: (a) adoption of high levels of electric vehicles in the transportation sector, which affects overall electricity demand and its shape; (2) production of synthetic electric fuels, such as hydrogen from electrolysis, which will increase the demand for clean electricity generation; and (3) deployment of distributed energy resources across homes and businesses. However, the likelihood and timing of these developments and other potential decarbonization efforts is uncertain.

Our study aims to provide an understanding of the broad choices available to achieve deep decarbonization across the economy and the potential implications on the electricity sector. To inform this understanding, we develop a range of plausible energy futures for PGE's service territory that achieve steep reductions in energy-related CO_2 emissions between now and 2050. These future energy scenarios outline: (1) potential sources and demands for energy types over time; and (2) the scale and timing of change over the next three decades.

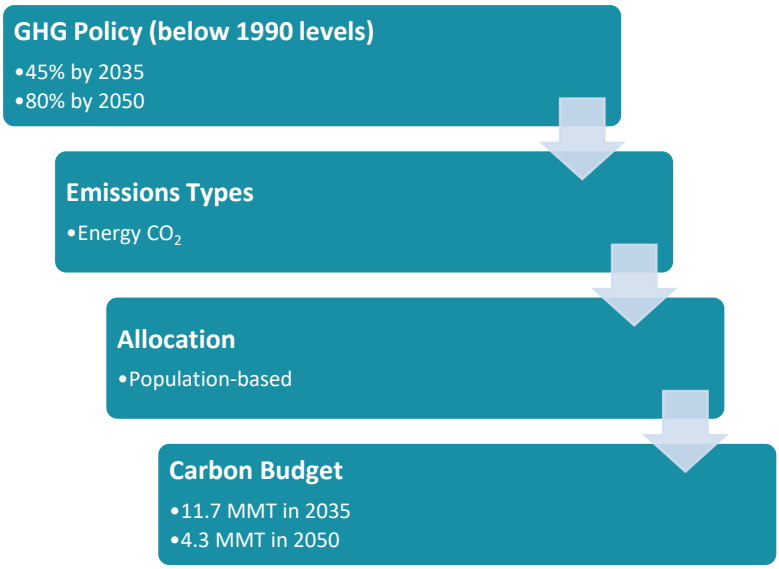
B. Study Scope

Our study scope includes designing and evaluating three future energy scenarios that deeply decarbonize the PGE service territory's energy system. We refer to these scenarios throughout the report as "deep decarbonization pathways" or simply "pathways". We also developed a Reference Case reflecting current policy to provide a benchmark against the pathways scenarios.

The primary results of our study include projections from today to 2050 of: (1) energy demand by sector and type; (2) energy supply; (3) energy-related CO_2 emissions; and (4) energy system-related costs. This is supplemented by detailed results for the electricity sector, including electricity demand, installed capacity, generation, and hourly dispatch results for PGE's bulk power system.

Given our focus on exploring energy system transformation, we account for all forms of energy (e.g., gasoline, pipeline gas, hydrogen) and our analysis is not limited to electricity. We include CO_2 emissions from energy use, but we do not track non-energy CO_2 and non-CO_2 GHGs. The geography for our analysis is confined to PGE's service territory and excludes the rest of Oregon. Since one of the primary objectives of the study is to explore economy-wide compliance with a GHG target, we include load from customers that are currently under direct access to account for all energy use.

[3] These strategies are commonly referred to as the "three pillars".



Given the exploratory nature of this study, it is important to emphasize what this study *is not*:

- Our scenarios are not a forecast of the future;
- We are not predicting future outcomes or assigning probabilities to scenarios;
- We are not choosing or recommending a pathway to 2050;
- Scenarios assessed here are not exhaustive and thousands of plausible alternatives exist;
- Scenarios do not reflect PGE's business plan or future resource acquisitions; and
- This study's modeling approach and results do not replace existing tools or processes used in IRP, such as defining "need" for resource adequacy or identifying optimal portfolios, nor do they replace cost-effectiveness evaluation, etc.

C. Study Emissions Target

For the purposes of this study, the energy-related CO_2 emissions budget for PGE's service territory is 11.7 million metric tons ($MMTCO_2$) in 2035 and 4.3 $MMTCO_2$ in 2050. Developing an appropriate emissions budget to evaluate deep decarbonization requires numerous assumptions to account for: (a) the fact that currently there is no binding, economy-wide GHG policy covering PGE's service territory; (b) any state-wide emissions limit must be translated into a budget for PGE's service territory; and (c) the scope of our work includes energy-related CO_2 emissions and excludes non-energy CO_2 and non-CO_2 GHGs. Our approach for deriving the study's emissions budget is summarized in Figure 1 and further described below:

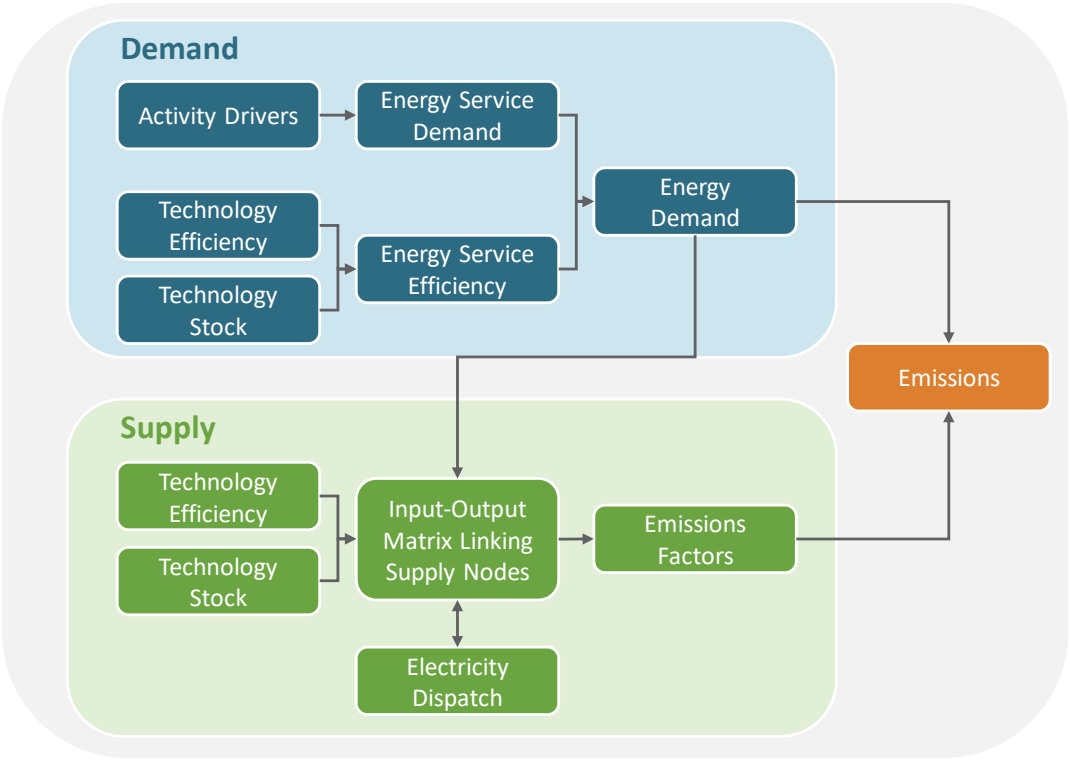
Figure 1 Approach to Develop Study's CO_2 Target

- **GHG Policy**. The context for emission reductions, discussed in the proposed cap-and-trade legislation, requires a reduction in statewide GHG emissions to: (a) 45 percent below 1990 levels by 2035; and (b) 80 percent below 1990 levels by 2050.

- **Emissions Types**. CO_2 emissions from fossil fuel combustion have been the predominant source of Oregon's historical GHG emissions, and, since 1990, energy-related CO_2 emissions have accounted for four-fifths of total gross GHG emissions in the state. For simplicity, we apply the emissions reductions from the above GHG policy to Oregon's 1990 energy-related CO_2 emissions, which were approximately 46 $MMTCO_2$.[4] This results in a state-wide budget for CO_2 emissions from fossil fuel combustion of approximately 25.2 $MMTCO_2$ in 2035 and 9.2 $MMTCO_2$ in 2050. Based on a state population forecast of 5.59 million in 2050, this results in a per capita emissions budget of 1.6 tCO_2 per person, which is consistent with prior decarbonization studies.
- **Budget Allocation**. We allocate the state-wide emissions budget to PGE's service territory using its projected share of Oregon's population. In 2015, the PGE service territory included approximately 1.8 million people or 45 percent of Oregon's population. Projections of long-term population growth show counties within PGE's service territory growing at a slightly faster rate than the state as a whole. PGE's share of the state's population is projected to increase to 46.3 percent in 2035 and 47 percent by 2050. This translates into a carbon budget of 11.7 $MMTCO_2$ in 2035 and 4.3 $MMTCO_2$ in 2050.

The carbon budget we have developed for PGE's service territory is specific to this study. Any future policy mechanisms used to achieve emissions reductions, such as a price on carbon or complementary measures, may result in alternative emissions outcomes than those modeled here. In other words, the *total* statewide GHG emissions target may be compliant in the future, but *where* mitigation occurs is not definite. For example, more or less mitigation may occur between: (a) PGE's service territory and the rest of Oregon; (b) buildings and the industrial sector; and (c) sources of energy CO_2 and other GHGs.

[4] We note that our approach implicitly assumes that non-energy CO_2 and non-CO_2 GHGs will be reduced on an equivalent percentage basis in order to achieve the overall GHG targets. Historical emissions data from DEQ (2016).



II. Study Assumptions and Approach

A. EnergyPATHWAYS Modeling Framework

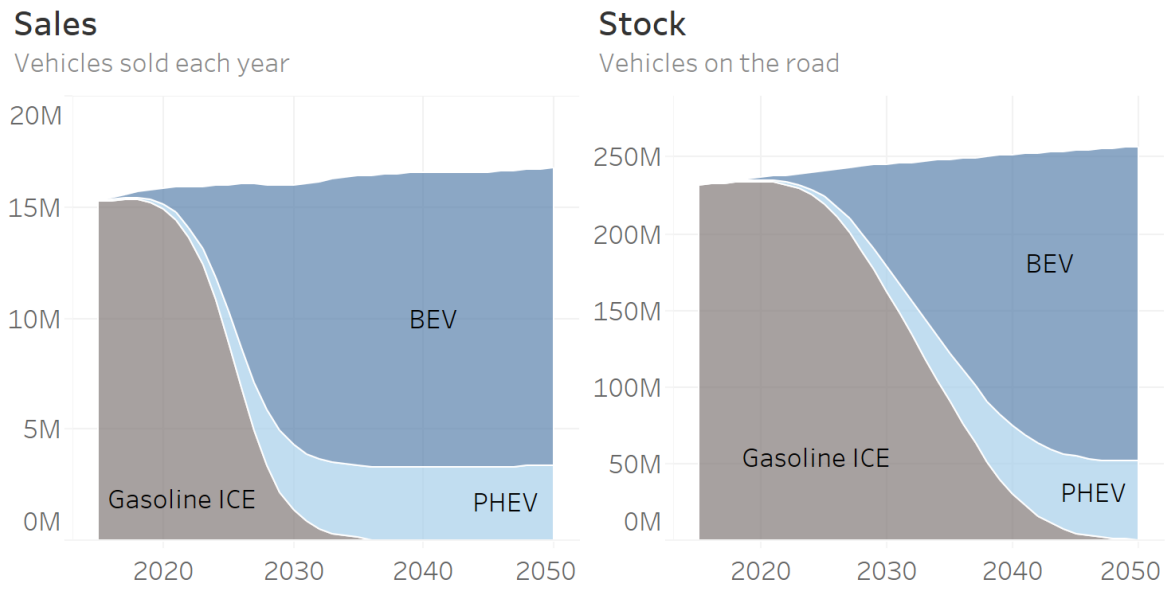
We use EnergyPATHWAYS, a bottom-up energy systems model, to estimate energy demand, emissions and costs for each future energy scenario. Our analysis starts with the same model and approach we have previously used to evaluate deep decarbonization for the United States, the State of Washington and other jurisdictions. We developed a detailed representation of the PGE service territory's energy system, including infrastructure stocks and energy demands for buildings, industry, and transportation. Our analysis incorporates an hourly dispatch of PGE's electricity system, which allows us to better understand fundamental changes to electricity supply and demand, such as how to balance very high levels of intermittent renewables and the impact of electrification on hourly load.

Figure 2 depicts the general structure of EnergyPATHWAYS with the demand- and supply-side of the energy system shown separately. The demand-side calculates the quantity of energy demanded by different services at the technology level, such as the kWh of electricity and therms of pipeline gas demanded by water heaters in the residential sector. The supply-side determines how energy demand is met, such as the share of electricity provided by gas-fired combined cycle power plants, onshore wind power plants and rooftop solar PV. The energy system is simulated in sequence with the demand-side run prior to the supply-side.

Figure 2 General Structure of EnergyPATHWAYS

The demand-side starts with exogenous projections of activity drivers, such as population, households, commercial floorspace and industrial value of output. These drivers serve as the basis for projecting demand for energy services. For example, as the number of total residential households and square footage increases, then the demand for lighting will similarly increase. The technology composition of the stock along with the efficiency of each technology creates a service efficiency. In the lighting example, a transition from incandescent to CFL and LED light bulbs would improve service efficiency. Energy service demand and service efficiency are then combined to calculate the demand for energy, while the fuel type depends on the stock of technologies used to satisfy the demand for energy services.[5]

The supply-side is characterized by an input-output (IO) matrix that specifies the flow of energy between "supply nodes" that produce or deliver energy. Examples of supply nodes include power plants and transmission and distribution infrastructure. The coefficients in the matrix specify the amount of input energy required to produce one unit of output energy. For example, a gas-fired combined cycle power plant with a heat rate of 6,824 Btu/kWh (50% efficiency) would require 2.0 units of natural gas to generate 1.0 unit of electricity. These coefficients are dynamic and reflect: (1) changes in the composition and efficiency of supply-side technologies; and (2) outputs from an hourly electricity dispatch (i.e., the generation mix). From this process, emission factors are developed for each fuel. Finally, the emission factors from the supply-side are combined with final energy demand from the demand-side to estimate system-wide emissions.



To reduce emissions, we develop measures to replace existing demand- and supply-side equipment and infrastructure with efficient and low-carbon technologies. For example, passenger travel currently provided by a gasoline vehicle is replaced by an EV, and a CFL light bulb is replaced by an LED light bulb. Future energy scenarios are designed by combining measures across sectors at the scale and rate necessary to meet the study's emissions target.

We implement measures through a stock rollover process, where a portion of energy infrastructure retires in each year and must be replaced by new energy infrastructure. In a baseline scenario, retiring infrastructure is generally replaced with the same category of technology, but the cost and performance characteristics reflect the more recent installation year (e.g., a retiring reference dishwasher is replaced by a new reference dishwasher). Alternatively, measures specify the composition of new energy infrastructure (e.g., half of vehicle sales are plug-in hybrid electric vehicles by 2025).

The stock rollover process is illustrated for light-duty vehicles in Figure 3, where the measure shown on the left-hand side of the chart specifies that sales of new light-duty vehicles are 80 percent BEV and 20 percent PHEV by 2035. Changes to the vehicle stock, shown on the right-hand side, are moderated by this process and BEV/ZEV vehicles do not make up all vehicles on the road until 2050. All scenarios in this study assume that infrastructure is retired naturally (i.e., at the end of its lifetime), and there are no early retirements.

[5] A portion of electric energy can be dispatched (i.e., flexible load), and this process is modeled on the supply-side.

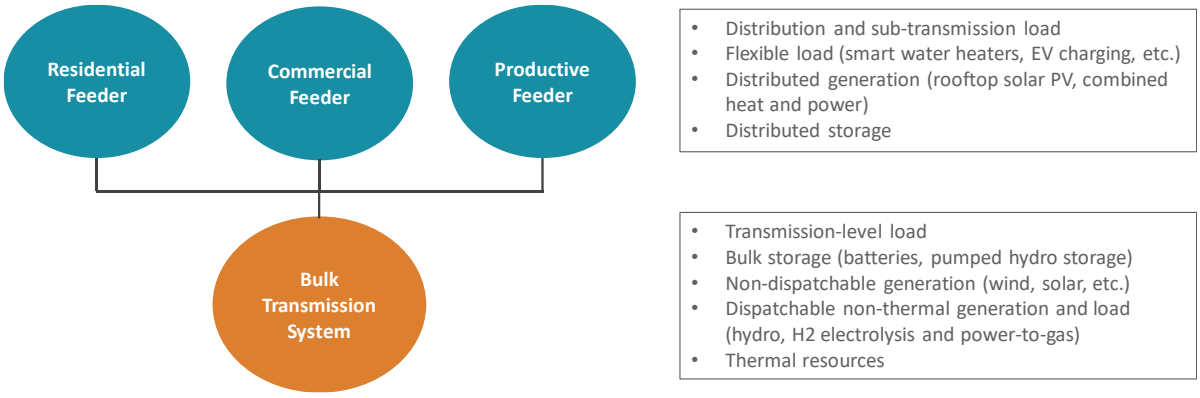


Figure 3 Illustrative Example of Stock Rollover in EnergyPATHWAYS

B. Electricity Sector Modeling

Electricity system operations in EnergyPATHWAYS are modeled on an hourly basis for each year through 2050. This includes a detailed representation of loads and resources at the feeder-level and the bulk transmission system. The structure of the electric system is shown in Figure 4 below, with the boxes illustrating the type of resources included within each node. Electricity dispatch and the development of load shapes are further described below, and we illustrate our approach for a three-day period (February 6-8, 2050).

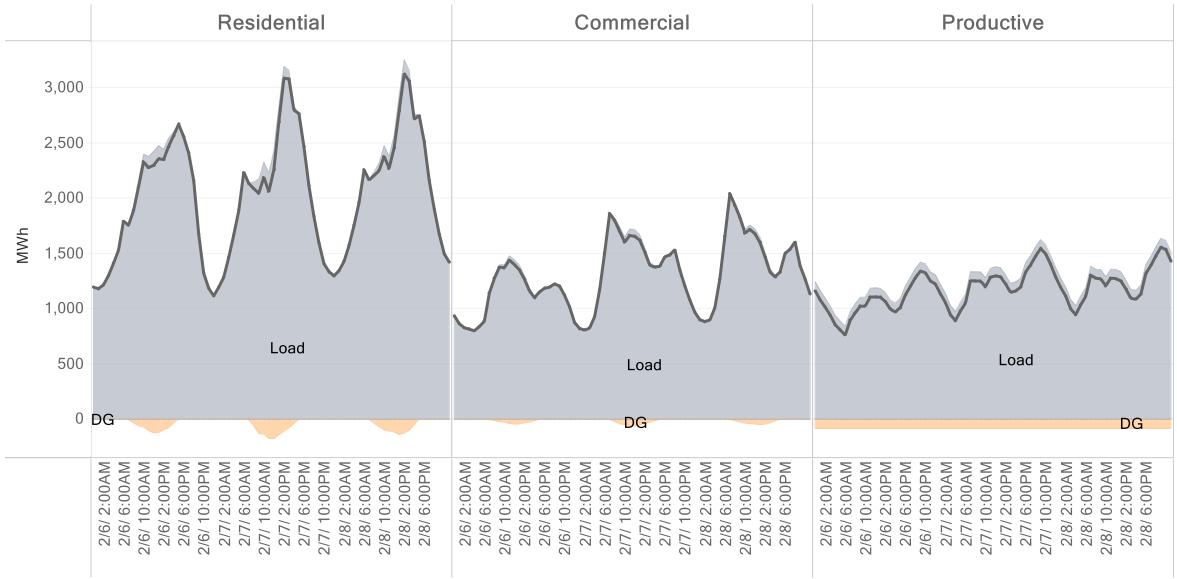

Figure 4 EnergyPATHWAYS Electricity System Structure

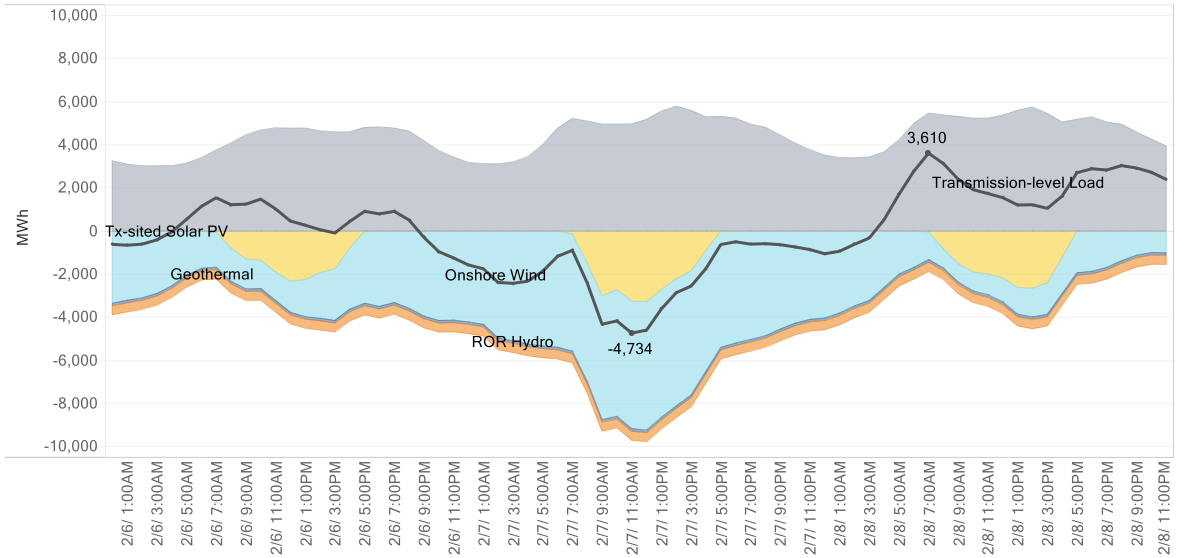
System load shapes are developed from the "bottom-up" by multiplying hourly sector, sub-sector, and technology-specific load shapes by the associated annual electricity consumption.[6] The bottom-up shape is then calibrated against a historical, top-down system load shape. Going forward, the system load shape changes in each year as the contribution from end-uses evolves. For example, as LED lighting penetration increases, then night-time demand will decrease due to their higher efficiency relative to incandescent and CFL light bulbs. In addition, the electrification of space heating will increase electric load during winter hours to account for the contribution of heating during winter months.

Sub-sector loads are aggregated to sectors and mapped to a "stylized" residential, commercial and/or productive (industrial) feeder, which models customer type at the distribution level. This is primarily to allocate electric vehicle charging, which could take place at home or at the workplace, onto the electricity distribution system. Distributed generation, such as combined heat and power (CHP) and rooftop solar PV resources are modeled across feeders. Figure 5 shows load and distributed generation for three feeders with the net load shown as the black line.

Figure 5 Distribution System: Net Load



Note: figure is illustrative.

The bulk transmission system receives the distribution-level net load and combines them with transmission-level loads, such as electrolysis and power-to-gas facilities. Output from non-dispatchable resources on the transmission system, such as wind, solar, geothermal and run-of-river hydro, is then accounted for to produce an initial system net load signal, as shown in Figure 6 below. During this three-day snapshot, the minimum net load in a single hour is -4,734 MW due to the coincidence of high wind and solar generation.

[6] Load and resource shapes reflect 2011 weather conditions.

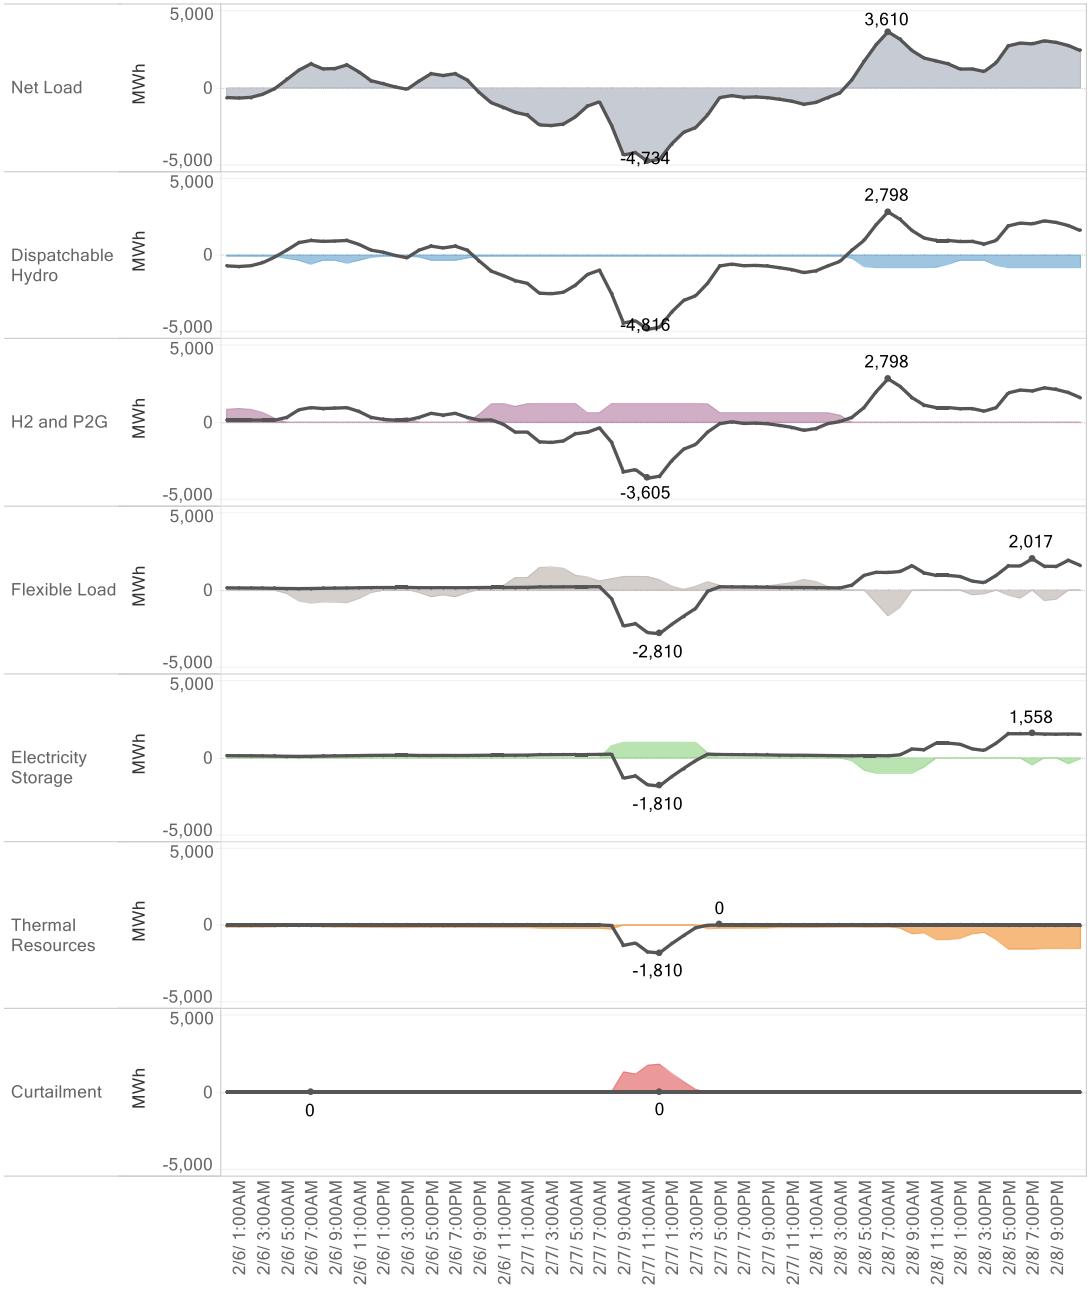


Figure 6 Transmission System: Net Load

Note: figure is illustrative.

Figure 7 illustrates the dispatch of flexible resources in sequence, with each resource dispatching to minimize the net load peaks and valleys. During the three-day period, net load starts with a maximum of 3,610 MW and and a minimum of -4,734 MW. Flexible, carbon-free resources, including dispatchable hydro plants, electric fuel production facilities, flexible loads and energy storage, flatten the net load to a maximum of 1,558 MW and a minimum of -1,810 MW. Thermal generators are dispatched in order of marginal cost to serve the remaining positive net load, while the remaining negative net load is curtailed.

Figure 7 Flexible Resource Dispatch

Note: figure is illustrative.

We model all generation resources in PGE's system, including existing power plants and contracts. The capacity of these resources was provided by PGE, and we developed plant heat rates (efficiencies) for thermal resources based on historical generation and fuel input data from Form EIA-923. Hydro resources are differentiated between dispatchable (e.g., Pelton-Round Butte) and run-of-river, and both resources types are constrained by a monthly energy budget. For imports, we use projected electricity

market prices (in $/MWh) and natural gas prices (in $/MMBtu) provided by PGE to develop market heat rates (in MMBtu/MWh) to both cost and assign an emissions intensity.

We use the following heuristic to ensure the quantity of installed generating capacity meets system load in every hour of the year. First, "annual capacity need" is estimated as the maximum hourly net load plus operating reserves. Next, the installed capacity of dispatchable resources is de-rated by their forced outage rate to estimate their contribution. Finally, generic capacity resources are added to fill any gap between "annual capacity need" and the contribution of dispatchable resources. We assume generic capacity resources have the cost and performance characteristics of a frame type combustion turbine, which is consistent with PGE's IRP.

We note that our modeling results may differ from PGE's IRP due to the use of alternative models and the inclusion of direct access loads in our scope. We describe the electricity resources for each scenario in Section III.B.1 below.

C. Energy Demand and Supply

EnergyPATHWAYS was originally developed to assess deep decarbonization for the United States, and most of the energy demand and supply inputs are drawn from the EIA's National Energy Modeling System (NEMS) that produces the *Annual Energy Outlook*.[7] NEMS input data is comprehensive of the U.S. energy system and internally consistent. The primary geography for energy demand in NEMS is the census division, which each include a collection of states. For example, the Pacific census division includes Washington, Oregon and California, while the Mountain census division aggregates the remaining states in the West.

Given the common input data and energy system representation, EnergyPATHWAYS also uses census division as the primary geography. However, the model is geographically flexible by accepting energy demand and supply input data at a variety of geographical resolutions (e.g., state-level) and mapping these together onto one consistent geography. We used this geographic mapping feature to develop the underlying energy system representation for PGE's service territory. Figure 8 illustrates this process, where energy system data for a variety of geographies is mapped to PGE's service territory. This "downscaled" energy data is combined with direct inputs of PGE's service territory to characterize the entire energy system. To allocate input data at various geographical resolutions to PGE's service territory, we used: (1) households by county in PGE's service territory; (2) land area (in square miles) by county in PGE's service territory; and (3) value of shipments of products by industrial sector by state of origin, which allows us to estimate the quantity of industrial activity within a given subsector and state.[8]

[7] For example, see Risky Business Project (2016).

[8] PGE provided county-level households and land area. Value of shipments data is from the Bureau of Transportation Statistics and Federal Highway Administration's 2015 Freight Analysis Framework.

Figure 8 Geographic Downscaling

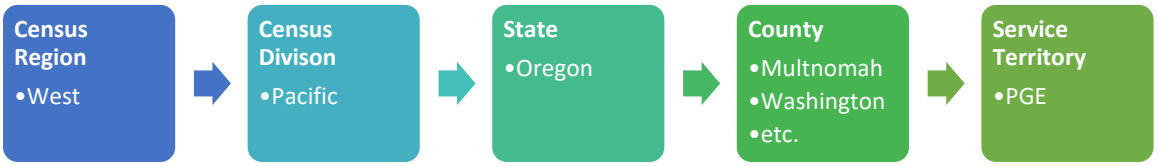

Table 2 summarizes the primary input data sources for energy demand by subsector. We use the 2013 PGE Residential Appliance Saturation Survey (RASS) to characterize the existing stock of the residential space heating, air conditioning and water heating subsectors. This includes the composition of technologies and fuels used in single-family, multi-family and manufactured homes. Energy use intensity (energy consumption per stock) is derived from the EIA's Residential Energy Consumption Survey (RECS) and the Northwest Energy Efficiency Alliance's (NEEA) Residential Building Stock Assessment. Energy demand for the remaining residential subsectors (e.g., refrigerators, dishwashers, etc.) is from the EIA AEO 2017. Vehicle miles traveled (VMT) for light-, medium- and heavy-duty vehicles are from Oregon's 2017 Highway Cost Allocation Study (HCAS), while the remaining energy demand is primarily from the EIA's AEO 2017.

Table 2 Summary of Energy Demand Input Data

Demand Subsector	Input Data Sources	Input Data Geography
Residential Space Conditioning and Water Heating	PGE 2013 RASS Study: existing stocks	Service Territory
	EIA RECS and NEEA: energy use intensity	State
Other Residential Subsectors	EIA AEO 2017: energy demand	Census Division
Commercial Subsectors	NWPCC 7th Power Plan: square footage	State
	EIA AEO 2017: energy demand	Census Division
Industrial Subsectors	EIA AEO 2017: energy demand	Census Region
Passenger and Freight Transportation	2017 Oregon HCAS: vehicle miles traveled	State

We compared the initial bottom-up energy demand projections against top-down energy demand data from the EIA's State Energy Data System (SEDS), which includes historical energy demand by fuel and sector. We calibrated EnergyPATHWAYS to reconcile any differences between our near-term modeling outputs and historical data by scaling energy service demand or energy demand. We further calibrated electricity consumption by sector to ensure consistency with PGE's load forecast through 2050.

Energy demand projections are developed separately for a variety of final energy types, which can broadly be categorized as: (1) electricity; (2) pipeline gas; and (3) liquid fuels.[9] Table 3 summarizes the types of resources that can supply each final energy type, and the supply mix determines the emissions intensity of fuels. For example, electricity can be supplied by a variety of fossil and carbon-free

[9] Additional final energy types are modeled, but these represent the vast majority of final energy demand.

resources, and Section III.B.1 details electricity supply assumptions for PGE's service territory. Pipeline gas can be supplied with a mix of natural gas, renewable natural gas (RNG) produced from bioenergy, hydrogen (H2) produced through electrolysis, and synthetic natural gas (SNG) produced though power-to-gas (P2G). Liquid fuels are supplied by refined fossil sources, as well as fuels developed using bioenergy (i.e., renewable diesel and jet fuel).

Table 3 Final Energy Types and Supply Sources

Category	Final Energy Type	Supply Sources
Electricity	Electricity	Coal and natural gas (fossil); hydro; wind; solar PV; geothermal
Pipeline Gas	Pipeline Gas	Natural gas (fossil); RNG (biomethane); H2; SNG
	Compressed Pipeline Gas (CNG)	
	Liquefied Pipeline Gas (LNG)	
Liquid Fuels	Gasoline	Fossil gasoline; ethanol
	Diesel	Fossil diesel; renewable diesel
	Jet Fuel	Fossil jet fuel; renewable jet fuel

D. Biomass

Biomass is key resource for decarbonizing energy systems due to its versality, which allows for biofuels to directly replace both liquid and gaseous fossil fuels. Examples of conversion routes include renewable natural gas (RNG) that replaces natural gas and renewable diesel that replaces diesel. However, the supply of sustainable or net-zero carbon bioenergy resources is limited, and, in prior analyses, scarce bioenergy resources are allocated to fuels and sectors that are challenging to electrify, such as jet fuel for aviation.

In this study, we use the U.S. Department of Energy's *2016 Billion-Ton Report* as the primary source for the availability and cost of bioenergy resources. Given that the supply curve is for the U.S., we make the following assumptions. First, the PGE service territory's allocation of the national supply is its population-weighted share, which is equal to 7.3 million dry tons (MDT), as shown below:

$$PGE's\ share = \frac{PGE\ population}{U.S.\ population} \times U.S.\ supply\ of\ sustainable\ biomass\ feedstocks$$

$$7.3\ MDT = \frac{1.8\ million}{320.9\ million} \times 1{,}300\ MDT$$

Second, we assume that other jurisdictions pursue similar bioenergy-related actions, which means that the cost of producing and consuming biofuels reflects movement up the national supply curve. This assumption addresses two considerations: (1) for sub-national (e.g., state or utility service territory) deep decarbonization analyses, it would be unrealistic to assume individual jurisdictions all consume the same (low-cost) portion of the bioenergy supply curve; and (2) given the high cost of transporting biomass across long distances, it's likely that biofuels would be developed close to their source and transported across the country via the same networks that currently transport fossil fuels. Finally, we assume that the biomass feedstock is net-zero carbon, which results in biofuels with very low emissions rates due to some emissions from non-bioenergy use in conversion and refining processes.

E. Key Data Sources

Table 4 summarizes the key data sources used in our energy system modeling. We use data from PGE's 2016 IRP to characterize the cost and performance of electricity supply technologies and rely on the 2013 PGE RASS study to characterize the existing stock of residential appliances, as described above. This is supplemented by state and regional data sources, such as Oregon's Office of Economic Analysis (OEA) and the Northwest Energy Efficiency Alliance (NEEA). Most of the remaining sources are publicly-available reports produced by national laboratories, such as the U.S. Department of Energy (DOE).

Table 4 Overview of Key Data Sources

Category	Sources
Energy Supply Technology Cost and Performance	• PGE 2016 Integrated Resource Plan • NREL Annual Technology Baseline 2017 • EIA Form 923 • DOE Hydrogen Analysis (H2A) Project • ENEA Consulting (2016)
End-Use Technology Cost and Performance	• Input data for EIA's National Energy Modeling System (NEMS) used to produce the Annual Energy Outlook • NREL Electrification Futures Study: End-Use Electric Technology Cost and Performance Projections
Building Stock Characteristics	• PGE 2013 Residential Appliance Saturation Study • NEEA Building Stock Assessment reports
Fossil Fuel Prices	• EIA Annual Energy Outlook 2017
Miscellaneous	• DOE 2017 Billion-Ton Report • FERC Form 714 • 2017 Oregon Highway Cost Allocation Study • OEA Forecasts of Oregon's County Populations and Components of Change, 2010 – 2050

Note: DOE is the U.S. Department of Energy; EIA is the U.S. Energy Information Administration; FERC is the Federal Energy Regulatory Commission; NEEA is the Northwest Energy Efficiency Alliance; NREL is National Renewable Energy Laboratory; and OEA is Oregon's Office of Economic Analysis.

III. Scenarios

A. Overview

Table 5 provides an overview of the three pathways included in this study, which each incorporate alternative emissions reduction strategies and technologies. One of the primary objectives of our scenario design was to reflect a broad range of outcomes for the electricity sector.

The **High Electrification** pathway relies on electrifying space and water heating in buildings and deploying bulk energy storage to balance high levels of renewable generation. Passenger transportation is characterized by high levels of battery electric vehicles (BEV), while freight transportation includes both battery electric and hybrid diesel trucks. The **Low Electrification** pathway decarbonizes energy supply with a variety of renewable fuels, and electrolysis and power-to-gas facilities provide both electricity balancing services and decarbonized pipeline gas. Passenger transportation is primarily BEV, while compressed and liquefied natural gas trucks are incorporated in the freight transportation sector. The **High DER** pathway is highly electrified and distributed, with increased rooftop solar PV and distributed energy storage in buildings and industry.

To provide a benchmark to compare the pathways against, we developed a **Reference Case** that projects business-as-usual conditions. This includes compliance with state-level policy such as the OCEP and CFP, as well as major federal policy such as improvements in corporate average fuel economy standards. The scenario is not designed to achieve an emissions target.

Table 5 Overview of Scenarios

Scenario	Description
High Electrification	Fossil fuel consumption is reduced by electrifying end-uses to the extent possible and increasing renewable electricity generation
Low Electrification	Greater use of renewable fuels, notably biofuels and synthetic electric fuels, to satisfy energy demand and reduce emissions
High DER	Distributed energy resources proliferate in homes and businesses, which also realize higher levels of electrification
Reference	A continuation of current and planned policy, and provides a benchmark against the deep decarbonization pathways

Although the future energy scenarios are characterized by alternative mitigation strategies, they are all constrained by a set of common scenario design principles. This conservative approach allays a broad range of concerns surrounding the technical feasibility and economic affordability of realizing a deeply decarbonized energy system, such as the need for revolutionary technological improvements or disruptive lifestyle changes. The scenario design principles in this analysis include: (a) applying the same demand for energy services; (b) replacing energy infrastructure at the end of its natural life (i.e., there are no early retirements); (c) using commercial or near-commercial technologies; (d) limiting the supply of sustainable bioenergy use; and (e) ensuring there are sufficient electricity resources to serve load in all hours. The sections below describe the energy supply and demand assumptions for each pathway.

B. Energy Supply

1. Electricity Resources

Table 6 summarizes our electricity supply assumptions for each pathway. Coal-fired resource assumptions are consistent with PGE's 2016 IRP and OCEP, where Boardman ceases operations by the end of 2020 and Colstrip units 3 and 4 are out of the resource mix by 2035. We assume the capacity of PGE's existing gas-fired resource fleet is online through 2050, while the amount of energy generated from these resources is a function of our electricity dispatch.

Hydroelectric resources include Pelton-Round Butte, run-of-river (ROR) hydro, Mid-C hydro and other contracts. We assume projected hydro resources and contracts are extended through 2050 (a total of 933 MW), and an additional 23 MW of small hydro is placed on-line in 2035. We assume new geothermal resources of 100 MW in 2035 and growing to 500 MW by 2050. Prior studies have identified 832 MW of conventional geothermal potential in Oregon with a further undiscovered enhanced geothermal system potential of 1,800 MW.[10]

The High DER pathway includes approximately 2,500 MW of behind-the-meter (BTM) solar PV resources across buildings and industry by 2050. We developed this target based on the technical potential of distributed solar PV across PGE's service territory identified in the 2016 IRP.[11] The High and Low Electrification pathways assume approximately 400 MW of BTM solar PV, which is two times the highest level of adoption from the same study.

Pathways rely on high levels of transmission-connected wind and solar PV to decarbonize electricity generation, including: (a) onshore wind located in the Pacific Northwest (PNW); (b) onshore wind located in central Montana; and (c) solar PV located in central Oregon. Approximately 75 percent of electricity generation comes from these resources in the High and Low Electrification pathways, and this level is lower in the High DER pathway due to the quantity of BTM solar PV resources. The installed capacity of these resources depends on the level of transmission-connected load.

Our Reference Case reflects current RPS policy (i.e., 50% in 2040) and any gap between the RPS obligation and generation from existing/projected qualifying resources is met with an equal amount of energy from PNW onshore wind and central Oregon utility-scale solar PV resources. Our analysis did not consider low-carbon generation from new carbon capture and storage (CCS) or nuclear resources.

[10] See Pletka and Finn (2009).
[11] See Table 1-3 of Black and Veatch (2015). Technical potential of 2,810 MW_{dc} translated to 2,555 MW_{ac} assuming an inverter loading ratio of 1.1.

Table 6 Electricity Supply

	High Electrification	Low Electrification	High DER
Coal	Boardman ceases operations by the end of 2020 Colstrip 3 and 4 out of the resource mix by 2035		
Gas	Maintain current fleet		
Hydro	Extend projected hydro contracts through 2050 (933 MW) Additional 23 MW of small hydro		
Geothermal	500 MW additional		
Behind-the-meter Solar PV	405 MW_{ac}		2,555 MW_{ac}
Utility-scale Wind and Solar PV	75% of electricity generation		67% of electricity generation

Note: values for 2050 unless specified otherwise.

The high levels of variable renewable generation included in the pathways necessitate balancing resources to ensure renewables are sufficiently integrated. Table 7 summarizes the flexible resource assumptions for each pathway, all of which include 36 MW/160 MWh of energy storage that comes online in 2021 to approximate PGE's proposed energy storage projects. Balancing in the High Electrification pathway is accomplished through 1,000 MW of bulk 8-hour energy storage, whereas the High DER pathway relies on 2,555 MW of distributed 6-hour storage, which is sized to the same capacity of distributed solar PV. No additional energy storage is developed in the Low Electrification pathway, which alternatively relies on flexible electrolysis and P2G loads. The size of these facilities depends on demand for hydrogen and synthetic natural gas, respectively.

All pathways incorporate flexible demand from select end-use sectors where: (a) load automatically shifts with changing electricity grid conditions; and (b) total electricity consumption does not change.[12] For example, the owner of an EV may wish to charge his or her vehicle when they arrive home, but they're willing to delay charging to later in the evening without affecting the ability to take future trips. Two promising electric loads to operate flexibility include: (1) loads that have a thermal storage medium (i.e., hot water heater) that can operate within a range and allow for flexible operation without service degradation; and (2) transportation loads that require battery storage, which can allow for flexible charging and state-of-charge management without degrading service.

We assume 75 percent of load from light-duty vehicles and water heaters in buildings is flexible by 2050, and 50 percent is flexible in residential space conditioning, residential clothes washing and drying, and commercial space heating subsectors. The amount of flexible load in each pathway depends on the level of electrification, and the higher quantity of electric appliances (e.g., heat pump water heaters) in the High Electrification and High DER pathways provides higher end-use demand flexibility relative to the Low Electrification pathway.

[12] Flexible load is further constrained by the number of hours load can be delayed and advanced in time.

Table 7 Balancing Resources

	High Electrification	Low Electrification	High DER
Energy storage	Proposed energy storage resources (36 MW / 160 MWh)		
	1,000 MW bulk 8-hour storage	No additional	2,555 MW distributed 6-hour storage
Flexible Electric Fuel Loads	Excluded	H2 electrolysis and P2G facilities	Excluded
Flexible End-Use Loads	Percent of electric load that is flexible by 2050: • Light duty vehicles = 75% • Residential and commercial water heating = 75% • Residential space conditioning = 50% • Residential clothes washing and drying = 50% • Commercial space heating = 50%		

2. Liquid and Pipeline Gas Fuel Blends

Table 8 summarizes our assumptions about the composition of pipeline gas, diesel and jet fuel in 2050. The Low Electrification pathway is characterized by several renewable fuels to decarbonize energy supply. Pipeline gas for buildings and industry is assumed to contain 15 percent renewable natural gas (RNG) and 15 percent synthetic electric fuels (H2 and SNG). The share of RNG is 85 percent in pipeline gas that is further liquefied or compressed for transportation vehicles, while the share of H2 and SNG is the same. Biomass is further used to produce liquid transportation fuels (e.g., renewable diesel). The High Electrification and High DER pathways assume no change to the supply of pipeline gas, with all biomass resources allocated to liquid transportation fuels.

Table 8 Liquid and Pipeline Gas Fuel Blend Assumptions in 2050

Type	Blend	High Electrification and High DER	Low Electrification	
		All Sectors	Res/Com/Ind	Transportation
Pipeline Gas	Natural Gas	100%	70%	0%
	RNG	0%	15%	85%
	SNG	0%	8%	8%
	H2	0%	7%	7%
Diesel	Fossil Diesel	0%	0%	0%
	Renewable Diesel	100%	100%	100%
Jet Fuel	Fossil Jet Fuel	0%	0%	0%
	Renewable Jet Fuel	100%	100%	100%

C. Energy Demand

1. Buildings and Industry

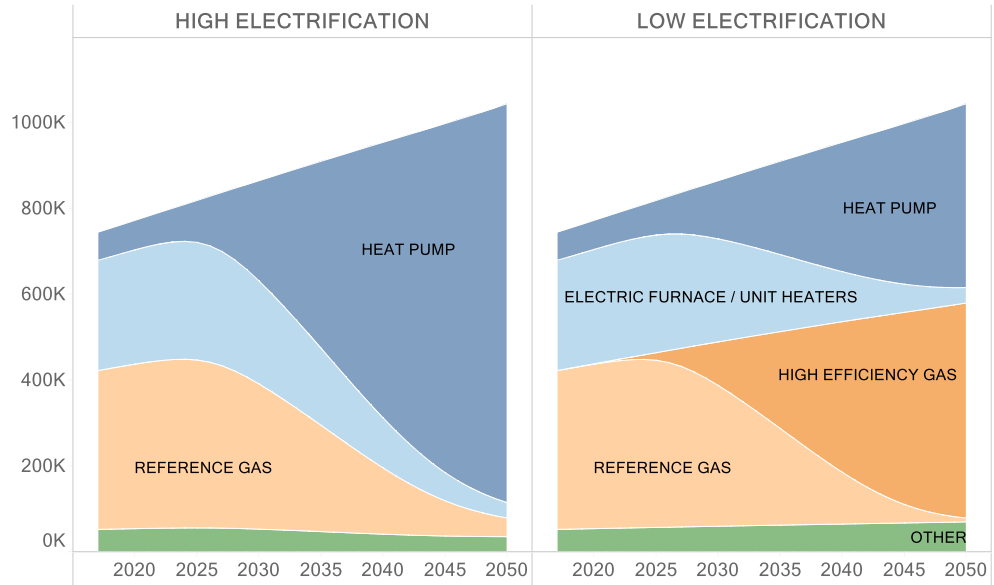

Table 9 summarizes the major low-carbon and efficient technologies in residential and commercial buildings. The High Electrification and High DER pathways are characterized by high levels of air source heat pump (ASHP) adoption for space heating and cooling needs, as well as efficient heat pump water heaters. The Low Electrification pathway relies on high efficiency gas-fired equipment to service space and water heating loads. In both pathways, lighting is provided by LEDs and the best available technology is adopted for other appliances, such as clothes washers, clothes dryers, refrigerators, etc.

Table 9 Predominant End-use Technologies in Buildings

	High Electrification and High DER	Low Electrification
Space Conditioning	Air source heat pump	High efficiency gas furnace High efficiency air conditioner
Water Heating	Heat pump water heater	High efficiency gas water heater
Lighting	LED	
Other Appliances	Best available technology	

We illustrate the change in today's building equipment by showing the evolution of the residential space heating stock through 2050 in Figure 9. Heat in the High Electrification and High DER pathways is largely provided by heat pumps, which includes both standard systems and ductless, mini-split heat pumps. In contrast, heat in the Low Electrification pathway is met by adopting high-efficiency natural gas furnaces, as well as pursuing electric energy efficiency by replacing electric furnaces and heaters with heat pumps.

Figure 9 Residential Space Heating Stock

We incorporated electrification measures in the High Electrification and High DER pathways for a limited number of industrial end-uses, including process heat and boilers. This was informed by NREL's Electrification Futures Study and includes adoption of electrotechnologies such as industrial heat pumps, resistance heating, induction furnaces and electric boilers.[13] These measures translate into electricity representing slightly less than 10 percent of final energy demand for industrial boilers and process heat by 2050.

2. Transportation

Table 10 summarizes our assumptions for vehicle sales shares in 2035 for passenger transportation and freight trucks. In all pathways, battery electric vehicles (BEV) are 90 percent of light-duty vehicle sales, while the remaining 10 percent is: (a) plug-in hybrid electric vehicles (PHEV) in the High Electrification and Higher DER pathways; and (b) hydrogen fuel cell vehicles (HFCV) in the Low Electrification pathway. We assume battery electric trucks account for half of freight truck sales, while the remaining 50 percent is: (a) hybrid diesel trucks consuming renewable diesel fuel in the High Electrification and High DER pathways; and (b) CNG and LNG trucks consuming decarbonized gas in the Low Electrification pathway.

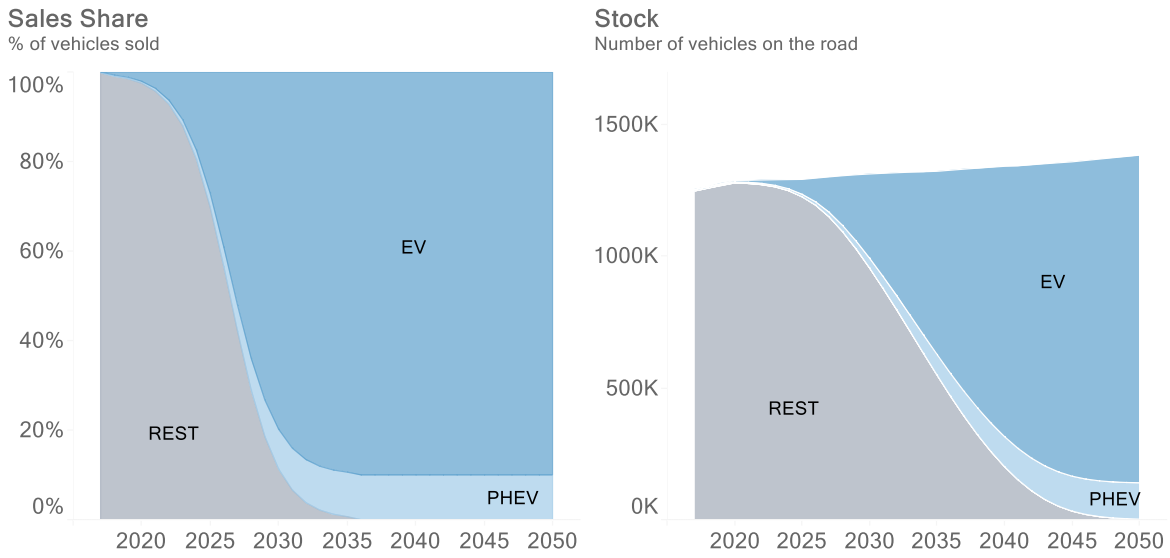

Table 10 On-Road Transportation Vehicle Sales Shares in 2035

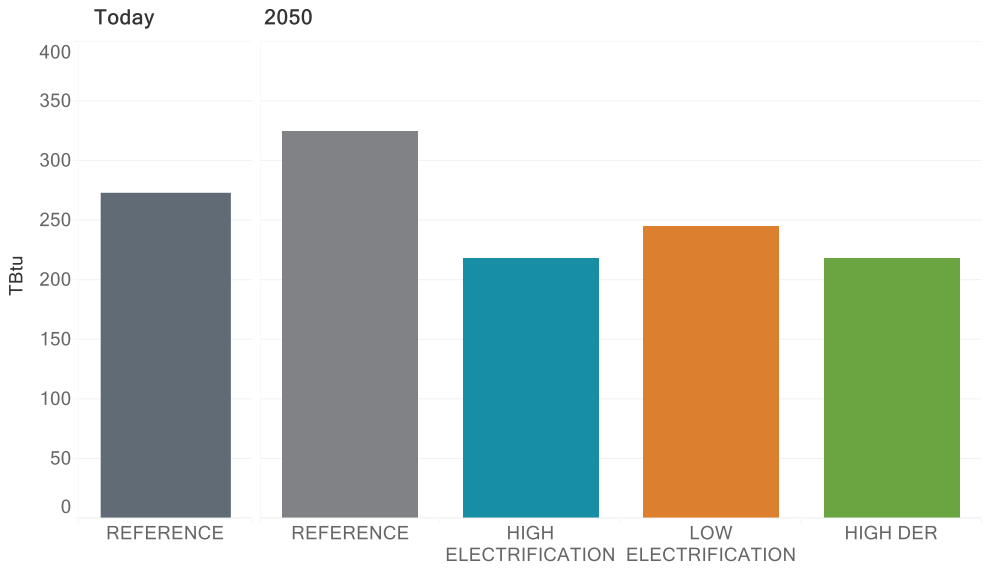
Subsector	Technology Type	High Electrification and High DER	Low Electrification
Light-Duty Vehicles	Battery Electric	90%	90%
	Plug-in Hybrid Electric	10%	0%
	Hydrogen Fuel Cell	0%	10%
Medium-Duty Vehicles	Battery Electric	50%	50%
	Hybrid Diesel	50%	0%
	Hybrid CNG	0%	50%
Heavy-Duty Vehicles	Battery Electric	50%	50%
	Hybrid Diesel	50%	0%
	Hybrid LNG	0%	50%

Figure 10 shows how the assumptions in Table 10 change the stock of infrastructure over time, with light-duty vehicle sales shown on the left-hand side and the light-duty stock shown on the right-hand side. In the near-term, EV and PHEV light-duty autos and trucks make up a small portion of sales, but then increase to all vehicle sales in 2035. By the early 2030s, there are more than half a million EVs and PHEVs on the road, but the stock of vehicles does not completely turn-over to ZEVs until the mid-century.

[13] See Section 4 of P. Jadun, et al. (2017).

Figure 10 Light-Duty Vehicle Stock-Rollover: High Electrification Pathway



IV. Results: Energy System

In this section, we summarize the changes in the energy system for our future energy scenarios. We report several metrics for the energy system, including final energy demand, energy supply, energy related CO_2 emissions, and incremental energy system costs.

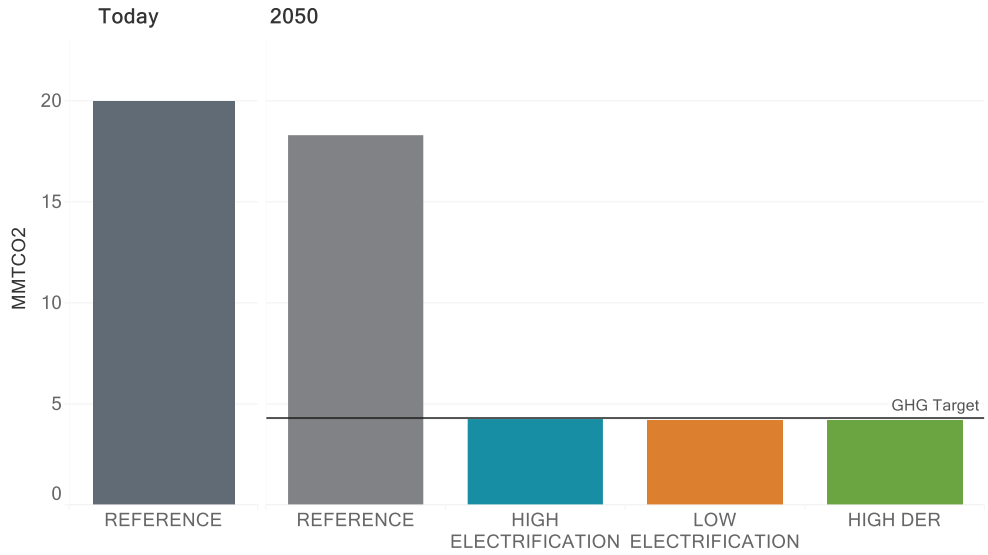
A. High-Level Summary

Reference Case final energy demand is projected to increase from 272 TBtu today to 325 TBtu, approximately a 20 percent increase, as shown in Figure 11 below. End-use demand is projected to increase as the drivers of energy use, such as population and economic activity, all grow through 2050. Final energy is used more efficiently in the pathways scenarios with a range of 218 to 245 TBtu by 2050, which represents a decrease of 25 to 33 percent below the Reference Case in 2050, and 11 to 19 percent below today's level.

Figure 11 Final Energy Demand

Energy-related CO_2 emissions are projected to slightly decrease (-4%) in the Reference Case between 2017 and 2050, as shown in Figure 12. This is largely due to existing policies decarbonizing electricity generation and transportation fuels being offset by growth in overall electricity consumption and vehicle miles traveled. Emissions for all three pathways are below the study's 2050 GHG target of 4.3 $MMTCO_2$. Emissions per capita decrease from 10.9 tCO_2 per person in 2017 to 1.6 tCO_2 per person in 2050, an 85 percent decrease.

Figure 12 Energy-related CO_2 Emissions



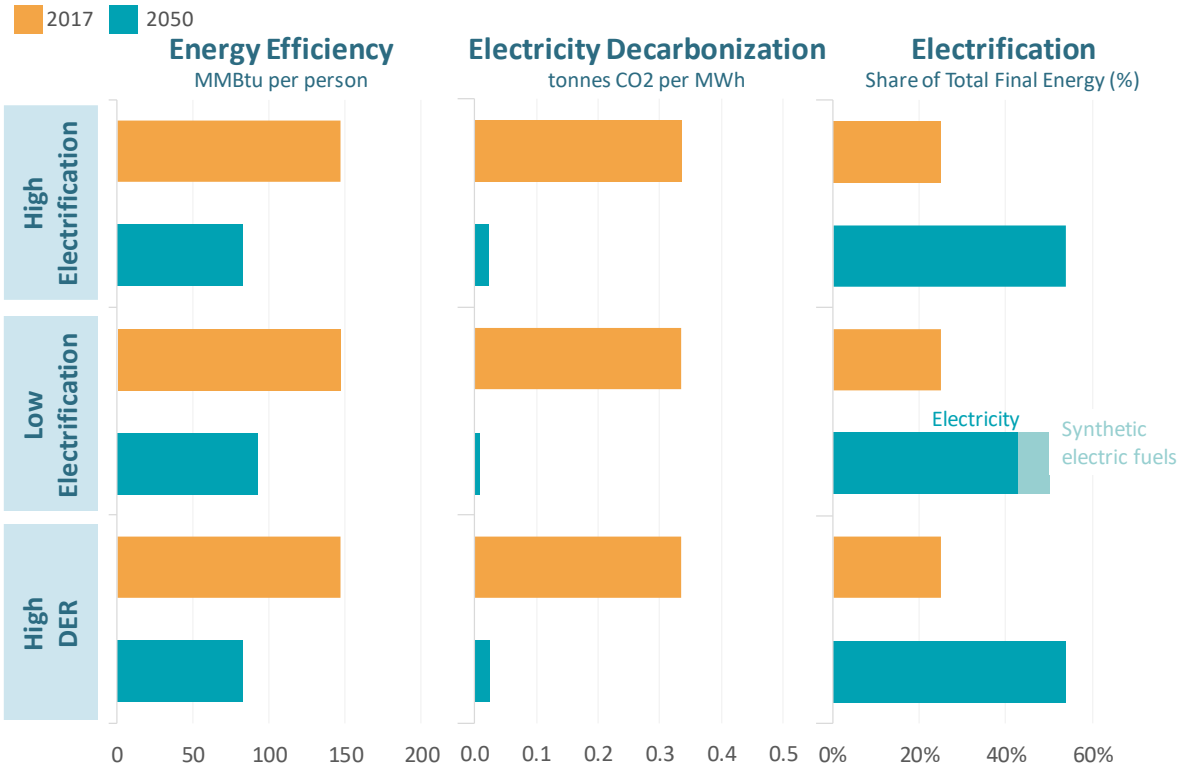


Figure 13 shows three metrics for decarbonization strategies ("three pillars"): (1) energy efficiency, which is estimated as final energy consumed per person; (2) electricity decarbonization, which is measured in tCO_2 emitted per MWh of generation; and (3) electrification, which is expressed as the share of total final energy that is electricity and electric fuels. Per capita energy consumption decreases from approximately 150 MMBtu per person today to between 83 and 93 MMBtu per person, a 37 to 44 percent decrease. This is accomplished without explicit reductions from baseline (Reference Case) energy service demand (e.g., vehicle miles traveled). The carbon intensity of electricity generation decreases by more than 90 percent and is below 0.03 tCO_2/MWh (300 kg CO_2/MWh) in all pathways. The percentage of electricity and electric fuels in total final energy increases from one-quarter today to at least half by 2050. In the Low Electrification pathway, the share of electricity is 43 percent (11 percentage points below the High Electrification pathway), but electric fuels make up 7 percent of total final energy, resulting in a total of 50 percent.

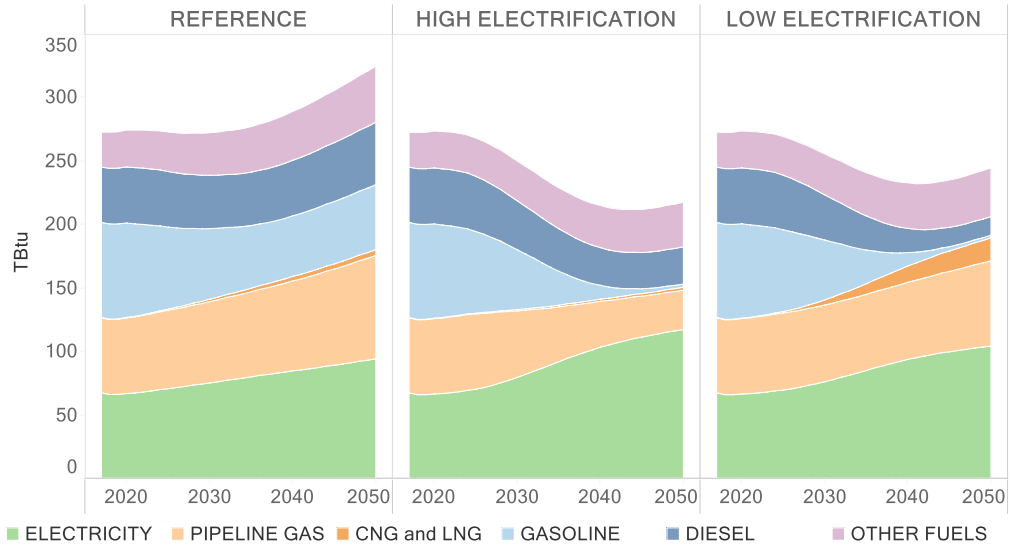
Figure 13 Three Pillars of Decarbonization



B. Energy Demand

Figure 14 shows end-use demand disaggregated by final energy type for each energy future.[14] The role of electricity expands across all pathways and increases from 25 percent of total end-use demand to 43 to 54 percent in 2050.[15] For comparison, the share of electricity only increases to 29 percent by 2050 in the Reference Case. Demand for liquid transportation fuels, such as gasoline and diesel, sharply decrease in all pathways. This decrease is compensated by higher demand for electricity, as well as CNG and LNG demand in freight transportation in the Low Electrification pathway.

[14] In this section, results for the High DER scenario are not shown, because final energy demand is equivalent to the High Electrification scenario. The impact of increased rooftop solar PV is accounted for when we show retail energy deliveries, which is discussed in Section V.A.

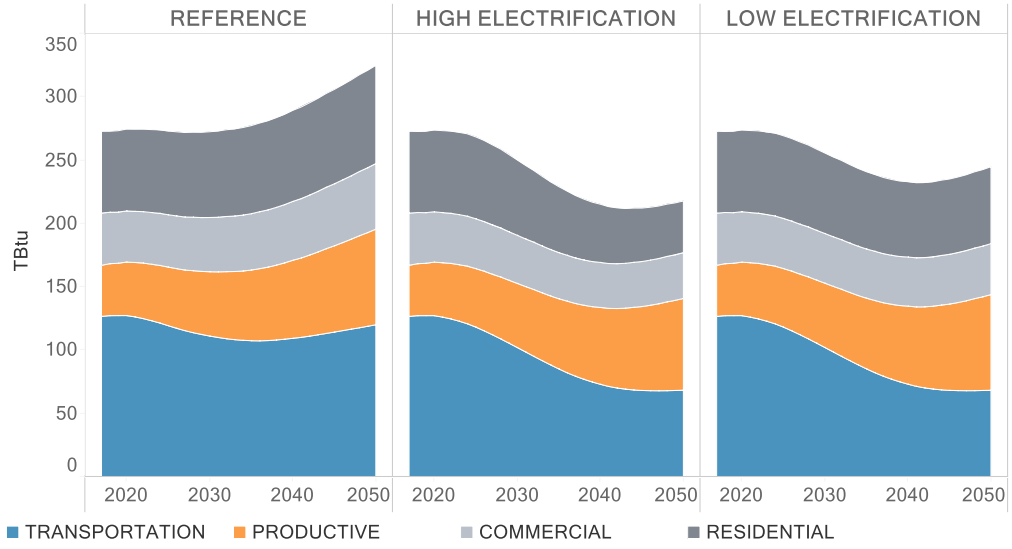
[15] This excludes synthetic electric fuels, which are categorized as "intermediate energy carriers".

Figure 14 Final Energy Demand by Type

Note: "Other Fuels" includes final energy types such as jet fuel, liquefied petroleum gas, biomass, and steam.

Figure 15 summarizes final energy demand for the residential, commercial, productive and transportation sectors. The figure shows Reference Case final energy demand growing over time, with decreases in the transportation sector (primarily due to fuel economy standards) offset by increases in buildings and industry. Total end-use demand decreases by 2050 for all pathways largely due to the efficiency improvements in passenger transportation related to adopting battery electric vehicles. As a result, the transportation sector's share of end-use demand decreases from approximately 46 percent today to 30 percent in 2050. Energy is used more efficiently in residential and commercial buildings, but the level of change varies across pathways based on technology adoption, which we discuss in more detail below.

Figure 15 Final Energy Demand by Sector



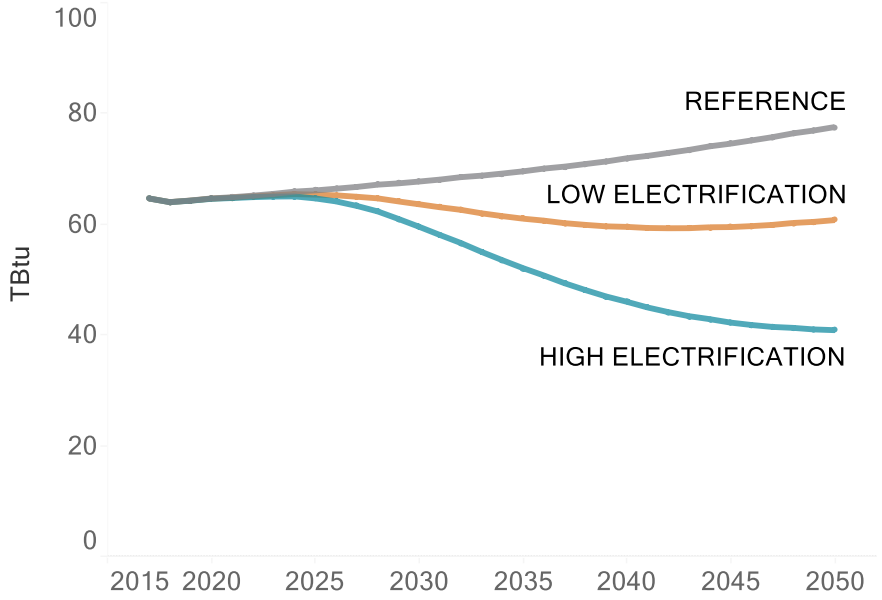


Figure 16 compares projections of residential energy demand and illustrates the improved use of energy in homes in the pathways scenarios relative to the Reference Case. All pathways include several electric energy efficiency measures, such as more efficient clothes washers and dryers, refrigerators, dishwashers and LED lighting. However, the large difference in final energy demand by 2050 between the High and Low Electrification scenarios is due to choices in space and water heating. The High Electrification pathway represents a world where households replace combustion-based furnaces and water heaters with air source heat pumps and heat pump water heaters, respectively. In the Low Electrification pathway, households adopt the most efficient gas furnaces and gas water heaters. However, the efficiency of heat pump technology relative to the best-in-class combustion equipment translates into deeper energy demand reductions.[16]

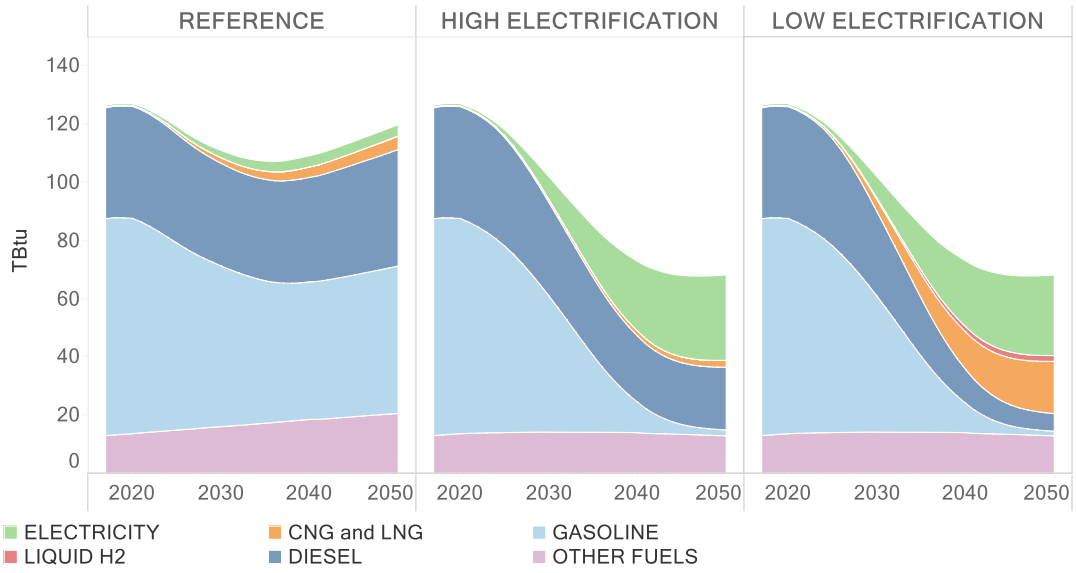

Figure 16 Residential Sector Energy Demand

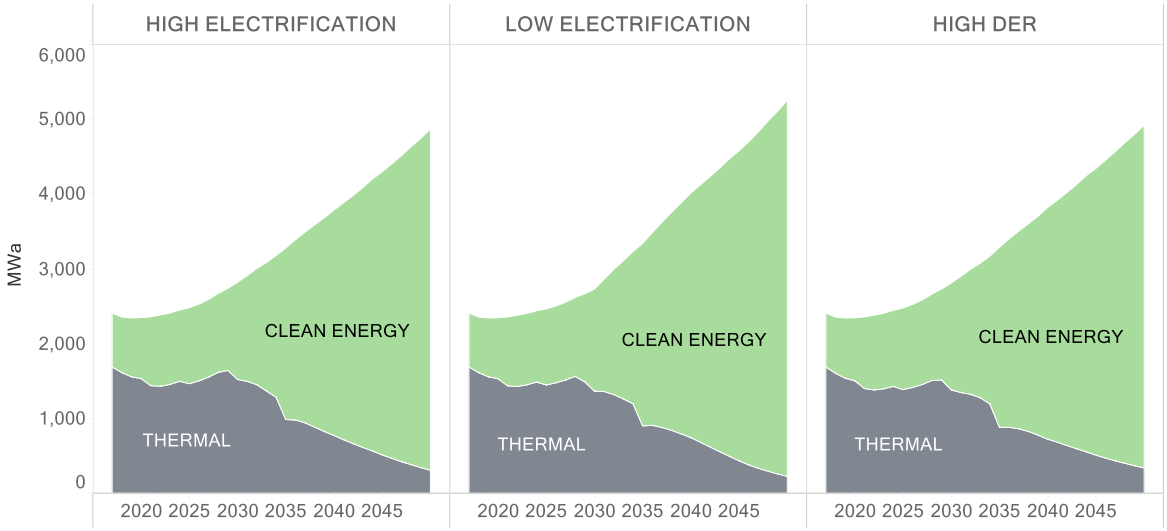
The projections of energy demand for the transportation sector shown in Figure 17 reflect the changing composition of vehicles on the road. By 2050, the light-duty vehicle fleet is almost entirely electric vehicles, which results in significant decreases in gasoline fuel consumption and only modest increases in electricity consumption, because battery electric powertrains are more efficient than internal combustion engines. In all pathways, half of all freight trucks are electric by 2050, resulting in electricity becoming the largest transportation fuel type. The High Electrification pathway continues to use diesel fuel for the remainder of its freight trucks, but the supply is increasingly renewable diesel (100 percent by 2050). The Low Electrification pathway alternatively relies on hybrid CNG medium-duty trucks and LNG hybrid heavy-duty trucks. By 2050, demand from the CNG and LNG trucks in the Low Electrification pathway accounts for over 20 percent of total pipeline gas demand.

[16] For example, a high efficiency gas furnace has an annual fuel utilization efficiency (AFUE) of 0.98, whereas a standard air source heat pump installed in 2015 in the U.S. has a seasonal coefficient of performance (COP) of 2.45 and this is projected to increase to 3.75 by 2030. See Navigant Consulting (2014) and Jadun, et al. (2017).

Figure 17 Transportation Sector Energy Demand by Final Energy Type



C. Energy Supply

1. Electricity

Figure 18 summarizes electricity supply through 2050, with generation from various resource types categorized as: (a) thermal, which includes generation from coal- and gas-fired resources, generic capacity and market purchases; and (b) clean energy, which includes generation from wind, solar, hydro and geothermal resources.[17] The figure shows that total electricity generation across all pathways grows rapidly, and total generation requirements in 2050 are more than double today's level. In all pathways, generation from non-emitting resources is more than 90 percent of the total and increases by 165 to 190 MWa per year between 2030 and 2050. Generation from thermal resources decreases significantly after 2035, and annual generation falls between 300 and 400 MWa by 2050.

[17] Our generation projections are not directly comparable to PGE's most recent IRP dispatch modeling due to the vintage of the load forecast provided for this study and the inclusion of direct access loads.

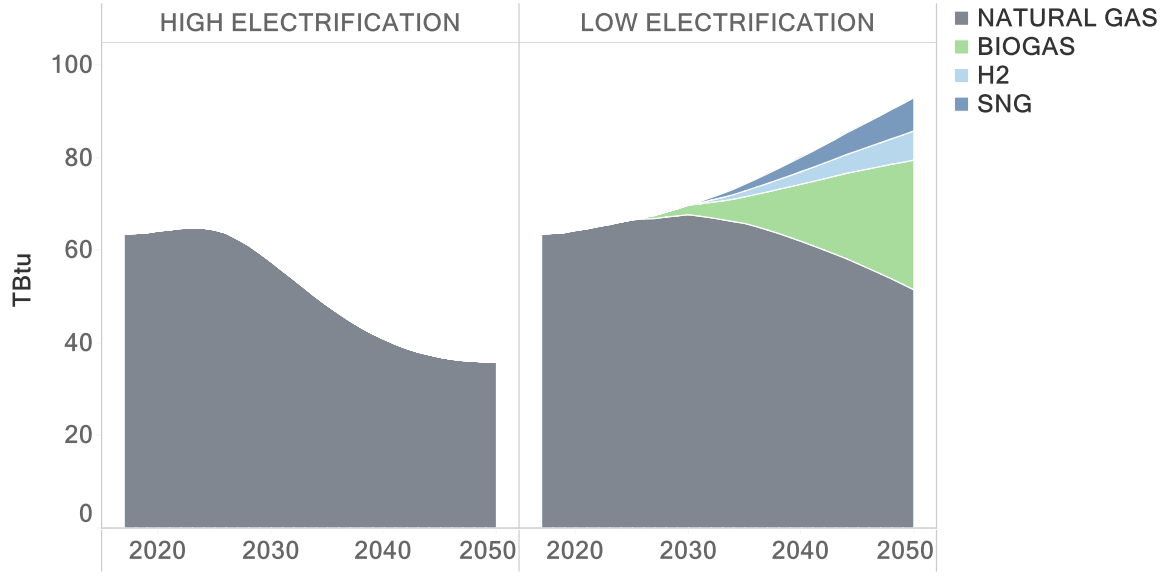


Figure 18 Electricity Supply

2. Pipeline Gas

Figure 19 compares pipeline gas supply for the High Electrification and Low Electrification pathways. In the High Electrification pathway, the pipeline gas supply remains entirely natural gas and total supply decreases by more than 40 percent relative to today due to electrification in buildings. Pipeline gas is decarbonized in the Low Electrification pathway with a combination of biogas and synthetic electric fuels, which reduces the share of natural gas to approximately 55 percent by 2050. Total gas supply increases by approximately 40 percent relative to today largely due to incremental gas demand from freight trucks with only a portion offset by more efficient use of pipeline gas in buildings.

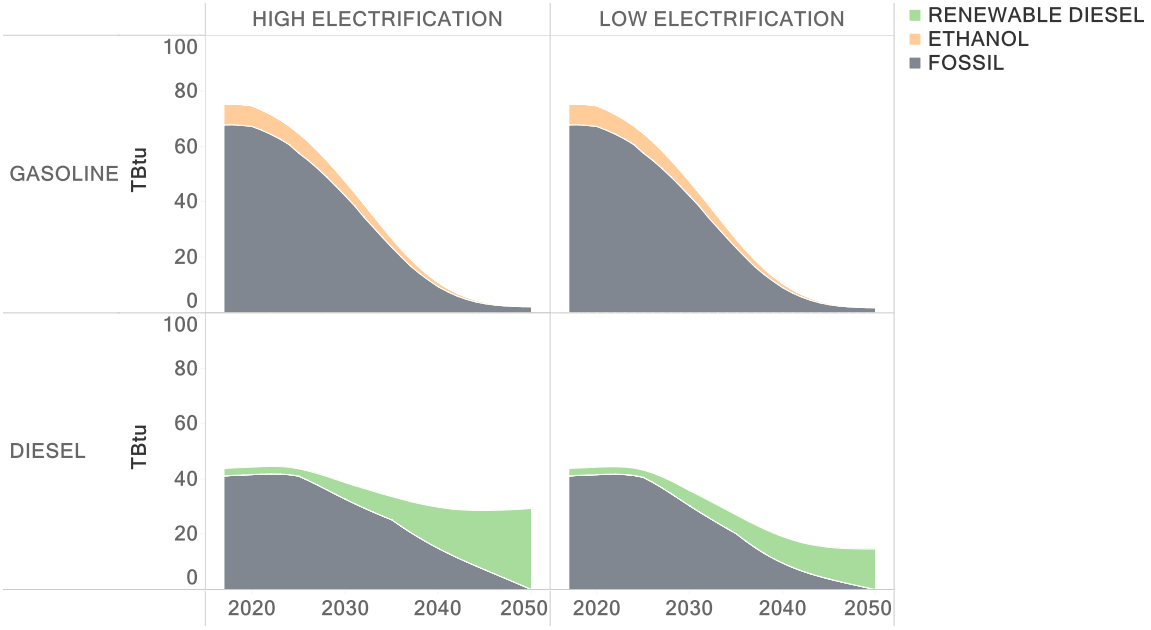

Figure 19 Pipeline Gas Supply

3. Liquid Fuels

Figure 20 summarizes the supply of today's two largest liquid fuels: gasoline and diesel. The supply of gasoline decreases by more than 95 percent by 2050 due to adoption of BEV, PHEV and HFCV vehicles in passenger transportation. Diesel remains a major fuel type in the High Electrification pathway, where half of freight trucks are hybrid diesel trucks. However, diesel supply transitions to 100 percent renewable diesel by 2050. The same supply transition occurs in the Low Electrification pathway, but total demand decreases by two-thirds by 2050 relative to today due to a shift from diesel trucks towards LNG and CNG freight trucks.

Figure 20 Liquid Fuels Supply

D. Energy-related CO_2 Emissions

Figure 21 and Figure 22 summarize energy-related CO_2 emissions by sector and energy type, respectively. The transportation sector's emissions, which is the largest source of emissions today, decrease by more than 90 percent across all pathways. This is the largest reduction by sector and total transportation emissions are less than the combined emissions from residential and commercial buildings by 2050. The transportation sector is primarily decarbonized through the following strategies: (1) electrification of passenger vehicles and freight trucks paired with very low-carbon electricity generation; and (2) decarbonization of liquid and gaseous fuels supplying the remaining fleet of freight trucks with bioenergy. The productive sector contains the largest remaining CO_2 emissions by 2050, and these are primarily from the direction combustion of fossil fuels, as opposed to emissions associated with electricity consumption. Most of the residual emissions in buildings are from combusting pipeline gas, and these are 50 percent higher in the Low Electrification pathway relative to the other pathways.

Figure 21 CO_2 Emissions by Sector

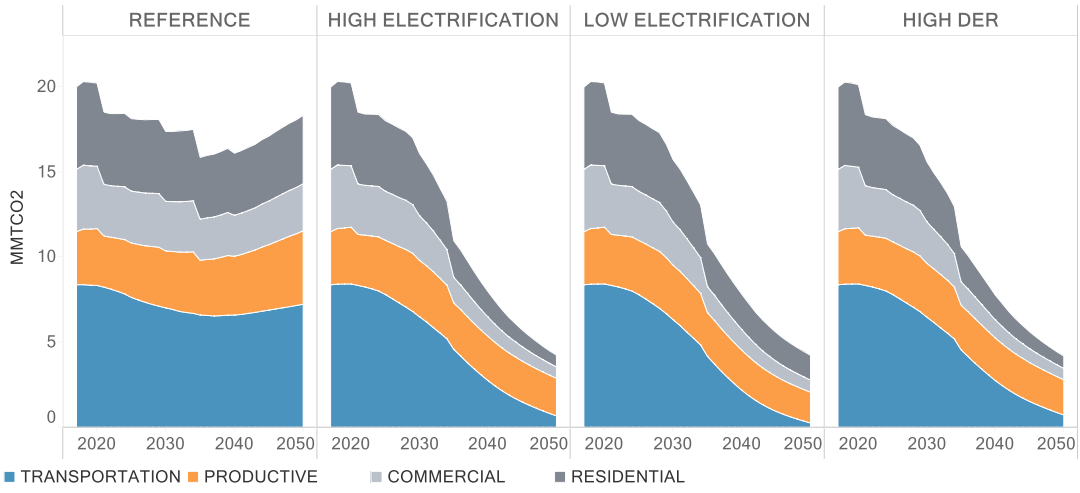

Figure 22 CO_2 Emissions by Energy Type

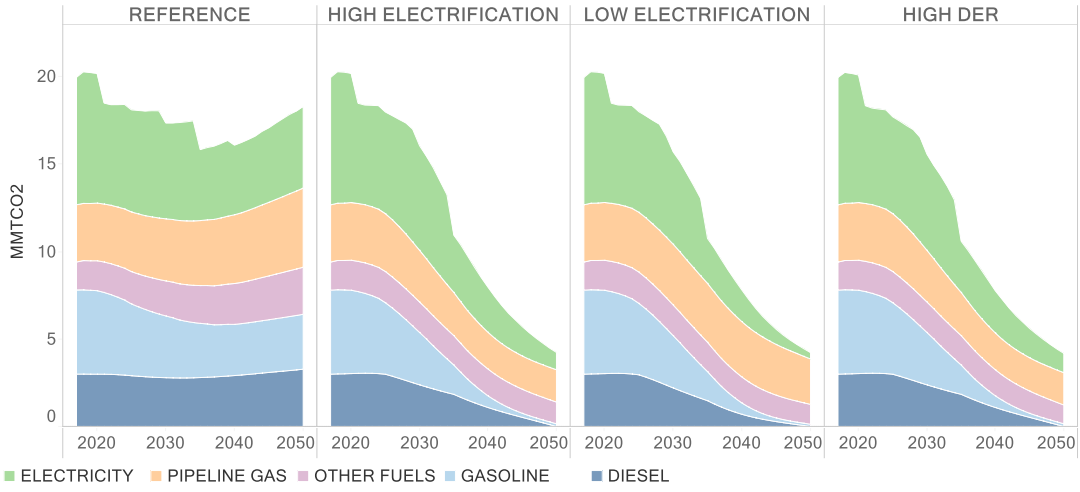

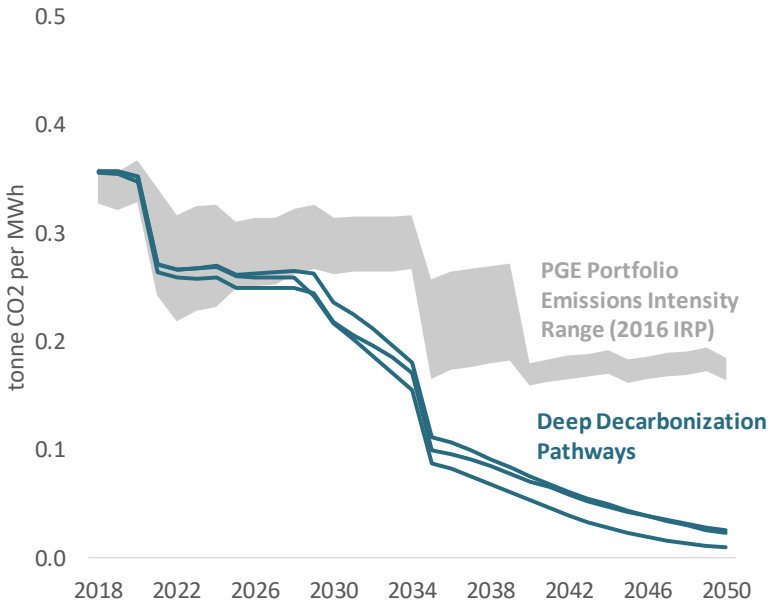

Figure 23 compares the emissions intensity of electricity generation from the three pathways against the range of PGE's portfolio from the 2016 IRP. Both projections decrease over time, with noticeable drops in 2020 and 2035 due to the assumed phase out of coal-fired electricity supply. The emissions intensity in the pathways scenarios begins to aggressively decrease beginning in the mid-2020s, and, relative to the minimum of the range, is at least 33 percent lower in 2035 and more than 85 percent lower by 2050. In 2050, the emissions intensity is below 0.03 tCO_2/MWh for all pathways, while the 2016 IRP ranges from 0.16 to 0.19 tCO_2/MWh.

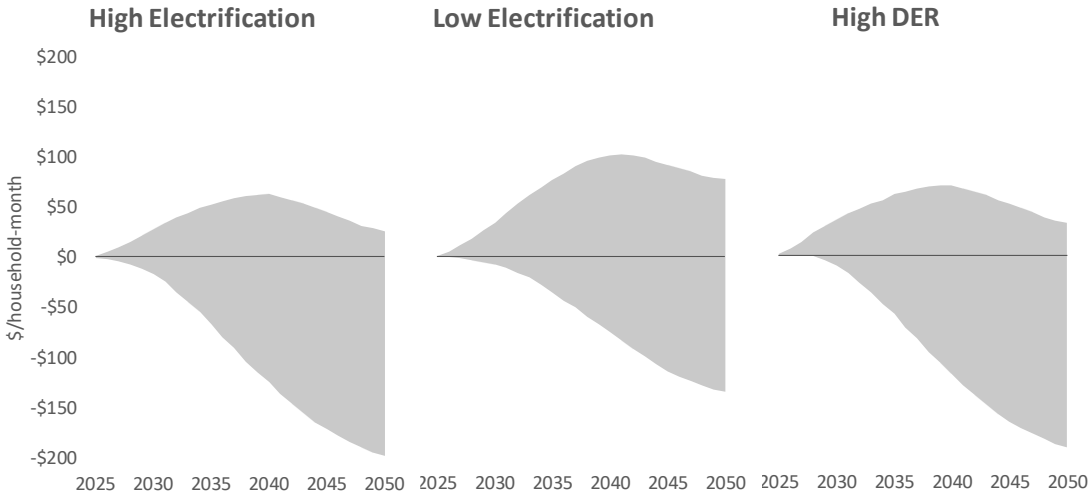
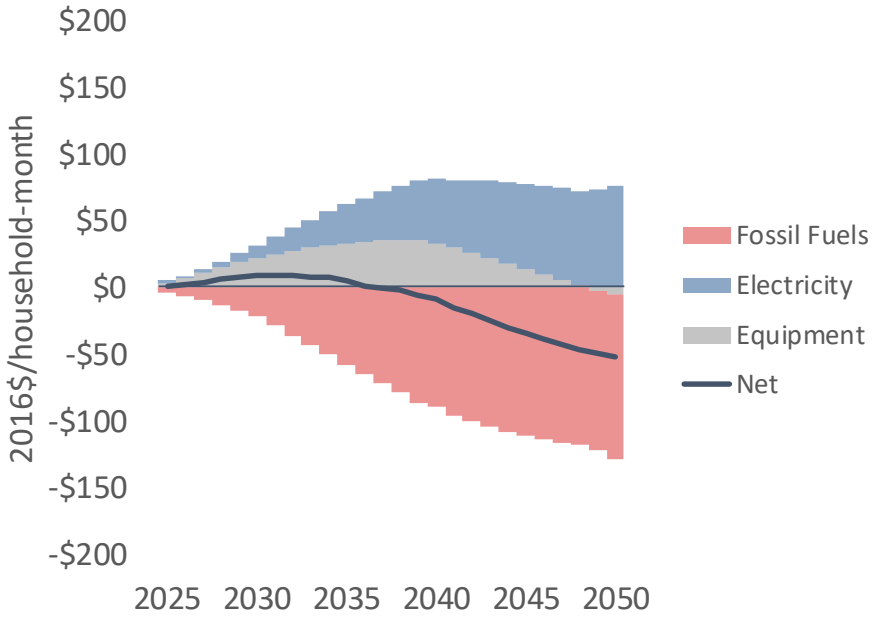
Figure 23 Emissions Intensity of Electricity Generation



E. Energy System Costs

We measure the cost of transitioninig towards a low-carbon energy economy by comparing the incremental cost of investment in low-carbon and efficient equipment and infrastructure against the savings from avoiding fossil fuel purchases. This is calculated by taking the difference in energy system-related costs between a pathway scenario and the Reference Case. We exclude costs outside of the energy system, as well as benefits from avoiding climate change and air polution.

The annual, incremental cost for households is shown in Figure 24, which includes: (a) the annualized cost of appliances (e.g., high efficiency dishwasher); (b) the annualized cost associated with passenger transportation (e.g., electric vehicle); and (c) energy costs associated with using the equipment (e.g., gasoline for a vehicle and electricity for lighting). Given the challenge of projecting relative costs through a long study horizon (i.e., 2050), we show the results across a range of alternative fossil fuel price and end-use electric technology cost projections.[18] Year-to-year variations are due to: (a) the timing of investment needs; and (b) the assumed projections of technology costs and fuel prices. The range of uncertainties encompass both net cost increases and net cost decreases (savings) by 2050.

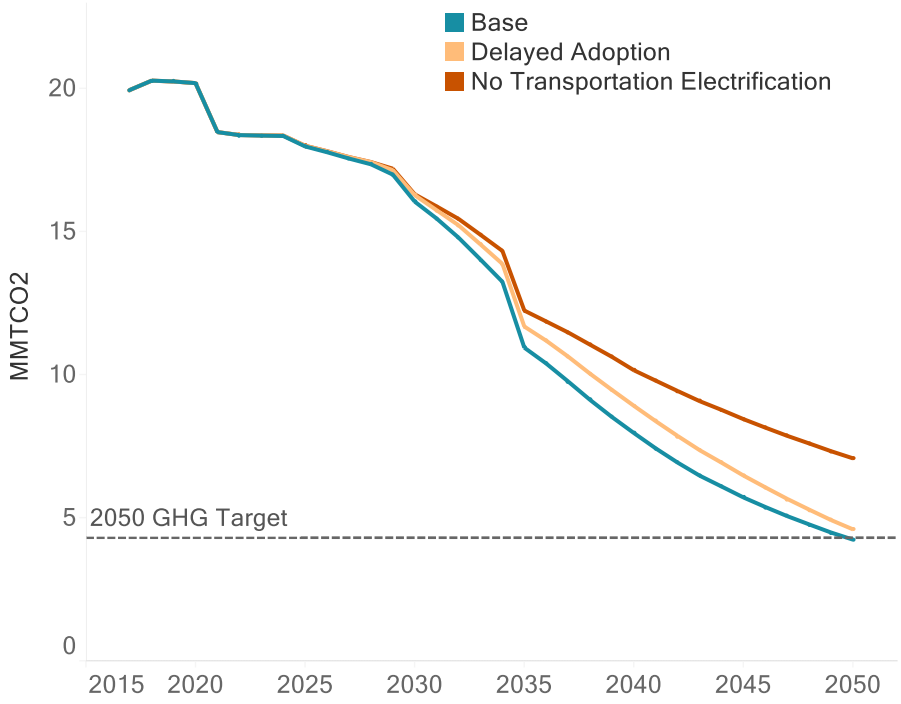


[18] Range of fossil fuel price projections are from the EIA's *Annual Energy Outlook 2017* and end-use electric technology cost projections are from NREL's *Electrification Futures Study*.

Figure 24 Range of Incremental Household Costs

Incremental household costs reflect the underlying changes in the energy system, such as: (a) increased spending on efficient end-use equipment (fixed costs); (b) increased spending on clean electricity infrastructure (fixed costs); and (c) decreased spending on fossil fuel costs (variable costs). Figure 25 illustrates how the structure of incremental household costs evolve over time for the High Electrification pathway under base fossil fuel price and end-use electric technology cost assumptions. Between 2025 and 2050, the average household spends additional money on equipment, such as an electric vehicle, air source heat pump and heat pump hot water heater, as well as additional money to power their equipment with clean electricity, including renewable power plants and transmission/distribution network upgrades. Meanwhile, households spend less money on fossil fuels, such as: (1) gasoline and diesel for their cars and trucks; and (2) natural gas for space and water heating.

Figure 25 Incremental Household Costs by Component: High Electrification Pathway

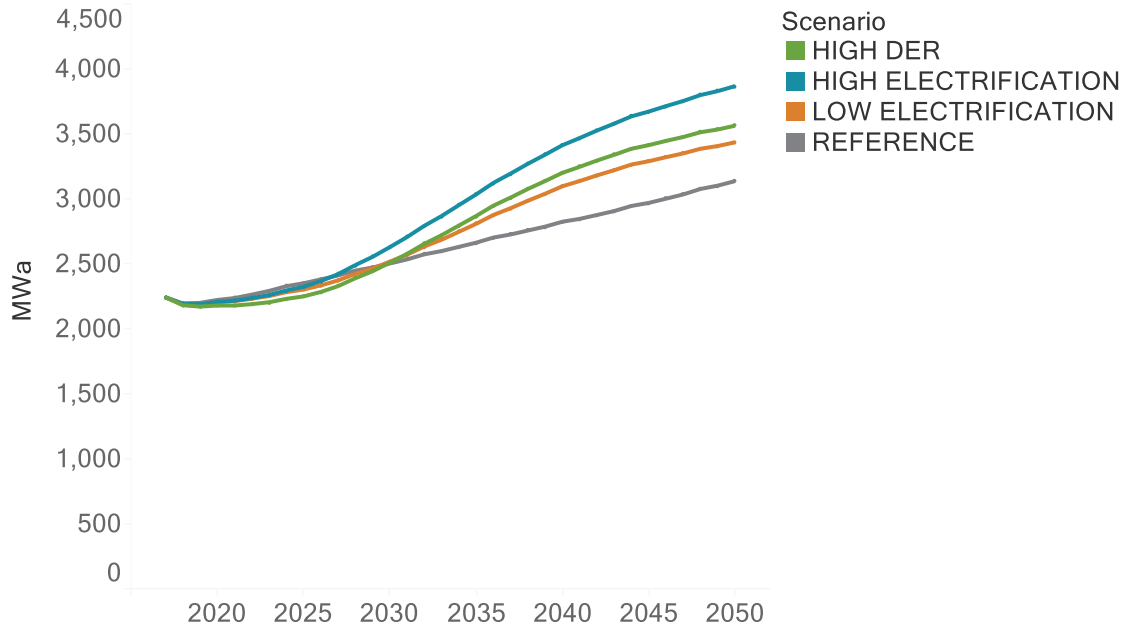


F. Transportation Electrification Sensitivity Analysis

Decarbonizing the transportation sector is essential to realizing economy-wide GHG reduction goals, and the pathways outlined above rely on passenger and freight transportation electrification. This requires aggressive consumer adoption by the mid-2030s for the fleet of vehicles on the road in 2050 to have the necessary low-carbon attributes. In the High Electrification pathway, 100 percent of light-duty vehicle sales are BEV or PHEV by 2035 and 50 percent of medium- and heavy-duty vehicle sales are BEV by 2035. To assess the importance of these aggressive transportation electrification strategies, we tested two sensitivities: (1) delay the assumed year of 100 percent BEV/PHEV adoption for light-duty vehicles from 2035 to 2050 ("Delayed Adoption"); and (2) remove all passenger and freight transportation electrification measures ("No Transportation Electrification").

Figure 26 shows the difference in CO_2 emissions between the High Electrification pathway ("Base") and the two sensitivities. The figure shows that delaying adoption of EVs in passenger transportation increases emissions in 2050 by 8 percent or 0.36 $MMTCO_2$, which results in the pathway no longer complying with the study's 2050 GHG target. This is because more than 10 percent of cars and trucks on the road in 2050 still consume petroleum rather than clean electricity as their fuel. CO_2 emissions increase by two-thirds without any transportation electrification (above 7 $MMTCO_2$) and the sensitivity does not achieve the emissions reductions necessary to meet the 2050 GHG target. We also note that the increase in emissions is partially mitigated through increased renewable diesel consumption by freight trucks (i.e., diesel freight trucks that transition to electric freight trucks in the base case now consume renewable diesel). However, the amount of bioenergy in this sensitivity exceeds the limit described in Section II.D, and, if strictly enforced, then emissions would be higher than shown here.

Figure 26 Energy-related CO_2 Emissions: Transportation Electrification Sensitivities



V. Results: Electricity System

This section summarizes results for the electricity system, including load, resources and hourly system operations. We also report the sensitivity of the results to variations in flexible end-use load, flexible electric fuel production, battery energy storage and pumped hydro storage assumptions.

A. Load

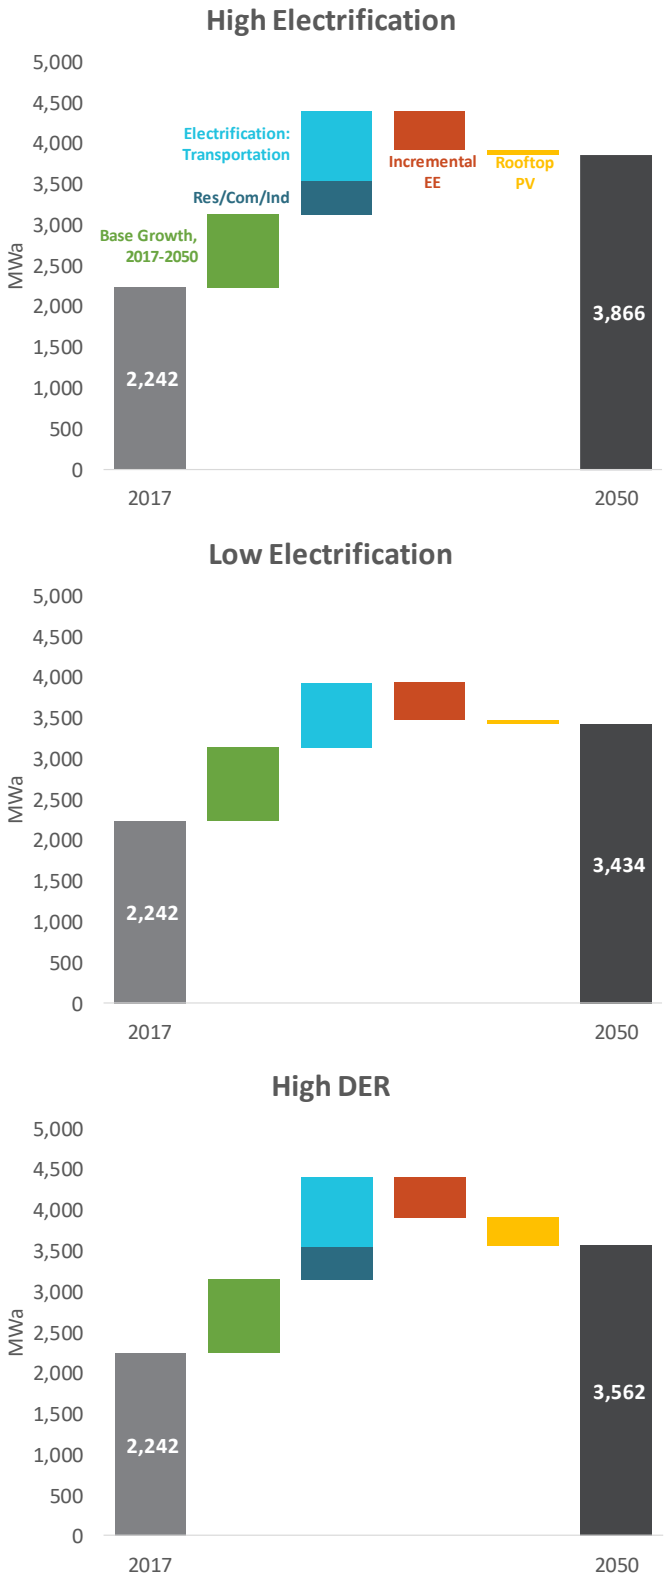


Figure 27 shows the trajectory of retail electricity sales for each scenario through 2050. In the long-run, retail sales in all pathways are higher than the Reference Case, and, as expected, the High Electrification pathway is the highest. Deployment of rooftop solar PV resources in the High DER pathway partially offsets end-use electrification measures, resulting in retail sales that are slightly above the Low Electrification pathway in 2050. Relative to today, retail sales increase by 50 to 70 percent by 2050.

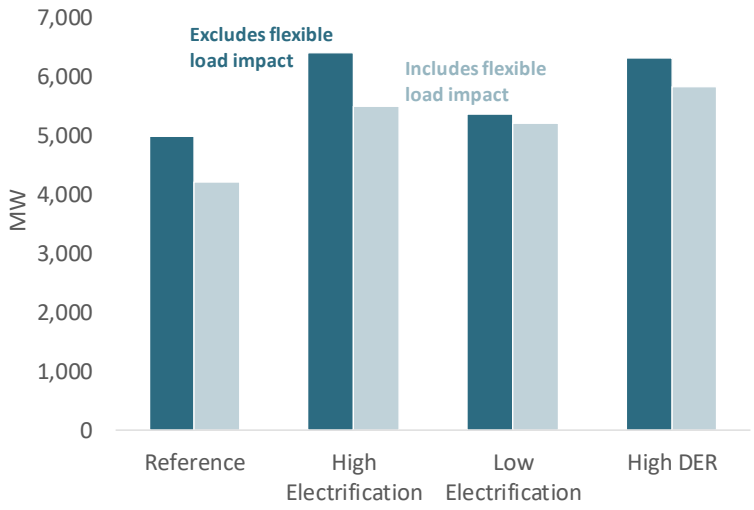
Figure 27 Retail Electricity Sales



The components of the change in retail sales between 2017 and 2050 are shown in Figure 28, which separates: (a) baseline growth (i.e., growth that is embedded in the Reference Case); (b) electrification of buildings and industry; (c) transportation electrification; (d) incremental energy efficiency (EE measures beyond what's embedded in the Reference Case); and (e) rooftop solar PV generation. This figure highlights two key insights. First, transportation electrification is responsible for 50 to 65 percent of the net increase, as liquid fuels are replaced by electricity. Second, generation from rooftop solar PV has a smaller than expected *net* impact on retail sales. This is most apparent in the High DER scenario, where rooftop solar PV exceeds 2,500 MW (larger than today's average load). In this pathway, incremental electricity demand from end-use electrification still outweighs the directionally opposite impact from rooftop solar. This is a result of the lower-quality solar resource (i.e., low capacity factor) in PGE's service territory, and we would not expect similar conclusions to be drawn in geographies such as California or Arizona.

Figure 28 Evolution of Retail Electricity Sales, 2017-2050

We estimate the system peak load as the highest hourly load value from our simulations. As discussed in Section II.B, our hourly load (and resource) shapes reflect 2011 weather conditions, which means that the results we report here will not exactly match a 1-in-2 (weather-normalized) peak demand. Figure 29 plots the system peak load in 2050 in two ways. The first metric (in dark blue) represents "fixed demand" and excludes any impacts from load shifting, storage charge/discharge and flexible electric fuel production. The chart illustrates how widespread end-use electrification in the High Electrification and Higher DER pathways results in a system peak load of approximately 6,400 MW, which is about 1,400 MW higher than the Reference Case. Despite the proliferation of rooftop solar PV in the High DER pathway, the system peak load is nearly equivalent to the High Electrification pathway since it occurs during a winter morning before meaningful insolation. The second system peak load metric (in light blue) accounts for impacts from flexible end-use loads during the same hour, which moderates the impacts of electrification on peak loads.

Figure 29 2050 System Peak Load

B. Resources

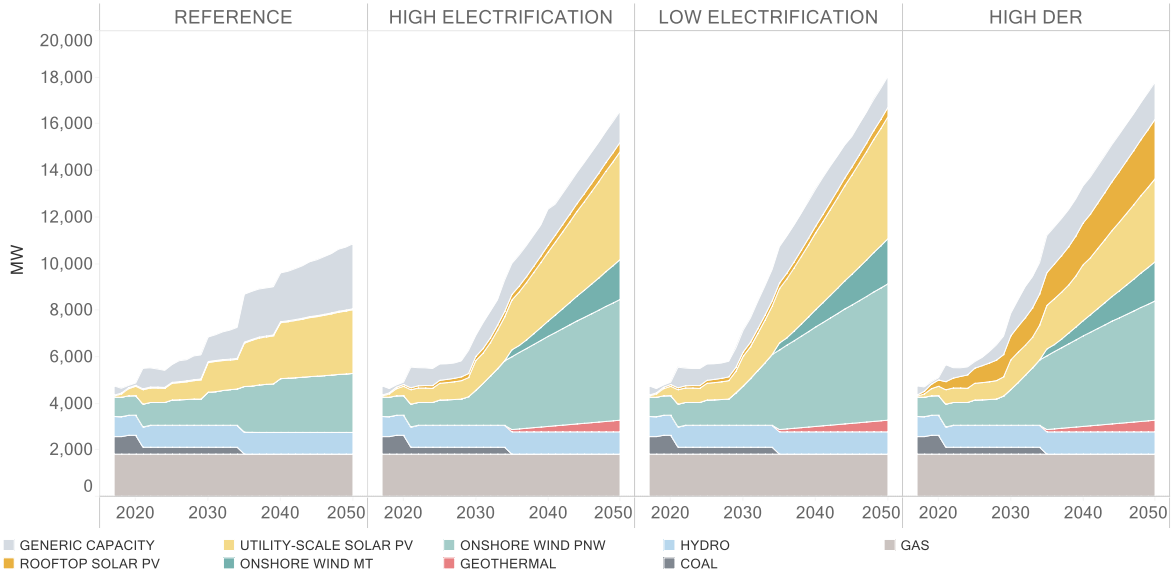
1. Installed Capacity

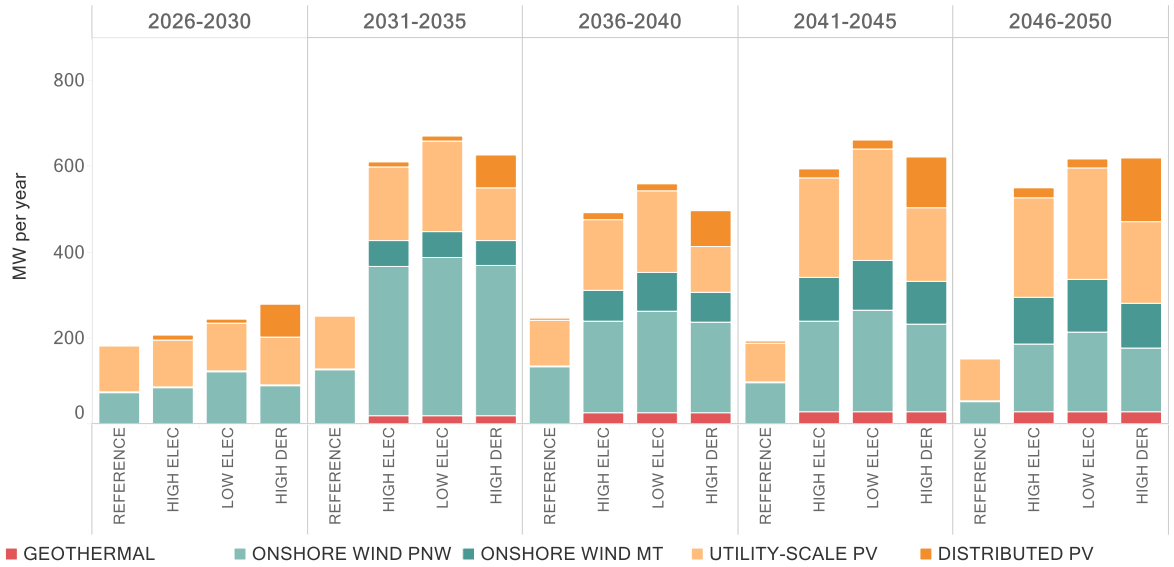
Figure 30 shows the projection of installed capacity for thermal, generic capacity and renewable resources. Decarbonization of electricity generation and electrification requires renewable resource additions that far exceeds additions included in the Reference Case. The installed capacity of wind, solar, geothermal and hydro resources in the pathways is more than 2x the Reference Case quantity by 2050 and includes: (a) 5,100 to 5,900 MW of onshore wind in the Pacific Northwest; (b) 1,700 to 1,900 MW of onshore wind in Montana; and (c) 3,600 to 5,200 MW of utility-scale solar PV in central Oregon.[19] Rooftop solar PV in the High DER scenario reduces the amount of transmission-connected renewable generation, but its generation portfolio still requires utility-scale additions to reduce the carbon

[19] For context, NREL estimates technical potential of onshore wind resources in Oregon and Washington of approximately 45,480 MW and Black & Veatch estimates approximately 56,150 MW of utility-scale solar PV in Oregon alone. See Lopez et al. (2012) and Black & Veatch (2015).

intensity of electricity generation to levels consistent with the study's carbon budget. The Low Electrification pathway contains the highest installed capacity due to the amount of electricity required to serve synthetic electric fuel production loads.

Figure 30 Installed Generating Capacity





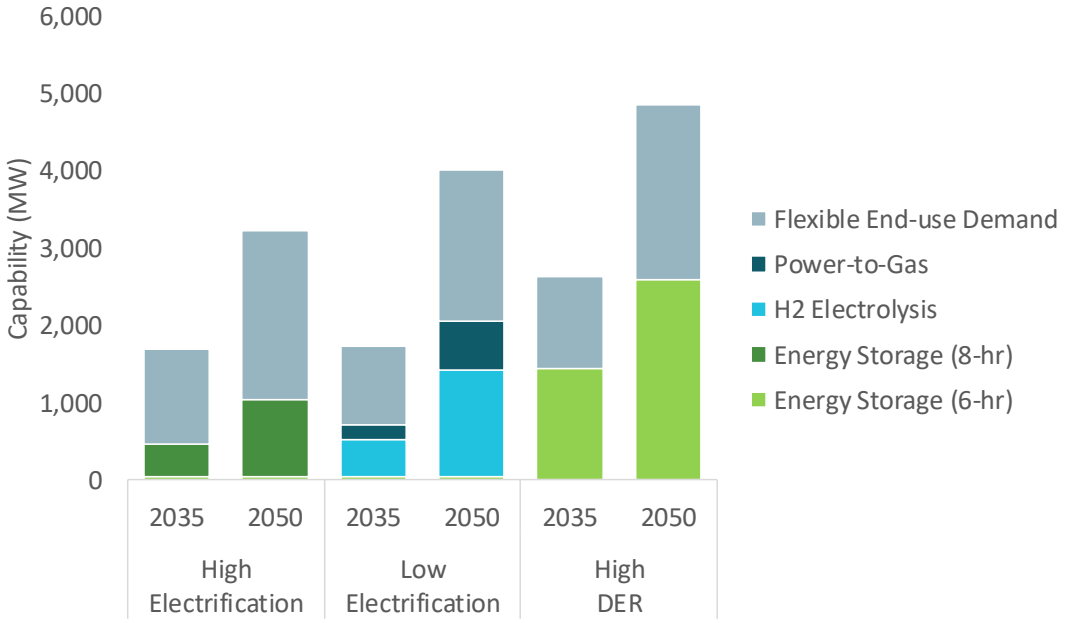


Figure 31 shows the annual average capacity additions of renewable resources, which are approximately 600 MW per year between 2030 and 2050 for the pathways scenarios. Annual renewable additions for the pathways scenarios are more than 2.0x Reference Case levels during the 2030s and more than 3.0x during the 2040s. For context, the amount of new onshore wind capacity beginning in 2030 is the equivalent to one to two Tucannon River (267 MW) wind power plants installed each year.

Figure 31 Average Annual Renewable Installations

The high penetrations of must-run renewable resources added across the pathways necessitate resources to balance electricity supply and demand. In addition to traditional sources of flexibility, such as hydro and thermal, the pathways incorporate a variety of new balancing resources to mitigate curtailment of renewable generation. Figure 32 shows the type and quantity of balancing resources incorporated in each pathway, including: (a) energy storage, which is differentiated between 6- and 8-hr duration; (b) hydrogen electrolysis facilities; (c) power-to-gas facilities; and (d) flexible end-use demand, which is estimated as the maximum hourly load shift in each year. The High Electrification and High DER pathways rely on a combination of flexible end-use demand and energy storage, while the Low Electrification pathway incorporates more than 2,000 MW of hydrogen electrolysis and P2G facilities by 2050 to consume excess renewable electricity generation and produce decarbonized pipeline gas. The High Electrification pathways contains the lowest quantity of physical / central-station balancing resources (i.e., 1000 MW of 8-hr energy storage) and relies on end-use loads to shift energy. The ability of these balancing fleets to minimize curtailment is further discussed in Section C.4 below.

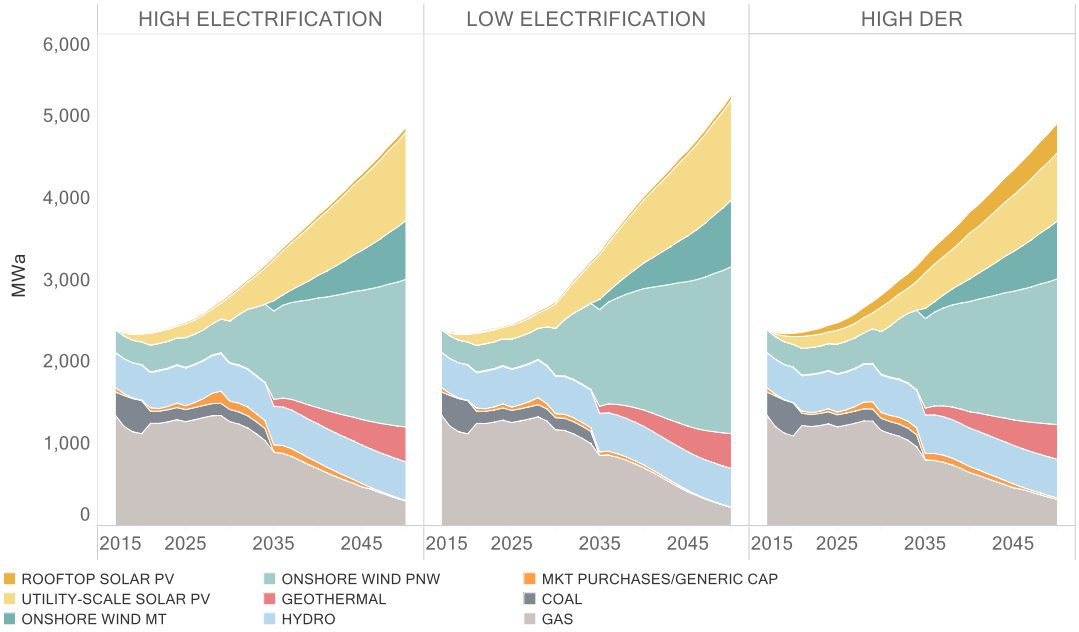

Figure 32 Balancing Resources

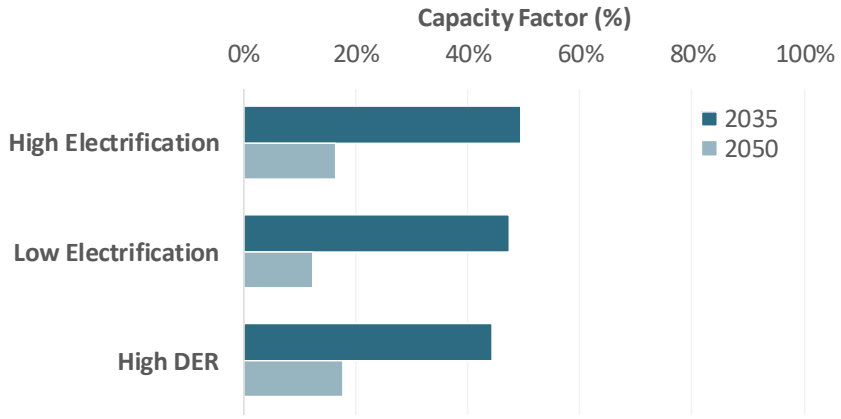
2. Generation



The overall generation mix by resource type for each pathway is shown in Figure 33. Annual generation more than doubles from approximately 2,400 MWa today to between 4,900 and 5,300 MWa by 2050. Carbon-free generation is more than 90 percent of the total by 2050, including an approximate mix of: (a) 50 percent onshore wind in the Pacific Northwest and Montana; (b) 25 percent solar PV, including both utility-scale in central Oregon and rooftop PV resources located within PGE's service territory; (c) 9 percent hydro; and (d) 8 percent geothermal. Due to the increased penetrations of renewable resources, thermal generation decreases significantly over time and is between 4 to 7 percent of total generation by 2050.

Figure 33 Generation by Resource Type

The capacity factor of PGE's existing gas-fired resource fleet is shown in Figure 34. The figure highlights how the growth in intermittent renewable generation between 2035 and 2050 decreases the utilization of these dispatchable resources from approximately 50 percent in 2035 to below 20 percent in 2050, a decrease of approximately 30 percentage points. The highly renewable power systems modeled in this study still require dispatchable resources to maintain reliability, and the gas-fired resource fleet, along with a variety of other balancing resources, have the characteristics to avoid unserved energy. The results here do indicate a shift in the role of these resources, particularly for combined cycle plants, from an energy to a capacity resource.

Figure 34 Gas-fired Resource Fleet Capacity Factor

C. System Operations

1. Load and Net Load

We compare the distribution of hourly load and net load in 2050 for each scenario as histograms in Figure 35, and report summary statistics in Table 11. These two metrics are estimated as follows: (a) load includes inflexible, transmission-level load less behind-the-meter generation (e.g., rooftop solar PV); and (b) net load is load minus non-dispatchable generation, including onshore wind, utility-scale solar PV, geothermal and run-of-river hydro resources. Both exclude the impact of flexible loads and resources.

The load distributions show the expected impacts of electrification, with the High Electrification and High DER distributions shifting towards the right. The net load distributions provide a more meaningful benchmark in terms of assessing the amount of dispatchable capacity needed to reliably meet demand and the flexibility required to avoid curtailment. The net load distribution for the Reference Case, which includes a 50% RPS in 2050, shows net load below zero for 5 percent of hours in the year. The pathways scenarios, which include at least twice as many non-dispatchable renewables, have net load distributions that are much flatter than the Reference Case and frequently below zero.

The High Electrification net load distribution is below zero in approximately 50 percent of hours per year, and the minimum net load experienced is approximately -8,000 MW. During these hours, flexible resources are needed to consume additional load (e.g., energy storage charge) to avoid curtailment. The maximum net load is approximately 5,000 MW, which is about 4 percent higher than the Reference Case's maximum net load. The High DER pathway shows similar net load distribution results due to comparable levels of electrification and renewables.

Relative to the other pathways, the Low Electrification pathway's net load is distributed further left (i.e., more hours with negative net load). Net load is below zero for 64 percent of hours in the year and nearly reaches -10,000 MW in a single hour. This shape is due to different load and resource characteristics, including: (a) lower levels of end-use electrification; and (b) higher levels of inflexible renewable generation. Flexible hydrogen electrolysis and power-to-gas facilities consume load during these negative net load hours to produce low-carbon electric fuels and avoid curtailment.

Figure 35 Distribution of Hourly Load and Net Load in 2050

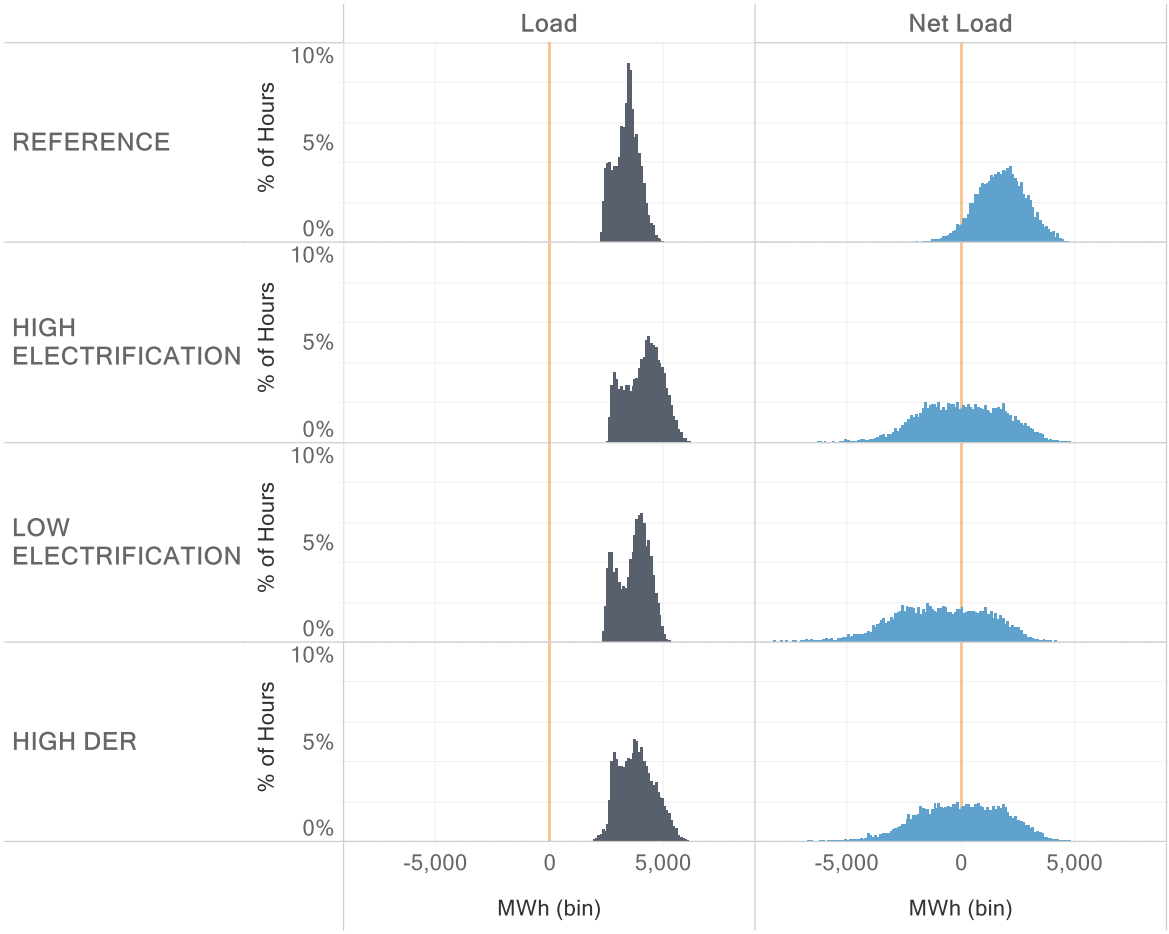


Table 11 Statistics for Hourly Load and Net Load in 2050

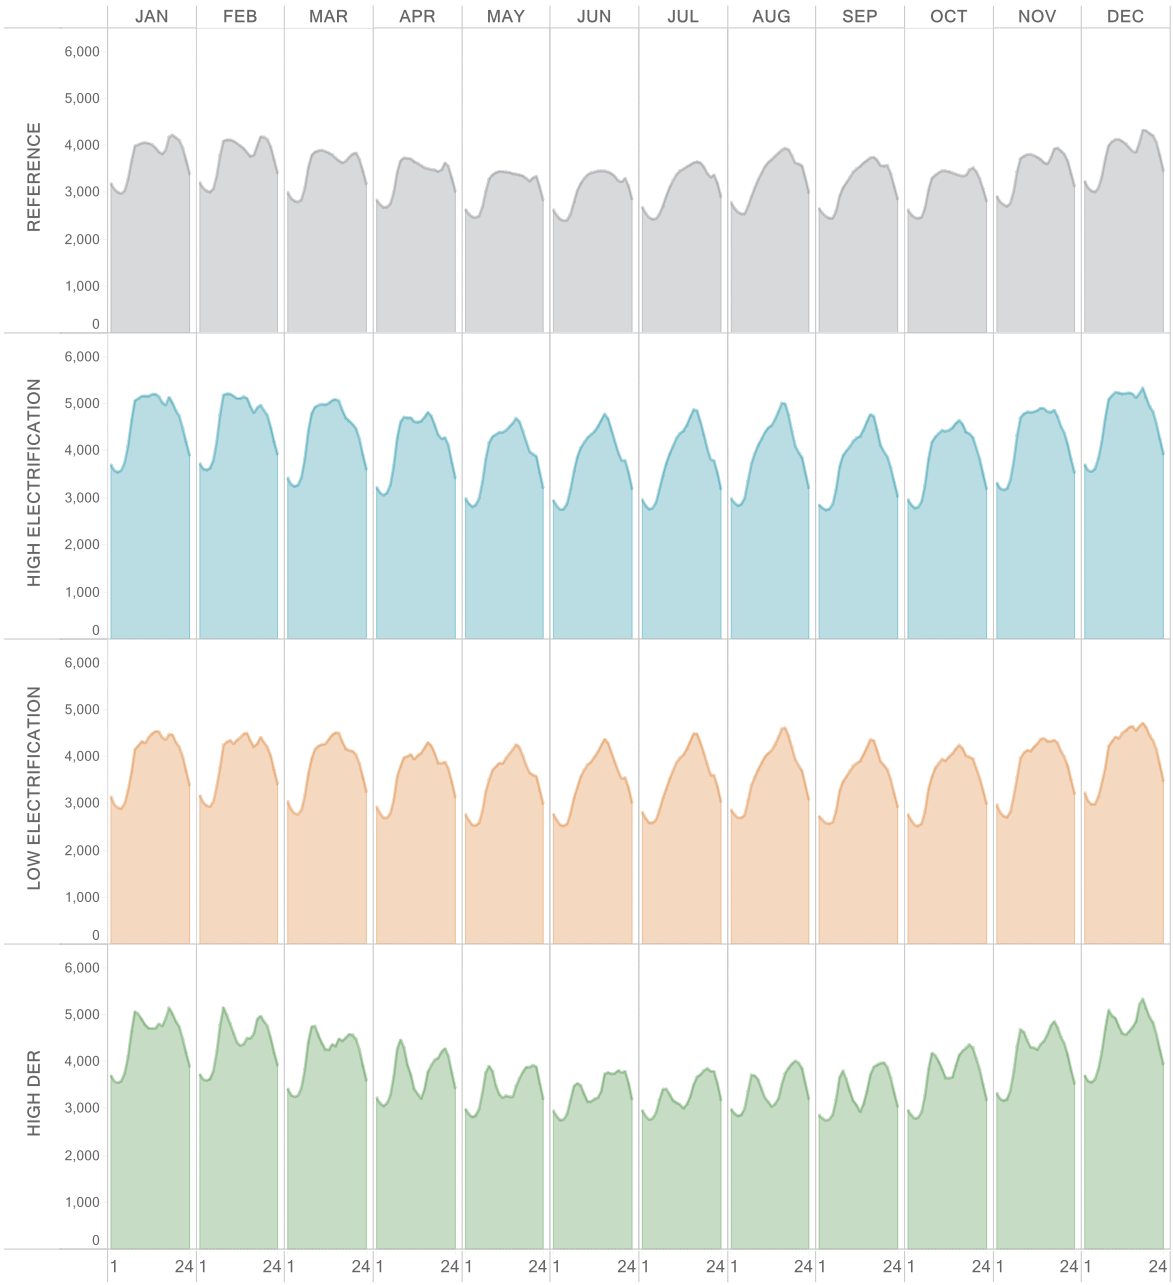

Scenario	Load		Net Load			
	Max	Min	Max	Min	Frequency below 0 MW	
	MW	MW	MW	MW	hrs	% of hrs
Reference	4,972	2,191	4,758	-2,392	457	5%
High Electrification	6,391	2,555	4,957	-7,942	4,346	50%
Low Electrification	5,351	2,273	4,261	-9,996	5,600	64%
High DER	6,310	1,920	4,961	-8,574	4,337	50%

2. Hourly System Load Shape

The average load by month and hour in 2050 for each scenario is summarized in Figure 36. The figure shows the system load shape prior to accounting for flexible loads and illustrates how the nature of electricity demand is affected by rooftop solar PV and varying levels of electrification.[20] The High Electrification pathway shows higher winter loads relative to the Reference Case primarily due to the electrification of space heating, but large new loads are also present in non-winter months largely due to transportation electrification. These non-heating related load increases are also present in the Low Electrification pathway and are most apparent in the early evening hours when most EV charging is assumed to take place. Although the High DER pathway contains the same electrification measures as the High Electrification pathway, the proliferation of rooftop solar PV changes both the daily and seasonal characteristics of electricity demand, including: (a) steep upward and downward ramps during the daylight hours across all months; and (b) large differences in daily energy requirements between winter and spring/summer months.

[20] The load shapes for the pathways also reflect high levels of electric energy efficiency.

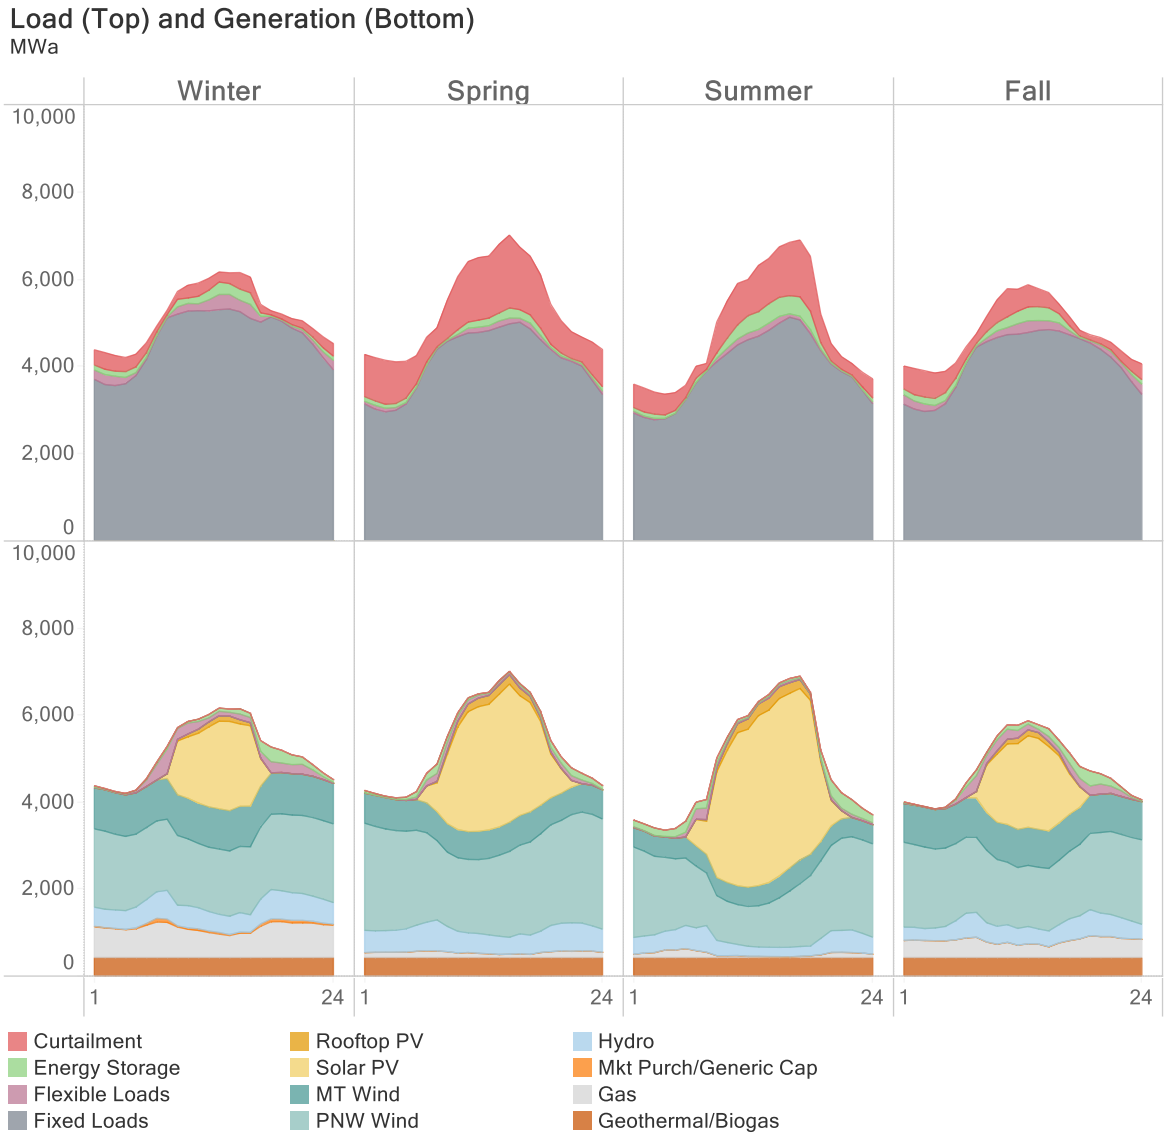

Figure 36 System Load Shape: Month-Hour Average in 2050

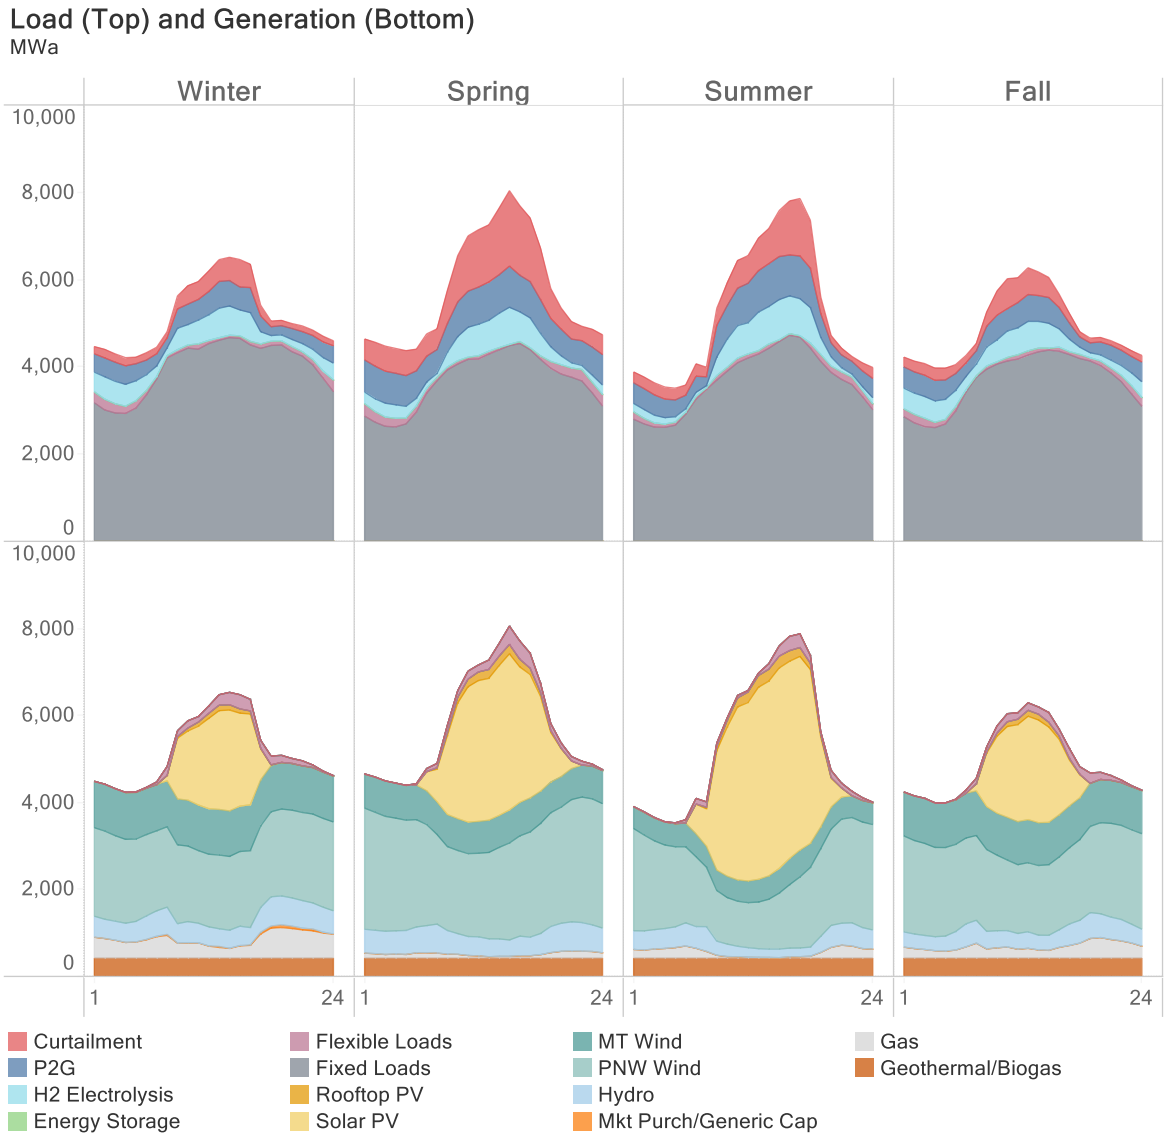
3. Month-Hour Electricity Dispatch

Figure 37 through Figure 39 show hourly average dispatch profiles by season for each pathway, where the top panel contains all sources of load and the bottom panel contains all sources of generation.[21] The figures illustrate how electricity supply and demand technologies combine across hours and seasons, and the operating profiles of flexible balancing resources.

Figure 37 Electricity Dispatch: High Electrification Pathway, 2050

[21] Seasons defined as: (a) winter includes December through February; (b) spring includes March through June; (c) summer includes July through September; and (d) fall includes October through November.

Figure 38 Electricity Dispatch: Low Electrification Pathway, 2050



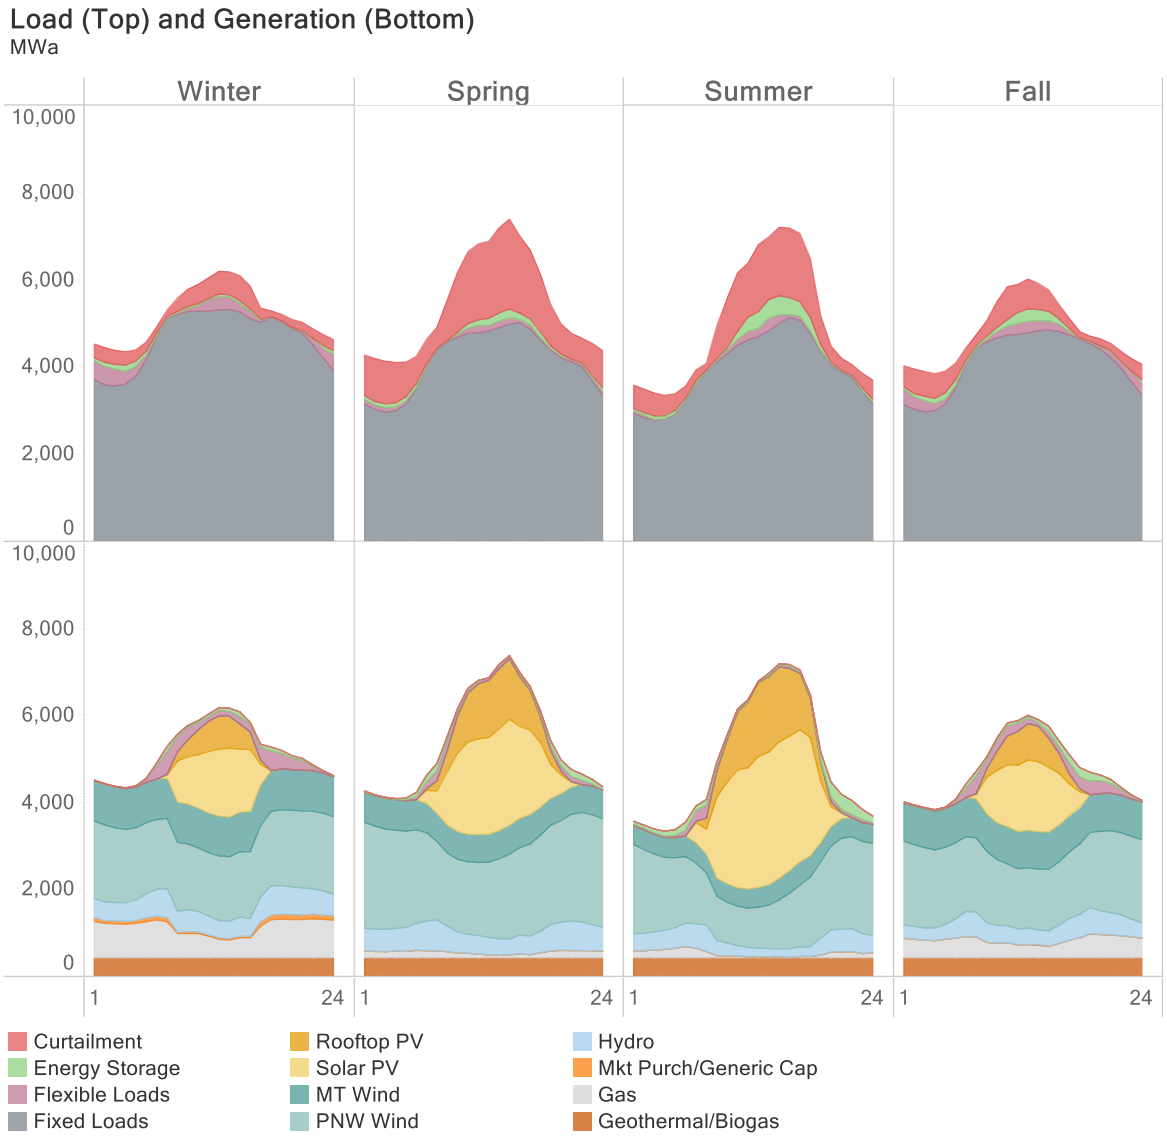


Figure 39 Electricity Dispatch: High Distributed Energy Resources Pathway, 2050

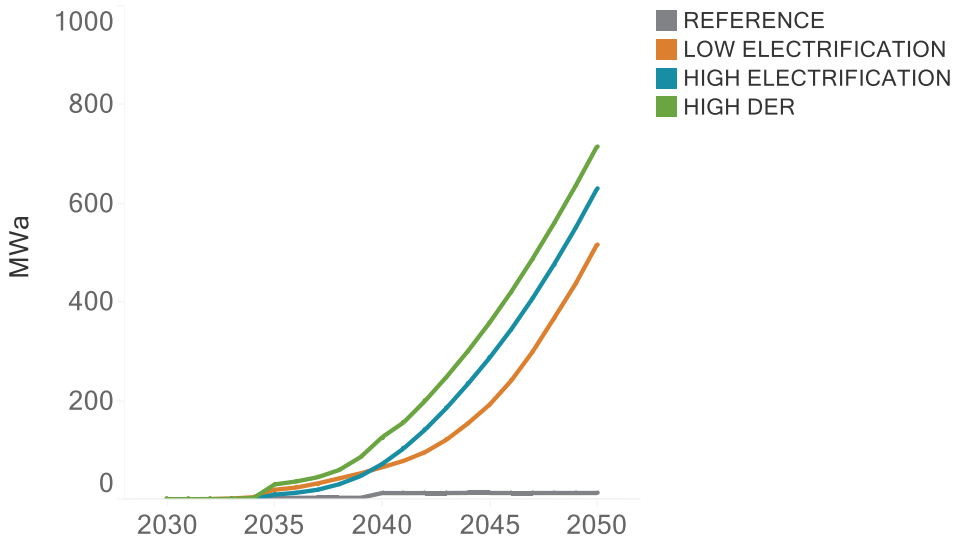
4. Curtailment

Curtailment of renewable generation occurs during periods where: (1) must-run generation exceeds load, resulting in an initial negative net load signal; and (2) balancing resources are unable to shift surplus energy to hours with energy deficits (i.e., positive net load signal). Figure 40 plots annual curtailment for each scenario and shows that curtailment does not become prevalent until the 2035 timeframe. As the share of inflexible, renewable generation increases above 85 percent by 2050, curtailment increases exponentially even after the impacts of balancing resource are accounted for.

Figure 40 Annual Curtailment



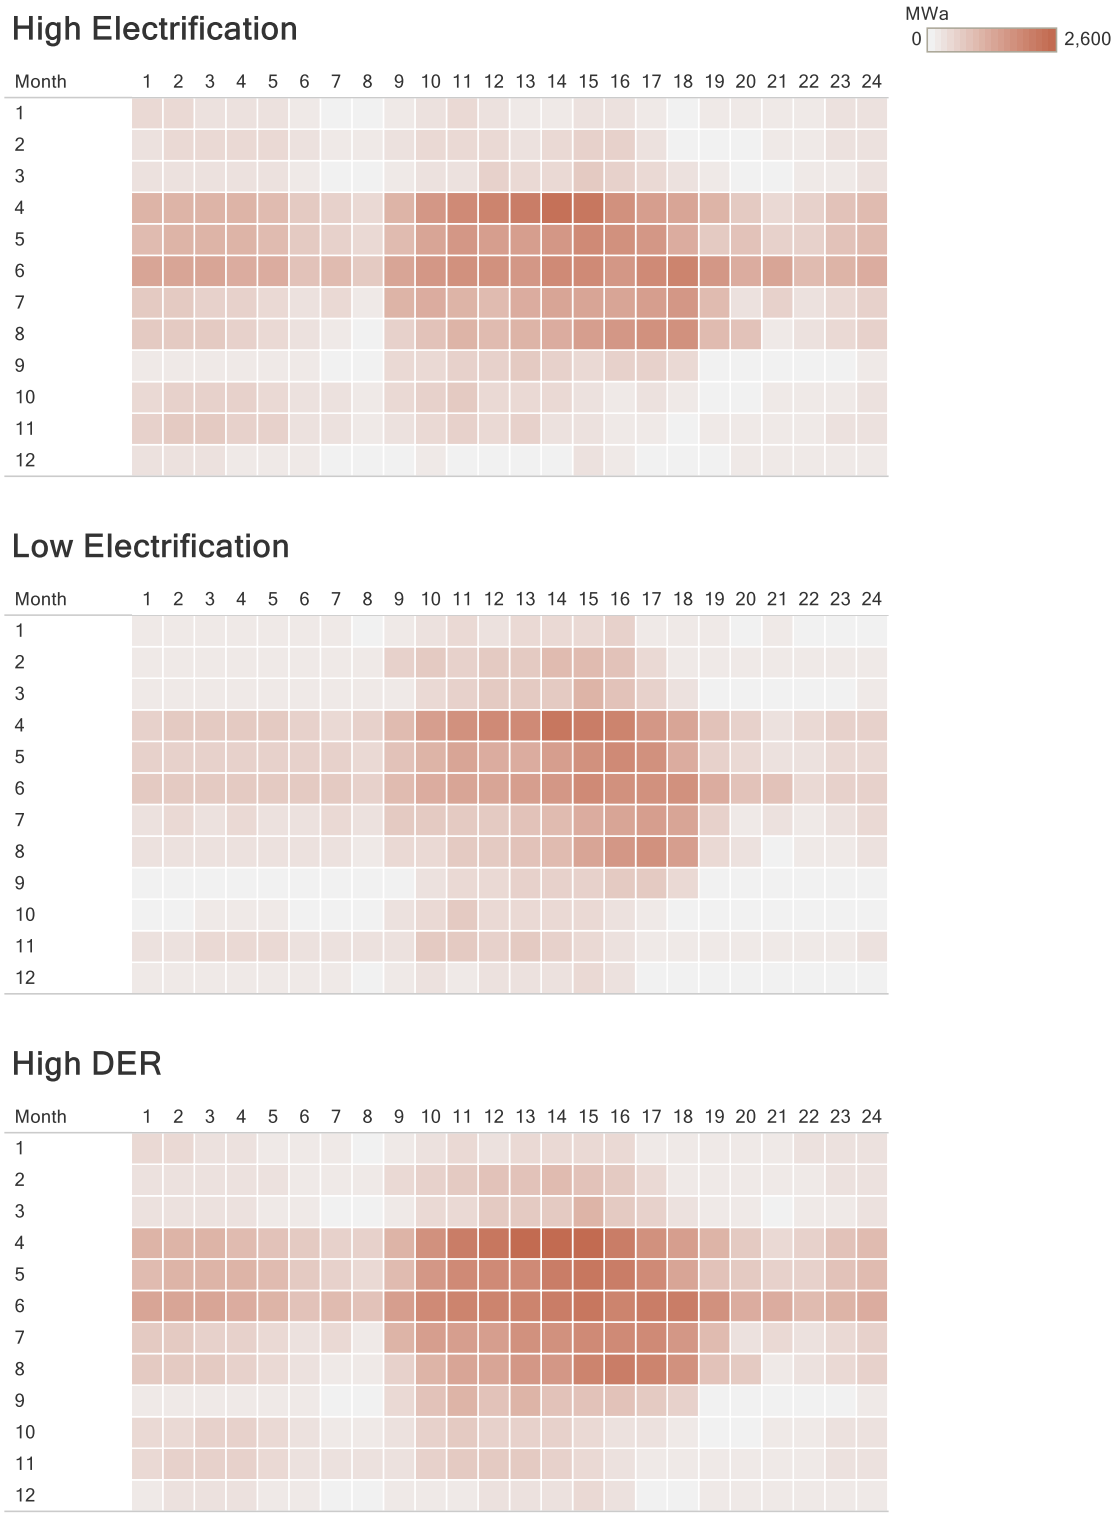


Table 12 summarizes several curtailment metrics for 2035 and 2050, including: (a) the amount of energy curtailed in average megawatts; (b) curtailment normalized as a percentage of available renewable energy; (c) maximum hourly observation; and (d) frequency, expressed in percentage of hours in a year. Curtailed generation is less than 2 percent of available renewable energy in 2035 across all pathways and increases to between 11 and 17 percent by 2050. Curtailment is experienced between 40 and 55 percent of hours in 2050, which is a decrease from the number of hours with negative net load (see Table 11) and reaches a maximum depth between 7,600 and 8,700 MW in a single hour. We explore the impact of alternative demand- and supply-side balancing resource assumptions on curtailment in the following section.

Table 12 Curtailment Metrics for 2035 and 2050

Scenario	Energy		Percent of Available RE		Hourly Maximum		Frequency	
	2035 MWa	2050 MWa	2035 %	2050 %	2035 MW	2050 MW	2035 % hours	2050 % hours
Reference	2	13	0.2%	0.8%	966	2,048	1%	3%
High Electrification	9	630	0.5%	15.0%	2,146	8,032	2%	39%
Low Electrification	19	517	0.9%	11.1%	2,378	7,597	4%	53%
High DER	30	716	1.5%	16.9%	3,121	8,663	5%	46%

The average amount of curtailment for each month and hour in 2050 is depicted as a heat map in Figure 41, with a darker red highlighting more extreme curtailment. The heat maps show that curtailment is concentrated during spring months when loads are low and renewable generation is high. Curtailment experienced during April through June makes up approximately half of annual curtailment, while only 11 to 13 percent occurs between December through February. Although most curtailment is concentrated during day-light hours, it is still experienced during the night-time and is up to 30 percent of the total in the High Electrification pathway.

Figure 41 Curtailment Heat Map for 2050

D. Sensitivity Analyses

In this section, we evaluate the sensitivity of our modeling results to alternative assumptions about the availability of demand- and supply-side resource flexibility. These sensitivities explore the impacts of alternative assumptions from the High Electrification pathway, including: (a) varying the availability of flexible end-use load; (b) including flexible electric fuel production (i.e., electrolysis); and (c) varying the quantity and type of energy storage. These sensitivities are summarized below.

Flexible End-use Load. In the High Electrification pathway, we assume a percentage of electric load is flexible in key end-uses: (a) 75 percent of light-duty vehicle electric load is flexible by 2050; (b) 75 percent of residential and commercial water heating electric load is flexible by 2050; and (c) 50 percent of electric load is flexible for residential space conditioning, residential clothes washing and drying and commercial space heating. We tested three cases designed to assess the importance of end-use flexibility: (a) no flexible end-use load; (b) only flexibility from electric vehicles; and (c) only flexibility from water heaters.

Flexible Electric Fuel Production. The results presented in the prior section highlight the seasonal imbalance between electricity supply and demand in a highly renewable power system. The base assumption in the High Electrification pathway is that energy storage and flexible end-use loads are the principal balancing resources. To assess the impact of long-term or seasonal storage, we conducted a sensitivity analysis where hydrogen produced from electrolysis facilities provides 3.5 percent of pipeline gas supply, which translates into more than 300 MW of electrolysis facilities.

Variation in Energy Storage. Varying the quantity of energy storage affects the ability of a power system to successful integrate inflexible renewable electricity generation. In the High Electrification pathway, the base assumption is that 1,000 MW of 8-hour energy storage is in-service by 2050. In this sensitivity, we assess the implications of: (a) increasing the quantity of 8-hour energy storage from 1,000 MW to 1,500 MW; and (b) assuming 500 MW of 24-hour pumped hydro storage (PHS) by 2050.

Table 13 summaries the results of our sensitivity analyses for 2050, which are shown as differences relative to the High Electrification pathway. We report changes in: (a) curtailment, in terms of average megawatts and percent difference; and (b) energy system CO_2 emissions, in million metric tonnes and percent difference. Removing flexibility from end-use loads increases curtailment by nearly 10 percent and emissions increase by 5 percent due to higher thermal generation, which results in the sensitivity exceeding the study's 2050 carbon budget. Including flexibility from electric vehicles and hot water heaters dampens the effect of losing other end-use flexibility, with curtailment and emissions rising modestly. The sheer volume of electric load from electric vehicles (more than 15 percent of total load in 2050) relative to water heaters allows for better curtailment and emissions outcomes. Electrolysis facilities and pumped hydro, both long-duration storage, show similar outcomes with curtailment decreasing by more than 10 percent. In contrast, increasing the quantity of 8-hour storage produces less than half the reductions in curtailment. The results of these sensitivity analyses highlight the importance of flexible end-use loads for integrating renewable generation, as well as the effectiveness of long-duration energy storage to reduce curtailment and address seasonal energy imbalances that occur in highly renewable electricity systems.

Table 13 Flexibility Sensitivity Analysis Results (Relative to Base Assumptions)

Sensitivity	Curtailment (MWa)	Curtailment (%)	Emissions ($MMTCO_2$)	Emissions (%)
Flexible End-Use Load				
None	+54	+9%	+0.21	+5%
Flexible EV Load Only	+14	+2%	+0.05	+1%
Flexible WH Load Only	+36	+6%	+0.14	+3%
Flexible Electric Fuel Production				
Add Electrolysis Facilities	-78	-12%	-0.08	-2%
Energy Storage				
Increase 8-hr energy storage	-31	-5%	-0.07	-2%
Add 24-hr PHS	-68	-11%	-0.15	-4%

Notes: values for 2050 and relative to High Electrification pathway base assumptions.

VI. Summary

We find that deep decarbonization of the PGE service territory's energy economy is possible and can be achieved using a variety of energy technologies and mitigation strategies. Our analysis of multiple pathways shows that they depend on a set of three pillars that are consistent with many studies examining deep decarbonization in the U.S. and abroad, including: (1) energy efficiency; (2) decarbonizing electricity generation; and (3) increasing the share of electricity and electric fuels. All three pillars are required and pursuing only one is insufficient.

The level of change to the energy system identified in this study is transformational and cannot be achieved with incremental improvements to energy supply and demand. In order to facilitate a pathway to 2050, both consumers and producers will need to participate to ensure that energy infrastructure is low-carbon and efficient. Although 2050 is more than three decades away, a successful transition to a low-carbon economy requires timely planning to account for: (a) the pace of consumer adoption; and (b) the fact that energy infrastructure is long-lasting and takes years to plan for. Despite the ambitious transformation of the energy system, the changes would not entail major lifestyle changes, but the structure of a household's energy bill will shift from fossil fuel expenditures to investments in technology.

Economy-wide decarbonization will profoundly change the way electricity systems are operated and planned for. In terms of power system operations, balancing electricity supply and demand becomes more challenging as inflexible, variable renewable generation becomes the principal source of supply. For example, the three pathways show renewable generation exceeding load in approximately half of all hours by 2050. This operational paradigm necessitates a transition to new forms of balancing resources to integrate renewables and avoid curtailment. New sources of flexibility, including energy storage and flexible demand, can complement traditional sources of flexibility, such as hydro and thermal resources. This also provides an opportunity for PGE's customers to facilitate renewable integration by playing a more active role through smart EV charging and water heating (among others), which expands upon traditional demand response programs.

Electricity system planning in the context of deep decarbonization will need to account for broad changes across the energy economy to ensure that infrastructure with the right attributes is available to come online in a timely fashion. For example, future resource adequacy analyses will need to address changes in: (a) overall load requirements; (b) the shape of hourly load; (c) the level of inflexible renewable resources; and (d) penetration of flexible demand. In addition, the scale of resource additions identified in this study exceeds historical levels due to: (1) reducing the carbon intensity of electricity generation to nearly zero; and (2) increased generation requirements from electrification and/or producing fuels from electricity (i.e., H2 and SNG). As a result, the installed capacity of renewables is substantially higher than what's anticipated in any current planning proceedings and is more than double the quantity we would expect under current RPS policy. If regulators pursue policies commensurate with the emissions reductions evaluated here, then the results of this study highlight a number of considerations that could be investigated in PGE's integrated resource planning efforts to ensure that near-term actions are consistent with a long-term decarbonized future.

Liquid Storage Tanks at the Critical Energy Infrastructure (CEI) Hub

Seismic Assessment of Tank Inventory

May 2019

ACKNOWLEDGEMENTS

This report was written for the city of Portland's Bureau of Emergency Management (PBEM). The work was conducted though a collaboration between Mapleaf LLC and Portland State University.

Appreciation is extended to Anne Castleton, Ph.D., Emergency Management Coordinator with the Bureau of Development Services, City of Portland, for her insightful questions and perspectives.

REPORT SUMMARY

Seismic vulnerability of the Critical Energy Infrastructure (CEI) hub in Portland has been recently highlighted in several regional resiliency assessments. This report focuses on the liquid fuel storage tanks located at the CEI hub due to the adverse consequences of failure. General structural and geotechnical damage of similar facilities were identified by reviewing the seismic performance of liquid fuel storage tanks during past earthquakes. Data was then gathered on the storage tanks at the CEI hub and analyzed in an effort to quantitatively assess the tank inventory. There are nine different companies with hundreds of in-service tanks holding various forms of liquid products that have a potential storage capacity of over 8.6 million barrels. Over 95% of this capacity can be stored in large tanks that are 25ft in diameter or larger. The majority of the large tanks were built prior to 1970s and the vast majority prior to 1990s, eras when regional seismicity and seismic design were not fully appreciated or developed. Consequently, the structural and geotechnical issues revealed in tanks from past earthquakes are likely to manifest at the CEI hub unless mitigation steps are taken to minimize the risk. A conceptual order of magnitude cost of seismic mitigation for the large capacity tanks was estimated to exceed $300 million. This estimate made gross assumptions on soil mitigation, structural anchoring and design/permitting costs and did not consider fuel distribution past the tanks. Based on the findings and associated limitations of this study, recommendations are made for next steps that would fill gaps in existing data and generate new critical knowledge to better quantify and mitigate the seismic risk of this critical facility.

INTRODUCTION

Brief Background

The six-mile stretch of industrial land along the west shore of the Willamette River in Northwest Portland is often referred to as the Critical Energy Infrastructure (CEI) hub. Energy facilities in the CEI hub include liquid fuel port terminals, storage tanks, pipelines and transfer stations, natural gas transmission and storage, electrical substations, and high voltage transmission lines. There are no petrochemical refinery operations in Oregon, so all of Oregon's liquid fuel is imported and over 90% is stored at fuel storage facilities in the CEI hub. This includes gas and diesel for the Portland metro area and all of the jet fuel for the Portland International Airport. These liquid fuel storage facilities are located along the river with the original intent for ships to import the fuel through port terminals. Now, most of the liquid fuel is brought in and out through pipelines. Numerous reports have highlighted the criticality of the CEI hub, the interconnectivity and the general earthquake risk to Portland and to the State (DOGAMI 2012, Bureau of Planning and Sustainability 2012, OSSPAC 2015, City Club of Portland 2017).

Purpose of Study

The purpose of this study was to focus on the liquid fuel storage aspect of the CEI hub and more specifically the storage tanks that hold the fuel. The storage tanks were chosen because they are some of the most visible aspects of the hub and pose the greatest risk if the tanks were to fail. The risk includes not only the regions inability to access fuel following a major earthquake, but also health and environmental concerns should failure occur.

This report summarizes the findings of the study, which had three main goals:

- Review past earthquake experiences from available literature of liquid fuel storage facilities in order to identify common vulnerabilities and key factors leading to tank damage and failure.
- Gather data from publicly available sources to identify the quantity and characteristics of the tanks and the supporting soil at the CEI hub. Contrast the information with past earthquake observations in order to gain a better appreciation of the expectations for seismic performance of the fuel storage tanks at the hub.
- Review potential mitigation options that aim to enhance the seismic performance of liquid storage tanks and estimate order-of-magnitude costs for implementing the mitigations.

The subsequent sections of the report address the above goals in a similar chronological order.

EARTHQUAKE DAMAGE TO LIQUID FUEL STORAGE TANKS

OVERVIEW FROM PAST EARTHQUAKES

Liquid petroleum products are commonly held in cylindrical, above-ground storage tanks. These are relatively simple structures comprised of a soil supported base-plate, a welded or riveted steel wall supported on a ring reinforced concrete foundation and a roof. The tanks are often categorized by their roof type; floating or fixed. To store liquids with low vapor pressures, such as propane, butane, or kerosene, a fixed roof tank is required to maintain pressure. For liquids that do not need to be pressurized for storage, floating roof tanks are utilized. As liquid is drained from a floating roof tank, the roof descends with the liquids surface and prevents the buildup of vapors that would otherwise form in the void of a fixed roof tank. Floating roof tanks are desirable for products such as crude oil, gasoline and diesel. The presence or absence of a floating roof in a large tank can influence the dynamic behavior when shaken by an earthquake.

Above ground storage tanks are well known to be vulnerable to seismic events. Since their simple design has been relatively unchanged for over a century, their seismic reliability has been tested numerous times. Previous earthquakes involving documented cases of tank damage are listed in Table 1. Selected examples from these earthquakes are used in the following sections to highlight some of the common vulnerabilities and the resulting damage.

Table 1: Earthquakes with Documented Significant Damage to Fuel Storage Tanks

Location	Magnitude	Date
Tokyo, Japan	8.3	September 1, 1923
Long Beach, California	6.4	March 10, 1933
Kern County, California	7.3	July 21, 1952
Prince William Sound, Alaska	9.2	March 27, 1964
Niigata, Japan	7.6	June 16, 1964
San Fernando, California	6.5	February 9, 1971
Managua, Nicaragua	6.3	December 23, 1972
Miyagi-Ken-Oki, Japan	7.7	June 12, 1978
Imperial County, California	6.5	October 15, 1979
Greenville, California	5.9	January 24, 1980
Central Greece	6.7	February 24, 1981
Coalinga, California	6.2	May 2, 1983
Loma Prieta, California	6.9	October 17, 1989
Marmara, Turkey	7.6	August 17, 1999
Tōhoku, Japan	9.0	March 11, 2011

STRUCTURAL DAMAGE

Although there are some references to an event in 1923 in Tokyo, the first reasonably well-documented case of damage to oil storage tanks followed the 1933 earthquake in Long Beach, California. The earthquake affected an industrial area that produced, refined, and stored petroleum. Complete tank failures were reported at three different locations, all less than 30 miles from the epicenter of the magnitude M6.4 earthquake. Peak ground acceleration (PGA) of 0.19g recorded at stations with similar distance from the epicenter were thought to be representative of those at the storage tanks (Housner 1952). Many tanks exhibited distortion, elongation, strain in riveted joints and buckling of the roof plates. Two of the tanks' riveted joints failed and while the tanks did not collapse as a result, the oil leaked. In one group of tanks, three partially full tanks sustained no damage while a full tank experienced total failure. The lost oil overcame the firewall and damaged neighboring buildings over 300 ft away (Nielsen & Kiremidjian 1986). There were other failures including overtopping where the roof was found 200 ft from the failed tank as shown in Figure 1. Other tanks did not necessarily fail in their structure, but were not anchored and separated from the inlet/outlet (I/O), resulting in loss of the oil. All failed tanks were of riveted construction and their structural failures were due to damage in the tank shell. The behavior of riveted shell wall tanks differs from the newer, welded shells construction. The long beach earthquake demonstrated that structural vulnerabilities of tanks relate to the riveted shell construction, to how full the tank is and to the connectivity of the I/O piping.

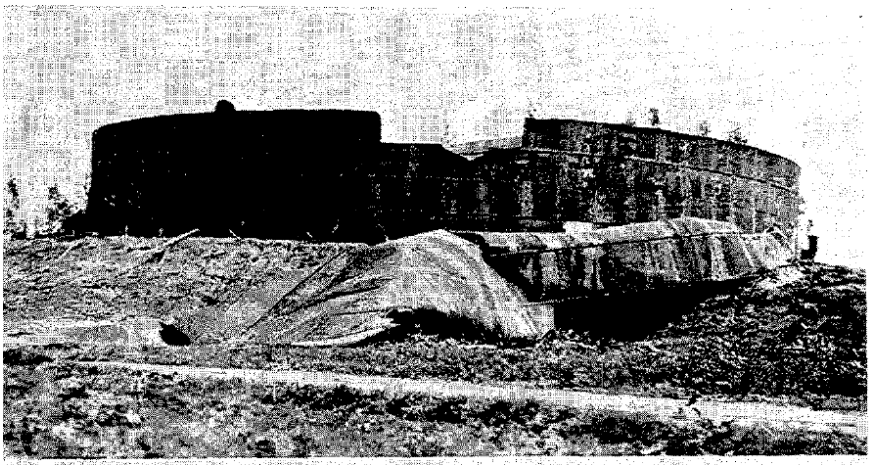

Figure 1: Failed Tank following 1933 Long Beach Earthquake (Cooper 1997)

The Great Alaskan earthquake of 1964 significantly influenced numerous aspects of earthquake engineering and also highlighted the vulnerability of petroleum storage tanks. The magnitude M9.2 subduction zone earthquake is the most powerful earthquake on record in North America. At the time of the earthquake,

the petroleum industry was Alaska's largest mineral industry and damage to petroleum storage facilities was reported in the cities of Valdez, Whittier, Seward, Anchorage, and Nikiska. Direct structural damage to fuel storage tanks included: shell buckling near the bottom of the tank, buckling of cone roofs and top courses of shells, damage to floating roofs and accessories, and damage to I/O connecting piping (Rinne 1967). These were the result from liquid sloshing induced deformations, hydrodynamic pressure acting on the tank walls, shear force and overturning moment acting at the base of the tank, the buckling strength of tanks and, uplift on the axial stresses acting on the tank wall in contact with the ground. Sloshing can damage the top of the tank and can also result in roof damage. Buckling of the steel shell near the bottom of the tank is referred to as elephant-foot buckling. An example of roof damage and elephant-foot buckling is photographed in Figure 2. This type of damage usually occurs in tanks with a low height to radius ratio. Many tanks experienced elephant-foot buckling in this earthquake, all of them were near full capacity. Extreme elephant-foot buckling had resulted in leakage and also complete collapse. Sudden loss of oil from a leak can produce suction that implodes the roof of a tank. The structural damage to fuel storage tanks following the Great Alaskan earthquake exposed vulnerabilities even when the tank shells were welded.

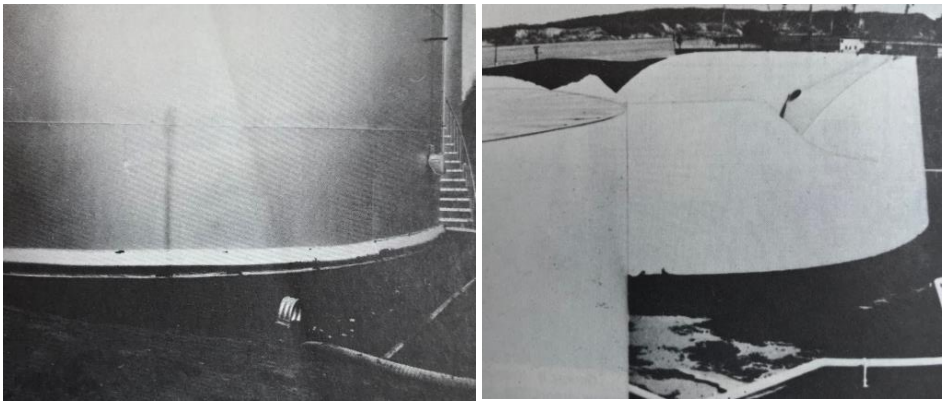

Figure 2: Elephant Foot Buckling (left) and Roof Collapse (right) following 1964 Great Alaskan Earthquake (Hanson 1973)

In 1978, a magnitude M7.4 earthquake occurred of the east coast of Japan with the epicenter approximately 95 km to 120 km from several oil storage or refineries. The peak ground acceleration near Sendai City was thought to have exceeded 0.25 g. The complex of over 87 fixed and floating roof tanks containing various petroleum products was constructed in 1971 and had been designed with reasonable seismic criteria. All piping as well as the tanks were anchored, where the tank anchors were located around the perimeter and embedded into a concrete pad (NBS 1980). Stretched anchor bolts indicated that tank uplift was limited to approximately 6 inches. Three crude oil tanks failed and the contents spilled. The

tanks were surrounded by a reinforced concrete dike, but the volume of spilled oil exceed the capacity of the dike and the oil escaped as shown by the dark areas in Figure 3. The top of the fixed roof tank buckled inward due to low pressure caused by rapid evacuation of the oil through the ruptured connection of the base and wall of the tank. While containment areas in the form of dikes or walls are common, the consequence of failure of fuel storage tanks can extend beyond these containment areas due to overtopping following multiple tank failures or due to potential earthquake damage to the walls themselves.

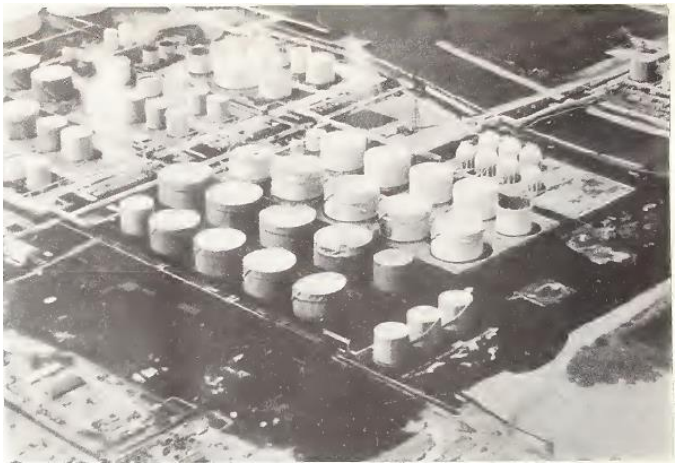

Figure 3: Spilled Oil Past the Containment Dikes following 1978 Earthquake in Japan (NBS 1980)

Soil Induced Damage

There are two major aspects of soil behavior during an earthquake that can influence the overall damage to the fuel storage tanks; amplification and liquefaction. Amplification of the ground motion has been recognized and documented for soft soils in numerous earthquakes, including the iconic 1985 Mexico City and 1989 Loma Prieta. The resulting accelerations manifest in the severity of the above discussed structural damage. Liquefaction of the ground on the other hand, can result in additional damage that is related to permanent settlement of the ground or to lateral soil movement referred to as lateral spreading.

The Great Alaskan earthquake of 1964 resulted in numerous examples of damage caused by liquefaction. Another 1964 earthquake occurred in Japan and was a magnitude 7.6 near the city of Niigata. Two oil refineries were located near a river and had liquid fuel storage tanks built on loose sandy ground. Settlements due to liquefaction were observed to be 8 to 12 inches on compacted ground and up to 20 inches of unequal settlement in uncompacted sand. These resulted in many damaged tanks in both refineries. In contrast, newly built tanks constructed

on compacted soil at the refineries settled uniformly, and approximately 1 in. These tanks exhibited minimal to no damage and remained operational, while surrounding tanks were severely damaged from large ground settlement (Watanabe 1966).

Liquefaction induced lateral spreading can move entire tanks or cause relative ground deformations of the tank. During the 2011 Tohoku subduction zone earthquake, surrounding soil spread and caused uplift on the side of a tank of approximately 20 inches, resulting in the tank cracking and the contents leaking out (Zama et al 2012). An example of tank settlement and of lateral spreading induced uplift is photographed in Figure 4. In addition to damaging the tank itself, liquefaction can sever I/O connectivity. These examples underscore that minimizing the effects of liquefaction can minimize the risk of damage to liquid fuel storage facilities.

Figure 4: Liquefaction Induced Settlement following 1964 Niigata and 2011 Tohoku Earthquakes in Japan (Watanabe 1966, Zama et al 2012)

FIRE

While fire can be thought of as a secondary effect resulting from the damage caused by the earthquake, it is particularly relevant given the volatile contents of the tanks. Numerous instances of fires at liquid fuel storage facilities following an earthquake have been reported, with examples provided in Figure 5. Approximately 37 miles from the epicenter of the Great Alaskan earthquake, oil storage tanks were constructed in the port city of Whittier on fill that consisted of delta deposits and glacial outwash. All of the storage tanks were completely destroyed by a fire that broke out and burned for three days. The fire, and subsequent tsunami, destroyed the evidence and the cause of the fire was never determined. Two possible causes included a live power line that was snapped during the earthquake, or fuel from a leaking tank could have spilled into an operating boiler (Kachadoorian, 1965).

A refinery was located approximately 19 km from the epicenter of magnitude 7.4 earthquake near Istanbul, Turkey. Constructed in 1961 and expanded in 1974 and

1983, the facility had a large tank farm with over 100 unanchored, aboveground liquid storage tanks. The tanks were designed by American contractors adhering to seismic design code of California in 1961 (Sezen & Whittaker 2004). The damage at the refinery is thought to have been largely overlooked due to the extensive damage in more populated areas. The majority of the damage was caused by a fire that was ignited by sparks created from the collision of a metallic floating roof seal against the tank wall. The tanks contained naphtha, a highly volatile and flammable petroleum product. A total of 6 tanks of diameter 33ft to 82 ft, completely burned down. The fire spread to other tanks and 30 of the 45 floating roof tanks were damaged (Yazici and Cili 2008). More recent examples of fire at fuel storage was also observed in 2011 Tohoku, Japan in different refineries built in 1963 and 1971. The fire was attributed in different instances to damage to the tanks themselves or to leaks in the surrounding pipes. In these examples, fire remains a threat to fuel storage facilities despite construction practices that had at least some awareness of the associated earthquake risk.

Figure 5: Fire Caused by Tank Damage following 1999 Turkey (left) and 2011 Tohoku Earthquakes (right) (French Ministry of Ecology, Sustainable Development and Energy, 2013)

LIQUID FUEL STORAGE TANKS AT THE CEI HUB

OPERATING COMPANIES

While the CEI Hub is generally referred to as a singular area, the liquid storage tanks are actually clustered in a few distinct locations and are owned by different operating companies. Map with relative locations of the various companies between U.S. Route 30 and the Willamette River is shown in Figure 6. The majority of the fuel storage facilities are either near the Linnton neighborhood to the north or within the Northwest Industrial Area to the south.

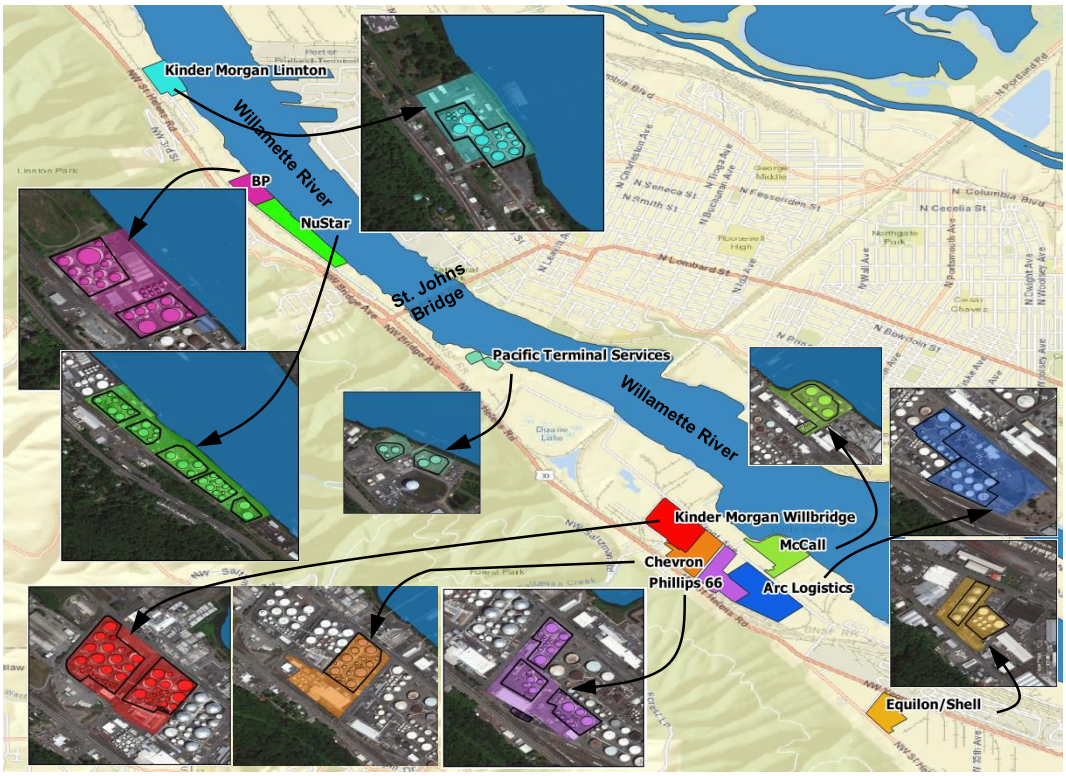

Figure 6: Companies with Liquid Fuel Facilities at the CEI Hub (background Google Maps)

The petroleum storage tank owners are required to submit an oil spill contingency plan to the Department of Environmental Quality (DEQ). In 2015 Oregon Public Broadcasting (OPB) made a public records request and attained records from seven owners of liquid fuel storage tanks (Schick 2015). These included BP, Chevron, Kinder Morgan, McCall, NuStar, Pacific Terminal Services and Phillips 66. Further queries into the City of Portland permits

database indicated that no additional fuel storage tanks were constructed since 2015, making the data set relevant to date. In addition to this dataset, two additional companies were identified through review of The City of Portland Bureau of Planning and Sustainability documentation from 2016 (Bureau of Planning and Sustainability 2016). These companies were Arc Logistics and Shell/Equilon.

In all, there were 10 properties with liquid fuel storage tanks, owned by 9 different companies. Within each property, large tanks appear to be collocated within shared secondary containment areas that are built to contain potential spillage or leaks. These containment areas are typically intended to contain the volume of the largest tank in the group and are constructed using soil dikes or structural walls. No data was found related to the secondary containment aspect of the facilities in any of the properties, so the areas were manually traced and acreage calculated based on satellite imagery. The resulting tank locations and associated containment areas are depicted in Figure 6 via zoomed in details for each property. The acreage and the number of storage tanks are summarized in Table 2 for each company. To help parse the data when available, the tanks were grouped into tank diameters that were 25 ft and larger or smaller than 25 ft.

Table 2: Total Area and Fuel Storage Overview

Company	**Site Area** (acres)	**Secondary Containment** No.	(acres)	**No. of Storage Tanks** ≥ 25ft	< 25ft	**Tank Capacity** (million Gallons) ≥ 25ft	< 25ft
Kinder Morgan							
Linnton Terminal	13	1	5.5	19	14	20.4	0.3
Willbridge Terminal	33	2	17.0	46	88	70.0	1.5
BP	18	2	5.6	26	6	23.9	0.0
NuStar	22	5	11.8	31	4	53.4	0.1
Pacific Terminal Services	2	2	3.2	5	2	11.6	0.0
Chevron	21	1	8.5	35	109	47.4	3.0
Phillips 66	21	4	10.8	36	61	29.3	1.1
McCall	19	2	10.0	10	16	40.0	0.5
Arc Logistics	39	2	14.0	25		61.6	
Equilon/Shell	38	2	6.8	13		16.8	

TANK TYPE AND QUANTITY

The records for seven of the companies list a total of 514 tanks, of which 146 were tagged to be out-of-service (O.O.S). While it is unclear if O.O.S. tanks could be brought back to service, examination of aerial photographs of some of the known locations of large O.O.S. tanks show visual signs of tank deterioration that make that possibility less likely. The data for each tank include the storage capacity, substance, and year built for each tank. Tank type is also included, although this identification is not consistent across the different companies.

Phillips 66 reported container type as welded or riveted steel while the others reported container type by the roof characteristics (e.g. floating roof, fixed roof, cone roof, vertical fixed roof). There were no tank details available for Shell/Equilon and Arc Logistics, so the additional 38 tanks were estimated from satellite imagery. The number of tanks breakdown along with the fuel storage capacity for each of the companies is summarized in Figure 7. Given that floating roof tanks can exhibit different dynamic behavior to fixed roof under earthquake motion, the tank types are differentiated where known.

Discounting the O.O.S. tanks, there are at least 362 tanks with a total capacity of 8.64 million barrels (362.9 million gallons) of liquid product of various types. Despite approximately 40% of the tanks being 25 ft in diameter or larger, they can hold over 95% of the total volume capacity. The total volume is not present on site at any given time because the tanks are not always full. The average fill varies, nonetheless there is a significant amount of liquid fuel products stored in above ground storage tanks at the CEI Hub. There also appear to be a wide spectrum of tank types. The tank construction includes riveted and welded, as well as fixed and floating roof. The variability in construction and tank type make relevant all of the aforementioned structural damage vulnerabilities exposed by past earthquakes.

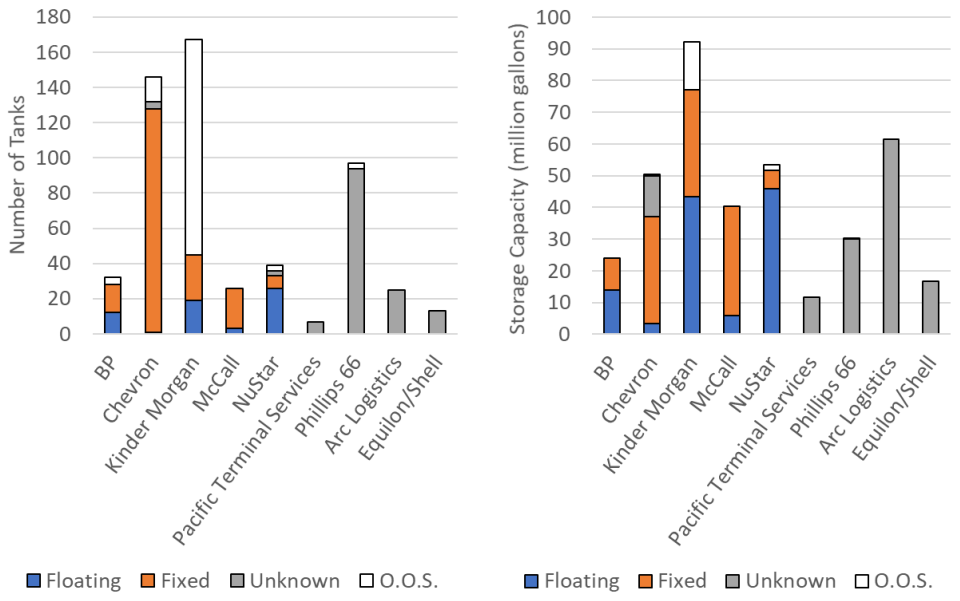

Figure 7: Number of Tanks (left) and Total Storage Capacity (right) by Company

TANK AGE AND SIZE

Knowledge about a seismic hazard evolves over time. In Oregon, our understanding of the threat of the looming Cascadia Subduction Zone (CSZ) has only come to light in the last 20 years. Design standards follow and therefore the age of any structure is often a strong indicator of the potential vulnerability. To get a sense of the age of the tank inventory at the CEI Hub, the tank age is summarized in Figure 8 by showing the number of in-operation storage tanks built within a particular decade. Within each decade, the number of tanks are binned by the tank diameter in increments of 20 ft. This allows for a visual representation of the physical size of the tank and indirectly the volume of fuel capacity. The tank diameters were only provided for approximately half of the tanks. Regression model based on the tank volume and the known tank diameters was developed and used to estimate the tanks for which diameters information was not available.

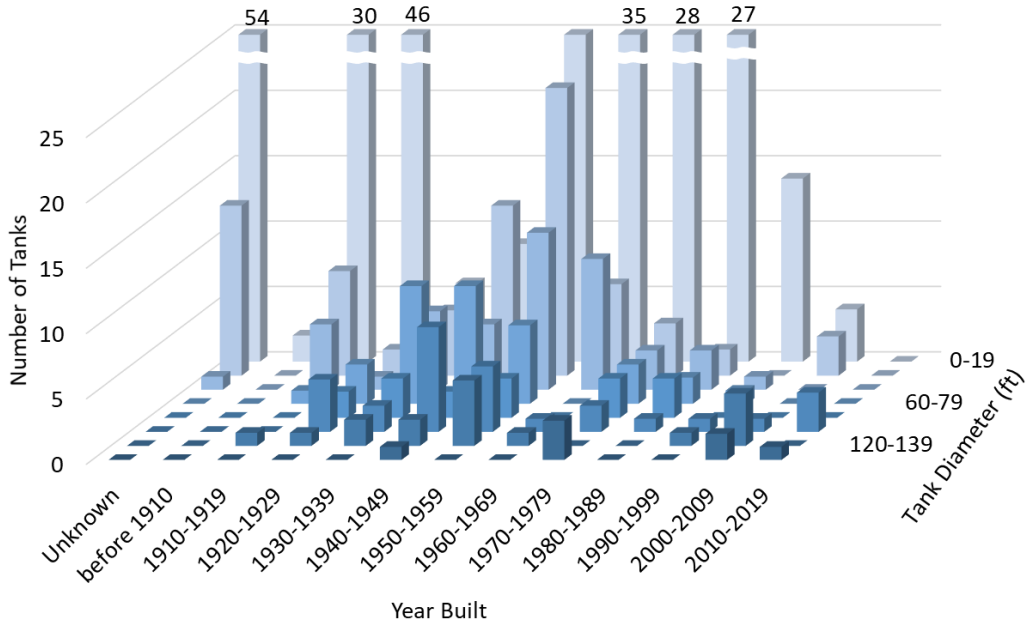

Figure 8: Distribution of In-operation Tank Age and Size

There are numerous in-service large tanks built prior to 1930s. Most significantly, majority of the tanks and majority of the fuel capacity within the hub has been built prior to 1960s. Even if the designers were fully aware of the seismic hazard, this time frame is prior to any design and performance lessons learned from the damaging Great Alaskan earthquake of 1964 and the many other

documented earthquakes that followed. The next construction active period in the CEI hub spanned 1970s-1980s, with only a few large tanks built in the last couple of decades.

The industry standard for the design of petroleum storage tanks is published by the American Petroleum Institute (API); API Standard 650 establishes the minimum design requirements for welded tanks. It is unclear what standards were used for the design of the tanks as the City of Portland had not been overseeing these non-building structures. Even so, the seismic load requirements in Portland have significantly increased for buildings during the 1990s, reflecting the state of science of the regions seismicity. Regardless of the design standards followed, the vast majority of the tanks were constructed with minimal, if any, considerations of seismic loading given their vintage.

Soil Characterization

Detailed subsurface information at CEI hub in general is very limited. Based on the available information, loose to medium dense silty sand lie below the groundwater table and the soil is susceptible to liquefaction (Beaty et al 2014). There is also a possibility of landslides from the nearby slope entering the area. Raster data that included permanent ground deformations from liquefaction was made available by the Oregon Department of Geology and Mineral Industries (DOGAMI 2012) and was overlaid on the fuel storage facilities as shown in Figure 9. Because of the proximity to the river, the permanent ground deformations due to liquefaction and lateral spreading is expected to be very high at all fuel storage tank locations. The underlying raster data is a high level assessment and serves only as an indicator for liquefaction risk at any particular location within the hub. More detailed geotechnical assessment would be needed to quantify the severity, nonetheless, liquefaction clearly poses a significant risk for all of the liquid fuel tanks in the CEI Hub. If left unmitigated, the seismically induced damage observed in past earthquakes is likely to manifest.

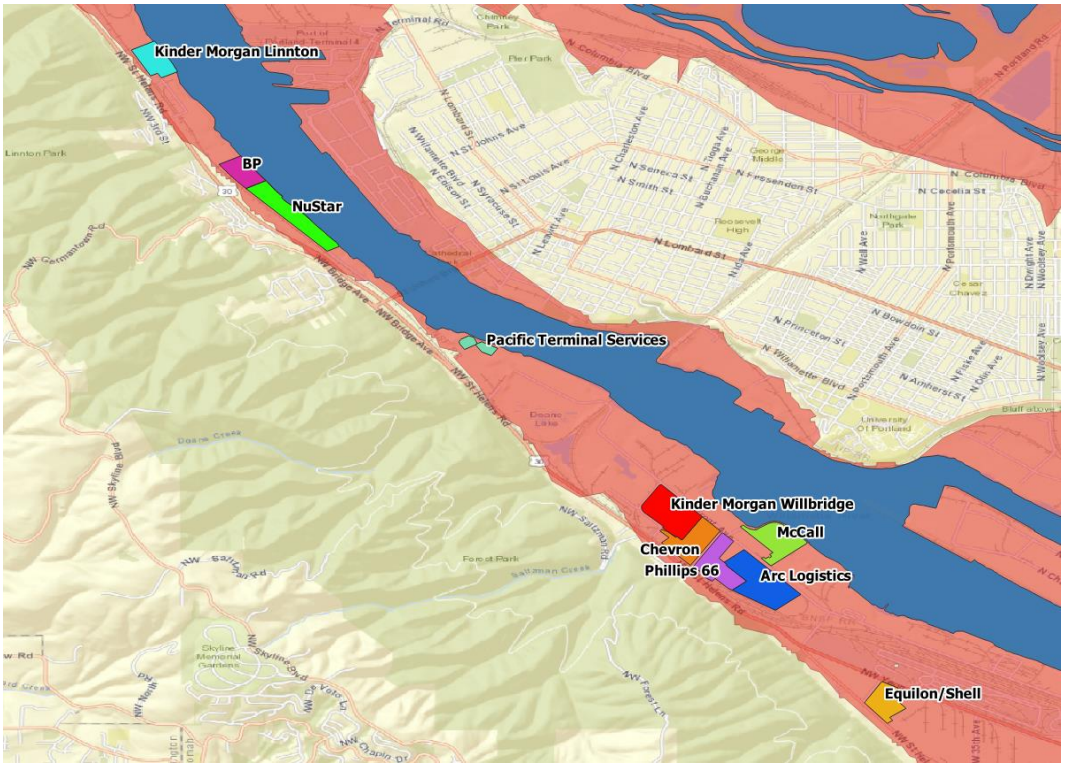

Figure 9: Areas of High Permanent Ground Deformations (shaded red) following CSZ Earthquake (background Google Maps)

POTENTIAL SEISMIC HAZARD MITIGATIONS

SEISMIC HAZARD

Factors contributing to seismic performance of above ground storage tanks include the amount of shaking, the existence of anchorage, subsurface soil condition and the amount filled at the time of the earthquake. The amount of shaking relates to the seismic risk characteristics and for Portland and Oregon, the CSZ is one of the more significant considerations. The expected severity of the shaking is represented by the 5% critically damped spectral acceleration plot in Figure 10 and includes a probabilistic hazard of a 500 year return and 1000 year return earthquake as well as the anticipated full rupture of the CSZ. These values consider the location of the CEI hub relative to the earthquake as well as a relatively soft soil (Vs_{30}=270 m/s). The expected accelerations ranging between 0.2g and 0.56g are well within the range of accelerations where structural tank damage as well as soil liquefaction were reported in past earthquakes. The level of shaking is therefore expected to be significant and have the potential to cause damage or failure to vulnerable fuel storage tanks.

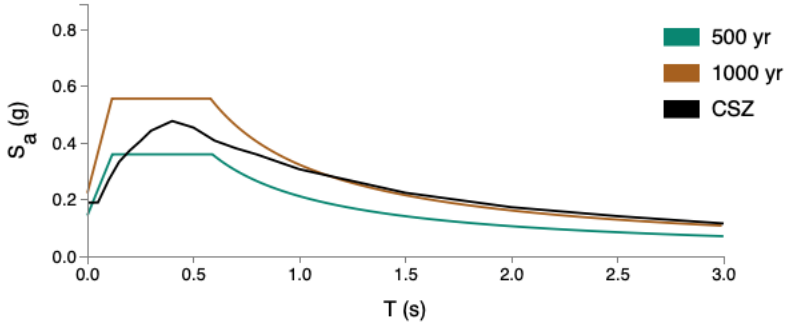

Figure 10: Spectral Acceleration for Portland's CEI Hub

The stresses generated on the tank can be correlated to the amount of fuel in the tank. Performance during past earthquakes have indicated a lower susceptibility to damage for tanks that are partially filled. One potential mitigation of the risk of damage can therefore employ practices that at maximum only partially fill any vulnerable tank.

STRUCTURAL MITIGATION

The large diameter fuel storage tanks are typically above-ground and constructed with flexible floors and steel perimeter shell that is supported on a reinforced

concrete ring foundation. Smaller diameter tanks are likely to be supported by a reinforced concrete slab on grade. In either case, anchorage for the tanks have the potential to limit or minimize the uplift of the walls of the tank as the liquid imposes stresses on the tank walls. Effectiveness of anchoring storage tanks has been demonstrated in past earthquakes and would most likely be implemented for any new tank construction. Tanks in the CEI hub are unlikely to be anchored and would need to be retrofitted. As with most seismic retrofit cases, mitigating existing structures is more challenging than starting with a blank site. The anchorage would need to be implemented around the perimeter, connecting the steel shell with the foundation. The details of the connectivity will need to be evaluated depending on the individual tank as additional challenges may arise from having the ability to attach to the tank wall or the foundation. Issues with welding ranging from the steel vintage to shell thickness need to evaluated as is the ability of the foundation to resist the anchorage forces.

Soil Mitigation

For storage tanks located further away from the edge of the river, lateral spreading may not necessarily be as great a concern. However, liquefaction settlement and bearing capacity failures could result in damage to the tanks. To mitigate liquefaction settlement, the ring foundations could be mitigated by installing sheet piles or compaction grout columns around the perimeter. Sheet piling consists of installing steel interlocking sheets around the perimeter. Compaction grouting displaces and densifies loose granular soils by staged injection of fluid grout. These sub surface columns would support the tank shell and potentially the I/O connections, but the centers of the tanks could still settle. Site specific studies would be necessary to assess the differential.

To mitigate lateral spreading in addition to settlement, jet grout columns could be installed under the tanks. Jet grouting is a hydrodynamic jet process that breaks up and loosen the ground, and mixes fluid grout with the soil. The jet grouting can be inserted at an angle, potentially reaching and mitigating soil under the tank as well as the perimeter. For large diameter tanks the jet grouting might require the tanks to be drained and cut open so that low-overhead equipment can work from within the tank.

Alternatively and less conventionally, instead of treating the soil, the water table could be lowered because without water, no liquefaction of the soil can occur. An example of this was implemented in three sites in Japan in 1970s. Underground cutoff wall was constructed using the slurry wall technique with soil/bentonite backfill. The cutoff wall surrounded a group of tanks and the water table was lowered. The refinery reported that these tanks had no damage after the 2011 Tohoku Earthquake.

CONCEPTUAL ESTIMATION OF SEISMIC MITIGATION COSTS

In order to get a sense of the magnitude of costs required to mitigate the major vulnerabilities of the liquid fuel storage tanks at the CEI hub, a high level cost estimation was made based on the tank data available. Three components of the mitigation costs were estimated; soil mitigation, structural anchoring and associated design/permitting. These were estimated as follows:

- Soil mitigation – in order to address both liquefaction induced settlement as well as lateral spreading, jet grouting was selected for estimating the cost. Jet grouting estimates were obtained from one of the major national geotechnical construction contractors. The calculated cost include an initial mobilization of $100K/tank plus the cost of the grouting procedure. While economies of scale could be employed to lower the mobilization costs, there is much uncertainty at this conceptual stage to be fine-tuned. The grouting procedure costs were estimated at $400/cubic yard of grout, 35% grouted mixing for 40ft depth under the entire area of the tank. This cost was calculated for each 25ft diameter or larger tank, each rounded to the nearest $100K. The resulting cost aims to represent the material and labor cost of soil mitigation implementation for the larger tanks.

- Tank anchoring – as an initial estimate, mobilization cost of $50K/tank was used plus an additional $1K/ft of the tank perimeter. This cost was calculated for each 25ft diameter or larger tank, each rounded to the nearest $100K. The resulting cost aims to represent the material and labor cost of implementation for the larger tanks.

- Design and permitting – in order to implement the above mitigation, engineering assessment, design and permitting needs to be conducted. This cost was simply estimated as 10% percent of the total cost for both soil and structural mitigation implementation combined.

The calculated cost is summarized in Figure 11. Values are separated for floating tanks and other because floating tanks on average have larger diameters and at a future date could also include the cost of installation of fire suppression measures, which at this time were not estimated. The total cost for implementing these conceptual mitigation measures to storage tanks of 25 ft diameter and larger is estimated to exceed $300 million. Over one third of the cost is for floating roof tanks alone. Unsurprisingly, the cost of soil remediation dominates the overall cost for all tanks, especially for floating roof tanks that tend to have a higher ratio of area to perimeter given their general larger size. The cost of mitigating storage tanks smaller than 25 ft in diameter is expected to only incrementally add to the overall cost as the mitigation measures would more likely be associated with structural anchoring rather than deep soil mitigation.

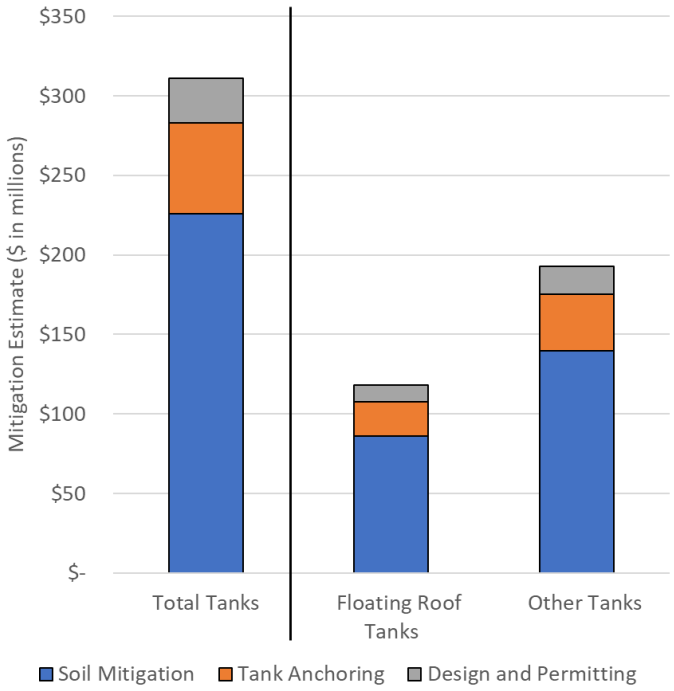

Figure 11: Conceptual Seismic Mitigation Cost Estimates for Tanks 25ft in Diameter and Larger

The conceptual cost estimate was intended as a first pass order of magnitude number for mitigating the damage and failure of only the tanks. No cost consideration was given to maintaining integrity of the fuel distribution system, support mechanical systems, secondary containment areas or the shore terminals that are also located on the site. And, the aim of the remediation measures for the tanks was to minimize the potential for failure that would result in loss of fuel. Much more detailed analyses would need to be conducted to estimate each property ability to operate following a major earthquake event.

RECOMMENDATIONS FOR NEXT STEPS

This study provided a closer look at the seismic vulnerability of the CEI hub by assessing more quantitatively the available inventory of fuel storage tanks at the site. The recommended next steps aim to build on this work to fill information gaps and generate new critical knowledge with the overarching goal of quantifiable assessment and mitigation of seismic risk.

- Develop seismic performance criteria for storage tanks at the CEI hub:

  The philosophy behind majority of design standards and codes is to prevent catastrophic failure. Given the criticality of the fuel, specific seismic performance criteria for the storage tanks in the CEI hub need to be developed. The criteria need to address the input earthquake motion as well as the desired output performance goals, such as tank collapse, prevention of leakage, access to fuel or continued operations. Having established criteria will provide basis for evaluation and eventual design. The decisions made in establishing the criteria can significantly affect the mitigation costs and if adhered to, the associated performance level of post-earthquake performance.

- Quantify tank seismic fragility:

  Seismic fragility describes the anticipated performance for a particular ground motion input parameter. For example, the potential for tank wall collapse given the earthquake peak ground acceleration. Limited literature exists on the topic, quantifying liquid storage tank fragility difficult. To address this shortcoming, archetype tanks should be defined that represent different storage sizes, roof types, structural as well as soil characteristics. Numerical models of the archetypes need to be analyzed to determine their seismic fragility. This new knowledge would be used to inform the seismic loss assessment process and provide a tool to quantify the effectiveness of particular mitigation measures. For example, the amount of fuel fill in the tank can be used as a variable in the analyses to determine the seismic performance benefit gained by lowering the amount of fuel stored. The fragility is useful on individual tank basis, can be applied across the tank inventory and can be used to better understand cost/benefit.

- Investigate mitigation options for fuel distribution:

  The focus of the study has been on the storage tank inventory, but aspects related to connectivity and distribution of the fuel are also important. Pipelines, support mechanical systems and access terminals need to be better understood, existing condition assessed and mitigation options investigated.

- Conduct subsurface geotechnical investigations:

  All of the sites are located close to the river and have been generally identified as susceptible to liquefaction. Detail survey of the properties of the soil at depth are needed. This information could then be used to estimate soil amplification of ground motion, the amount of settlement as well as lateral spread from liquefaction, and be used to refine the cost of the extent of the soil remediation required.

- Obtain detailed structural tank information:

  The current tank data set is incomplete and basic information that was inferred needs to obtained, including missing tank diameters, tank roof types and physical locations. Additional structural data currently not available needs to be gathered. Details of existing foundation size, tank to foundation anchorage, tank wall thickness, roof support and I/O connectivity. Some of this information can be gathered through site visits while other would require more direct tank owner cooperation.

- Prioritize fuel storage tanks:

  From the hundreds of tanks identified, certain types of fuel and certain size of tanks are likely to be more critical to post-earthquake recovery than others. Prioritization of the tanks based on post-earthquake needs and consequences of failure should be conducted. Having prioritized tanks would help focus the associated assessment and mitigation efforts.

Re: Testimony - Proposed Re-adoption of the Fossil Fuel Terminal Zoning Amendments, November 20, 2019 Hearing

Dear Mayor Wheeler and City Council Members:

Zenith Energy Terminals Holdings LLC ("Zenith") owns and operates a terminal located at 5501 NW Front Avenue in Portland (the "Terminal"; parcels R315777, R315845, R315892) that stores Zenith's customers' liquid products, which Zenith receives from, and delivers to, marine vessels, railcars and/or trucks on behalf of its customers. These liquid products currently include petroleum, petroleum products and renewable fuels, which are brought to the Terminal from outside Oregon and returned to customers for transportation within Oregon and elsewhere in the United States. The Terminal meets the City's proposed definition of a "Bulk Fossil Fuel Terminal" and, along with other terminals, would be subject to the proposed Fossil Fuel Terminal Zoning Amendments ("FFTZA").

Zenith objects to the City's proposed action to readopt the FFTZA. The FFTZA will inhibit infrastructure upgrades for safety and to meet changing market demands. In light of the recent decision from the City's Office for Community Technology ("OCT") prohibiting development for renewable fuels at Zenith's Terminal, the FFTZA also fails to adequately authorize storage capacity development for renewable fuels. The FFTZA was remanded to the City because the City relied on "unsupported speculations" rather than factual evidence to make its original decision adopting the FFTZA. The City now proposes to adopt a substantively identical version of the FFTZA, but to date (years after the evidentiary deficiencies were recognized in the courts), the City has not identified and made available for public review any additional facts that support readopting the FFTZA.

Please include this testimony in the record of the above-referenced proceeding and provide us notice of the final decision.

The FFTZA Inhibits Safety and Modernization Improvements

The FFTZA prohibits expansion of fossil fuel storage capacity at existing Bulk Fossil Fuel Terminals even in conjunction with facility modernization or otherwise desirable safety upgrades, such as to address seismic concerns. As was detailed by many terminal operators and representatives during the City's original consideration of the FFTZA in 2016, owners and operators of Bulk Fossil Fuel Terminals are unable to invest the significant private resources needed for these improvements without incentives, including opportunities for expansion to meet market demand. Moreover, upgrading tanks, pipes, containment, and associated infrastructure to a new seismic or safety standard often requires the construction of new infrastructure so that

repairs/upgrades can be made without interrupting service to customers, including service to end users. As relevant here, storage tanks cannot be upgraded while containing product, so new storage tanks would need to be constructed before existing storage tanks are taken out of service. The FFTZA, though, prevents that as constructing new storage tanks would (at least temporarily) increase storage capacity. As a result, if adopted in its current form, the FFTZA will most likely prevent the City's desired upgrades from occurring at Bulk Fossil Fuel Terminals. Importantly, this conflicts with Resolution 37168, which prohibits the City Council from restricting (i) improvements in safety, efficiency, seismic resiliency, or operations of existing Bulk Fossil Fuel Terminals, (ii) the provision of service by Bulk Fossil Fuel Terminals directly to end users, and (iii) development of emergency backup capacity at Bulk Fossil Fuel Terminals.

The FFTZA Provides Inadequate Protection for Renewable Fuel Development

Based on recent City actions, Zenith has serious concerns about implementation of the FFTZA, should it be enacted, with regard to increasing Portland's storage capacity for renewable fuels. The City's draft findings state that "the City Council expressed support for accelerating the transition to non-fossil fuel energy sources" under Resolution 37168, and indicate support for the DEQ-led Oregon Clean Fuels Program, which promotes increased use of ethanol, biodiesel and other renewable fuels. The City's draft findings conclude that "in order to facilitate implementation of the Clean Fuels Program" and provide capacity needed for renewable fuels, "non-fossil fuel storage tanks are not subject to the capacity limits" under the FFTZA.

Zenith desires to increase the Terminal's capacity to handle and store renewable fuels and strongly supports excluding renewable fuels, including renewable diesel and biodiesel from the FFTZA storage tank capacity limits. However, Zenith has grave concerns about the implementation of this renewable fuel exclusion due to a recent decision involving Zenith's Terminal. Last month, the OCT, with full support of the City Attorney's Office and Mayor Wheeler, relied on the same Resolution 37168 to deny Zenith's proposal to construct two pipelines that would be exclusively used for renewable diesel and biodiesel (and a third pipeline that would be exclusively used for a non-fuel liquid). The OCT denied the proposal because it found the pipelines (which like any pipes capable of transporting liquids) were "capable" of being used to transport fossil fuels, despite Zenith proactively offering a condition prohibiting such use. Given this very recent history, Zenith is concerned that the City will also deny any proposal to increase renewable fuel storage capacity at a Bulk Fossil Fuel Terminal for the same reason.

As the City is no doubt aware, much like pipes, storage tanks are capable of storing a variety of liquids. If the City interprets its existing policies to not allow new pipelines for renewable fuels because the pipes are "physically capable" of being used to transport fossil fuels, what assurance do Zenith and other operators seeking to add renewable fuel storage capacity have that the City will not similarly prohibit new storage tanks that are "physically capable" of storing fossil fuels, even if that capacity is dedicated to renewables (or other non-fuel liquids)? Zenith urges the City to revise the FFTZA to make abundantly clear that new non-fossil fuel storage capacity at a Bulk Fossil Fuel Terminal is allowed and there is no requirement to prove, under either the FFTZA or

ZENITH ENERGY

ZENITH ENERGY TERMINALS HOLDINGS LLC

Resolution 37168, that such storage facilities are not "physically capable" of being used for fossil fuels.

Emergency Ordinance

In January 2018 the Oregon Court of Appeals confirmed the existence of glaring evidentiary deficiencies regarding the market demand for fossil fuels. The subsequent passage of almost two years indicates that the City Council's use of an emergency ordinance in this situation is without justification.

Sincerely,

JT Hendrix

Re: Testimony - Proposed Re-adoption of the Fossil Fuel Terminal Zoning Amendments, November 20, 2019 Hearing

Dear Mayor Wheeler and City Council Members:

Zenith Energy Terminals Holdings LLC ("Zenith") owns and operates a terminal located at 5501 NW Front Avenue in Portland (the "Terminal"; parcels R315777, R315845, R315892) that stores Zenith's customers' liquid products, which Zenith receives from, and delivers to, marine vessels, railcars and/or trucks on behalf of its customers. These liquid products currently include petroleum, petroleum products and renewable fuels, which are brought to the Terminal from outside Oregon and returned to customers for transportation within Oregon and elsewhere in the United States. The Terminal meets the City's proposed definition of a "Bulk Fossil Fuel Terminal" and, along with other terminals, would be subject to the proposed Fossil Fuel Terminal Zoning Amendments ("FFTZA").

Zenith objects to the City's proposed action to readopt the FFTZA. The FFTZA will inhibit infrastructure upgrades for safety and to meet changing market demands. In light of the recent decision from the City's Office for Community Technology ("OCT") prohibiting development for renewable fuels at Zenith's Terminal, the FFTZA also fails to adequately authorize storage capacity development for renewable fuels. The FFTZA was remanded to the City because the City relied on "unsupported speculations" rather than factual evidence to make its original decision adopting the FFTZA. The City now proposes to adopt a substantively identical version of the FFTZA, but to date (years after the evidentiary deficiencies were recognized in the courts), the City has not identified and made available for public review any additional facts that support readopting the FFTZA.

Please include this testimony in the record of the above-referenced proceeding and provide us notice of the final decision.

The FFTZA Inhibits Safety and Modernization Improvements

The FFTZA prohibits expansion of fossil fuel storage capacity at existing Bulk Fossil Fuel Terminals even in conjunction with facility modernization or otherwise desirable safety upgrades, such as to address seismic concerns. As was detailed by many terminal operators and representatives during the City's original consideration of the FFTZA in 2016, owners and operators of Bulk Fossil Fuel Terminals are unable to invest the significant private resources needed for these improvements without incentives, including opportunities for expansion to meet market demand. Moreover, upgrading tanks, pipes, containment, and associated infrastructure to a new seismic or safety standard often requires the construction of new infrastructure so that

repairs/upgrades can be made without interrupting service to customers, including service to end users. As relevant here, storage tanks cannot be upgraded while containing product, so new storage tanks would need to be constructed before existing storage tanks are taken out of service. The FFTZA, though, prevents that as constructing new storage tanks would (at least temporarily) increase storage capacity. As a result, if adopted in its current form, the FFTZA will most likely prevent the City's desired upgrades from occurring at Bulk Fossil Fuel Terminals. Importantly, this conflicts with Resolution 37168, which prohibits the City Council from restricting (i) improvements in safety, efficiency, seismic resiliency, or operations of existing Bulk Fossil Fuel Terminals, (ii) the provision of service by Bulk Fossil Fuel Terminals directly to end users, and (iii) development of emergency backup capacity at Bulk Fossil Fuel Terminals.

The FFTZA Provides Inadequate Protection for Renewable Fuel Development

Based on recent City actions, Zenith has serious concerns about implementation of the FFTZA, should it be enacted, with regard to increasing Portland's storage capacity for renewable fuels. The City's draft findings state that "the City Council expressed support for accelerating the transition to non-fossil fuel energy sources" under Resolution 37168, and indicate support for the DEQ-led Oregon Clean Fuels Program, which promotes increased use of ethanol, biodiesel and other renewable fuels. The City's draft findings conclude that "in order to facilitate implementation of the Clean Fuels Program" and provide capacity needed for renewable fuels, "non-fossil fuel storage tanks are not subject to the capacity limits" under the FFTZA.

Zenith desires to increase the Terminal's capacity to handle and store renewable fuels and strongly supports excluding renewable fuels, including renewable diesel and biodiesel from the FFTZA storage tank capacity limits. However, Zenith has grave concerns about the implementation of this renewable fuel exclusion due to a recent decision involving Zenith's Terminal. Last month, the OCT, with full support of the City Attorney's Office and Mayor Wheeler, relied on the same Resolution 37168 to deny Zenith's proposal to construct two pipelines that would be exclusively used for renewable diesel and biodiesel (and a third pipeline that would be exclusively used for a non-fuel liquid). The OCT denied the proposal because it found the pipelines (which like any pipes capable of transporting liquids) were "capable" of being used to transport fossil fuels, despite Zenith proactively offering a condition prohibiting such use. Given this very recent history, Zenith is concerned that the City will also deny any proposal to increase renewable fuel storage capacity at a Bulk Fossil Fuel Terminal for the same reason.

As the City is no doubt aware, much like pipes, storage tanks are capable of storing a variety of liquids. If the City interprets its existing policies to not allow new pipelines for renewable fuels because the pipes are "physically capable" of being used to transport fossil fuels, what assurance do Zenith and other operators seeking to add renewable fuel storage capacity have that the City will not similarly prohibit new storage tanks that are "physically capable" of storing fossil fuels, even if that capacity is dedicated to renewables (or other non-fuel liquids)? Zenith urges the City to revise the FFTZA to make abundantly clear that new non-fossil fuel storage capacity at a Bulk Fossil Fuel Terminal is allowed and there is no requirement to prove, under either the FFTZA or

ZENITH ENERGY

ZENITH ENERGY TERMINALS HOLDINGS LLC

Resolution 37168, that such storage facilities are not "physically capable" of being used for fossil fuels.

Emergency Ordinance

In January 2018 the Oregon Court of Appeals confirmed the existence of glaring evidentiary deficiencies regarding the market demand for fossil fuels. The subsequent passage of almost two years indicates that the City Council's use of an emergency ordinance in this situation is without justification.

Sincerely,

JT Hendrix
Terminal Manager - Portland

Portland City Council
Fossil Fuel Zoning Testimony
1221 SW Fourth Avenue, Room 130
Portland, Oregon 97204

RE: Fossil Fuel Terminal Zoning Amendments Remand Report

Mayor Wheeler and Honorable Members of the City Council:

I am writing on behalf of Western States Petroleum Association ("WSPA"), a nonprofit trade association that represents companies engaged in petroleum exploration, production, refining, transportation, and marketing in the western United States. As we did in 2016, we are writing in opposition to the City's proposed amendments to its zoning code targeting fuel facilities (the "Proposed Amendments"). We ask the City to reject this policy because it is bad for the local economy, hinders transition to cleaner fuels, and hinders safety upgrades.

WSPA members have operated in the energy corridor along Northwest St. Helens Road for decades. This corridor provides key energy and emergency infrastructure as recognized by various city, state, and federal documents. WSPA members remain concerned that the Proposed Amendments lock existing infrastructure in place, which prevents efficiency, environmental, and safety improvements. It also undercuts the ability to meet future energy needs.

If adopted, the Proposed Amendments would be a public policy failure because they create significant adverse impacts on local energy supply, transportation resources, safety, and the economy without achieving their purported objectives, including the intent to reduce greenhouse gas emissions and to mitigate risks posed by earthquakes.

The Proposed Amendments Will Have Significant Adverse Impacts on Regional Energy Supply, Clean Fuels Transition, and Safety.

The Proposed Amendments create more harm than good. They will inflict significant impacts on the ability to supply fuel and change fuel types as the region grows, technology advances, and fuel standards change. The Proposed Amendments freeze existing infrastructure in place by location and size. They would hinder improvements to fuel infrastructure.

1415 L Street, Suite 900, Sacramento, California 95814
(916) 498-7752 ▪ Fax: (916) 444-5745 ▪ Cell: (916) 835-0450
cathy@wspa.org ▪ www.wspa.org

Specifically, the Proposed Amendments would:

- Prevent and discourage terminal upgrades, including tank seismic upgrades, due to the business impacts of capping tank capacity, resulting in *fewer* upgraded tanks;
- Prevent and discourage equipment upgrades necessary to meet market demand or comply with federal and state clean fuels law;
- Prevent and discourage infrastructure upgrades, which typically occur concurrently with market-based infrastructure expansion and improvement;
- Prevent and discourage efficiency upgrades that generally reduce greenhouse gas emissions;
- Prevent and discourage the transition to newer lower-carbon-fuel sources in opposition to Oregon's low-carbon-fuel standards, Oregon's Renewable Fuel Standards, federal Renewable Fuel Standards, and similar laws;
- Fail to provide for sufficient facilities and tank capacity to serve future energy needs;
- Thwart future technologies that do not fit within the current infrastructure framework;
- Exclude Portland from the national and international energy markets;
- Introduce a host of ambiguities and uncertainties to the marketplace that are necessary for a thriving economy;
- Not align with state and federal policy regarding siting energy infrastructure or transportation of fuels;
- Encourage less efficient, higher emission, and potentially less safe transportation by truck over more efficient modes of transportation, such as pipeline; and
- Prohibit new terminals and new intermodal links that can deliver fuel more efficiently and with lower emissions.

In short, the Proposed Amendments would freeze current infrastructure in place. This infrastructure is insufficient for future fuel demand, by both quantity and type of fuel. If Portland had passed a similar ordinance 10, 20, or 30 years ago, the fuel infrastructure in Portland today would have a higher carbon footprint and be less safe.

1415 L Street, Suite 600, Sacramento, California 95814
(916) 498-7752 ▪ Fax: (916) 444-5745 ▪ Cell: (916) 835-0450
cathy@wspa.org ▪ www.wspa.org

The Proposed Amendments will fail to deliver the intended benefits, including any reduction of greenhouse gases ("GHGs") and any increased safety.

While the Proposed Amendments will inflict these negative impacts on the local, state, and regional economy, and ability to transition energy resources, they simultaneously fail to achieve some of their basic objectives. Most notably, they will not reduce GHG emissions. The Proposed Amendments suffer from an incorrect understanding of how GHG emissions occur in the fuel supply chain.

The Proposed Amendments do not limit the regional demand for fuel. Fuel is a classic example of a product with inelastic demand. There are few to no supplements for most types of fuel, so consumers will continue to demand fuel, even if it must be delivered though less efficient modes with greater cost and emissions. As regional demand for fuel quantity grows and demand for types of fuel changes (including increased demand for fuel with less carbon), that fuel will be supplied through some delivery mechanism. The Proposed Amendments, which prohibit new terminals, new intermodal links, and new fuel tanks in Portland, will result in dramatically increased fuel transport by truck. Moving fuel by truck costs more, clogs roads, and increases GHG emissions compared to transport by pipe and tank.

The Proposed Amendments undercut the City's goals. Specifically, the Proposed Amendments would:

- Prevent and discourage terminal safety improvements, including tank seismic upgrades, due to the business impacts of capping tank capacity, resulting in *fewer* upgraded tanks;
- Prevent and discourage safety upgrades, which typically occur concurrently with market-based infrastructure expansion and improvement;
- Require locating fossil fuel tanks in liquefaction zones by prohibiting relocation of fossil fuel tanks outside of mapped liquefaction areas in Portland;
- Prohibit siting newer, lower emission fuel facilities;
- Prevent and discourage efficiency upgrades that generally reduce greenhouse gas emissions;
- Prohibit new fuel tanks for blended fuels that transition towards lower-carbon-fuel sources; and
- Encourage higher emission and potentially less safe transportation by truck over more efficient modes of transportation, such as pipeline.

The Proposed Amendments unfortunately do not help—and in fact, significantly hinder—the City's goals of reducing GHG emissions and increasing facility safety, particularly as it relates to earthquake hazards.

1415 L Street, Suite 600, Sacramento, California 95814
(916) 498-7752 ▪ Fax: (916) 444-5745 ▪ Cell: (916) 835-0450
cathy@wspa.org ▪ www.wspa.org

Conclusion.

We respectfully ask that the City Council reject the Proposed Amendments. If enacted, the Proposed Amendments would cause significant negative impacts to the City's economy, energy supply, and transportation resources. At the same time, the amendments would undercut the City's goals by causing a net increase in GHG emissions, hinder the transition to cleaner fuels, reduce the number of safety improvements in Portland, and prohibit relocating fuel tanks out of liquefaction zones.

We welcome any questions or comments you might have. Please contact me or my staff Holli Johnson at (360) 352-4506 or by email at hjohnson@wspa.org.

Sincerely,

To:	Council Clerk – Testimony
Subject:	Linnton Neighborhood Association Written Testimony on CEI Hub, Zenith Energy
Attachments:	CC Testimony Zenith Energy Expansion.docx; CC Testimony Tank Farm Statement.docx

Dear Mayor Wheeler and City Commissioners,

Since we are unable to be present on 4/20/19 to testify before you, please find 2 written documents from
Linnton Neighborhood Association:
1) Tank Farm Position Statement (September 2018)
2) Zenith Energy Expansion Position Statement (September 2019)

Past President of LNA, Shawn Looney, testified before the Multnomah County Commissioners on 10/31/19 about
The CEI Hub and Zenith's planned expansion. We were very pleased in the Commissions unanimous vote to reject
Zenith's expansion and to seek financial surety for any potential damage caused by the tank farms.

We look forward to learning of the city's decisions on these matters.

Sincerely,

Nancy Hiser
Linnton Neighborhood Association Co-Chair
503-713-3468

189807

Linnton Neighborhood Association
Environmental Committee
September 13, 2019

We are concerned that transporting tar sands crude oil by rail poses immense risks to our community and the environment from accidents, potential spills, and explosions. We think the terminal facility site is prone to soil liquefaction that could cause tank failure during a Cascadia Subduction Zone earthquake or other seismic event. The marine tankers also pose unique risks to the Willamette River from spills or leaks. The City of Portland's Climate Action Plan acknowledges the need to dramatically reduce greenhouse gas emissions to mitigate the effects of climate change and tar sands are the most polluting form of fossil fuel.

We oppose the Zenith Energy expansion and all projects for new or expanded facilities that will result in an increase of tar sands transport or storage in Portland. We urge the Portland City Council, Multnomah County Commission, agencies, and officials to deny all support and permits for Zenith Energy and all future permits for new or expanded fossil fuel facilities. Portland City Council, Multnomah County Commission, and relevant agencies should conduct a neighborhood-by-neighborhood fossil fuel risk assessment that studies routine and worst case scenarios for spills, leaks, explosions, and train derailment.

We urge the Portland City Council and Multnomah County Commission to pursue policies that hold fossil fuel companies financially accountable for their pollution and other potential and real damage to Portland and surrounding waterways.

As a community living and working along the rail line, we are concerned about the threat to life, safety, health, and the environment due to accidents, potential spills, and explosions posed by oil trains carrying tar sands crude, by marine tankers, and at the CEI Hub. Increased rail traffic brings additional health impacts to Portland residents from diesel pollution.

Sincerely,

Nancy Hiser
Environmental Co-Chair for Linnton Neighborhood Association

Endorsed by Linnton Neighborhood Association

TANK FARM POSITION STATEMENT

Communities along the Willamette, such as Linnton, value our views of four mountains and the sight of the flowing river. The forests surround us and sounds of foghorns are heard in the early morning hours. It is generally a peaceful scene. But the 6-mile riverfront is also home to scores of fuel tanks—a potentially catastrophic threat to local people and their homes. However, these tanks supply 90% of the entire state's fuel (gasoline, diesel, jet fuel, electricity) and pose a severe challenge to all of Oregon's resilience following a major seismic event. The Cascadia fault, the primary seismic hazard, runs for 700 miles from northern California to southern Canada.

History of Reports

The Oregon Resiliency Plan was published in 2013 by the Oregon Seismic Safety Policy Advisory Commission. After Oregon's Department of Geology and Mineral Industries (DOGAMI) staff studied the Critical Energy Infrastructure (CEI) Hub, they cited "major seismic vulnerabilities" due to "no or antiquated standards of building structure" and "soils susceptible to liquefaction." According to this report, "Cascadia earthquakes pose substantial risk to the CEI Hub and to Oregon. Not only are the energy sector facilities in the CEI Hub dependent on other sectors and systems in Oregon, including transportation and communication, they are interdependent upon each other." They recommended to the state that placement of tanks be diversified and located on bedrock.

Tony Schick, writing for OPB in 2015 in "How We Mapped NW Portland's 'Tank Farms'" furthered our knowledge of the CEI Hub risks. Schick dubbed the CEI Hub "Oregon's Seismic Achilles Heel" and stated, "when OPB began its coverage of the Cascadia subduction zone and Oregon's seismic vulnerabilities, the 'tank farms' in Northwest Portland emerged very quickly as an important part of the series." OPB produced a mapped database of storage tanks and their contents, each tank shaded according to the year of its construction, confirming these tanks dated back to the 1920's when seismic standards did not exist. Map tiles from historic topographic maps from 1905 were used to show where lakes, marshes, and the river path used to be. Then, using Portland's building footprint data, they identified where fill had been used to create the infrastructure to support the creation of commercial and industrial areas, including fuel tanks, substations, pipelines and transmission lines, thus confirming the locations of liquefaction risk.

So, how vulnerable are we?
Consider the variables here, each of which causes concern but taken together are a recipe for disaster.

- The CEI Hub is built on dredged soil which is likely to liquefy in an earthquake. In OPB's report, "the soils could become permeated with water, giving them the consistency of a sandy pudding. If that happens, it can damage buildings, tanks, and pipes." A report from the City Club of Portland, "Big Steps Before The Big One," echoes that prediction.

- Tanks were constructed scores of years ago. They date back to 1929, before any modern day seismic standards were established. This heightens the risk of their failure during an earthquake: toppling, splitting, and exploding are all possible.

- Pipelines are projected to suffer hundreds of breaks and scores of leaks. How effective will the current remediation efforts of operators be? These efforts include remotely operated valves, check valves, enhanced leak detection systems, and increased surveillance.

- Geologic fault structure and the activity of the Juan de Fuca plate have been studied by experts. They state there is a 15% probability of a whole margin subduction event in the next 50 years, and this figure jumps to 37% for a southern margin subduction event. Predictions of destruction are huge: 15 of 17 bridges, 1 out of every 3 fire stations, 1 of every 2 police stations, 2 out of 3 hospitals, and 3000 schools, according to Scott Burns, PSU seismic geologist. Following a major seismic event there will be no electricity for 1-3 months, no water for 1 month, no sewer or highways for 6 months, and taxpayers will pay 75% of the cost. The New Yorker predicts the devastation in detail at https://www.newyorker.com/magazine/2015/07/20/the-really-big-one

- Structures which are responsible for gasoline, diesel, jet fuel, and electricity are located in close proximity. The energy required for disaster recovery will be high. Resiliency will be inversely proportional due to impaired infrastructure for these key resources: energy, communication, and transportation.

What should we do?
This is not a NIMBY ("not in my backyard") position. Energy sources should not be centralized in any singular location, but especially not in one that is unstable and hazardous. Not only will their proximity exacerbate a disaster, but they will collectively handicap our recovery efforts. Those knowledgeable about the world's seismic events, such as Scott Burns, report the recovery efforts following a major seismic event are daunting and we must do all that we can to minimize the risk and maximize our recovery potential.

We acknowledge the following efforts:

The City Club of Portland recommends the following to reduce the risk of catastrophic CEI Hub Failure:

1. Oregon's DOGAMI should commission a geotechnical study of soils of the CEI Hub and alternatives for soil hardening. If grant funding is available, the Legislature should appropriate funds for the study.
2. The Governor and Legislature should designate a single state agency to oversee seismic risks at the CEI Hub. That agency should have the authority to:
   - Require all owners of CEI Hub facilities to provide an engineering assessment of their facilities' vulnerability to a CSZ earthquake and other information relevant to mitigating the current risks.
   - Develop and implement, in collaboration with industry stakeholders, standards for construction and retrofit of storage tanks at the CEI Hub. The standards should be designed to prevent releases and to preserve substantial functionality in the event of a CSZ earthquake.

The Oregon Seismic Safety Policy Advisory Committee has been formally tasked to conduct a 15-month study of the CEI Hub with a report to be submitted to the Office of the State Resilience Officer by December 31, 2019. The report will be provided to the House and Senate Veteran and Emergency Preparedness Committees with recommendations for the 2020 legislative short session which will focus on:

1. Conducting an analysis of state and federal guidance on the regulatory authority for seismic upgrades to both structures (tanks, terminals) and pipelines, to include land mitigation.
2. Working in conjunction with Oregon Solutions, determine incentives from a public-private view that focuses on hardening current infrastructure.
3. Showcasing the Earthquake Early Warning (ShakeAlert) system to encourage seismic awareness within the private sector.
4. Determining if a current state agency has statutory authority to develop long-term mitigation efforts. If not, recommend which state agency would be best suited for this new authority.

SB 850, Community Resilience Report, will be released in September 2018. https://gov.oregonlive.com/bill/2017/SB850/

The above efforts promise to be lengthy and costly processes with unknown success. We don't need to make decisions about what is to be done; the experts have already done that: The CEI Hub must be decentralized and relocated to stable bedrock areas.

Sarita Vasquez

#62458 | November 13, 2019

Testimony to on the **Fossil Fuel Terminals Zoning Amendments, Remand Draft**

Hello Council Members, Quite simply, supporting fossil fuels and all of their evils way back when we didn't have solar ad wind maybe was ok but now we are in a different era. We can do things differently and one of those things we can do differently is make better choices. We've seen time and time again the issues with regard to the impact on our environment. It's time we choose the environment over big bully corporate pressure and let's keep moving forward with clean fuels that are renewable and don't create harm to our environment. No to fossil fuel terminals.

Testimony is presented without formatting.

Todd Aschoff

#62415 | November 9, 2019

Testimony to on the **Fossil Fuel Terminals Zoning Amendments, Remand Draft**

If Les Schwab wants to expand a truck tire facility (trucks deliver gasoline, oil) , wouldn't that be improving Fossil Fuel infrastructure. Their competitors will sue and stop the expansion. When PGE upgrades their natural gas lines, isn't that ..... When an asphalt factory improves their pollution control schemes, aren't they improving fossil fuel infrastructure? I think the ordinance , while well intentioned, is severely flawed.

Testimony is presented without formatting.

Fossil Fuel Terminal Zoning Amendments
Technical Amendment
Neighborhood Contact in EG and I zones

November 20, 2019

Commentary

33.140.050 Neighborhood Contact in EG and I zones

Paragraph B.2 is being amended to include reference to sites with a Bulk Fossil Fuel Terminal use. The contact requirement in the EG and I zones was specifically intended for Bulk Fossil Fuel Terminals as is clearly described in the purpose statement. Reference to sites with Bulk Fossil Fuel Terminal uses was inadvertently left out of the code.

33.140.050 Neighborhood Contact in EG and I Zones

A. Purpose. Neighborhood contact is required when a new storage structure for any type of fuel will be built on a Bulk Fossil Fuel Terminal because of the impacts that fuel projects can have on the surrounding community.

B. Neighborhood contact requirement. Proposals meeting the following conditions are subject to the neighborhood contact steps of 33.705.020.B., Neighborhood contact II. All of the steps in 33.705.020.B must be completed before an application for a building permit can be submitted.

1. The proposed development has not been subject to a land use review; and

2. The proposed development includes at least one new structure for the storage of any type of fuel on a site with a Bulk Fossil Fuel Terminal use.

Commentary

33.730 Quasi-Judicial Procedures

The following amendments correct a mistake that was made as part of the recently adopted Neighborhood Contact Update project. The Neighborhood Contact Update project simplified, clarified and made the existing neighborhood contact requirements more effective. The only existing neighborhood contact requirement in the EG and I zones is a requirement related to development of new fuel storage tanks on fossil fuel terminals. In keeping with the policy direction of the project (clarify the exisiting rules), the Neighborhood Contact Update project did not add neighborhood contact requirements for development other than fuel tanks in the EG or I zones. However, an exemption for development in EG and I zones was inadvertently left out of the code that details the neighborhood contact steps for a land use review. The following amendments add that exemption.

33.730.013 Expedited Land Division Procedure

The Expedited Land Division (ELD) procedure provides an alternative to the standard procedures for some land divisions. The applicant may choose to use the ELD process if the land division request meets all of the elements specified in ORS 197.360. The steps of this procedure are in ORS 197.365 through .375. The application requirements are listed in Section 33.730.060, below. Two additional steps are required for land division requests using the ELD Procedure:

A. Neighborhood contact.

1. When the ELD includes four to ten lots, the applicant is required to meet the neighborhood contact requirements specified in 33.705.020.A., Neighborhood contact I. If the proposed expedited land division is in an EG or I zone, it is exempt from the neighborhood contact requirements.

2. When the ELD includes eleven or more lots, the applicant is required to meet the neighborhood contact requirements specified in 33.705.020.B., Neighborhood contact II. If the proposed expedited land division is in the EG1, EG2, or an I zone, it is exempt from the neighborhood contact requirements.

B. Pre-application conference. A pre-application conference is required for all land division requests processed through the ELD procedure. See 33.730.050, Pre-Application Conference. The pre-application conference must be held before applying for an ELD review.

33.730.014 Type I Procedure

The Type I procedure is an administrative process with public notice but no hearing.

A. Pre-application conferences. A pre-application conference is not required.

B. Neighborhood contact.

1. When the proposed development associated with the land use review will result in the addition of at least 10,000 square feet and not more than 25,000 square feet of net building area to the site, the neighborhood contact steps of 33.705.020.A., Neighborhood contact I, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

Commentary

2. When the proposed development associated with the land use review will result in the addition of more than 25,000 square feet of net building area to the site, the neighborhood contact steps of 33.725.020.B., Neighborhood contact II, are required. If the proposed development is in the EG1 , EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

C.-H.[No change]

33.730.015 Type Ix Procedure
The Type Ix procedure is an administrative process with public notice but no hearing.

A. Pre-application conferences. A pre-application conference is optional.

B. Neighborhood contact.

1. When the proposed development associated with the land use review will result in the addition of at least 10,000 square feet and not more than 25,000 square feet of net building area to the site, the neighborhood contact steps of 33.705.020.A., Neighborhood contact I, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

2. When the proposed development associated with the land use review will result in the addition of more than 25,000 square feet of net building area to the site, the neighborhood contact steps of 33.705.020.B., Neighborhood contact II, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

C.-H.[No change]

33.730.020 Type II Procedure
The Type II procedure is an administrative process, with the opportunity to appeal the Director of BDS's decision to another review body.

A. Pre-application conference. A pre-application conference is optional unless it is a specific requirement of a review. See 33.730.050, Pre-Application Conference.

B. Neighborhood contact.

1. When the proposed development associated with the land use review will result in the addition of at least 10,000 square feet and not more than 25,000 square feet of net building area to the site and no portion of the site is in the Design overlay zone, the neighborhood contact steps of 33.705.020.A., Neighborhood contact I, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

Commentary

2. When the proposed development associated with the land use review will result in the addition of more than 25,000 square feet of net building area to the site and no portion of the site is in the Design overlay zone, the neighborhood contact steps of 33.705.020.B., Neighborhood contact II, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

3. When the proposed development associated with the land use review will result in the addition of more than 10,000 square feet of net building area to the site and the site is in the Design overlay zone, the neighborhood contact steps of 33.705.020.C, Neighborhood contact III, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

C.-J. [No change]

33.730.025 Type IIx Procedure

The Type IIx procedure is an administrative process, with the opportunity to appeal the Director of BDS's decision to another review body.

A. Pre-application conference. A pre-application conference is optional. See 33.730.050, Pre-Application Conference.

B. Neighborhood contact.

1. The neighborhood contact steps of 33.705.020.A., Neighborhood contact I, are required when:

   a. The application is for a land division that includes four to ten lots; or

   b. The application is for a land use review other than a land division and the proposed development associated with the land use review will result in the addition of at least 10,000 square feet and not more than 25,000 square feet of net building area to the site. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

2. When the application is for a land use review other than a land division and the proposed development associated with the land use review will result in the addition of more than 25,000 square feet of net building area to the site, the neighborhood contact steps of 33.705.020.B., Neighborhood contact II, are required. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

C.-J. [No change]

Commentary

33.730.030 Type III Procedure

A Type III procedure requires a public hearing before an assigned review body. Subsections A through ED apply to all sites. If the site is within the City of Portland, Subsections FE through IH also apply. If the site is in the portion of unincorporated Multnomah County that is subject to City zoning, Subsection JI also applies.

A. Pre-application conference. A pre-application conference is required for all requests processed through a Type III procedure. See 33.730.050, Pre-Application Conference.

B. Neighborhood contact.

1. The neighborhood contact steps of 33.705.020.A., Neighborhood contact I, are required when:

   a. The application is for a land division that includes four to ten lots and does not include an environmental review; or

   b. The application is for a land use review other than a land division and the proposed development associated with the land use review will result in the addition of at least 10,000 square feet and not more than 25,000 square feet of net building area to the site and no portion of the site is in the Design overlay zone. If the proposed development is in the EG1, EG2, or an I zone, or it has already met the neighborhood contact requirements as part of a building permit process, it is exempt from the neighborhood contact requirements.

2. The neighborhood contact steps of 33.705.020.B., Neighborhood contact II, are required when:

   a. The application is for a land division that includes eleven or more lots and does not include an environmental review; or

   b. The application is for a land use review other than a land division and the proposed development associated with the land use review will result in the addition of more than 25,000 square feet of net building area to the site and no portion of the site is in the Design overlay zone. If the proposed development is in the EG1, EG2, or an I zone, or it was subject to a building permit process, it is exempt from the neighborhood contact requirements.

3. The neighborhood contact steps of 33.705.020.C., Neighborhood contact III, are required when:

   a. The application is for a land division that includes an environmental review; or

   b. The application is for a land use review other than a land division and the proposed development associated with the land use review will result in the addition of more than 10,000 square feet of net building area to the site and the site is in the Design overlay zone. If the proposed development is in the EG1, EG2, or an I zone it is exempt from the neighborhood contact requirements.

The Bureau of Planning and Sustainability is committed to providing equal access to information and hearings.

If you need special accommodation, please call 503-823-7700, the City's TTY at 503-823-6868, or the Oregon Relay Service at 711.

Fossil Fuel Terminal Zoning

RETURN SERVICE REQUESTED

Fossil Fuel Terminal Zoning

Portland City Council Hearing
November 20, 2019 at 2:00 P.M.

Council Chambers, City Hall
1221 SW 4th Avenue, Portland, Oregon.

Watch City Council sessions live: www.portlandoregon.gov/28258

City Council Hearing on:
Fossil Fuel Terminal Zoning

Why am I receiving this notice?

You are receiving this notice because you responded in writing to the matter, testified at a previous related hearing, or have requested notice of this hearing.

What is this project about?

This City Council hearing is a reconsideration of Fossil Fuel Terminal Zoning amendments that were adopted in 2016. That ordinance was appealed to the Oregon Supreme Court and is now back before City Council. These code changes restrict development and expansion of Bulk Fossil Fuel Terminals.

- Bulk Fossil Fuel Terminals are characterized by (a) marine, railroad, or pipeline transport access and (b) either storage capacity exceeding 2 million gallons or transload facilities (such as rail-to-ship loading)
- Fossil fuels include petroleum products (such as crude oil and gasoline), coal, natural gas, and propane, and methanol, which is produced from natural gas.
- No new Bulk Fossil Fuel Terminals are allowed.

The existing Bulk Fossil Fuel Terminals in Industrial and General Employment zones become "limited uses" that can continue to operate. Expansion of fossil fuel storage at these existing terminals would be prohibited, with limited exceptions.

The code changes will not apply to gas stations; distributors and wholesalers that receive and deliver fossil fuels exclusively by truck; industrial, commercial, institutional, and agricultural uses that store fossil fuels for use as an input; uses that involve the transfer or storage of solid or liquid wastes are classified as Waste-Related uses. Fossil fuel storage facilities for airports, marine terminals, rail yards, and fleet vehicle fuel facilities are specifically exempted.

How can I review this proposal?

The Remand Report is available at www.portlandoregon.gov/bps/71118. Hard copies are available at the BPS office at 1900 SW 4th Avenue, 7th floor. The bureau receptionist will mail you a copy if you call 503-823-7700.

How can I comment on this proposal?

Testify at the City Council hearing. The hearing, on **November 20, 2019, at 2:00 p.m.**, will be in Council Chambers at City Hall, 1221 SW 4th Avenue. MAX and many buses serve this building; call Tri-Met at 503-238-7433 or go to their web site at http://www.trimet.org for routes and times.

Submit written testimony to City Council. Written testimony can be provided by the following options and must be received by the time of the hearing and include your name and address.

Use the Map App	Use U.S. Mail:
www.portlandoregon.gov/bps/mapapp Select **Fossil Fuel Terminal Zoning** and click on the "Testify" button. Testifying in the Map App is as easy as sending an email.	City Council Fossil Fuel Terminal Zoning Testimony 1221 SW Fourth Avenue, Room 130 Portland, OR 97204

Portland

Your notice of a proposed change to a comprehensive plan or land use regulation has been received by the Oregon Department of Land Conservation and Development.
Local File #: Fossil Fuel Terminal Zoning Re-adoption
DLCD File #: 006-19
Proposal Received: 10/16/2019
First Evidentiary Hearing: 11/20/2019
Submitted by: tarmstrong

If you have any questions about this notice, please reply or send an email to plan.amendments@state.or.us.

2020 Clean Fuels Forecast

Background

Oregon Revised Statutes (2017) Chapter 750, Section 163[1] authorizes the Office of Economic Analysis (OEA), in coordination with the Department of Environmental Quality, to assess the availability of fossil and alternative fuels in Oregon. In particular, the forecast is to determine whether fuel supply will be sufficient to generate alternative fuel credits (on ethanol, electricity, and diesel substitutes - including biodiesel, renewable diesel, natural gas, and propane) to meet the scheduled low carbon fuel standards for the compliance period. The forecast report is required to include an assessment of total deficits and banked credits at the beginning of the compliance period.

In preparing the forecast, the Office of Economic Analysis has formed a Clean Fuels Forecast Advisory Committee comprised of relevant experts and stakeholders to assist in reviewing methodological considerations and various data sources. A membership list can be found in Appendix A.

Data Sources

The forecast uses available public and program data to develop the estimates of low-carbon fuels available to Oregon and estimated consumption of fossil and alternative fuels in Oregon. The sources of this data include:

- Oregon Clean Fuels Program (CFP) Online System
- Fuel Pathway Codes (carbon intensity values) approved in Oregon and California
- Oregon Department of Transportation's (ODOT) Revenue Forecast
- Oregon DMV vehicle registration data
- Annual Energy Outlook and other resources from the US Energy Information Administration
- Trade associations (Renewable Fuels Association and the National Biodiesel Board) on their members' production capacity

Clean Fuels Program 2020 Consumption Forecast

To determine the amount of deficits that will be generated in 2020, and thus the amount of credits needed for compliance, a forecast for consumption of all relevant fuels must be made. The following are the volume projections for each fuel type.

Gasoline Consumption

1,708 million gallons of gasoline, including ethanol, were consumed in 2018, the most recent year of data collected. Growth projections exhibited in the Oregon Department of Transportation's December 2018 forecast equal an annualized 0.8 percent from 2018 to 2020. There were two factors considered in making adjustments to these initial growth parameters: ODOT observed gasoline consumption coming in lower than projected through the first two quarters of 2019. Secondly, the mandated decreases in the carbon intensity targets for fossil fuels incentivize reporting parties to record supplies of fuel in the earliest year

[1] https://olis.leg.state.or.us/liz/2017R1/Downloads/MeasureDocument/HB2017/Enrolled

possible to minimize the deficits generated. For the first factor, growth was adjusted down to 0.4 percentage points. Given that the reduction in the carbon intensity target is the same in percentage terms for 2020 and 2021, ultimately no adjustment was made for potential pull forward in reporting. The final annualized growth in motor gasoline from the 2018 base year through 2020 is 0.4 percent annually, resulting in a projected 1,720.4 million gallons for the total gasoline pool. To determine the amount of conventional gasoline represented, ethanol must be subtracted. The blend rate assumed for 2020 is 10.1 percent, equal to that observed for 2018. The final forecast for conventional gasoline is 1,546.3 million gallons.

Diesel Consumption

According to CFP reported data, 771.2 million gallons of diesel, including bio- and renewable diesel, were consumed in 2018, the most recent year of data collected. Growth projections exhibited in the Oregon Department of Transportation's December 2018 forecast equal an annualized 1.4 percent from 2018 to 2020. The same add-factor considerations noted under the gasoline section were made for diesel as well, particularly the fact that diesel consumption fell far below projections through the first two quarters of 2019. The final annualized growth in total diesel from the 2018 base year through 2020 is -0.6 percent, resulting in a projected 762.5 million gallons of total diesel. To determine the amount of conventional diesel, biodiesel and renewable diesel must be subtracted. The blend rate for these biofuels are assumed to be 6.9 percent and 3.5 percent, respectively. The final forecast for the consumption of conventional diesel in 2020 is 683.2 million gallons.

Ethanol Consumption

The amount of ethanol reported for 2018 equaled 172.2 million gallons. As described above, the amount of ethanol projected for 2020 is based on a blend rate assumption driven by historical observations and trends, as well as blend rates observed in California. Given that the last actual blend rate observation, (for the 2018 compliance year), was 10.1 percent and that most gasoline consumed in Oregon is E10, the assumption for 2020 was maintained at 10.1 percent. This results in a forecast for ethanol consumption of 174.1 million gallons, which is 0.5 percent above the 2018 volume on an annualized basis. As with the fossil fuels, no adjustment was made for behavioral factors associated with the phasing in of the carbon intensity reductions given that the incentive would be similar on either end of the compliance period. This is true for the remaining alternative fuel forecasts, as well.

Electricity Consumption

Consumption of electricity for on-road vehicles is based on a projection of the number of plug-in hybrid and battery electric vehicles in use for the compliance period. DMV vehicle registration data provides actual vehicle numbers historically, from which growth projections and variances are derived to produce the number of electric vehicles projected to be in operation for the 2020 compliance period. This equaled an average of 13,050 Plug-in Hybrids and 19,772 Battery Electric vehicles. Historical volumes of electricity, including estimates for residential charging, are used to calculate average Kilowatt hours per vehicle year. For 2018, this parameter equaled 3,621 Kilowatt hours per year, which was in turn assumed for the 2020 compliance period. When converted to gasoline gallon equivalents, the forecast is 3.5 million gallons including residential charging. This is equivalent to a 25 percent increase from 2018 on an annualized basis.

Biodiesel Consumption

The reported volume of biodiesel in 2018 amounted to 51.7 million gallons. As described above, the amount of biodiesel projected for 2020 is based on a blend rate assumption driven by historical observations and trends, as well as blend rates observed in California. The highest observation in the Clean Fuels program data was 6.9 percent in 2017. This value was assumed for the 2020 forecast, resulting in a consumption projection of 52.6 million gallons. This represents growth of 0.9 percent from the 2018 actual on an annualized basis.

Renewable Diesel Consumption

The amount of renewable diesel reported in 2018 was 1.2 million gallons. Similar to biodiesel, the forecast for renewable diesel is driven by the assumption of the fraction of total diesel consumed comprised of renewable diesel. The blend rate observed for 2018 in the Clean Fuels data was 0.2 percent. In California, similarly small blend rates quickly escalated to 3.0 percent and beyond. Such an adoption schedule is assumed for Oregon, resulting in a blend rate projection for renewable diesel in 2020 of 3.5 percent. This leads to a consumption forecast of 26.7 million gallons, a substantial 369.8 percent above the 2018 value on an annualized basis.

Natural Gas and Propane Consumption

The amount of natural gas, including renewable natural gas (biogas), reported in 2018 in diesel gallon equivalents equaled 3.2 million gallons. This represented 14.7 percent growth from the prior year. Annualized growth from the 2018 base year to 2020 is assumed to be 6.9 percent, equal to the Energy Information Administration's outlook for the Pacific region. This results in a forecast of 3.6 million gallons, which is 6.9 percent annually above the 2018 level.

Propane exhibits the smallest quantity of alternative fuel reported in 2018 at 0.7 million gasoline gallon equivalents. However, this was 477.1 percent above the 2017 reported value. Annualized growth from the 2018 base year to 2020 is assumed to be 213.9 percent, resulting in a forecast of 7.3 million gallons.

The following table presents the 2020 consumption forecast in detail. Note that the percent change figures for 2020 represent annual growth from the last available actuals in 2018. To the extent that 2018 actuals were not known at the time the 2019 forecast was released, this explains the significant variance in changes related to the 2019 forecast. Presenting annualized changes from 2018 is thus more informative.

Table 1: Summary of fossil and alternative fuel consumption

(Mil. gallons, percent)	2018 Actual	2019 Forecast*	% change	2020 Forecast	annual %change vs 2018
Conventional Gasoline	1,535.4	1,437.0	-6.4%	1,546.3	0.4%
Ethanol	172.2	165.0	-4.2%	174.1	0.5%
Ethanol Blend Rate	10.1%	10.3%		10.1%	
Blendstock	1,707.6	1,602.0	-6.2%	1,720.4	0.4%
Fossil Diesel	718.2	705.0	-1.9%	683.2	-2.5%
Biodiesel	51.7	57.5	11.1%	52.6	0.9%
Biodiesel Blend Rate	6.7%	7.3%		6.9%	
Renewable Diesel	1.2	29.9	2370.6%	26.7	369.8%
Renew diesel Blend Rate	0.2%	3.8%		3.5%	
Total Diesel	771.2	792.3	2.7%	762.5	-0.6%
Electricity (on-road)	2.2	2.7	23.0%	3.5	25.0%
Electricity (off-road)	1.7	N/A		N/A	
Fossil Natural Gas	1.5	1.2	-17.8%	1.1	-13.6%
Biogas	1.7	2.8	62.9%	2.5	21.6%
Biogas Blend Rate	54.1%	70.0%		70.0%	
Total Natural Gas	3.2	4.0	25.8%	3.6	6.9%
Propane	0.7	1.3	72.2%	7.3	213.9%
*Forecast equals average of range published for 2019 forecast.					
On-road electricity include calculation of residential charging.					

Deficit and Credit Generation and Banked Credits

In order to estimate the number of deficits and credits associated with the consumption of each fuel type, the energy densities and carbon intensity differentials must be known. Most of the pertinent parameters are published here in administrative rule by the Department of Environmental Quality (see Tables 1, 2, and 4 starting on page 209). The following table presents these parameters for each fuel. Details regarding the estimation of carbon intensities for ethanol, biodiesel and renewable diesel can be found in Appendix B. Also included are the two parameters associated with electricity consumed by passenger vehicles. The carbon intensity assumption is adjusted for the energy economy ratio (EER). The actual carbon intensity of electricity is 109.3.

Table 2: Parameter values for the 2020 forecast

	Energy Density	Carbon Intensity Target	Carbon Intensity Assumption
Units	MJ/gallon	gCO2/MJ	gCO2/MJ
Gasoline	122.48	95.61	100.14
Ethanol	81.51	95.61	57.76
Diesel	134.48	96.27	100.74
Biodiesel	126.13	96.27	35.40
Reneweable Diesel	129.65	96.27	29.17
Electricity	3.6	95.61	32.15
KWh/vehicle	*3621*		
EER	*3.4*		
Natural Gas	134.48	96.27	79.98
Biogas	134.48	96.27	50.00
Liq. Petroleum Gas	89.63	95.61	80.88

Banked Credits

The number of credits is taken from the CFP Online System. The number of gross credits registered through the end of calendar year 2018 equaled 2.73 million, while the number of deficits recorded amounted to 2.23 million. The net credits banked equaled 502,608. Originally, OEA projected that another 365,348 credits will be banked during calendar year 2019. Given that another year of data are available, including actual fuel volumes (and thus blend rates for alternative fuels) for the 2018 compliance period, the 2019 estimated deficits and credits have been updated to reflect this. The total projected banked credits at the beginning of the 2020 compliance period is now expected to be 649,829.

Table 3: Summary of actual and projected net banked credits

Year	Deficits	Credits	Net Banked Credits
2016	-617,071	830,714	213,643
2017	-715,057	924,793	209,736
2018	-899,260	978,489	79,229
2019 (Proj.)	-1,015,633	1,162,854	147,221
Total	-3,247,021	3,896,850	649,829

Credit and Deficit Summary

The table below summarizes the forecast for deficit generation and credit generation. The equations for calculating the deficits and credits can be found in Appendix B.

Table 4: Summary of Deficits and Credits

Credit / Deficit Summary		
Deficits	Gasoline	-857,916
	Diesel	-410,701
Deficit Total		**-1,268,617**
Credits	Ethanol	537,140
	Biodiesel	403,946
	Renewable Diesel	232,191
	Electricity, on-road	92,317
	Electricity, off-road	25,784
	Natural Gas	17,896
	Propane	9,629
Credit Total		**1,318,903**

2020 Net Credits/Deficits	**50,286**
2019 Estimated Ending Banked Credits	**649,829**
Total Net Credits/Deficits	**700,115**

Forecasted Fuel Supply Deferral Analysis

As shown above, the forecast does not imply such an action.

Potential Supply of Alternative Fuels

Oregon Revised Statutes (2017) Chapter 750, Section 163[2] directs the Office of Economic Analysis to estimate the "potential volumes of gasoline, gasoline substitutes and gasoline alternatives and diesel, diesel fuel substitutes and diesel alternatives available to Oregon." In order to make such estimates, a number of assumptions must be made. Potential is read to mean "could be made available to Oregon under a wide range of market conditions". Currently, suppliers must be certified by the Department of Environmental Quality to receive credits for fuel delivered into Oregon. In addition, they must report volumes of fuel sold in Oregon to the Clean Fuels reporting system. It is assumed that selling fuel in Oregon implies established supply chains. Thus, the capacity of facilities that were certified and supplied fuel to Oregon for the most recent compliance period (2018) is assumed to be theoretically "available" to Oregon. The potential supply figures presented in the following sections correspond to the most recently available nameplate capacities for these facilities manufacturing the respective fuels. Where multiple values are available, the highest is presented.

[2] https://olis.leg.state.or.us/liz/2017R1/Downloads/MeasureDocument/HB2017/Enrolled

In addition to estimating potential supply, the Office of Economic Analysis is directed to consider "Constraints that may be preventing access to available and cost-effective low carbon fuels by Oregon, such as geographic and logistical factors, and alleviating factors to the constraints". Only biofuels that might pose a supply constraint that could ultimately limit the number of credits available to deficit holders to comply with the Clean Fuels program requirements are called out explicitly. Should supply issues arise for the more mature fuel markets such as conventional gasoline and diesel, as well as electricity, such issues would be added to the report. This is not anticipated for the foreseeable future.

Ethanol

As exhibited in Table 5, the potential supply of ethanol to Oregon as outlined above is 3.8 billion gallons. This compares to a projected "demand" for ethanol previously characterized of 174.2 million gallons.

Table 5: Ethanol Supply

Ethanol Supply Available to Oregon
(Existing Suppliers in 2018)

State	Nameplate Capacity (Mil. Gallons)	Number of Facilities
South Dakota	900	11
Nebraska	817	10
Iowa	650	7
Minnesota	478	6
North Dakota	300	2
Kansas	220	3
Colorado	110	2
Idaho	75	1
California	50	1
Oregon	43	1
Total Oregon Suppliers	3,643	44

Data from Energy Information Administration and Clean Fuels Program.

Biodiesel
Table 6 presents the potential supply of biodiesel to Oregon, equaling 743 million gallons in capacity for certified facilities with established supply chains in 2018. This compares to a projected demand for biodiesel in 2020 of 52.6 million gallons. Note that the Energy Information Administration is currently updating their data collection regarding biodiesel producers to match that for ethanol. When these data become available, more current estimates of nameplate capacity will be incorporated into the analysis.

Table 6: Biodiesel Supply

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Missouri	155	4
Iowa	106	2
Washington	105	2
Oregon	105	2
Nebraska	63	1
Arkansas	59	1
Korea	50	2
Oklahoma	35	1
Minnesota	30	1
Canada	22	4
Texas	15	1
Total Oregon Suppliers	743	21
Data from the Clean Fuels Program		

Renewable Diesel
As presented below, the potential supply of renewable diesel to Oregon equals 475 million gallons. This compares to a projected demand for renewable diesel in 2020 of 26.7 million gallons.

Table 7: Renewable Diesel Supply

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Singapore	291	1
Wyoming	109	1
Louisiana	75	1
Total Oregon Suppliers	475	3
Data from the Clean Fuels Program		

Renewable Natural Gas
The amount of renewable natural gas potentially available to Oregon amounts to 2.2 billion gallon equivalents. This compares to a projected demand for this biofuel of 2.5 million gallon equivalents. The

committee discussed the fact that a number of applications to supply additional renewable natural gas to Oregon are in the process of being evaluated. Given the modest volumes of natural gas currently used in transportation, incorporating these potential supplies would not alter the conclusion that there are no current constraints on the availability of natural gas in Oregon.

Table 8: Renewable Natural Gas

Locality	Nameplate Capacity (Mil. Gallons)	Number of Facilities
Kentucky	1,179	1
Ohio	990	1
Total Oregon Suppliers	2,169	2
Data from the Clean Fuels Program		

Forecast Risks

A risk is defined as a deviation from one or more assumptions that would alter the conclusion outlined in the previous sections. There are a number of potential risks to this 2020 Clean Fuels Forecast, both positive and negative and they are:

(a) The most fundamental risk to the forecast amounts to potential deviations from the assumptions highlighted in each fuel type discussion. In particular, blend rates and carbon intensities for biofuels could be subject to significant error. In addition, this forecast contrasts with prior forecasts in that it assumes that the incentives inherent in the value of the credits generated by supplying alternative fuels will drive the carbon intensities of these fuels downward. Failure to realize these declines would result in fewer credits than currently anticipated.

(b) This forecast represents a "current law" representation of the compliance period in question. OEA's methodology does not take potential future state policy actions into account.

(c) There is a discrepancy between the diesel consumption numbers reported to the Clean Fuels Program data and the taxable gallons tabulated by ODOT. Explicitly, more gallons of diesel are reported to the former that the latter. This forecast applies projected growth of taxable diesel, at least initially, to the base year 2018 reported volumes of diesel in the CFP. To the degree that taxable gallons per ODOT is not a perfect proxy for reported gallons in the CFP, actual consumption of diesel and thereby the number of deficits generated could deviate from this forecast.

(d) House Bill 2017 (2017 Legislative Session) created a rebate for sales of electric vehicles in Oregon. The electric vehicle forecast underlying the credit projections for electricity consumption do not explicitly account for the potential impact of this rebate. To the degree that electric vehicle sales skew higher than expected herein, net credits would be even higher, constituting an upside risk to the forecast.

(e) The ethanol availability presented above is not comprehensive and does not include other potential sources, such as sugarcane ethanol imported from Brazil. Given that potential supply characterized in table 5 greatly exceeds projected demand, this is not an immediate threat to the forecast. However, it may need to be addressed as consumption increases or as carbon intensity targets are lowered.

(f) Alternative fuels used in forklifts, aviation , and certain other uses such as transport refrigeration units were recently added to the Clean Fuels Program but have not been included in the 2020 forecast These uses would generate credits in the program, constituting an upside risk to the forecast.

Appendix B

The estimated carbon intensities for ethanol, biodiesel and renewable diesel that are not published in rule are projected based on the historical trend in reported carbon intensities. Add factors may be employed where steeper declines are expected due to the incentives inherent in the program, as well as new information regarding potential changes in the mix of feedstocks and the composition of facilities that supply biofuels to Oregon. Currently, thirteen quarters of data are available for ethanol and biodiesel, while six quarters are available for renewable diesel. As more data become available, more advanced econometric techniques (including dynamic modeling) may be employed to provide more accurate projections. The following charts show the expected declines in all three series:

Appendix C

The following are the formulas resulting in the deficits and credits presented in Table 4.

Gasoline
$Deficit_G = CBOB * ED_G * (CIT_G - CIA_G)/1{,}000{,}000$

Diesel
$Deficit_D = V_D * ED_D * (CIT_D – CIA_D)/1{,}000{,}000$

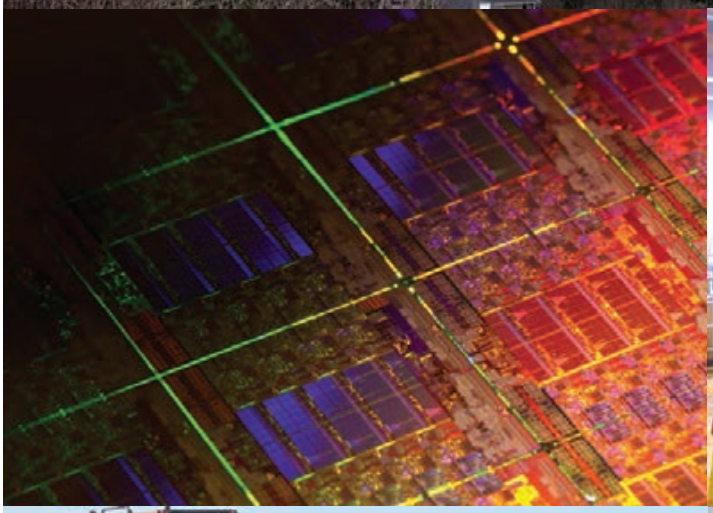
Ethanol
$Credit_E = V_E * ED_E * (CIT_G – CIA_E)/1{,}000{,}000$

Biodiesel
$Credit_{BD} = V_{BD} * ED_{BD} * (CIT_D – CIA_{BD})/1{,}000{,}000$

Renewable Diesel
$Credit_{RD} = V_{RD} * ED_{RD} * (CIT_D – CIA_{RD})/1{,}000{,}000$

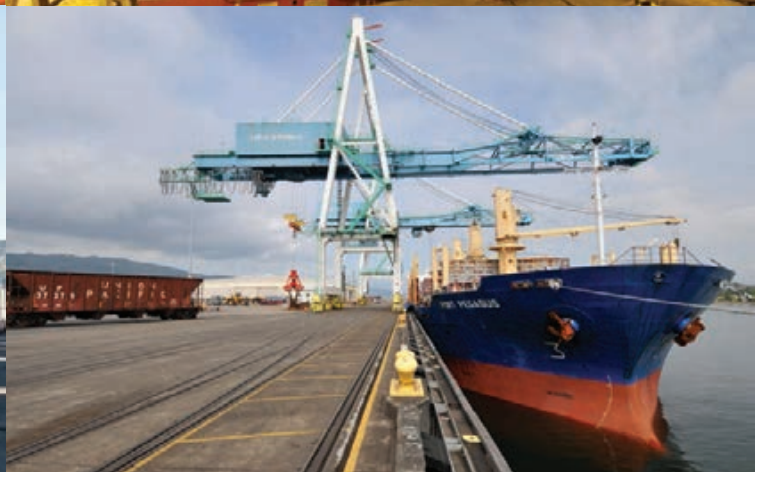
Electricity
$Credit_C = K_C * EER_E * ED_E * (CIT_G – (CIA_C/EER_E)/1{,}000{,}000$

Natural Gas
$Credit_{NG} = V_{NG} * ED_{NG} * (CIT_D – CIA_{NG})/1{,}000{,}000$



Propane
$Credit_P = V_P * ED_P * (CIT_D – CIA_P)/1{,}000{,}000$

GREATER PORTLAND GLOBAL



GLOBAL TRADE AND INVESTMENT PLAN

Oregon Iron Works

5056
5056

INTRODUCTION

GREATER PORTLAND'S REGIONAL ECONOMIC DEVELOPMENT community is uniting locally to compete globally, with a shared focus on target industry clusters, innovation, and international trade and investment as the essential elements of a competitive, sustainable and globally integrated region. Greater Portland Global, a global trade and investment plan, draws on the region's work in the Global Cities Initiative, a joint project of the Brookings Institution and JPMorgan Chase, to integrate exports and foreign direct investment (FDI) into one strategic plan that replaces the Greater Portland Export Initiative and escalates global engagement to realize a stronger regional economy. The plan recognizes Portland's rich interaction between local innovation, exports, global excellence, and foreign direct investment as the foundation of a unique process that can propel small, innovative entrepreneurs and domestically-focused companies along a continuum to become companies with global presence.

A shared focus on target industry clusters, innovation, and international trade and investment are the essential elements of a competitive, sustainable and globally integrated region.

LUBA No. 2020-009
Page 4664

THE IMPERATIVE TO GO GLOBAL

GLOBAL ENGAGEMENT IS NOT OPTIONAL if Greater Portland is to realize widely-shared economic growth and prosperity—it is imperative. Increased access to global markets and foreign investment is the most direct path for Greater Portland to create and maintain a sufficient number of quality jobs to support the region's growing population.

The need to embrace international markets is urgent. Ninety-five percent (95%) of the world's consumers live outside the United States, and 79% of global GDP growth is projected to occur outside the U.S. over the next five years. Fortunately, the region has within its reach the building blocks of enviable innovation, globally-competitive industries, and a productive, educated and increasingly diverse workforce to compete.

Greater Portland has a long history as a leading exporter and since the 1980s has attracted substantial FDI. But while Greater Portland has made progress, it remains the case that too few firms and industries are benefiting from global engagement, pointing to the need for a better integrated, more strategic focus on exports and FDI.

Greater Portland's opportunity for heightened global engagement is immediate and compelling, as evidenced by the following conditions:

- **Greater Portland is a trading region, but recent export growth is lagging.** Exports are critical to regional economic growth and job creation, supporting approximately 145,000 direct and indirect jobs (including some outside the region). Yet, while ranking high in 2013 Brookings Institution data in total exports ($26.7 billion or 13th highest metro) and exports' share of metro economic output (17.4% or 11th highest metro), the region's top ranked export growth rate is slower in the recovery from the Great Recession than in pre-recession years.

- **Foreign owned enterprises (FOEs) can bring highly productive and high-paying jobs to the region.** FOEs account for 20% higher wages and doubling of money spent on benefits compared to the average U.S. firm, and for 19% of all corporate R&D in the U.S., which facilitates the spread of new knowledge, technologies and ideas—all drivers of job creation and economic growth.

- **Foreign direct investment can strengthen the region's dynamic, growing companies.** Foreign direct investment is attracted to innovative companies and clusters that possess excellence in talent, processes, products, services, and exporting. The region has emerging excellence in such in-demand sectors as software and clean tech/sustainability, adding to its established computers and electronics (C&E) industry and its attractive legacy sectors of metal manufacturing and wood products.

LUBA No. 2020-009
Page 4665

➤ **The region's plentiful and diverse assets have not been adequately promoted internationally.** FOE executives interviewed, who made either a greenfield investment or acquisition into the local market, mentioned a variety of assets that attracted them to the region:

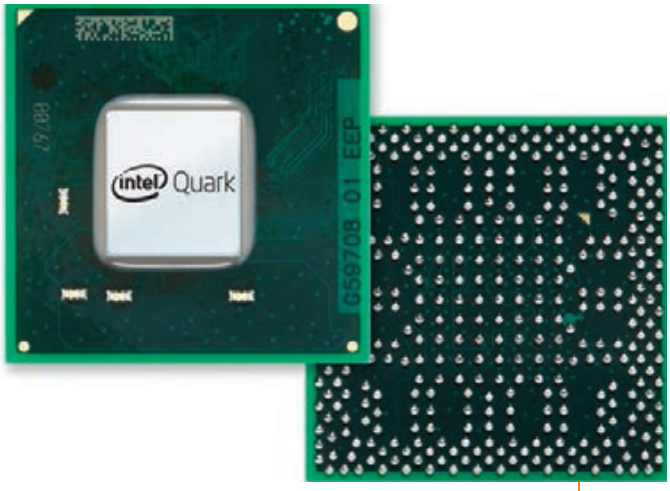
- Natural resources – water, low cost of electricity, climate security
- Logistics – rail access and a port with room to expand
- Quality of life – low cost of living, natural beauty, transit
- A resurgent real estate market that is largely untouched by foreign investment
- The anchor educational institutions of Oregon Health & Science University (OHSU), Portland State University (PSU), and Washington State University (WSU) Vancouver

➤ **Greater Portland has the opportunity to solidify its global business prominence.** The region's traditional strengths in advanced manufacturing and computers and electronics have attracted high levels of FDI concentrated in German and Japanese companies; leading international brands such as Adidas, Ajinomoto, Daimler, Epson, and Genentech are prominent foreign investors in the regional economy, and many of them export from Greater Portland.

➤ **Unprecedented expansion by Greater Portland's largest employers will position the region well for international interest and investment.** The region's largest employers are on the cusp of enormous transformation. Intel's presence, already its largest in the world, is still growing; the $1 billion Knight Cancer Challenge at OHSU in Portland will attract worldwide attention in bioscience. Joined by Nike, these three major companies/institutions have embarked upon mega-expansions that, as regional business history has shown, will spin out new clusters, accelerate innovation and further the excellence that will attract investment interest.

➤ **Deep international ties exist in Greater Portland's community that can be the foundation for business growth.** The local business community's key connections to fertile foreign markets encompass PSU's deep ties to Qatar, a vibrant local Chinese community, cultural institutions like the German American Society and Japan-America Society of Oregon, and long-standing Asian sister city relationships established by Portland, Beaverton and Hillsboro.

LUBA No. 2020-009
Page 4666



GREATER PORTLAND'S RESPONSE TO A GLOBAL ECONOMY

Greater Portland is doing business in an age of global competition. As the region builds a stronger economic foundation for current and future generations, it requires a bold, strategic response to new and evolving market realities. In 2011, Greater Portland's aspirations for effective economic development on a global stage found a home in the Global Cities Initiative (GCI), a joint project of Brookings and JPMorgan Chase, when the region was named one of four metros selected for the Metro Export Initiative pilot. Greater Portland Inc (GPI), the region's public-private economic development organization, received additional resources from key partners to create a new position to oversee coordination and implementation of the Export Initiative beginning in 2012.

The Greater Portland Export Initiative broke ground from the start, achieving export wins and drawing national and international press coverage of the region's export strengths and its dynamic export growth. Greater Portland was selected as the top metropolitan region in the Exports category in the 2013 "Top Ten Innovations to Watch List" developed by Brookings' Metropolitan Policy Program and The Rockefeller Foundation. The National Journal selected the We Build Green Cities initiative, led by the Portland Development Commission (PDC), as the winning innovation of 2013 for "Expanding Exports."

Greater Portland conducted training sessions for economic development professionals to provide greater export assistance to local businesses, and two of those key partners—the City of Beaverton and Business Oregon—were named the U.S. Export-Import Bank's 2014 City/State Partners of the Year. The Export Initiative's Westside Freight and Logistics Analysis and a separate supply chain study both focused on the computer and electronics industry. The former stimulated a $10.1 million U.S. Department of Transportation TIGER grant for

LUBA No. 2020-009
Page 4667

Washington County, and the latter was immediately incorporated into the region's business recruitment efforts.

We Build Green Cities has helped companies make export sales in Japan and inspired the U.S. Department of Commerce to award PDC $300,000 from the International Trade Administration's Market Development Cooperator Program to help the green building and clean tech industries generate foreign exports.

Greater Portland seized the opportunity again to apply for a Brookings FDI pilot in early 2014, recognizing it as a natural progression for the development of a globalized metro and a transformative regional economic development and business culture. Greater Portland was one of six metros selected for the FDI pilot. Guided by new partnerships and a fortuitous alignment of federal, state and local efforts, Greater Portland's global strategy is expanding to include a deliberate plan to attract more FDI.

The push for greater global engagement dovetails with the region's current work creating Greater Portland 2020, a five-year regional comprehensive economic development strategy prioritizing international trade and investment to be publicly unveiled in fall 2015. It also coincides with the 2015 Year of Trade campaign led by the Port of Portland and the Pacific Northwest International Trade Association.

Greater Portland has strong international ties, productive working relationships among key public, private, and nonprofit partners, and a track record of pursuing innovative economic development projects. The region is well positioned and prepared to pursue Greater Portland Global, an ambitious trade and investment plan.

As the region builds a stronger economic foundation for current and future generations, it requires a bold, strategic response to new and evolving market realities.

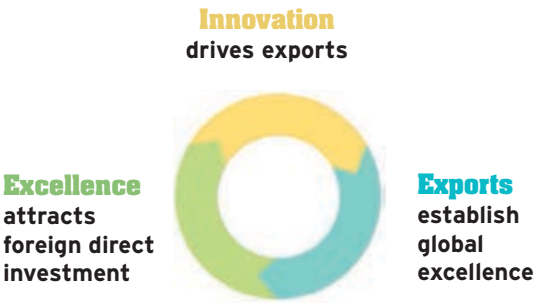
LUBA No. 2020-009
Page 4668

THE INTERACTION BETWEEN EXPORTS AND FDI

Exports and FDI are integrated parts of global business, but until now they have not been unified under a coordinated regional approach. With distinct assessments of both exports and FDI now in hand, areas of linkage have surfaced, with a key overlap centered on the concept of excellence. The interaction between exports and FDI are highlighted by these facts:

- **Foreign-owned companies account for 20% of U.S. exported goods.** In Greater Portland, foreign-owned firms like Daimler Trucks North America are among the largest exporters.

- **FDI is relatively concentrated in advanced industries and manufacturing**, with 18% of U.S. manufacturing jobs in foreign-owned companies, many of which are strong exporters. In Greater Portland, examples include Wafertech, Evraz, and Fiskars.



- **Foreign students and tourists, which can be considered as a service export for the region, are key links for potential future FDI.** Alumni (and their parents) have lasting ties to this region. Chinese and Saudi Arabian students account for 55% of foreign students at Oregon universities, but Chinese and Saudi Arabian FDI is almost nonexistent in the region.

- **Some FDI is part of a value chain that involves importing into the U.S. from a foreign market**, adding value, and then exporting to a foreign market. Greater Portland's role in the global computers and electronics supply chain (with companies like Asahi Glass and Tokai Carbon) exemplifies this process.

Greater Portland's market assessments, first of exports and more recently of FDI, have illuminated the rich interplay between exports and FDI and its roots in innovation. Whether in the laboratory, on the shop floor, or in a line of code, products and services seeking to do something new—or something old in a vastly new and improved manner—will find reception in the global marketplace. Firms marketing their products internationally not only bring home new revenue streams but also manifest processes and labor honed by global competition.

Products and services seeking to do something new—or something old in a vastly new and improved manner—will find reception in the global marketplace.

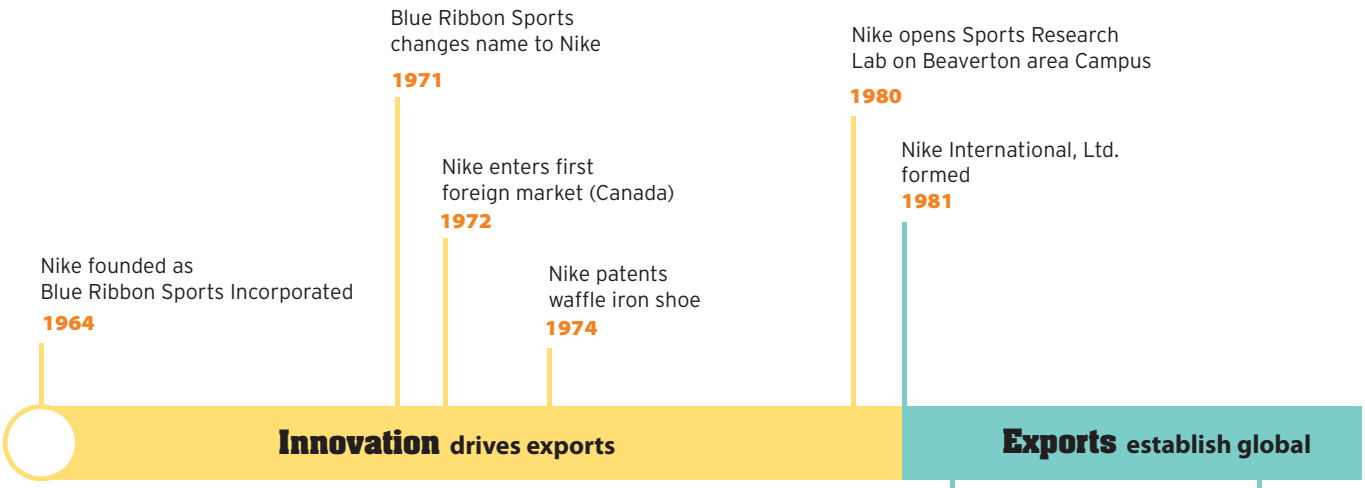
Greater Portland sees the link between exports and FDI as a three-step interaction:

This interaction is enhanced by an added element that extends beyond industry: Greater Portland's unique excellence of place, which has incalculable influence on the influx of talent and the attraction of FDI.

As firms in a region move through this virtuous cycle, the cluster matures and moves from a position of early, nascent innovation to emerging excellence and, finally, established excellence. During this maturation process, clusters often develop new innovations, spinning off new subsectors that go through their own maturation process.

Due to global trends and shifts in macroeconomic conditions, some established sectors transition to legacy sectors. These sectors are not seeing the growth and continued innovation of other sectors although they are often still rich with talent and in-demand products.

LUBA No. 2020-009
Page 4669



The continuum of industries has the following characteristics:

Stage	Sector Attributes	Examples
Nascent	• Often offshoots of established sectors • Result of significant new funding sources • Exist at junction between established sectors	Oregon Health & Science University's $1 Billion Knight Cancer Challenge; wearables sector
Emerging	• Known domestically for innovation and excellence • Showing early export success • Products/services have demonstrable demand in growth economies • Early, small-scale FDI successes	Software and We Build Green Cities
Established	• Region is globally known for excellence in sector • Significant FDI has occurred • Sector includes dominant exporters	Computer and electronics industry, athletic and outdoor industry
Legacy	• Sector has significant labor talent and uses advanced processes • Global need for sectors' assets exists • Need for expansion or exit capital	Metals manufacturing, family-owned industries, wood products industry

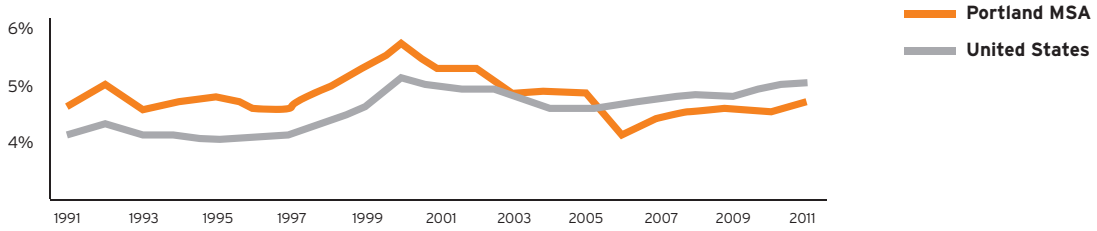
KEY FINDINGS
FROM THE FDI MARKET ASSESSMENT

Benchmade Knife Company

GREATER PORTLAND CONDUCTED AN IN-DEPTH FDI MARKET ASSESSMENT in the summer/fall of 2014 to serve as a foundation for the development of FDI components of Greater Portland Global. The assessment included Brookings data benchmarking against other metros and more than 35 one-on-one interviews with local companies and FDI service providers.



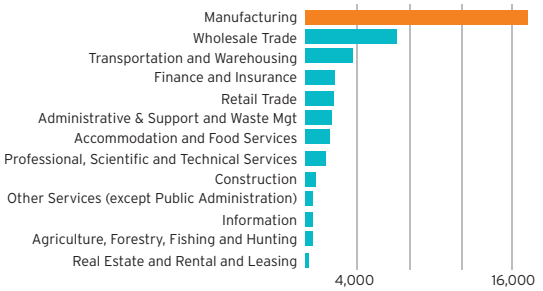
The following are key findings from the market assessment:

LUBA No. 2020-009
Page 4673

KEY FINDING 1

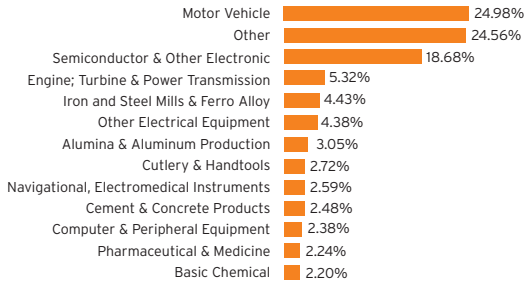
The Greater Portland region lags in FDI behind other comparably-sized metropolitan areas. According to the Brookings Institution, the region is the 23rd largest economy in the U.S., yet 29th in total FDI employment and 50th in FDI employment intensity. Employment growth in Greater Portland's foreign-owned enterprises (FOEs) has only been 1.6% annually since 1991, which ranks 67th out of the top 100 U.S. metros.

Foreign Share of Domestic Area Employment, Portland Metro and U.S., 1991 - 2011



Source: FDI in U.S. Metro Areas, Brookings Institution, 2014

KEY FINDING 2:



FDI has been concentrated in the region's legacy and established advanced manufacturing industries, specifically motor vehicle manufacturing and computers and electronics. Similar to national trends, FDI has gravitated to the region's manufacturing industries, accounting for 42% of total foreign-owned establishment employment.

The importance of Intel—the state's biggest exporter—and its supply chain as an attractor of foreign investment cannot be overestimated. The high concentration of FOEs in the semiconductor sector—3,200 jobs or 7.8% of FOE jobs—is proof of this strong investment by European and Japanese companies. Silicon expertise also set the stage for the investment by German manufacturer SolarWorld.

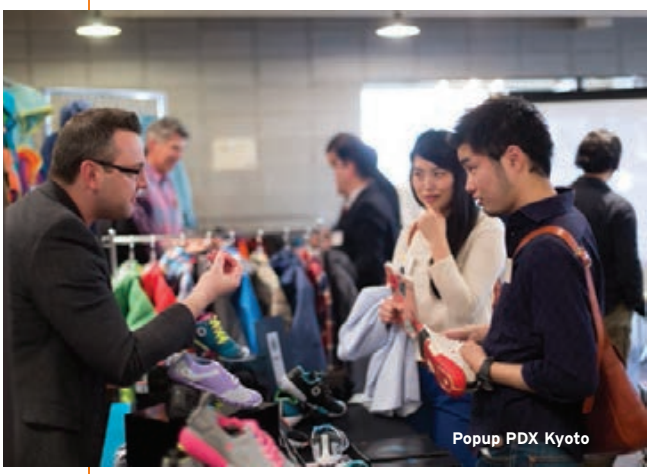
Greater Portland's FOE Employment by Industry, 2011

FOE Employment in Manufacturing Subsectors, 2011

Source: FDI in U.S. Metro Areas, Brookings Institution, 2014

LUBA No. 2020-009
Page 4674

Total Employment in Foreign-Owned Enterprises by Country, Greater Portland, 2011



Source: FDI in U.S. Metro Areas, Brookings Institution, 2014

KEY FINDING 3:

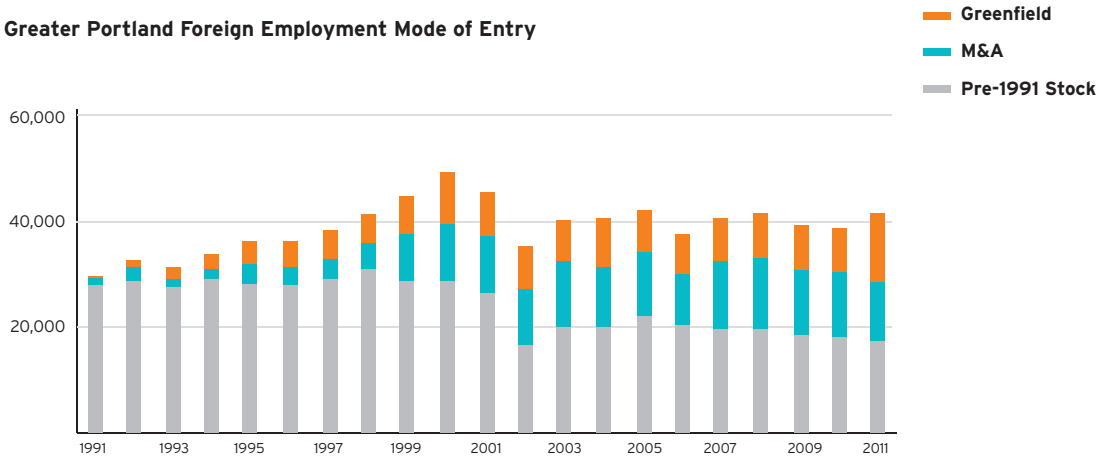
Germany and Japan are responsible for a large concentration of FDI in the region. Together, these two countries account for 43% of total foreign-owned employment in the region, with Switzerland a distant third at 8%. While German FDI is centered on landmark investments in the region by Daimler and Adidas, Japanese investment is spread across a larger number of firms and a variety of sectors.

Interviews revealed that the role of these two markets in Greater Portland's economy is no accident and directly resulted from many years of effort and relationship building by the local public and private sectors. Executives from local German and Japanese companies mentioned the importance of government outreach and cultural institutions as "guide rails" for their eventual investment in the region.

Popup PDX Kyoto

KEY FINDING 4:

The region's strategic positioning on the Pacific Rim is not reflected in the region's FDI partners, outside of Japan. Almost 30% of regional exports go to three East Asian countries: China, Japan and Korea. These same three countries also make up 50% of foreign students at Oregon universities and account for approximately 40% of tourists to the Portland metro (excluding Canada, Greater Portland's most proximate foreign country). Yet—outside of Japan, the region's 2nd largest FDI partner ranked by employment—Korean and Chinese investment has largely not flowed into the region.



LUBA No. 2020-009
Page 4675

KEY FINDING 5:

Greenfield investment, followed closely by mergers and acquisitions (M&A), has driven the region's growth in employment under foreign ownership. Since 1991, 53% of the new jobs under foreign ownership were the result of greenfield investment, representing 12,600 jobs. During the same period, 47% of the new jobs under foreign ownership were the result of M&A (approximately 11,100 jobs). Not all of these numbers or the greenfield jobs are net additions to the regional economy, as FOEs—like their domestic counterparts—are also responsible for job churn: jobs lost due to closings, relocations, or consolidations. FOE jobs have boosted the regional economy, which gained a net 11,000 jobs from FOEs, and this growth occurred predominantly in FOEs that technically have a small business presence in the region, employing 51-250 people, even if the parent company may be a large business.

The data confirms what FOEs stated in interviews: the region is attractive as a "beachhead" to North American markets; its attraction is further buttressed by assets such as cheap electricity and abundant water and the highly developed talent pool of established sectors such as athletic and outdoor and computers and electronics.

Greater Portland Foreign Employment Mode of Entry

Source: FDI in U.S. Metro Areas, Brookings Institution, 2014

KEY FINDING 6:

Traditional business retention and expansion (BR&E) strategies can play a large role in retaining and increasing FDI. Daimler's 1981 acquisition of local legacy manufacturer Freightliner Trucks has resulted in the acquired company's growth and the foreign parent's continued commitment in the region. But with foreign (or domestic) M&As, as stated in the previous finding, the new owner sometimes closes or shrinks local operations, highlighting the importance of BR&E.

Additionally, FOEs interviewed explained the complexities and risk that they often face in opening a foreign outpost, ranging from cultural issues and legal considerations, to the constant imperative of making the case for additional resources and investment from the corporate parent.

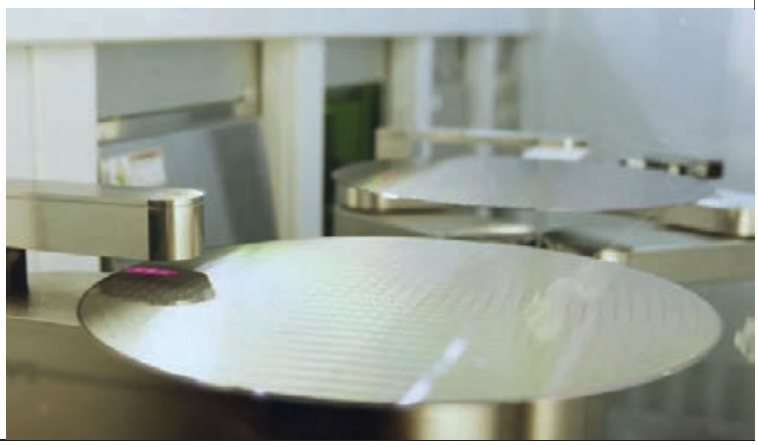
To mitigate these risks, business leaders interviewed saw an opportunity for the local economic development community to expand on existing business retention and expansion protocols to include aftercare for new FOEs and foster closer ties to local companies.

LUBA No. 2020-009
Page 4676

KEY FINDING 7:

Large-scale foreign capital flows have yet to enter the local market. Interviewees reported that large foreign investors view the region as a "Tier Two" metro, lacking the reputation and strong returns of investment havens like New York, Los Angeles and San Francisco. Nonetheless, reports have emerged of "under the radar" interest and investment activity by foreign investment banks, private equity firms, and sovereign wealth funds.

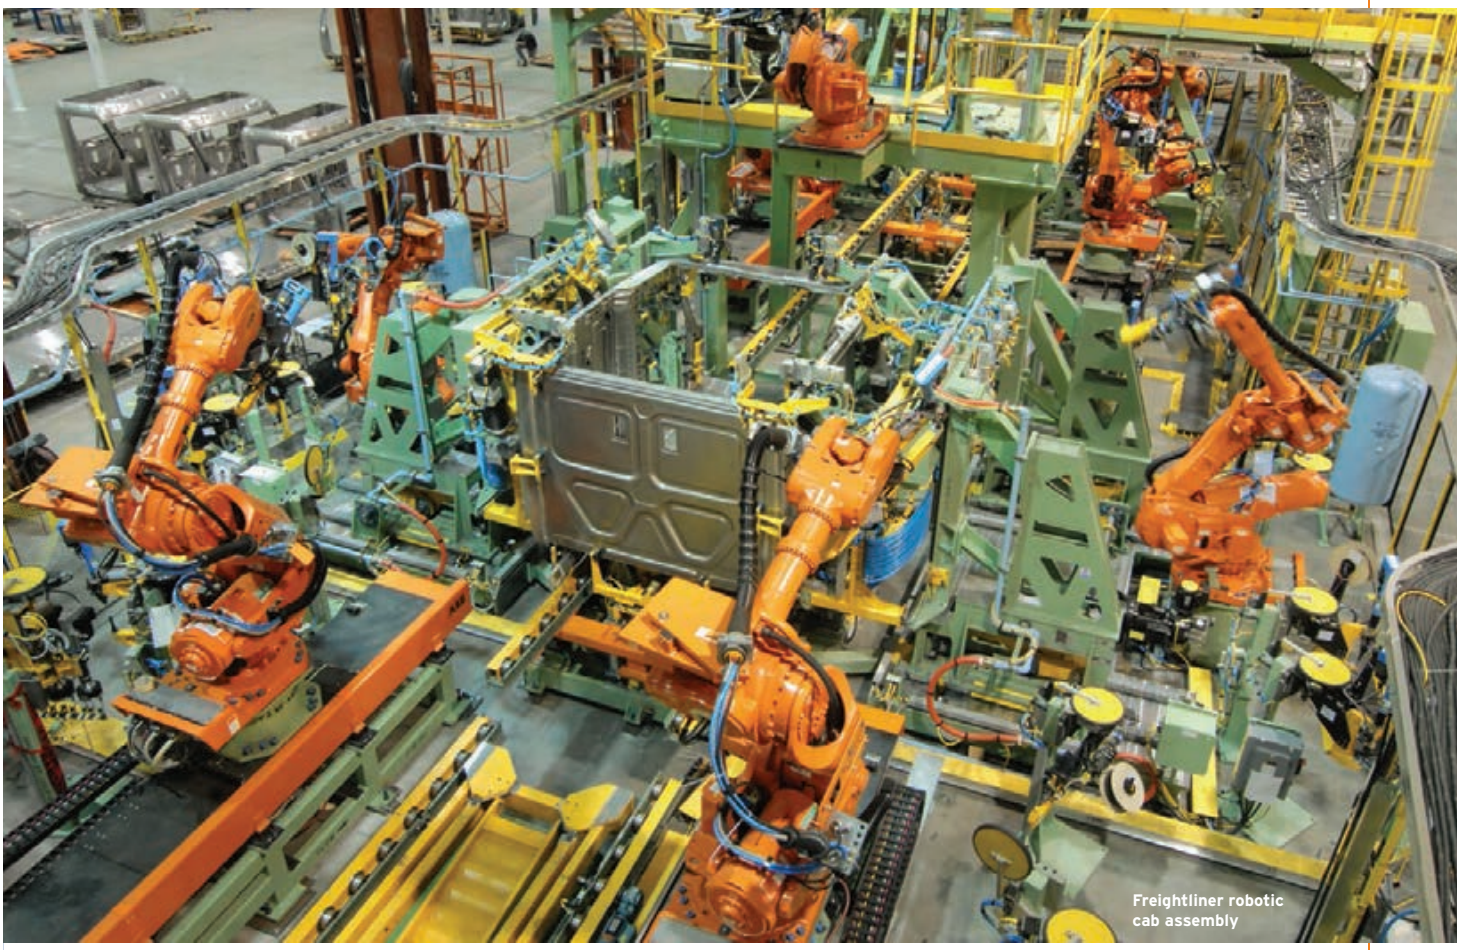
Business leaders and service providers alike expressed a lack of knowledge and expertise on attracting foreign investment capital to the region and local firms—an opinion shared by economic development professionals. Interviews also revealed many conflicting opinions on the pros and cons that large amounts of capital would have on the region's economy, and without data confirming best practices, a "wait and see" attitude has prevailed. As the region learns more about capital attraction, there are great possibilities in extending economic development practice to suit Greater Portland's goals of strengthening the region. The PDC, with assistance from Business Oregon, has developed an EB-5 immigrant investor visa program to connect foreign capital to local urban development projects. While in its infancy, this program could serve as a model for the region's new and open approach to capital attraction.



KEY FINDING 8:

Greater Portland's emerging sectors show strong potential for growth. In recent years, innovative sectors such as green building, clean tech and software—which are growing at home—have begun to establish excellence internationally and drive investment locally from M&A, such as the Korean company HanmiGlobal's acquisition of the local architectural/engineering/planning firm OTAK.

The Spanish Banco Bilbao Vizcaya Argentaria's (BBVA's) recent $117 million acquisition of Portland-based Simple was a landmark investment for the region's emerging software sector. A spillover from the region's established computers and electronics sector, software is gaining a reputation domestically but is still establishing its footing internationally. That a multinational bank of BBVA's stature—with $25 billion in yearly revenues—can find innovation worthy of investment in the region points to further opportunities for other firms in the software sector.



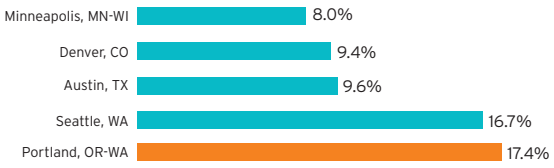
Climax Portable Machining & Welding Systems

LUBA No. 2020-009
Page 4677

KEY FINDINGS
FROM THE EXPORT MARKET ASSESSMENT

Freightliner robotic cab assembly

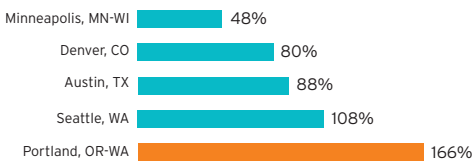
GREATER PORTLAND CONDUCTED AN IN-DEPTH EXPORT MARKET ASSESSMENT in 2011 to serve as a foundation for the development of the original Greater Portland Export Initiative. The assessment included Brookings data benchmarking against other metros, a survey of 268 local companies, and more than 40 one-on-one interviews with local companies and export service providers. Economic data from Brookings was updated in 2014 during the creation of Greater Portland Global.



In addition to the information gained from the initial market assessment, the region has embarked on a three-year education initiative around exports and effective service delivery through the implementation of the Greater Portland Export Initiative. The experience—comprising experimentation, success and failure—has provided grounding on where and how the economic development community can continue to be effective.

LUBA No. 2020-009
Page 4678

KEY FINDING 1:

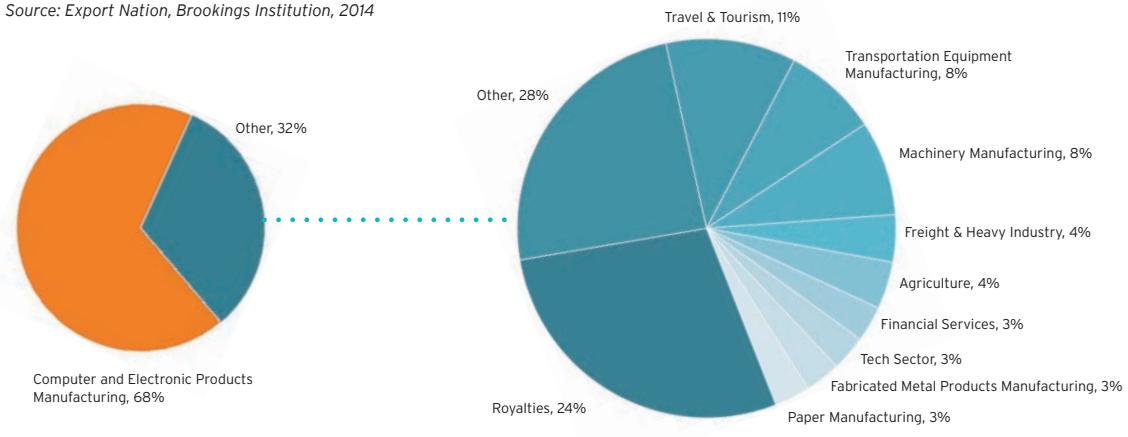


Exports are at the core of Greater Portland's economy. Between 2003 and 2013, Greater Portland increased its export volume by 166%, creating 39,374 direct new jobs for the region. This growth made Greater Portland the fifth-fastest growing export market among the 100 largest metropolitan areas. The region was 13th largest by export volume in 2013, with $26.7 billion in exports, and had the 11th highest export intensity, with exports accounting for 17.4 percent of its economy.

Exports as a Share of Output, 2013

Source: Export Nation, Brookings Institution, 2014

Real Export Growth, 2003 - 2013



Source: Export Nation, Brookings Institution, 2014

KEY FINDING 2:

A handful of companies and clusters drive much of Greater Portland's export strength. Eighty-eight percent of Greater Portland's exports in 2013 and 89 percent of export growth from 2003 to 2013 came from the region's top 10 exporting industries. The region's largest export industry, computers and electronics, anchored by Intel, accounted for 68 percent of total exports in 2013 and 69 percent of export growth, and grows each year.

Industry Share of Total Exports in 2013

Source: Export Nation, Brookings Institution, 2014

LUBA No. 2020-009
Page 4679

KEY FINDING 3:

Greater Portland's emerging export strengths show potential for growth. Though the computers and electronics industry plays the leading role in the region, Greater Portland possesses numerous other export sectors that have developed excellence and are just beginning to go abroad. Clean tech and sustainability firms, which have leveraged the region's excellence in urban development via the We Build Green Cities program, have made inroads in rapidly urbanizing markets in Asia and Latin America. The software sector—a spillover from the region's mature computers and electronics industry—has grown its brand domestically, and its most established companies are just beginning to enter international markets.

KEY FINDING 4:

The most successful exporting companies are intentional about exporting. Companies acknowledged that pursuing business opportunities in new foreign markets requires significant resources and persistence. While resources need to be set aside for relationship development (extensive travel, knowledge of foreign language and culture and even, in some cases, setting up a foreign outpost) and business development (legal expertise of foreign contracts, protecting intellectual property and securing payment), what is really needed is a commitment at all levels of a company that exporting is an important facet of the company's culture and future.

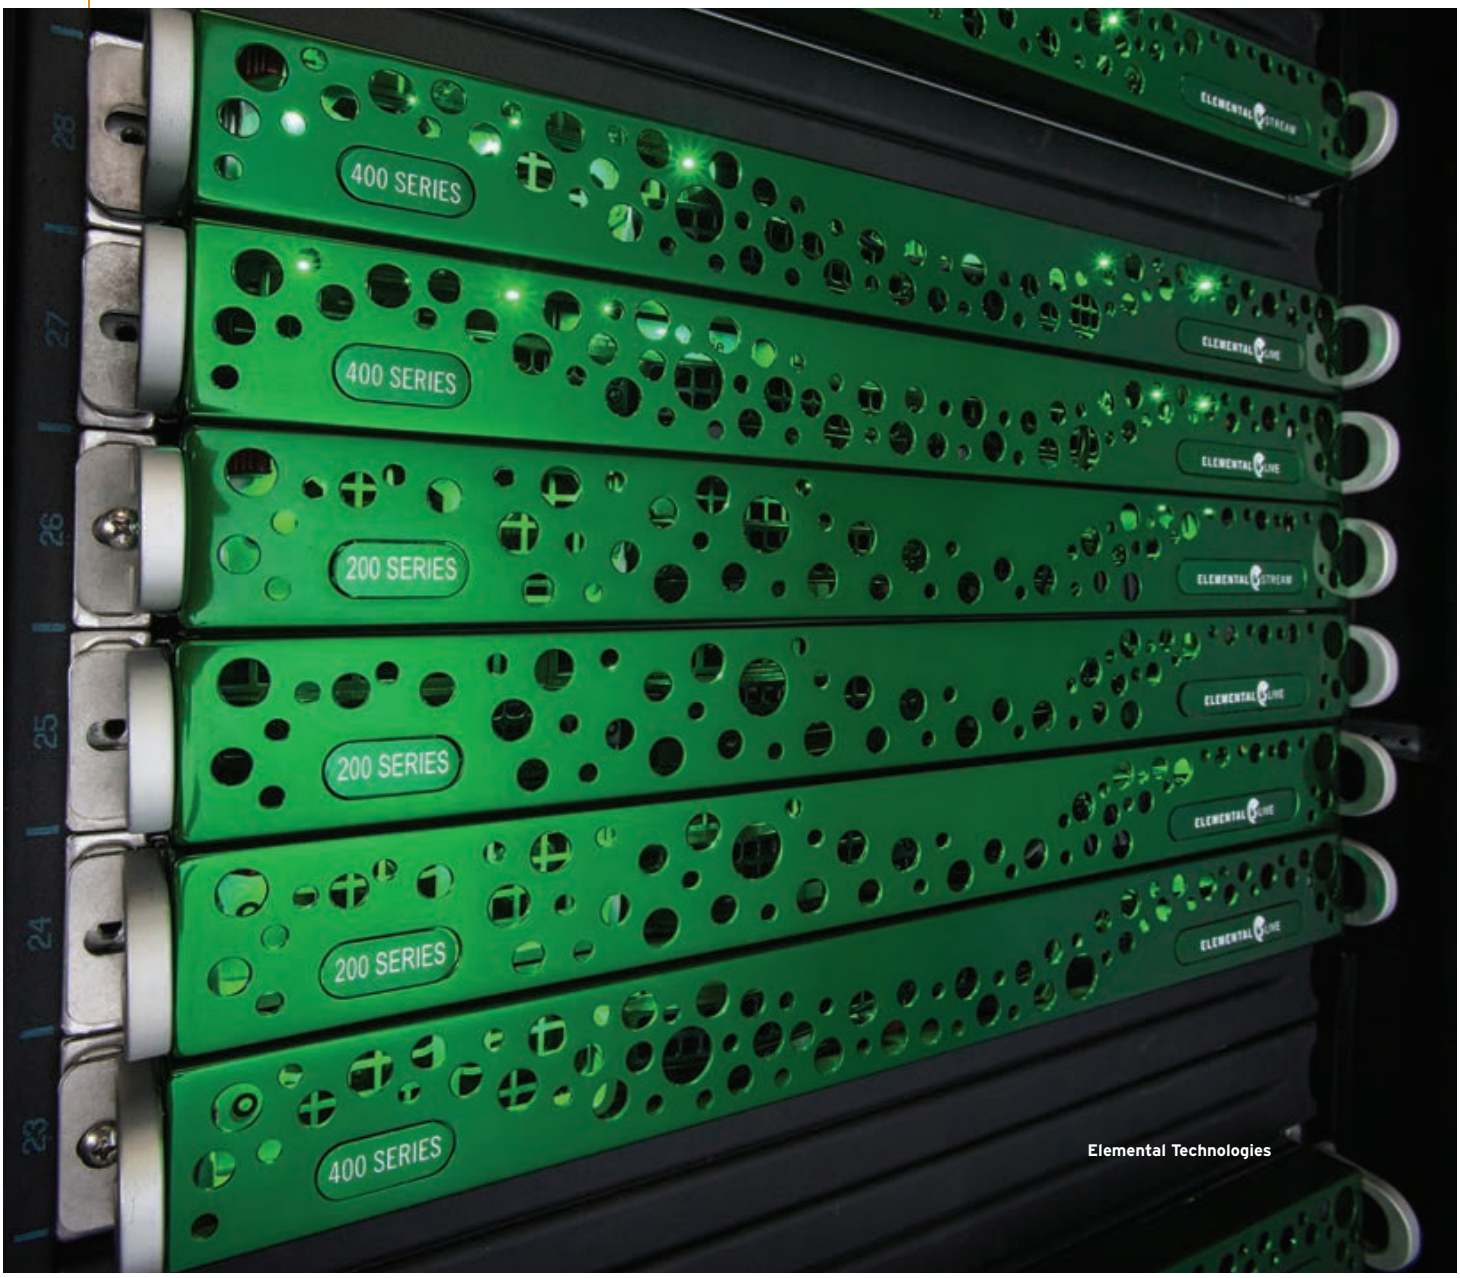
KEY FINDING 5:

Greater Portland's economy is replete with small and mid-sized companies that have limited awareness of global opportunities. Many of the small and mid-sized companies have trouble getting out of the gate to pursue exports. Companies most frequently cited their limited knowledge of foreign export opportunities as the most significant challenge to expanding into new markets. Many companies express a preference to stick to what they know and expand in the United States, where they are more comfortable.

KEY FINDING 6:

Greater Portland has developed an effective export services system, but serious risks will always remain with exporting. Under the Greater Portland Export Initiative, the region's export services system has become more streamlined. An array of services now exist locally: from economic development practitioners (on BR&E visits) asking firms about exporting and making referrals to the U.S. Export Assistance Center Portland and Business Oregon/Washington Department of Commerce to make use of their wide-ranging toolbox of services and tools, to more targeted services such as the We Build Green Cities program that seeks to develop business abroad for the region's clean tech and sustainability firms.

While the Export Initiative helped to develop a more robust export services system in the region, significant challenges still limit export opportunities for firms. During the last three years, impediments such as lack of financing, high tariffs, political uncertainty in foreign markets and transportation/shipping costs have held up export deals. Other companies do not even pursue export opportunities due to problems connecting to global partners, complying with foreign regulations, or competing against foreign tariffs and unfair trade practices.



LUBA No. 2020-009
Page 4680

KEY FINDING 7:

Service provision is most effective when delivered with an understanding that firms are on a continuum of preparedness for exporting. The needs of companies vary greatly based on where on the industry range they lie, from nascent to legacy. Working with trade associations and individual companies can help economic development professionals in general and export service providers in particular target their advice and assistance more effectively.

KEY FINDING 8:

An investment from abroad can also be an export opportunity. At the company level, the link between exports and FDI can be impossible to separate. FOEs who enter the market to export or foreign investors who seek early-stage investment in clean technology that can be commercialized to their home country are examples of "two-fers" that doubly benefit the regional economy.

Elemental Technologies

GOAL & OBJECTIVES

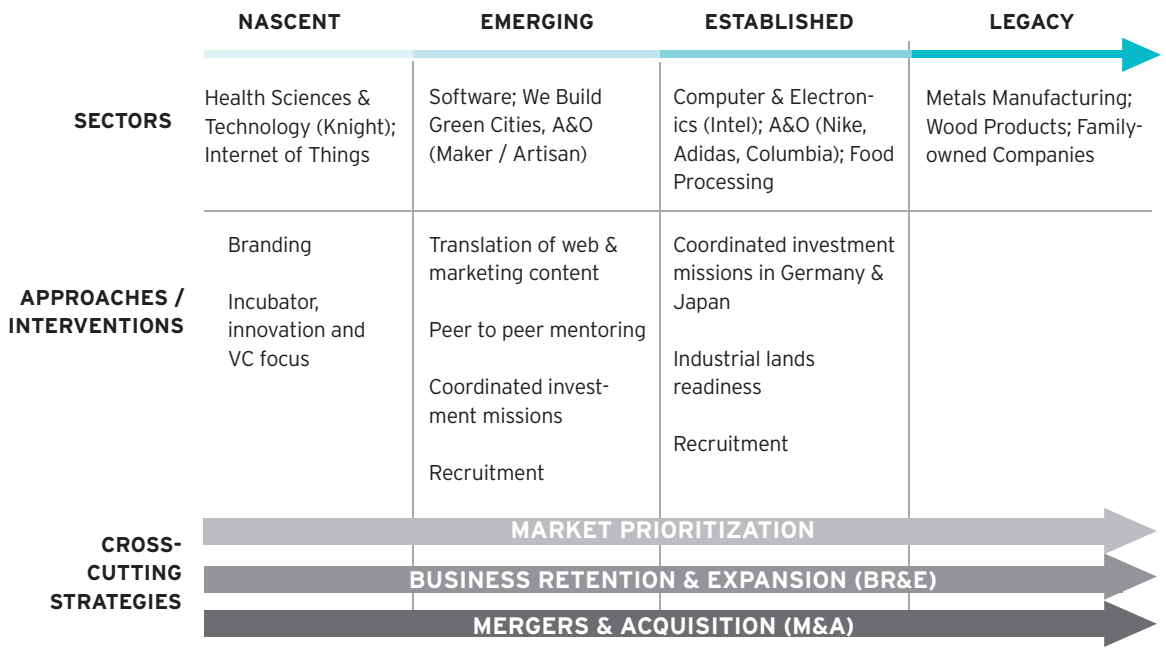
GOAL

THROUGH A HEIGHTENED, INTENTIONAL FOCUS ON REGIONAL ECONOMIC GROWTH, cluster development, exports and FDI, Greater Portland will secure and strengthen its long-term position as a competitive, sustainable, and globally integrated economic region.

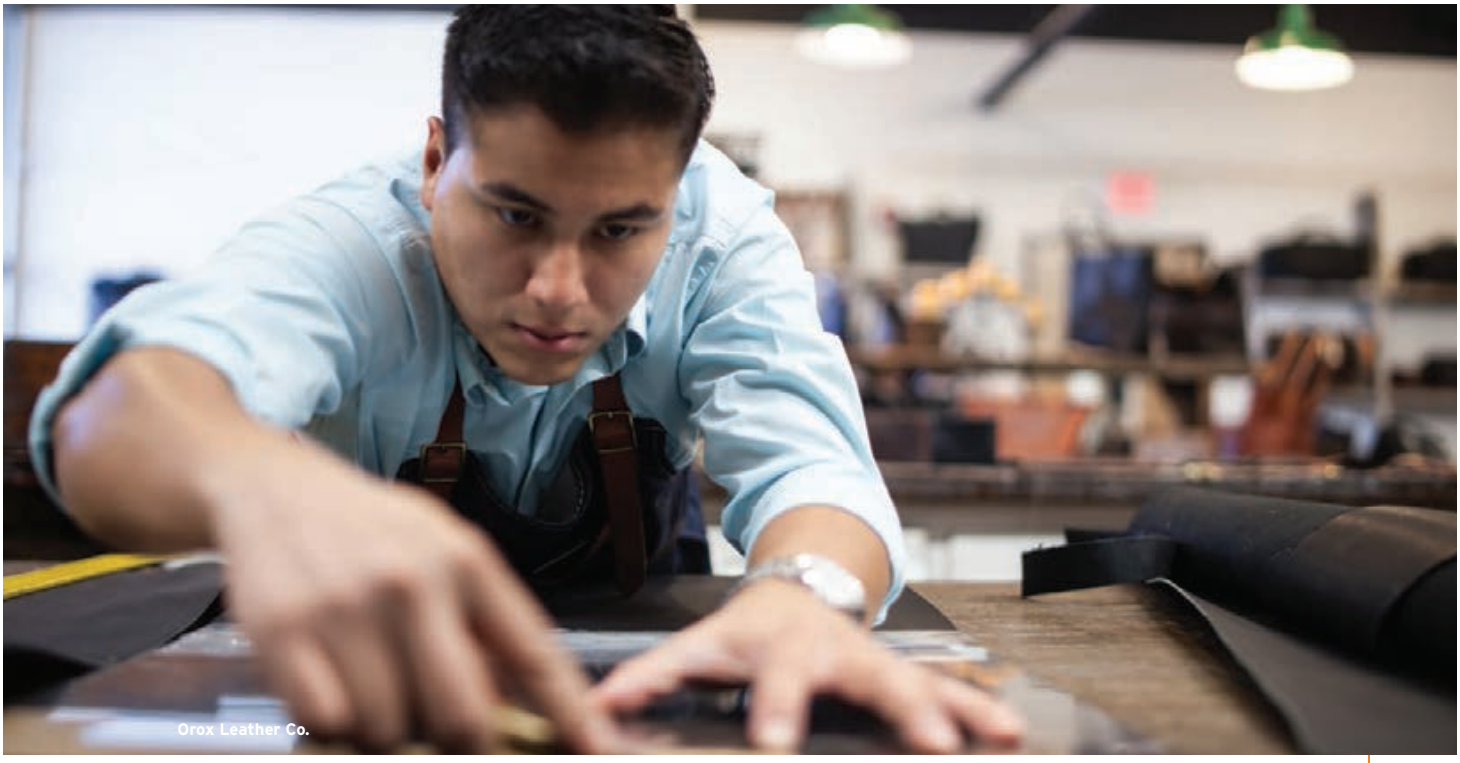
OBJECTIVES

BASED ON KEY FINDINGS FROM THE MARKET ASSESSMENTS, Greater Portland Global, the region's trade and investment plan, has four primary objectives designed to support the region's vision for growth:

1. Create a strong local export and FDI culture and a global reputation for Greater Portland as a competitive region for international business.
2. Grow exports and foreign direct investment by aligning and coordinating the region's economic development efforts around key industries and markets.
3. Diversify export industries, increasing the number of companies exporting and the markets they access.
4. Build on FDI from leading source countries and industries, while also seeking to grow FDI from underrepresented source countries and industries.



LUBA No. 2020-009
Page 4682



STRATEGIES & TACTICS

GREATER PORTLAND'S EXPERIENCES IMPLEMENTING THE GREATER PORTLAND EXPORT INITIATIVE and conducting the FDI market assessment have shaped how and where the region focuses its interventions. Hence Greater Portland's strategies and tactics are blended to serve both export and FDI objectives. The region seeks to investigate where sectors are in the continuum of excellence and develop strategies to nurture newly formed sectors, further the international aspirations of emerging sectors, and secure the future of key firms that anchor the region's most mature sectors.

The four stages in that continuum—nascent, emerging, established, and legacy—each call for differing levels of intervention, focus and support. In addition to stage-specific interventions, strategies around BR&E, M&A and market prioritization will be applied across the continuum.

LUBA No. 2020-009
Page 4683

Orox Leather Co.

STAGE-SPECIFIC STRATEGIES

NASCENT

Whether as spillover from established sectors, offshoots from state-funded incubators, or brainstorms from talented entrepreneurs, the region is full of companies trying to create the next great idea. The job of economic development professionals is not to pick which idea or technology may succeed, but to create a fertile ground where innovation will thrive locally and become a pipeline to the region's next emerging sector.

Knitting the story of innovation into Greater Portland's evolving global brand will not only tell the region's economic story more fully, it will also serve to attract investors who are not currently knowledgeable about Greater Portland's assets and opportunities.

This strategy aims to:

1. Include nascent innovative sectors in the region's brand, focusing on the Knight Cancer Institute opportunity at Oregon Health & Science University and the bioscience/medical products sector.

2. Support and work with Oregon Innovation Council initiatives and Signature Research Centers and the Washington Innovation Partnership Zone in Vancouver to accelerate technologies in nascent innovative sectors.

3. Facilitate introductions between early-stage firms and foreign companies for investment, commercialization and deployment opportunities at events such as Oregon BestFest.

4. Connect local venture capital firms to international sources of capital.

5. Leverage the role of universities in attracting foreign students and investment and cultivating foreign alumni to grow international business connections. For example, the strong student/alumni ties that Portland State University has with Saudi Arabia and the Gulf States present a particular opportunity.

6. Diversify participation in the region's startup ecosystem to create an environment where new products and services are applicable to broad global needs and tastes.

LUBA No. 2020-009
Page 4684

EMERGING

The Greater Portland Export Initiative focused attention on the We Build Green Cities program, which started as a marketing brand and transformed into a business development platform that has had initial success in securing work in target markets for local firms. The export market assessment further revealed that the software industry, known domestically and emerging internationally, would also benefit from an international marketing and business development program.

To address the finding that firms struggle with the "where and how" of exports—questions that also confront economic development professionals who often receive requests or host visitors from around the world—Greater Portland will develop a quantitative and qualitative model to prioritize outbound markets for the two emerging regional sectors of clean tech and software. A tool that can quantify which markets represent the most priority—based on Opportunity, Ease of Doing Business, Size of Market and Connections—will be useful to firms and economic development professionals alike.

This strategy aims to:

1. Translate/globalize web and marketing content for We Build Green Cities clean tech/sustainability and Techtown software brands.

2. Offer local export and investment case management services to companies, building on the work of the Export Initiative in partnership with state and federal partners:

    - Align regional clean tech and architectural and engineering firms with the We Build Green Cities program and its recent partnership with the U.S. Department of Commerce Market Development Cooperator Program

    - Partner with Business Oregon, Washington Department of Commerce and SelectUSA for inbound and outbound investment missions

The Poler flagship store in Portland

3. Expand pilot of peer-to-peer (P2P) mentoring program, which matches experienced exporters with new-to-export or new-to-market exporters, starting with the Technology Association of Oregon.

4. Create a quantitative and qualitative index that prioritizes export markets for software and clean tech/sustainability sectors.

5. Coordinate trade and investment missions to prioritized markets, working with local, regional, state and federal partners.

LUBA No. 2020-009
Page 4685

ESTABLISHED

The global excellence of the region is largely the result of its two biggest companies, Nike and Intel, and the industry clusters that orbit around them: athletic and outdoor, and computers and electronics. While neither firm needs direct assistance with exporting, their success has created a rich vein of ancillary opportunities to build on the Greater Portland Export Initiative work with secondary and tertiary suppliers and exporters in these industries.

Similar to the twin impacts of Nike and Intel in the region, Germany and Japan also tower over other markets' investment in the region. Local economic development professionals have spent considerable time and attention on German and Japanese markets, but their importance and value must be overtly acknowledged by the region and its leaders. Even as Greater Portland begins to look at other markets, the region's 30 years of history with Germany and Japan call for a renewed commitment through visits and closer ties to local firms and cultural institutions.

This strategy aims to:

1. Support established industry clusters with a focus on maintaining and protecting the region's location advantages.

2. Develop and prepare market-ready industrial sites in Greater Portland that will meet target cluster needs.

3. Connect existing businesses in the region to supply chain opportunities as part of business retention and expansion efforts (BR&E).

4. Implement the recommendations of the Regional Large Site Industrial Recruitment Strategy, including specific FDI-related aspects.

5. Coordinate investment missions between city, regional, state and federal partners to the key markets of Germany and Japan to recruit identified foreign supply chain targets and further strengthen cultural ties.

LEGACY

The region is rich with firms in legacy industries such as metals manufacturing and wood processing that use advanced processes and possess a highly skilled labor pool. Though they are not growing apace with other sectors, they represent an important and integral part of Greater Portland's economy. The region has a shining example of how foreign ownership can transform legacy firms into 21st century companies: Germany's Daimler-Benz's 1981 acquisition of Portland's Freightliner Trucks.

Daimler's recent innovations, investment in a new headquarters facility, and creation of hundreds of new jobs all demonstrate the capacity of FDI to shift legacy companies to an upward trajectory. In addition, while the FDI market assessment demonstrated that greenfield investment is the marginally preferred method of entry by foreign firms and that large-scale investment capital has not yet entered the market, it is time for the region to prepare the ground for such interest.

The region's intervention for legacy industries will be limited to the cross-cutting strategies described in the next section.

The Freightliner Cascadia

LUBA No. 2020-009
Page 4686

CROSS-CUTTING STRATEGIES

BUSINESS RETENTION & EXPANSION (BR&E)

Expanding BR&E protocols to deepen relationships with FOEs will allow the economic development community to monitor the pulse of these firms, yielding information on their needs and displaying that their community is willing to partner with them on success.

To address these goals, the strategy aims to:

1. Develop "Global 201" economic development professional training, in conjunction with state, federal, and private sector experts on exports and FDI that builds on the success of "Export 101" export assistance trainings.

2. Codify expanded BR&E protocols around financing and capital considerations for legacy firms.

3. Integrate aftercare strategies into existing FOE BR&E efforts.

4. Support the Port of Portland in efforts to reestablish air and sea cargo service with key Asian markets.

MERGERS & ACQUISITION (M&A)

To further prepare the ground for foreign direct investment, the region will develop M&A–specific strategies that market firms looking for capital or foreign acquisition, extend BR&E strategies, and develop regional procedures for effective response to foreign acquisition.

These strategies aim to:

1. Craft M&A policy and procedures to effectively manage responses by the region and individual jurisdictions.

2. Develop a portfolio of firms and projects seeking capital for inclusion in investment missions.

3. Tap foreign reach of regional companies and business facilitators (such as lawyers, accountants, and consultants) including those with overseas offices, to connect with potential customers and investors.

LUBA No. 2020-009
Page 4687

MARKET PRIORITIZATION

The data support Germany and Japan as the region's most established investment partners with long term investment in a variety of sectors and deeply embedded local cultural institutions. Greater Portland Global seeks to reaffirm the primary importance of these markets to the region, even as Greater Portland casts a wider net for nascent and emerging markets around the world. Similar to the industry approach outlined previously, these would be countries that are beginning to make investments in the region or those that demonstrate a strong complementarity between the region's assets and the country's recent investments.

Stage	Market Attributes	Strategies	Markets
Nascent	• Lack of familiarity with investing in U.S. • Complementarity between investment areas and region's assets/strengths • High growth in outbound investment or existence of sovereign wealth fund investment in U.S.	• Educating inbound investors • Implementation of BR&E aftercare protocols to nurture further investment	TBD by market prioritization
Emerging	• Recent beachhead investments in region • Growing tourist and student enrollment numbers • Deep local connections exist • "Top-down" nature • Ranks highly or growing rapidly in overall U.S. FDI • No restrictions in free flow of capital	• Development of translated investment portfolios • Setting yearly outreach goals • Coordinated response to inbound visits • Exploratory investment missions • Implementation of BR&E aftercare protocols to nurture further investment	TBD by market prioritization
Established	• Long term investment and engagement in variety of local sectors • Existence of local cultural institutions	• "High touch" inbound and outbound meetings • Support of local cultural institutions	Germany and Japan
Legacy	• History of investment but lack of recent investment	• Limited economic development role to play	TBD by market prioritization

LUBA No. 2020-009
Page 4688

PERFORMANCE MEASUREMENT

MANY OF THE FACTORS THAT AFFECT EXPORTS AND FDI are beyond local control (e.g., exchange rates, financial crises, global energy prices), creating challenges for performance measures. To track progress as effectively as possible, Greater Portland Global will use metrics at several different levels:

- Macro indicators in Brookings' Export Nation reports: export value; export intensity; export jobs; indexed performance rank; and diversification of export industries; and Brookings' FDI in U.S. Metro Areas, measuring FDI intensity, trends in greenfield and M&A, and jobs in foreign-owned establishments.

- Regional indicators derived from partners measuring changes in metro export activity, such as number of new firms entering the export service system or the export supply chain, or metro FDI activity, such as inbound and outbound missions or FDI leads; overall demand for export or FDI services; use of regional port facilities (marine and air service); new export markets and FDI source countries; trends in export and FDI services and industry clusters; and new sales contracts or investment deals.

- Qualitative changes to the export and FDI environment, such as recommended policies adopted; integration of export and FDI goals into regional planning; metro-led trade and investment missions and their outcomes; identification of executive level export and FDI leaders in metro companies; and increased media coverage.

Shimadzu

Lam Research

LUBA No. 2020-009
Page 4689

IMPLEMENTATION

GREATER PORTLAND INC (GPI), the region's public-private economic development organization, will coordinate Greater Portland Global's implementation.

GPI staffs a public/private Global Leaders steering committee, which reflects regional and industry balance across the metro area. The steering committee will:

- Oversee implementation of Greater Portland Global goals;
- Help generate public support and financial resources for Greater Portland Global;
- Issue periodic export and/or FDI policy recommendations on behalf of the region.

GPI's coordination will involve a Global Work Team reporting to the Global Leaders and comprising representatives from local/state/federal economic development organizations, trade associations, academic institutions, and private sector partners. The Global Work Team will evolve as needed.

The aim of the Global Work Team is to improve the pipeline from economic development to export promotion and FDI attraction, broadening outreach to export-ready companies and potential foreign investors. The successful implementation of Greater Portland Global should maximize regional participation in the strong export and FDI services provided by the state and federal governments. To ensure full alignment, the Global Work Team will include participation by the federal and state export promotion and FDI attraction organizations in the Greater Portland region: the U.S. Export Assistance Center Portland, the Small Business Development Center, the Columbia River Economic Development Council (an associate development organization in Southwest Washington of the Washington Department of Commerce), and Business Oregon.

The Greater Portland Global strategy proposes a five-year work plan as part of Greater Portland 2020, a five-year regional comprehensive economic development strategy that may include and/or replace oversight of certain strategic elements once the governing and implementation structure is determined. In addition to specific goals and objectives, Greater Portland Global will be truly successful when exports and FDI are mainstreamed into the daily processes of economic development and planning in the region.

GPI will require ongoing funding to provide project management, marketing resources, and administrative support for Greater Portland Global. Partner organizations will support implementation, primarily through existing resources and in-kind staffing, using program and grant funds to coordinate and implement strategies and tactics. This approach encourages regional efficiency and a cultural shift within organizations to support exports and FDI.

LUBA No. 2020-009
Page 4690

POLICY PROPOSALS

In the implementation of Greater Portland Global, the region will uncover obstacles facing both firms and economic development professionals. Part of Greater Portland Global's purpose is to identify these impediments to export and FDI growth, and to propose policy corrections for improved performance. During the development of Greater Portland Global, Greater Portland has gathered initial recommendations on the following topics for both federal and state/local policymakers:

1. Funding for economic growth through exports and FDI
2. Metro-level export and FDI tracking data
3. Freight strategy to support export growth and FDI
4. Strong workforce system
5. Conducive land use, tax structure and general business climate
6. Movement of people and ideas
7. Alignment of performance measures

For additional details please see the Greater Portland Global Policy Memo.

MARKETING AND COMMUNICATIONS

Greater Portland Inc will provide professional, proactive, and clear communications to both project participants and outside stakeholders (regional, national, and international). Marketing and communicating the successes of the region and companies located in Greater Portland will help fulfill the objective to create a strong local export and FDI culture and a global reputation for Greater Portland as a competitive region for international business. Specific tactics will include sector-specific work, like the We Build Green Cities website and translated materials. The launch of the Greater Portland Global will be followed by regional rollout presentations to interested business associations and economic development partners.

GPI's outreach will include:

- Release of Greater Portland Global (project participants and outside stakeholders)
- GPI website's Global section (project participants and outside stakeholders)
- Yearly updated reports (project participants and outside stakeholders)
- Meeting management, including clear definition of roles and responsibilities and conflict management as needed (project participants)
- Public presentations, status updates, and joint press release management/media interaction (outside stakeholders).

ACKNOWLEDGMENTS

For the Greater Portland Export Initiative, the City of Portland and the Portland Development Commission (PDC) led the export strategy process, with a core team that included the Port of Portland, Greater Portland Inc (GPI), Business Oregon, the U.S. Export Assistance Center (USEAC) Portland, and other regional stakeholders.

For Greater Portland Global, the Greater Portland Global Trade and Investment Plan, GPI and PDC co-led a FDI Pilot Core Team, which also included Business Oregon, the City of Hillsboro, the Port of Portland, Portland State University, and USEAC Portland.

In addition to the work of the strategy development teams, Greater Portland sought significant input from a wide range of public sector organizations, higher education institutions, regional decision-makers, and private sector businesses through working sessions, one-on-one meetings, and presentations to regional organizations.

Thanks also to the Metropolitan Policy Program at the Brookings Institution and JPMorgan Chase for support of this work and the Global Cities Initiative. Ryan Donahue of Brookings provided significant feedback and input for this report.

ABOUT THE GLOBAL CITIES INITIATIVE

The Global Cities Initiative is a five-year project of the Brookings Institution and JPMorgan Chase aimed at helping the leaders of metropolitan America strengthen their regional economies by becoming more competitive in the global marketplace. It seeks to catalyze a shift in economic growth policy and practice to position metro areas for high-quality growth and better jobs for more workers. The Global Cities Initiative has three pillars: research, forums, and the Exchange. The Exchange is a four-year learning and action network that enables leaders to act on the ideas and collaborations generated by GCI's research and forums. At the core of the Exchange are the efforts of 28 U.S. metropolitan areas, including Greater Portland, to create integrated export and FDI strategies in Global Trade and Investment Plans.

For more information, see
www.brookings.edu/projects/global-cities.aspx
#GlobalCities

This report was developed by Greater Portland Inc and the Portland Development Commission through the collaboration of political, business, and civic leaders of the Greater Portland Region. The conclusions and recommendations of this report are solely those of its authors and do not reflect the views of the Brookings Institution or JPMorgan Chase.

The Brookings Institution is a private non-profit organization. Its mission is to conduct high-quality, independent research and, based on that research, to provide innovative, practical recommendations for policymakers and the public. Brookings recognizes that the value it provides is in its absolute commitment to quality, independence and impact, and makes all final determinations of its own scholarly activities in the Global Cities Initiative, including the research agenda and products.

ABOUT GREATER PORTLAND ECONOMIC DEVELOPMENT DISTRICT

The Greater Portland Economic Development District (GPEDD), staffed by Greater Portland Inc, is a 501(c)4, not-for-profit organization serving Clackamas, Multnomah and Washington counties in Oregon and Clark County in Washington. GPEDD is funded primarily through grants awarded by the U.S. Department of Commerce's Economic Development Administration (EDA).

GPEDD focuses on regional economic development in two critical areas. First, GPEDD leads the regular update to the Comprehensive Economic Development Strategy (CEDS)—a cornerstone of the U.S. EDA's programs defined as a strategy-driven plan for regional economic development. The CEDS is a prerequisite for designation by EDA as an Economic Development District (EDD). Second, GPEDD coordinates regional responses to U.S. federal government economic development grant opportunities, such as the Investing in Manufacturing Communities Partnership (IMCP) and the Jobs and Innovation Accelerator Challenge (JIAC) grants.

ACCOMPLISHMENTS

Pacific Northwest Manufacturing Partnership (PNMP)
PNMP was formed in response to IMCP, a federal initiative which aims to accelerate the resurgence of manufacturing in the United States and create a competitive climate for job creation and private investment. On July 8, 2015, a bi-state supra-region led by Business Oregon that includes Greater Portland received the designation of "Manufacturing Community" that gives the supra-region elevated consideration for $1.3 billion in federal dollars and assistance from 13 cabinet departments and agencies. The strength and synergy of the PNMP is woven in our combined "manufacturing ecosystem". The PNMP region's historical strength in materials and metals forms the basis of the Advanced Materials Science for Advanced Manufacturing cluster.

PNMP's catalytic project component to the IMCP application is related to the commercialization of cross laminated timber (CLT) in the Northwest. CLT and associated advanced wood products manufacturing technologies combine our region's traditional competitive advantage in softwood timber supply from Pacific Northwest forests with advanced material science.

The JIAC grants are a partnership between the U.S. Department of Commerce's EDA, U.S. Department of Labor's Employment and Training Administration, and the U.S. Small Business Administration, with the Innovations in Advanced Materials and Metals grant also including the U.S. Department of Commerce's National Institute of Standards and Technology and the U.S. Department of Energy.

JIAC Clean Tech Advance Initiative
In October 2011, the Greater Portland region was awarded $2,150,000 in federal funds to accelerate innovation in clean technologies for the next three years, later extended. The Clean Tech Advance Initiative is a bi-state partnership under the leadership of the Portland Development Commission to support innovation and job creation in the Clean Tech and Advanced Manufacturing Industry Clusters.

JIAC Innovations in Advanced Materials and Metals
In October 2012, the Greater Portland region was awarded $2,192,000 in federal funds to accelerate innovation in the advanced materials and metals industries for the next three years. The Innovations in Advanced Materials and Metals is a bi-state partnership under the leadership on the Columbia River Economic Development Commission to support advanced manufacturers that specialize in metals, machinery, computer and electronics, plastics, composites, polymers and other advanced materials.

GREATER PORTLAND 2020 OVERVIEW

Greater Portland's business, education and civic leaders are collaborating to align economic priorities across the bi-state, multi-county region. For the first time, the region is coming together to develop an action-oriented, five-year comprehensive economic development strategy (CEDS) that builds on existing efforts and spotlights what's needed to achieve economic prosperity in Greater Portland.

Following is a summary of phases that have helped to shape the framework of the CEDS, which is also known as the Greater Portland 2020 plan. This research was guided by Atlanta-based economic development strategy firm, Market Street Services. Specific research relative to each phase is referenced throughout the following pages within each strategy. Data and information from these phases are included as an addendum to this document.

PHASE 1: COMPETITIVE BASELINE ASSESSMENT

The Competitive Baseline Assessment presented a detailed examination of the Greater Portland region's competitiveness as a place to live, work, visit and do business. Nine U.S. metros were selected to show not only those comparable to Greater Portland, but also which metros are ahead of or more competitive than the region, illustrating the strengths and weaknesses through a comparative data set. The Assessment leveraged a number of indicators through the use of benchmarking dashboards to outline the key strengths, weaknesses, opportunities and challenges facing the metro area. The Competitive Baseline Assessment was a starting point to lay the groundwork for the next research phases, stakeholder input, and strategic implications that directly informed the Greater Portland 2020 action agenda.

PHASE 2: REGIONAL TALENT REVIEW

Expanding on the findings and conclusions of the Competitive Baseline Assessment, the Regional Talent Review explored Greater Portland's current talent pool and examined its long-term capacity to drive job growth and prosperity in the region. This evaluation combined data, analysis, existing reports and some stakeholder input to paint a clear picture of the Greater Portland region's talent standing. This report highlighted the younger and advancing workforce cohort's trends and dynamics in the context of many of the initial indicators from the Competitive Baseline Assessment, and its findings related to the region's occupational structure directly informed the Target Business Analysis phase of the process.

PHASE 3: TARGET BUSINESS ANALYSIS

The Target Business Analysis phase provided a more complete picture of the competitive realities surrounding the development of identified target industries around which Greater Portland Inc (GPI) and partners should focus their economic, talent and site development efforts. Greater Portland has a strong complement of homegrown corporations and exciting startup activity, but the conditions that build economic clusters and launch new ventures are not necessarily the same conditions that sustain and grow these diverse components of the regional economy. The goal of the Target Business Analysis was to ensure that metro leaders gain a better understanding of Greater Portland's strengths and potential areas of challenge in each sector, particularly as they relate to technology, innovation, educational and research development assets. A fundamental belief in the three legs of the economic development stool (retention, recruitment and entrepreneurship) drove the analysis.

REGIONAL STRENGTHS + ADVANTAGES

There are three factors that contribute to the advancement of Greater Portland's economy: **Workforce**, **Business Infrastructure** and **Quality of Life**. While there are clear strengths within each factor, there are also areas of opportunity to build upon that help to frame the strategies contained within the CEDS. The following findings are derived from the Phase I Competitive Baseline Assessment.

WORKFORCE

High Productivity

Greater Portland businesses benefit from high workforce productivity. Each of the region's workers, on average, generates $195,143 in exports. Only San Jose ($201,644 exports per worker) displayed higher productivity levels. Gross metropolitan product (GMP), a measure of total economic output, is the 3rd highest ($169,209 GMP per worker) of Greater Portland's benchmark metros. Only tech hubs San Jose and Seattle boast higher productivity levels, but that gap is narrowing. In the last five years, Greater Portland (25.8 percent) experienced a larger GMP increase than both San Jose (16.7 percent) and Seattle (17.2 percent).

Talent In-migration

Over the last five years, Greater Portland added more than 110,000 new residents, a gain of five percent since 2008—growth that's on par with San Jose, San Diego and Salt Lake City. Despite moderate growth, the region remains a prime destination for domestic and international migrants. Total net migration between 2000 and 2013 represented 10.4 percent of the region's total 2013 population, the 4th-highest of all benchmark metros.

BUSINESS AND INFRASTRUCTURE

Air and Freight

Whether moving people by air or goods by sea, Greater Portland businesses can easily connect to global economic activity. From 2012-2013, Portland International air passenger departures per capita grew by 4.2 percent, the fastest of 10 benchmark metro regions. Portland International Airport also demonstrates strong capacity to handle air cargo, moving 437 million pounds in 2013 alone. As a major infrastructure asset to export-oriented trade activity, the Port of Portland handles roughly 11 million tons of exports, 14th out of the 171 ports in the nation. In comparison, the Port moves only four million tons of imported products, the 42nd busiest out of 171 ports.

QUALITY OF LIFE

Livability

While hard to quantify, quality of life is notably the region's strongest asset, nationally and increasingly, globally. The in-migration of talent that Greater Portland is experiencing affirms the region's reputation for livability. A quality of life scan shows that transportation options, job density and civic engagement are high. There is an intricate link between Greater Portland's quality of life and its capacity to provide its businesses with a sustainable pipeline of workers.

REGIONAL CHALLENGES + AREAS OF OPPORTUNITY

Factors that challenge the region's present and future economic growth include **Innovation and Entrepreneurship**, **Equity** and **Cost of Living**.

INNOVATION AND ENTREPRENEURSHIP

Access to Capital

Companies in Oregon received just $9.3 million in venture capital funding in 2013—0.02 percent of the nation's venture capital investment that year. At the same time, 35.5 percent of the state's total venture capital is generated in Oregon. In comparison, California reports a little over $10 billion in venture capital activity (68.4 percent from in state), and Texas reports almost $600 million of activity. Greater Portland has been proactive in filling venture needs through establishment of state- and locally-run venture capital funds to maximize the efficiency of capital used outside of more expensive innovation hubs like San Jose.

EQUITY

Lagging Economic Prosperity

Five-year changes in the region's household incomes show a reduction in the amount of middle-income households, and growth at the poles of the income scale. Between 2008 and 2013, the number of households with incomes of $24,999 or less increased by 9.4 percent and the number of households earning more than $100,000 annually rose 11.7 percent. Both of these growth rates far exceeded the increase in the total number of households in Greater Portland, which rose 5.6 percent during the five-year timeframe. This demonstrates a clear need to generate more opportunities for employment and advancement to give households at the low end of the income ladder an opportunity to move up.

COST OF LIVING

Affordability

Greater Portland's cost of living, ranging from annual congestion costs to housing and rental affordability are among the highest of all the 10 benchmark metros. In terms of rental affordability, more than half the region's residents pay 30 percent or more of their gross income on rent—a commonly used measure for housing affordability. With the U.S. cost of living indexed at 100, Greater Portland's cost of living index (121.7), a broad measure of a region's costs of goods and personal services, was well above the national average. While costs in California metros (San Jose and San Diego) were comparatively higher, it is important to note that both region's residents command higher wages and per-capita incomes.

WHERE IS GREATER PORTLAND NOW?

KEY RESEARCH AND INPUT FINDINGS

Market Street Services conducted three research phases, public surveys for input, and a close review of existing research that directly informed many of the objectives and actions of the Greater Portland 2020 strategy. These findings point to urgency for the region to accelerate positive momentum in Greater Portland's components of people, place and business and to address head-on the challenges and vulnerabilities that threaten to chip away at its current status. In order to improve Greater Portland's trends and assets, decisive, collaborative, regional action is necessary. The status quo will result in Greater Portland falling further behind.

At the onset of the Greater Portland 2020 research process, the general public and the Greater Portland 2020 Steering Committee were surveyed on their insights into the economic development climate of the region. They ranked lists of economic development activities on how effective or ineffective these tactics have been for Greater Portland.

This insight was important in understanding the regional context and economic development ecosystem in which the quantitative trends (examined in the research phases) play out. While some key parts of economic development are successful and well understood by the public and steering committee, much of the foundation of a sustainable, vibrant metro economy—the place for business to start and thrive—is on shaky ground. If those areas identified in the surveys as less successful do not improve, the competitive advantages and accomplishments in Greater Portland's startups, talent attraction and quality of life will not survive.

SURVEY RANKING OF ECONOMIC DEVELOPMENT ACTIVITIES

MOST SUCCESSFUL ECONOMIC DEVELOPMENT ACTIVITIES IN GREATER PORTLAND

1. Quality of life
2. Entrepreneurship and innovation
3. International exports and foreign direct investment
4. Existing business retention
5. Talent attraction and retention

LEAST SUCCESSFUL ECONOMIC DEVELOPMENT ACTIVITIES IN GREATER PORTLAND

1. Industrial site development
2. Competitive business climate
3. External marketing and communications
4. Infrastructure development (including transportation, utilities and technology)
5. Incentives and policy

WHERE IS GREATER PORTLAND NOW?

continued

COMPETITIVE BASELINE ASSESSMENT *(Phase 1)*
Greater Portland's middle or low rankings on many of the indicators in the five areas examined—economic performance, workforce competitiveness, innovation and entrepreneurship, business environment and quality of life—pointed to a significant amount of growth that must continue to maintain quality of life, economic opportunities and advancement across the region's businesses and workforce. The Competitive Baseline Assessment against nine other U.S. metros demonstrated that Greater Portland 2020 must have a spirit of urgency to slow or reverse some of the affordability, wage and unemployment trends that threaten the region's prosperity.

- **Low wages and relatively low share of per-capita income driven by wages** are a major concern for the region's economic prosperity. Greater Portland showed solid wage growth, but wages still lag competitor metros.
- Job growth has been coming from new establishments and seems to have the **strongest potential in businesses starting and expanding** in the region.
- **Bachelor's degree attainment and growth, and the potential to raise attainment through educated young adults and in-migrants, lags** peer metros. In addition, the larger share of the workforce who may be aging into retirement in the coming decade poses a concern for workforce sustainability.
- Greater Portland **competes for talent, funding and enterprises against some of the most innovative startup and research hubs in the world.** The region boasts a stronger-than-average startup density and relatively large share of self-employed workers and employment in small firms. However, with lower earnings and income growth and venture capital for these enterprises, it is clear many of the region's startups and entrepreneurs are bootstrapping, stretching lower revenues and investment dollars. On the positive side, stakeholders pointed to high capital efficiency among the region's startups and second-stage firms.
- The region has a favorable business climate, especially relative to other West Coast metros. In addition, its infrastructure for the movement of people and goods is competitive. Notable is water availability for businesses and residents, which will be an increasingly critical location decision factor for talent and firms.
- Residents' well-being—as measured in poverty rates, rates of uninsured, health outcomes and crime—is concerning. Greater Portland does not stack up to many peer metros on these well-being metrics. In addition, as residential growth expands in counties outside of the core while the central business district adds jobs, the already high cost of traffic congestion in Greater Portland could grow even more. A relatively high cost of living coupled with the region's lagging wages and per-capita income are likely serious hindrances to economic advancement for many residents.

COMPETITOR METROS

1. Austin, TX
2. Denver, CO
3. Minneapolis, MN
4. Phoenix, AZ
5. Raleigh, NC
6. Salt Lake City, UT
7. San Diego, CA
8. San Jose, CA
9. Seattle, WA

Nine U.S. metros were selected to show not only those comparable to Greater Portland, but also which metros are ahead of or more competitive than the region, illustrating the strengths and weaknesses through a comparative data set.

WHERE IS GREATER PORTLAND NOW?

continued

REGIONAL TALENT REVIEW *(Phase 2)*
At its most fundamental level, economic development is about increasing prosperity for individuals through creating, retaining and attracting quality jobs. A prosperous regional economy depends on a talented workforce, and the region's ability to retain and advance those workers. Nationally, businesses have begun to value skilled workforce availability above all over factors (including cost of labor and business climate).

The Regional Talent Review focused on Greater Portland's existing workforce strengths and shortcomings, and its opportunities for future talent growth, leveraging numerous existing reports and strategies. These reports build off a few key themes echoed in Greater Portland 2020 stakeholder input: equity, wages and opportunities for workforce engagement and advancement.

Some of Greater Portland's fundamentals are strong, but the competition is fierce and the region has achieved only modest gains in prosperity relative to comparison metros. The current economy is leaving behind many of the region's residents. Greater Portland must proactively work to boost its economic prosperity in the form of more jobs, better jobs and opportunities for advancement for all of its residents.

- **Young, more educated, increasingly diverse talent—but not at the level of its competitor metros.** Greater Portland has enough younger residents to replace those who will retire in the next 20 years. However, other competitor metros have even more favorable age dynamics. In every age group, the U.S. is more racially and ethnically diverse than Greater Portland, but overall, the region is clearly becoming more diverse. Just over 35 percent of adults have a bachelor's degree or higher—a larger share than the U.S. but behind some competitor metros. Education attainment levels in most of Greater Portland's race and ethnic groups are slightly higher than national averages, but gaps persist between white adults and Black and Hispanic adults.
- Greater Portland's **workers between the ages of 25 to 34 are more likely to be employed in food service or other service jobs** and less likely to hold a business, finance or computer-related occupation than young workers in competitor metros like Denver and Seattle.
- Greater Portland is a significant net attractor of people, particularly from other places in the West—Los Angeles, San Diego, Las Vegas and Honolulu. That said, Greater Portland has experienced a net loss of population to Seattle and Austin. Greater Portland's **status as a major talent magnet is somewhat dependent on the economic opportunities it can provide to new residents**. In the two most recent economic downturns, Greater Portland's in-migration slowed down much more so than out-migration sped up.
- **New residents bring more education but less income.** In-migrants into Greater Portland tend to be young and highly educated, indicating that educational attainment levels in the region are likely to rise as more new residents move in. However, in-migrants to Greater Portland are also less wealthy prior to moving to the region than in-migrants into comparison metros.
- **Mismatch between quality of life and quality of economic opportunities threatens long-term competitiveness.** While many regions must address significant quality of life concerns before they can even begin to attract significant levels of outside talent, Greater Portland's attractiveness as a place to live is perhaps its main strength. At the same time, the region must focus on providing jobs and advancement opportunities to match its overall quality of place.
- **The sheer number of scattered K–12 districts (50 in total) hinder strategies to address systemic issues.** Quantitative data confirms that the performance of the area's largest public school systems runs the gamut, and data show significant equity issues. Complicating matters further, districts are divided between two state systems that have different sets of administrators, funding structures and legislative mandates.

WHERE IS GREATER PORTLAND NOW?
continued

- Despite the lack of a single powerhouse research university, there are **major opportunities ahead for higher education in the region**. Greater Portland has strong higher education assets but produces relatively fewer degrees than its comparison metros. The region also lacks one major research university, but Portland State University (PSU) and Washington State University-Vancouver (WSUV) are growing rapidly. In addition, Oregon State University (OSU) and University of Oregon (UO) are increasingly expanding their reach into Greater Portland. In terms of research, the Life Sciences Collaborative of Oregon Health & Science University (OHSU), PSU, and OSU unites resources and OHSU's Knight Cancer Center will build even more research capacity.

- **Competitive workforce skill sets support Greater Portland's legacy, established and emerging industry sectors.** The region has a several core workforce competencies, including significant corporate capacity, a strong concentration of management occupations, and a thriving base of "creative" talent. Software development, metal manufacturing, semiconductor manufacturing, and engineering talent are also concentrated in Greater Portland relative to other metros. The depth and breadth of these occupational skill sets are highly competitive. It should also be noted that Greater Portland's overall production occupational capacity is average relative to the U.S., but compared to similar metro areas, it stands out as a competitive advantage.

- **Low wages could hurt emerging and nascent tech sectors.** Greater Portland's wages in software development occupations are significantly below the national average and pay levels found in comparison metros. Wages are important in software development—this could impact the region's ability to attract talent. Greater Portland's tech workforce is also older than comparison metros and the U.S. average—the region will need to work harder just to keep pace with its tech firms' talent needs.

- **A call for coordination and amplified efforts is necessary.** There are a number of positive initiatives underway in Greater Portland that help connect individuals, the education pipeline and the region's businesses. However, according to input participants, the major shortcoming is a lack of coordination between these efforts, creating "silos." The big need is for the region to coordinate more of these activities around shared workforce goals that are strategic and regional. Competition in the economic development world has never been more intense, and many of the regions with which Greater Portland competes for talent have similar advantages and are pulling ahead in some key objective workforce measures. This highlights a clear need for the region to take action to boost the skills and competitiveness of its talent, thereby increasing its ability to create wealth and prosperity for all its citizens.

TARGET BUSINESS REVIEW *(Phase 3)*
Targeting is the practice of focusing limited resources on those business sectors—and the asset base that supports them—that have the greatest potential to support future job creation, business investment, and wage growth in Greater Portland. The Target Business Review proposes six targets, which evolve out of Greater Portland's existing four target industries.

Metal + Machinery
With heavy investments from Vigor, Schnitzer Steel, Columbia Steel and Daimler, the region's significant manufacturing base stands apart from other metros. It has historical skill sets that remain entrenched, and the workforce is relatively young. However, the comparatively high business cost structure in Oregon and Washington make recruiting a challenge for any prospects looking at locations beyond the West Coast. There are also few prepared large sites in the region, and despite the presence of Asia-facing ports, transportation infrastructure to support the movement of goods is a concern for firms in this sector. Many of the Metal & Machinery occupations in Greater Portland require only a high school diploma, but regional employers still point to needs in increased STEM and career-preparation training.

WHERE IS GREATER PORTLAND NOW?

continued

Computer + Electronics
Though global competition and uncertainty persist, this is a mature, highly productive and well-known cluster in Greater Portland. While semiconductor manufacturing (anchored by Intel) is the most recognized component of this sector, Greater Portland is also concentrated in computer and peripheral equipment and communications equipment. Crucial to the local economy, this industry has site, regulatory and workforce needs that are critical to these employers' continued investment. The production, talent and market expertise of this sector also have good implications for the growth of emerging fields like Clean Tech or Health Sciences & Technology.

Clean Tech
Propelled by Greater Portland's sustainable mindset and its capacity for innovation, Clean Tech specifically focuses on manufacturing and associated research and development efforts. Clean Tech increasingly aligns with export efforts as U.S. demand is lower overall, and the *We Build Green Cities* program is a promising initiative for exporting Greater Portland's clean tech strengths—especially in consulting. The sector connects to other target strengths like metals and electronics, and these production jobs have low barriers to entry for the workforce. One challenge to address is that Greater Portland's clean tech firms tend to be small, and the field is not ideal for angel investors.

Athletic & Outdoor
Built around homegrown Fortune 500 company Nike, this sector in Greater Portland has since evolved into the most concentrated cluster of these firms in the U.S. The region's beautiful natural setting is ideal as a place to attract talent, innovate products and reach consumer markets. The industry centers on designing products and managing the corporate operations of these companies more than manufacturing products. There are relatively few entry points for less-skilled and local workers. Athletic & Outdoor is a great attraction target for Greater Portland as firms continue to relocate to the region. A major opportunity for this sector is crossing over into the Health Science & Technology emerging area to make the region a leader for "wearable" medical devices and other health and wellness technology that harnesses the Internet of Things.

Software + Media
This sector builds on Greater Portland's reputation as a tech and innovation hub. The diversity of the sector and the products it creates are evident in the region's mix of companies—from Ascension Software (mobile app developer for the hospitality industry) to Elemental Technologies (multiscreen video solution) to Salesforce (cloud-based customer relationship management), Greater Portland has a wide range of homegrown enterprises and major operations of firms headquartered elsewhere. While the software development side of this cluster is established, the emerging field of digital media can help it diversify. These firms are often small and need assistance to scale, but the overlap of Software & Media with so many other target industries is promising. Two major potential threats to this cluster's long-term success in Greater Portland: ages and wages. The region's computer occupations workforce is much older than the U.S. average, and local wages significantly lag competitor metros.

Health Sciences + Technology
Unlike other targets, this is primarily an emerging area. The region's medical devices niche is small but well established. This sector primarily builds off the opportunity from the Knight Cancer Challenge, which could help stimulate additional biotechnology and health innovation in Greater Portland. As found in the Regional Talent Review, there is some life sciences occupational capacity in Greater Portland, but not compared to the true sector hubs, so recruiting outside talent will be an absolute must as this sector gains steam. Still, many lab tech jobs require a two-year degree or less, so with focused STEM training, this sector could connect less-skilled workers to emerging opportunities in Health Sciences & Technology. A special confluence of factors could make Greater Portland a world leader in "wearable" medical devices—factors like its Athletic & Outdoor product innovation, computer manufacturing capacity, and Software & Media firm diversity.

COMMUNITY OUTREACH

Consensus-driven community input was critical to developing this strategy, which includes a diverse mix of realities and needs within the region. To guarantee proper representation of the diverse region, a committee of 40 members serving the public's interests convened regularly over 10 months. Input occurred through Steering Committee meetings, Technical Advisory Committee meetings, Small City Consortium meetings, regional economic development professional roundtables and a public regional community survey. Meetings took place throughout the region in Hillsboro, Portland, Tualatin and Vancouver to accommodate meeting participants and gain firsthand experience of the unique needs expressed about the surrounding area. The community survey was announced in a press release, advertised in the *Portland Business Journal*, distributed to local chambers of commerce and GPI's network.

In total, 21 input and planning meetings took place consisting of eight Steering Committee meetings, nine Technical Advisory Committee meetings, four Small City Consortium meetings and three regional economic development professional roundtables. These meetings were designed around three phases: Competitive Baseline Assessment, Regional Talent review, and Target Business Review.

The Steering Committee included key members of the public and private sectors who, combined, reflect the interests and diversity of the region at large. Committee member characteristics included: business leaders and executives (large and small employers), elected officials, young professionals, civic leaders, technology entrepreneurs and start-up community leaders, education leaders (community college and four-year research postsecondary institutions), public sector representatives, leaders reflecting diverse constituencies, leaders reflecting diverse geographies within the district and leaders representing major economic development assets in the region.

The Technical Advisory Committee was comprised of 24 professionals that provided additional economic development perspectives as needed to inform the process, review draft deliverables, and contribute input. The committee members consisted of community, economic, and workforce development practitioners from individual communities and organizations throughout the district.

The Small City Consortium is a group of small cities and public entities throughout the region that are represented by the city's mayor or economic development professional. This group provided key insights to their communities' issues and needs, as well as feedback on the development of the plan.

Economic development professional roundtables are meetings of economic development organizations, including cities, counties, economic development corporations, ports and utilities. This group provided key insights to their organizations' issues and needs, as well as feedback on the development of the plan.

PHASE 1: COMPETITIVE BASELINE ASSESSMENT

Phase 1 meetings occurred in September 2014 to assess the key strengths, weaknesses, and opportunities of Greater Portland's economic performance, workforce competitiveness, innovation and entrepreneurship, business environment and quality of life. The following four questions were asked of the meeting's attendees:

1. How do you define regional economic development?
2. What are Greater Portland's three greatest strengths, in terms of economic development?
3. What are Greater Portland's top three opportunities for economic development to further examine and develop in the next five years?
4. What are Greater Portland's three greatest weaknesses to overcome in order to remain economically competitive?

COMMUNITY OUTREACH
continued

PHASE 2: REGIONAL TALENT REVIEW
Phase 2 meetings occurred in October 2014 to explore the current talent pool and examine its long-term capacity to drive job growth and prosperity in the region. The following four questions rose in these meetings:

1. What do you see as Greater Portland's greatest talent advantage for businesses and job creation?
2. Which challenges are the most urgent to address regionally?
3. What big opportunities need to be addressed?
4. What efforts are in place to bridge the talent attraction/wealth creation divide in Greater Portland?
5. How should siloes among workforce development/education initiatives be overcome?

PHASE 3: TARGET BUSINESS ANALYSIS
Phase 3 meetings took place in December 2014 to examine the competitive realities within identified target industries around which GPI and partners should focus their economic, talent and site development efforts. Questions asked during these meetings were:

1. Where is Greater Portland's economy now in terms of job creation, wage growth, business success, economic advancement opportunities, and global and national competitiveness?
2. Where is the opportunity within the economy to build momentum?
3. Where are the weaknesses that would decline the status quo if something is not done about them?
4. What is the desired future for Greater Portland's economy?
5. What is success five years down the road?
6. What could be the region's boldest, most aspirational goal for economic development?
7. What are the biggest threats to getting there?
8. What are the biggest opportunities?

PUBLIC REGIONAL OVERVIEW
In addition to public meetings, a community survey captured the full spectrum of voices across the region and elicited responses aligned with the questions and discussions in the public meetings. Overall, 226 surveys were completed online and analyzed for trends and compelling content. The survey consisted of 45 multiple choice and open-ended questions, and below are a sample of questions.

Tell us about your connection or attachment to the Greater Portland region.

What, in your opinion, is the top action the Greater Portland region could initiate to improve its economy and drive job creation?

In your opinion, what industry faces the biggest challenges in the Greater Portland regional economy?

What do you think needs to be done to improve your school or school system?

Please list any degree programs not currently offered in the area that you feel should be added to local colleges' curricula.

Do you feel there will be job opportunities available to you (or your child) in Greater Portland upon graduation from high school, college, or university, or upon completion of military service?

What must the Greater Portland region do to attract and retain young and mid-career professionals? *(Examples could include efforts to increase nightlife/entertainment options, enhance networking/mentor opportunities, targeted job recruitment from regional colleges/universities, etc.)*

If you could make one recommendation for strengthening the effectiveness of your community's leadership (within the public or private sector), what would it be?

What do you feel is the greatest strength/ weakness of the regional workforce?

In your opinion, what is Greater Portland's greatest strength?

In your opinion, what is Greater Portland's greatest weakness or challenge to overcome?

COMMUNITY OUTREACH
continued

RESPONDENT DEMOGRAPHICS
The survey asked a series of demographic questions, which allowed the analysis to consider demographic sub-groups of the 226 respondents. The following is a brief summary of respondent characteristics:

County Residence
- 51% in Multnomah
- 20.8% in Clark
- 11.1% in Clackamas
- 9.3% in Washington
- 3.1% Skamania
- 4.7% did not live in the region

Self-described Area
- 46% urban or central city
- 41.2% suburban, close to an urban area
- 8% rural
- 6.2% small town

Length of Residence (of those living within the region)
- 60.8% for 15 or more years
- 21.2% for 6-15 years
- 8.1% for 3-5 years
- 9.9% fewer than 3 years

Ethnicity
- 87.9% White
- 3.6% Black
- 1.3% Asian or Asian-American
- 0.9% American Indian
- 0.9% Hispanic
- 1.8% Other
- 3.6% preferred not to answer

Age Range (for respondents 25 and older)
- 30.1% ages 55+
- 36.7% ages 40-55
- 31.9% ages 25-39

1.3% respondents were age 24 or younger.

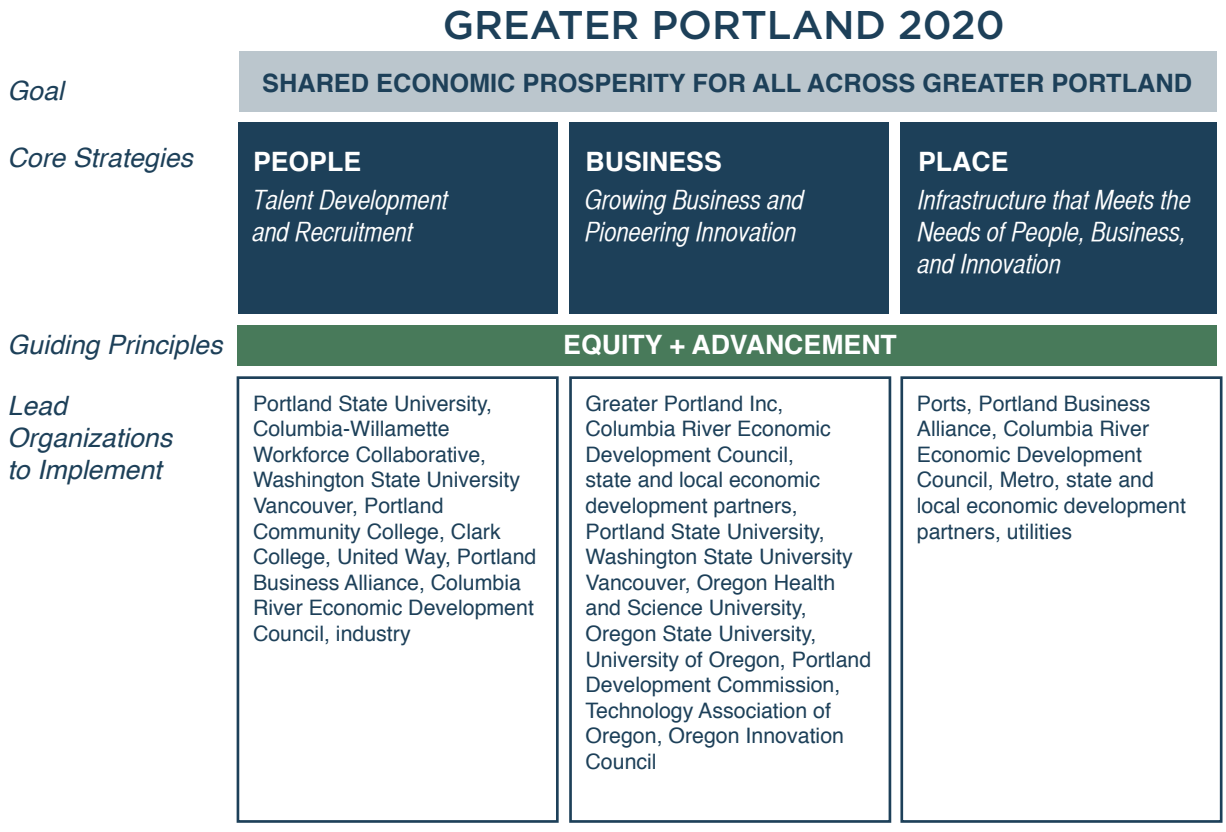
GREATER PORTLAND 2020 ACTION AGENDA

The goal of Greater Portland 2020 is **economic prosperity for all across the region**, which can be accomplished by aligning Greater Portland's business, education and civic leaders.

Three core strategies frame Greater Portland 2020 and are guided by principles of **equity** and **advancement**:

PEOPLE - Talent development and recruitment

BUSINESS - Growing business and pioneering innovation



PLACE - Infrastructure that meets the needs of people, business and innovation

The Greater Portland 2020 Action Agenda is structured throughout with these components:

CORE STRATEGIES: Broader themes for Greater Portland 2020 which set the direction and urgency of the effort—People, Place, and Business.

OBJECTIVES: Purpose and case building behind the strategies and actions.

ACTIONS: Concrete tactics, tasks, or initiatives that outline the steps to attain each objective.

CORE STRATEGY: PEOPLE

PEOPLE
The goal of this core strategy is to **recruit, develop and advance the region's talent**.

PRIORITIES
- Activate industry in training and education to advance career and technical education
- Own, practice, and perfect diversity
- Close the income gap in underrepresented, disadvantage populations

WHAT WE'RE AIMING FOR
- A workforce fully prepared to advance Greater Portland's target sectors and innovative businesses
- Greater Portland is the best metro in which diverse talent thrives and where businesses are at the forefront of attracting, advancing and effectively engaging diverse talent
- Access to quality jobs through adequate infrastructure between affordable places to live and employment centers

LEAD ORGANIZATIONS
- Portland State University, Columbia-Willamette Workforce Collaborative, Washington State University Vancouver, Portland Community College, Clark College, United Way, Portland Business Alliance, Columbia River Economic Development Council, industry

OBJECTIVE 1
ALIGN WORKFORCE DEVELOPMENT CAPACITY, RESOURCES AND ENERGY
Alignment of the region's collective impact partners is already underway; however, since education and workforce development funding flows from local and state sources, full coordination between Oregon and Washington efforts may be challenging. Improved communication and coordination among workforce development organizations, education partners and companies will help further career technical education objectives.

ACTION 1.1
Advance Career Technical Education (CTE) by Activating Industry in Education
Business and industry groups must continue to commit to communicating with training and education providers along the spectrum of talent development. The states' and region's extensive science, technology, education and mathematics (STEM) initiatives are a great example of how seriously some major employers take preparing Greater Portland's future workforce to support their growth. In addition, as postsecondary institutions grow rapidly and improve their programs, this growth should be aligned with the expansion and success of business partners.

- Integrate emerging and established businesses with roles in these initiatives to ensure a balanced investment from private, public and non-profit sectors.
- Work with public school systems' achievement gap efforts, identifying how the business community and stakeholders can invest in and engage with initiatives to close gaps through mentoring, training and public school foundations.
- Form new skills panels as needed to support target sector development, and partner with relevant organizations to develop appropriate strategies based on the skills panels' findings.
- Build a flexible relationship structure for industry and higher education institutions. Develop input opportunities between universities and target cluster businesses to create clear career pathways within universities.

CORE STRATEGY: PEOPLE
continued

- Understand how and where nascent and emerging sectors (ie, *Health Sciences & Technology* and *Software & Media*) should incorporate career preparedness, skills training and other curricula.
- Work with higher education, community colleges and K-12 institutions to design and implement world-class career pathway programs focused on preparing students and workers for the increasingly technology-driven jobs of the future.
- Advance the current career pathway programs by developing standards and systems to be applied throughout the region.

OBJECTIVE 2
ATTRACT AND EMBRACE DIVERSE TALENT
Greater Portland is known as a place for talent, yet its workforce is not growing as quickly and is older than most of its competitor metros. In addition, the share of in-migrants bachelor's degree or higher—while higher than the national average—still falls behind new residents in high-performing peer metros. The region's communities of color and international populations, however, are growing quickly and pose an incredible opportunity to build the long-term sustainability, vibrancy, and competitiveness of Greater Portland's talent.

ACTION 2.1
Own, Practice and Perfect Diversity
As consumer markets open up and expand across the world, businesses have increasingly understood the value of embracing a diverse global workforce. Still, the practice of and investment in diverse talent development are major hurdles for many businesses to overcome. As Greater Portland's population grows and changes, and as business actively recruits talent from outside of the area, it is important that leadership structures represent the changing stakeholders of the region. There is an opportunity to maximize existing programs that develop the current and next generation of leaders, to also develop more diverse leadership in the public, private and non-profit spheres of influence in the region.

Greater Portland also falls behind some of its larger competitor metros like Seattle in international in-migration, although 19 percent of the region's population growth between 2003 and 2013 came from new residents moving from outside of the U.S. With the integration of Greater Portland Global into GPI's business development efforts, the region will be better positioned to interact with talent from companies around the world. This is a prime opportunity for Greater Portland to embrace an approach for immigrant talent in industries with high demand.

- Draft a Greater Portland diversity and equity charter that defines the region's diversity values and intentional objectives to advance diverse, homegrown talent within target sectors and be the most welcoming global metro in the nation.
- Through Partners in Diversity and organizations with a diversity focus, gather best practices and innovative approaches to diverse talent attraction and leadership development from Greater Portland's businesses, non-profit organizations and public agencies and institutions, like Intel's Global Diversity Initiative and Clackamas County's Diversity, Equity and Inclusion program.
- Develop a "Next Generation Leadership" plan for the two-state region to tactically lay out an approach to advancing the types of voices and implementers that Greater Portland needs.
- Develop a plan to attract, embrace and advance global talent in target sectors.
- Develop an earned media campaign about Greater Portland's diverse talent and the commitment of employers to embrace and advance a dynamic, rapidly changing workforce base.
- Create a web presence to serve as the first stop for information for diverse talent to connect them with information about the region, schools, jobs (especially for trailing spouse) and civic or social groups.
- Outline pathways to employment for international talent in Greater Portland, and identify where gaps exist that need to be addressed through policy.

- Work with major employers in the region that sponsor international workers to ensure that new companies seeking to attract talent from outside of the U.S. are following best practices and federal and state guidelines.
- Identify ways to draw international talent to invest in Greater Portland as foreign direct investment grows and the region's international networks expand.
- Work with existing immigrant communities, resources, and employment hubs for immigrants to connect these efforts to a broader view of international investment in the region.

OBJECTIVE 3
FOSTER EQUITY AND ACCESS

One of the region's biggest opportunities for a healthier economy is to achieve equity in talent development, which requires the support and participation of many partners. As the Regional Talent Review uncovered, significant equity issues in the region's K-12 systems. Students of color and students from low-income households are struggling the most—and as incomes lag, housing costs increase, and the region diversifies, these achievement gaps and access to career opportunities could widen and spread out further across Greater Portland. The region cannot afford to let these students and workers fall further behind.

In addition, the region has expressed a commitment to equity and addressing Greater Portland's relatively lower—but growing—wages as jobs, wealth and investment increase during this period of post-recession growth. The Brookings Institution and other economic researchers have examined the trends of inequality and stagnant wages that are increasing in many of the nation's most vibrant metro economies. Greater Portland's time to address this dynamic is now, while there is urgency at the regional level and many local efforts to leverage.

ACTION 3.1
Close the Income Gap in Underrepresented, Disadvantaged Populations

Equity is often defined on a human capital scale, but businesses and other parts of the regional economy also have a stake in equity. As the value of equity for business is articulated, the leaders in developing Greater Portland's homegrown talent must convene around a common definition and metrics for human capital equity. Equity is inherently a human concept so the main outcome of this coordination is to determine how equity will be measured and actionably advanced. Too many in Greater Portland's minority populations fall behind their white peers in educational attainment.

The region's diversity is also not reflected in many of the visible leadership roles. The region's education leaders must decide what equity means for each point on the talent development spectrum and ensure that they are all playing their part advance a common agenda.

The region's relatively low wages are a major concern for long-term economic prosperity. The Oregon Business Plan (OBP) has a goal to raise per-capita income (PCI) to above the national average by 2020. With 66.8 percent of Greater Portland's PCI driven by its relatively low wages, the region faces an uphill climb in meeting its share of the OBP goal. Supporting business and quality-of-life infrastructure, and attracting and retaining top talent depend on regional wage advancement. Yet, the lower cost of labor is a competitive advantage for employers. Regional economic development partners must understand how businesses view wages and create a plan to address accordingly—either market this as a strength to attract more business, or accept the results and implications of less-competitive wages.

- Implement public-private programs and practices to improve wages and incomes in underserved-communities due to hurdles to quality employment. These populations may include communities of color and people who do not speak English at home.
- Create and agree upon a set of regional equity indicators with support from the business case for equity. Utilize these indicators to track and report inequality's growth and decline across key communities of the regional population.

CORE STRATEGY: PEOPLE
continued

- Align with existing metrics across the region such as All Hands Raised, Portland Public Schools' Racial Educational Equity Policy and Milestones Framework, and City of Beaverton's Diversity, Equity and Inclusion Plan.
- Identify partners to actionably address negative or concerning trends. Create short-term task forces and work plans to dig into these issues and prioritize next steps for action.
- Through meetings with business leaders and other tools for gathering information, identify employers' barriers to and concerns with raising wages for workers.
- Focus specifically on target sectors with wages below peer metro's averages, like *Software & Media*, to determine if low wages are the result of a lower flow of capital to startups in the region or overall less competitive pay at larger firms.
- Ensure the connection between wages and regional economic development goals are clearly defined and articulated to support complementary outcomes.

ACTION 3.1a
Build a Framework for Access to Economic Opportunities, and Identify/Eliminate Hurdles to Quality Employment
Partners must ensure that the region's residents have access to quality job opportunities. As the workforce shifts to find affordable housing, the network that connects these workers to jobs must also be modified. While options for transportation to and from jobs exist, these transit investments are not evenly distributed throughout the region, especially across state lines. Traffic congestion continues to be a costly burden for workers and businesses, and as housing gets less affordable, low- and middle-income workers will continue to be pushed into communities within the region that are farther from developed job hubs.

- Through input from businesses, workforce data, and community-pattern data, identify transportation gaps that limit worker mobility and access to jobs and workforce development resources.
- Support studies and analyses that examine disconnected workers, communities and other stakeholders in the region. Ensure that as research is conducted in Greater Portland on mobility and access, actionable strategies are developed and partners are activated to address these findings.
- Partner with bus, light rail and commuter rail transit services TriMet and C-TRAN to create or extend routes to efficiently connect disconnected workers to employment and training hubs.
- Work across state lines to update transportation planning and investments based on workforce commute flows and the movement of goods.
- Collect and share regional best practices of local economic development partners' improvements in neighborhoods, corridors and other place-based infrastructure that connect businesses to their workforce.

CORE STRATEGY: BUSINESS

BUSINESS
The goal of this core strategy is to **grow business and pioneer innovation.**

PRIORITIES
- Implement regional approach to traded-sector industries; advance Greater Portland as the global leader in its legacy, established and emerging target sectors; and develop opportunities to grow and converge sectors
- Formalize a global marketing program for business recruitment and expansion, trade and investment
- Build out the region's innovation infrastructure to capitalize on Greater Portland's entrepreneurial ecosystem
- Develop a regional public-private higher education innovation network

WHAT WE'RE AIMING FOR
- Net-new jobs in the region's core traded-sector industries and new target sectors
- Diverse, sustainable range of successful firms in every community within the region
- Cross-cluster connections among targets to develop new opportunities for job creation
- Greater Portland is the best location for foreign direct investment
- Early- and second-stage firms have access to support that enables them to launch and expand
- Higher education institutions are a platform for new business creation and innovation

LEAD ORGANIZATIONS
- Greater Portland Inc, Columbia River Economic Development Council, state and local economic development partners, Portland State University, Washington State University Vancouver, Oregon Health and Science University, Oregon State University, University of Oregon, Portland Development Commission, Technology Association of Oregon, Oregon Innovation Council

OBJECTIVE 4
GROW AND RECRUIT BUSINESSES
Existing businesses are the nation's job creation engine—studies show that between 70 and 95 percent of the country's employment gains is attributable to the expansion of existing companies. For early-stage, mid-sized or high growth-potential firms to scale within the region, stakeholders identified needs for improved infrastructure and tech transfer capabilities, support for potentially emerging clusters, public-private research and development collaboration and unified, efficient communication to existing businesses.

Likewise, it is also important to look beyond the boundaries of the region for business growth. Greater Portland has compelling assets for business recruitment—including its position in a region with two state business climates—but operates in constraints that require strategic and realistic plans for business recruitment. A balanced approach to business expansion and recruitment is especially critical in order to support the growth and competitiveness of firms in the region's target industries, since their suppliers, workforce and infrastructure cross city limits, county boundaries, state lines and even oceans.

ACTION 4.1
Execute a Regional Approach to Industries
Cluster strategies build off the foundation of a robust, well-coordinated regional business retention and expansion (BRE) program and sophisticated, multi-dimensional marketing and recruitment program. The region's targets and clusters—*Metals & Machinery*, *Computer & Electronics*, *Clean Tech*, *Athletic & Outdoor*, *Software & Media*, and *Health Sciences & Technology*—all have different needs but many overlapping assets.

As the principal regional business recruitment and attraction organization for Greater Portland, GPI must lead communication with prospective and existing firms to ensure the region remains highly competitive for these dynamic sectors of the economy. GPI must also be nimble enough to attract burgeoning opportunities for the region that fall outside of the established portfolio of target sectors. GPI's role as

recruiter of and marketer to external businesses can be more effective with direct and regular relationships with firms and leaders in the industries on which it has built an investment attraction platform.

- Build industry expertise through in-depth research to understand projected growth, and evaluate and pursue opportunities that align with market strengths and advantages.
- Develop and implement industry and stage-specific strategies (nascent, emerging, established and legacy).
- Engage industry leaders and partners in further identifying local/global trends to support marketing, recruitment and expansion efforts. Strategies should include these key activities:
    1. Improve services to businesses and entrepreneurs.
    2. Build capacity to respond quickly to changing industry trends and new opportunities.
    3. Develop and align better networks to connect businesses within the clusters.
    4. Create better cross-cluster collaboration across industries.
- Establish a research and competitiveness resource for regional partners and policy makers tied to place-based assets and challenges for businesses.
- Inventory industries pursued by city and county economic development professionals to identify where local targets are part of the broader regional clusters and where they differ from the regional portfolio. Acknowledge that regional target pursuits should not undercut local efforts to pursue a different range of targets.

OBJECTIVE 5
EXPAND GLOBAL REACH AND INVESTMENT
Having launched Greater Portland Global (GPG)—the region's global trade and investment plan—the opportunity exists to increase the region's international standing and reputation as a place for business investment and growth. GPG identified that while Greater Portland is the 23rd largest economy in the U.S., it is 50th in foreign direct investment (FDI) intensity. Greater Portland's persistent external perception as a "Tier 2" metro means significant work must be done to elevate its image and brand among global decision makers.

ACTION 5.1
Make Greater Portland a Top Location for Global Investment and Trade
GPG identified that recent export growth is lagging. However, conditions for FDI are ideal due to dynamic clusters of economic activity, diverse place-based and higher education assets, name-brand firms and existing international ties from Greater Portland to key markets. Market assessments of Greater Portland have uncovered overlap between the region's exports, FDI and innovation. Greater Portland is a smaller metro compared to other regions embarking on similar foreign investment plans, which makes it more nimble in implementation but also means some assets may not have as much capacity to leverage. GPI's parallel roles in business attraction and keeper of GPG strategies are key for maximizing the region's potential, recruiting investment and jobs from global markets, and coordinating myriad local, regional, state and federal partners.

- Use market prioritization findings to expand regional marketing activities and target foreign markets, industries and investors. In addition to stage-specific interventions, develop BRE and and merger-and-acquisition strategies to apply to the continuum.
- Work with state/local partners and companies to coordinate global marketing and sales mission activities.
- Develop a regional economic development clearinghouse for data and analysis related to the region's exports, FDI, supply chains, existing business trends, economic competitiveness, economic development equity and other research useful to local economic development professionals, prospective investors and location decision makers.

CORE STRATEGY: BUSINESS
continued

- Ensure economic development projects get extensive coverage in local media. Demonstrate how business investments strengthen quality of life, talent, access, equity and other priorities of Greater Portland's stakeholders.

OBJECTIVE 6
ADVANCE POLICY SOLUTIONS TO COMPETITIVE ISSUES

Greater Portland's distinct advantages for business and talent cannot be separated from the region's policy climate. The region's leaders must be responsible for advocating for policies that make the region competitive for sustainable, quality investments, while also aiming for the Greater Portland 2020 vision of economic prosperity across the region.

ACTION 6.1
Sharpen the Region's Competitiveness for Jobs and Investment from Target Sectors

Marketing Greater Portland, attracting business and investment, and working to expand existing companies cannot be effective if the business climate for traded-sector industries is uncompetitive. Without a strong product, business development efforts will fall short. GPI should influence conversations that inform policy relative to investment from target industries but not lead actual policymaking. This requires the ongoing leadership of many groups already engaged in this area to support a unified voice, alignment of goals and consensus actions that result from dialogue around economic development policy. From major tools like Oregon's Strategic Investment Program, enterprise zones and new market tax credits, to the city- and county-level regulations for businesses, Greater Portland has both significant advantages and challenges for which traded-sector businesses and regional economic development partners must take on a more vocal advocacy role.

- Examine gaps in advocacy on regional competitiveness and align efforts to more effectively relay the need for sound economic development programs.
- Develop an annual two-state economic development advocacy agenda.
- Through industry intelligence, site-selector insights and best practices from competitor markets, identify policy, programs, legislative and regulatory factors that encourage the growth of firms in the six target sectors.

OBJECTIVE 7
ADVANCE GREATER PORTLAND'S INNOVATION INFRASTRUCTURE

Over the past decade, the entrepreneurial ecosystem in Greater Portland has exploded with high-performing firms and new opportunities. Through more sophisticated opportunities for capital, an infusion of Bay Area-talent and money, advancement of universities into entrepreneurship and tech transfer, international visibility as a competitive location for startups and high-growth companies, and a cast of supporting organizations helping to create and scale new ventures, Greater Portland's innovation landscape has dramatically changed.

In addition to developing the future leaders and workers of the region, higher education institutions across Greater Portland must better align with each other and key traded sectors around entrepreneurship, licensing, technology transfer and commercialization as they build their own capacities in those areas. With investment from the Knight Cancer Center coming online, the region's ability to augment its higher education capabilities to create and leverage new products will be immense.

The role of the region's economic development leaders is to invest in this emerging infrastructure of innovation to maintain its momentum.

ACTION 7.1
Connect Entrepreneurial Support Initiatives and Networks

Greater Portland is home to a wide range of groups, programs and tools that support innovation and entrepreneurs, but efforts and outcomes need to better connect across the communities they serve while still maintaining the strategic purposes on which these programs were launched.

- Map and detail the range of incubators, accelerators, innovation zones, competitions, capital funds, networking and membership groups, and other efforts across the two-state region. Use this inventory to market the region as a destination for investment and capital.
- Convene these entities and groups to identify needs, where gaps exist and any urgent issues for the region's economic development professionals, industry leaders, public sector leaders and partners to act on.
- Ensure startup and second-stage firm information and input are captured in industry cluster research, BRE data and other intelligence that drives regional economic development priorities and business climate policy.

ACTION 7.2
Develop a Regional Public-Private Higher Education Innovation Network
With access to major employers and corporate innovators concentrated in Greater Portland, there are vast opportunities for corporate-sponsored innovation and more industry-university research collaboration.

The region is home to a number of pioneering university-led initiatives like the Portland State University (PSU) Business Accelerator. The Collaborative Life Sciences Building (Oregon Health & Science University, Oregon State University, and PSU) represents one type of cross-institutional collaboration, as does the partnership of Columbia River Economic Development Council, Clark College and Washington State University Vancouver around Vancouver's Innovation Partnership Zone. The entrepreneur development and business-facing programs of Greater Portland's universities and colleges could have an even farther-reaching impact on the innovation and new venture success of the region, if aligned and leveraged with each other and private industry.

While building better connections among institutions is critical, so is improving communication and an understanding among universities and industry. In a talent- and innovation-fueled regional economy like Greater Portland, the roles of both of these sectors cannot be understated.

- Work with partners like Business Oregon's innovation and entrepreneurship task force, Oregon InC innovation plan, local economic development plans and universities, to identify where industry and university players can partner directly in implementation.
- Identify local and national best practices in university-private sector innovation and commercialization that can be expanded in Greater Portland.
- Partner with community colleges and private universities and colleges to define their roles and strategies for advancing commercialization and industry engagement in innovation.
- Invest in and promote targeted initiatives, like the Northwest Collaboratory for Sustainable Manufacturing and Innovate Collaborate Oregon that bring together industry and universities around Greater Portland's target sectors.
- Work with partners to identify current nascent efforts to increase innovation between private sector and universities.
- Ensure these efforts to develop innovation partnerships among industry and businesses in the Greater Portland region are adequately resourced, staffed and have the capacity to get off the ground and meet the needs of their constituent institutions and businesses.

CORE STRATEGY: PLACE

PLACE
The goal of this core strategy is to **improve infrastructure to meet the needs of people, business and innovation.**

PRIORITIES
- Improve Greater Portland's transportation capabilities to mitigate congestion, enhance the positive impact of regional transit and augment freight movement
- Identify future needs for jobs-ready industrial and employment lands
- Address regional housing supply and affordability
- Plan for Greater Portland's economic resiliency

WHAT WE'RE AIMING FOR
- A coordinated portfolio of competitive offerings across the two-state metro in sites, access and cost for business investment and growth
- State and local policies that encourage investment from Greater Portland's high-value, traded-sector firms and industries
- Seamless movement of goods, people and ideas that enhance Greater Portland's global influence

LEAD ORGANIZATIONS
- Ports, Portland Business Alliance, Columbia River Economic Development Council, Metro, state and local economic development partners, utilities

OBJECTIVE 8
ACCELERATE SITE AND INFRASTRUCTURE OPPORTUNITIES
As the low-cost labor and land in other parts of the U.S. become increasingly imbalanced with the disadvantages of less-educated workforces and under-invested infrastructure in those regions, Greater Portland's assets in human capital and infrastructure will be even more critical for business growth. However, the region has distinct challenges that must be addressed to provide the type of place where businesses can expect to invest for the long term.

ACTION 8.1
Improve Greater Portland's Transportation Capabilities
Greater Portland's seaports and waterways, international airport, Class I rail, air and port cargo capacity, intermodal terminals, utility networks and interstates and highways facilitate the flow of commerce and wealth through the region. According to the Competitive Baseline Assessment, they are vital to the competitiveness of the regional business climate. However, Greater Portland is facing increasing road congestion, which threatens to chip away at the region's advantages for trade and mobility.

- Starting with the 2014 Cost of Congestion data, identify key points of congestion impacting freight and employee movement in the region.
- Develop plans for mitigating congestion from and augmenting freight activity for international trade.
- Prioritize regional investments, actions and locations that provide the most significant near-term impacts.
- Launch a bi-state coordination committee that includes public- and private-sector participation to address transportation issues across state lines. Identify regional priorities based on research, data and greatest return on investment.
- Generate ongoing advocacy for stable transportation funding for the Washington and Oregon region.

CORE STRATEGY: PLACE
continued

- Secure the regional transportation plan priorities in the tri-county Metro and Clark County regional transportation plans.

ACTION 8.2
Identify Future Needs for Jobs-ready Industrial and Employment Lands
Sites and buildings are at the critical convergence of the region's infrastructure assets. While much are constrained in the short-term by an urban growth boundary, Greater Portland still has a number of greenfield and brownfield sites that offer opportunities for local, national and foreign direct investment. As demand for office space increases (and as the cost for Class A and industrial space climbs), the region must ensure that permitting and responsiveness to development needs are keeping pace with the growth of business. Still, Greater Portland retains competitive advantages as the costs of industrial electricity and real estate, as well as the availability of water are all highly competitive relative to other West Coast metros.

- Implement the existing work of the Regional Industrial Site Readiness, Lands for Jobs and Regional Large Site Industrial Recruitment Strategy.
- Develop protocols to keep site data updated to share with prospects, key partners in business development and local economic development professionals.
- Maintain an up-to-date inventory of the region's brownfield sites and their development needs to market through GPG initiatives with prospective foreign investors.
- Develop a regional inventory of permitting and site development best practices to assist local governments in adopting and transitioning to responsive, streamlined, timely and efficient permitting protocols for businesses. Develop regional best practices for jurisdictions to provide business incentives and develop prepared sites.
- Identify and pursue projects that leverage Greater Portland's freight infrastructure through ports, airports and rail for international trade over the long term.
- Continue to study and market the advantages of Greater Portland's access to water.
- Pursue opportunities to increase competitive fiber capacity and connectivity throughout the region.

ACTION 8.3
Address the Regional Housing Supply and Affordability
Greater Portland's cost of living seems low compared to other West Coast metros, but when accounting for the lower wages of the region's workers and the constrained developable land, it is clear that workforce housing will increasingly be an issue, not only for individuals and families but also for businesses that need to attract and retain a skilled workforce. The region's high cost of living coupled with lagging wages and per-capita income are likely serious hindrances to economic advancement for many workers.

- Develop a region-wide housing plan.
- Ensure an adequate supply of workforce housing that is both affordable for middle-income workers and accessible from middle-income job sites.
- Create a plan that also addresses the regional availability of affordable housing for low-income workers.

ACTION 8.4
Plan for Greater Portland's Economic Resiliency
The departure of Hanjin and Hapag-Lloyd from the Port of Portland container cargo shipping and the resignation of Oregon's Governor show how quickly a chain of events can impact a significant share of the region's businesses or negatively skew the image of Greater Portland. More globally, natural or economic disasters in Greater Portland's priority markets like Japan and Germany could also wreak havoc on the regional economy. Greater Portland's larger global presence also makes it more exposed to cycles of international markets and disasters that happen far from the Pacific Northwest. While embracing the opportunities of global trade and increased FDI, it is also important to prepare for these unexpected catastrophes that can send shockwaves through Greater Portland's businesses.

CORE STRATEGY: PLACE
continued

- Develop the regional capacity to deploy support, make quick decisions and chart a new path in the face of major vulnerabilities to the regional economy.
- Through BRE and GPG intelligence, identify regional businesses' primary international and domestic markets, major infrastructure resources and other information so in the face of internal/ external disaster, firms can be quickly contacted for support and assistance in developing alternatives and accessing capital.
- Gather emergency preparedness plans for Greater Portland's communities, counties, Metro and major assets (like Port of Portland and Port of Vancouver), and aggregate the response to businesses at the regional level.
- Through existing business data gathered at the local level, identify barriers to businesses' adoption of disaster preparedness plans and protocols.
- Work with state and local officials to develop mitigation, preparedness, financial, response and outreach tools for businesses that can be activated in the event of a disaster.

IMPLEMENTATION PLAN 2016-2020

#	PEOPLE OBJECTIVES AND ACTIONS	YEAR 1	YEARS 2-5
1	**ALIGN WORKFORCE DEVELOPMENT CAPACITY, RESOURCES AND ENERGY**		
1.1	*Advance Career Technical Education (CTE) by Activating Industry in Education*		X
	• Integrate emerging and established businesses with roles in these initiatives to ensure a balanced investment from private, public and non-profit sectors.		X
	• Work with public school systems' achievement gap efforts, identifying how the business community and stakeholders can invest in and engage with initiatives to close gaps through mentoring, training and public school foundations.		X
	• Form new skills panels as needed to support target sector development, and partner with relevant organizations to develop appropriate strategies based on the skills panels' findings.		X
	• Build a flexible relationship structure for industry and higher education institutions. Develop input opportunities between universities and target cluster businesses to create clear career pathways within universities.		X
	• Understand how and where nascent and emerging sectors (ie, *Health Sciences & Technology* and *Software & Media*) should incorporate career preparedness, skills training and other curricula.		X
	• Work with higher education, community colleges and K-12 institutions to design and implement world-class career pathway programs focused on preparing students and workers for the increasingly technology-driven jobs of the future.	X	
	• Advance the current career pathway programs by developing standards and systems to be applied throughout the region.		X
2	**ATTRACT AND EMBRACE DIVERSE TALENT**		
2.1	*Own, Practice and Perfect Diversity*		
	• Draft a Greater Portland diversity and equity charter that defines the region's diversity values and intentional objectives to advance diverse, homegrown talent within target sectors and be the most welcoming global metro in the nation.	X	
	• Through Partners in Diversity and organizations with a diversity focus, gather best practices and innovative approaches to diverse talent attraction and leadership development from Greater Portland's businesses, non-profit organizations and public agencies and institutions, like Intel's Global Diversity Initiative and Clackamas County's Diversity, Equity and Inclusion program.	X	
	• Develop a "Next Generation Leadership" plan for the two-state region to tactically lay out an approach to advancing the types of voices and implementers that Greater Portland needs.		X
	• Develop a plan to attract, embrace and advance global talent in target sectors.	X	
	• Develop an earned media campaign about Greater Portland's diverse talent and the commitment of employers to embrace and advance a dynamic, rapidly changing workforce base.		X
	• Create a web presence to serve as the first stop for information for diverse talent to connect them with information about the region, schools, jobs (especially for trailing spouse) and civic or social groups.		X
	• Outline pathways to employment for international talent in Greater Portland, and identify where gaps exist that need to be addressed through policy.	X	
	• Work with major employers in the region that sponsor international workers to ensure that new companies seeking to attract talent from outside of the U.S. are following best practices and federal and state guidelines.	X	

IMPLEMENTATION PLAN 2016-2020

continued

#	PEOPLE OBJECTIVES AND ACTIONS	YEAR 1	YEARS 2-5
2	**ATTRACT AND EMBRACE DIVERSE TALENT**		
2.1	*Own, Practice and Perfect Diversity*		
	• Identify ways to draw international talent to invest in Greater Portland as foreign direct investment grows and the region's international networks expand.	X	
	• Work with existing immigrant communities, resources, and employment hubs for immigrants to connect these efforts to a broader view of international investment in the region.	X	
3	**FOSTER EQUITY AND ACCESS**		
3.1	*Close the Income Gap in Underrepresented, Disadvantaged Populations*		
	• Implement public-private programs and practices to improve wages and incomes in underserved-communities due to hurdles to quality employment. These populations may include communities of color and people who do not speak English at home.	X	
	• Create and agree upon a set of regional equity indicators with support from the business case for equity. Utilize these indicators to track and report inequality's growth and decline across key communities of the regional population.	X	
	• Align with existing metrics across the region such as All Hands Raised, Portland Public Schools' Racial Educational Equity Policy and Milestones Framework, and City of Beaverton's Diversity, Equity and Inclusion Plan.	X	
	• Identify partners to actionably address negative or concerning trends. Create short-term task forces and work plans to dig into these issues and prioritize next steps for action.	X	
	• Through meetings with business leaders and other tools for gathering information, identify employers' barriers to and concerns with raising wages for workers.		X
	• Focus specifically on target sectors with wages below peer metro's averages, like *Software & Media*, to determine if low wages are the result of a lower flow of capital to startups in the region or overall less competitive pay at larger firms.		X
	• Ensure the connection between wages and regional economic development goals are clearly defined and articulated to support complementary outcomes.		X
3.1a	*Build a Framework for Access to Economic Opportunities, and Identify/Eliminate Hurdles to Quality Employment*		
	• Through input from businesses, workforce data, and community-pattern data, identify transportation gaps that limit worker mobility and access to jobs and workforce development resources.		X
	• Support studies and analyses that examine disconnected workers, communities and other stakeholders in the region. Ensure that as research is conducted in Greater Portland on mobility and access, actionable strategies are developed and partners are activated to address these findings.		X
	• Partner with bus, light rail and commuter rail transit services TriMet and C-TRAN to create or extend routes to efficiently connect disconnected workers to employment and training hubs.		X
	• Work across state lines to update transportation planning and investments based on workforce commute flows and the movement of goods.		X
	• Collect and share regional best practices of local economic development partners' improvements in neighborhoods, corridors and other place-based infrastructure that connect businesses to their workforce.		X

IMPLEMENTATION PLAN 2016-2020

continued

#	BUSINESS OBJECTIVES AND ACTIONS	YEAR 1	YEARS 2-5
4	**GROW AND RECRUIT BUSINESSES**		
4.1	*Execute a Regional Approach to Industries*		
	• Build industry expertise through in-depth research to understand projected growth, and evaluate and pursue opportunities that align with market strengths and advantages.	X	
	• Develop and implement industry and stage-specific strategies (nascent, emerging, established and legacy).	X	
	• Engage industry leaders and partners in further identifying local/global trends to support marketing, recruitment and expansion efforts. Strategies should include these key activities: 1. Improve services to businesses and entrepreneurs. 2. Build capacity to respond quickly to changing industry trends and new opportunities. 3. Develop and align better networks to connect businesses within the clusters. 4. Create better cross-cluster collaboration across industries.	X	
	• Establish a research and competitiveness resource for regional partners and policy makers tied to place-based assets and challenges for businesses.	X	
	• Inventory industries pursued by city and county economic development professionals to identify where local targets are part of the broader regional clusters and where they differ from the regional portfolio. Acknowledge that regional target pursuits should not undercut local efforts to pursue a different range of targets.	X	
5	**EXPAND GLOBAL REACH AND INVESTMENT**		
5.1	*Make Greater Portland a Top Location for Global Investment and Trade*		
	• Use market prioritization findings to expand regional marketing activities and target foreign markets, industries and investors. In addition to stage-specific interventions, develop BRE and and merger-and-acquisition strategies to apply to the continuum.	X	
	• Work with state/local partners and companies to coordinate global marketing and sales mission activities.	X	
	• Develop a regional economic development clearinghouse for data and analysis related to the region's exports, FDI, supply chains, existing business trends, economic competitiveness, economic development equity and other research useful to local economic development professionals, prospective investors and location decision makers.	X	
	• Ensure economic development projects get extensive coverage in local media. Demonstrate how business investments strengthen quality of life, talent, access, equity and other priorities of Greater Portland's stakeholders.	X	
6	**ADVANCE POLICY SOLUTIONS TO COMPETITIVE ISSUES**		
6.1	*Sharpen the Region's Competitiveness for Jobs and Investment from Target Sectors*		
	• Examine gaps in advocacy on regional competitiveness and align efforts to more effectively relay the need for sound economic development programs.	X	
	• Develop an annual two-state economic development advocacy agenda.	X	
	• Through industry intelligence, site-selector insights and best practices from competitor markets, identify policy, programs, legislative and regulatory factors that encourage the growth of firms in the six target sectors.	X	

IMPLEMENTATION PLAN 2016-2020

continued

#	BUSINESS OBJECTIVES AND ACTIONS	YEAR 1	YEARS 2-5
7	**ADVANCE GREATER PORTLAND'S INNOVATION INFRASTRUCTURE**		
7.1	*Connect Entrepreneurial Support Initiatives and Networks*		
	• Map and detail the range of incubators, accelerators, innovation zones, competitions, capital funds, networking and membership groups, and other efforts across the two-state region. Use this inventory to market the region as a destination for investment and capital.	X	
	• Convene these entities and groups to identify needs, where gaps exist and any urgent issues for the region's economic development professionals, industry leaders, public sector leaders and partners to act on.	X	
	• Ensure startup and second-stage firm information and input are captured in industry cluster research, BRE data and other intelligence that drives regional economic development priorities and business climate policy.	X	
7.2	*Develop a Regional Public-Private Higher Education Innovation Network*		
	• Work with partners like Business Oregon's innovation and entrepreneurship task force, Oregon InC innovation plan, local economic development plans and universities, to identify where industry and university players can partner directly in implementation.		X
	• Identify local and national best practices in university-private sector innovation and commercialization that can be expanded in Greater Portland.	X	
	• Partner with community colleges and private universities and colleges to define their roles and strategies for advancing commercialization and industry engagement in innovation.		X
	• Invest in and promote targeted initiatives, like the Northwest Collaboratory for Sustainable Manufacturing and Innovate Collaborate Oregon that bring together industry and universities around Greater Portland's target sectors.		X
	• Work with partners to identify current nascent efforts to increase innovation between private sector and universities.		X
	• Ensure these efforts to develop innovation partnerships among industry and businesses in the Greater Portland region are adequately resourced, staffed and have the capacity to get off the ground and meet the needs of their constituent institutions and businesses.		X
	PLACE OBJECTIVES AND ACTIONS		
8	**ACCELERATE SITE AND INFRASTRUCTURE OPPORTUNITIES**		
8.1	*Improve Greater Portland's Transportation Capabilities*		
	• Starting with the 2014 Cost of Congestion data, identify key points of congestion impacting freight and employee movement in the region.	X	
	• Develop plans for mitigating congestion from and augmenting freight activity for international trade.	X	
	• Prioritize regional investments, actions and locations that provide the most significant near-term impacts.	X	
	• Launch a bi-state coordination committee that includes public- and private-sector participation to address transportation issues across state lines. Identify regional priorities based on research, data and greatest return on investment.	X	
	• Generate ongoing advocacy for stable transportation funding for the region.	X	
	• Secure the regional transportation plan priorities in the tri-county Metro and Clark County regional transportation plans.	X	

IMPLEMENTATION PLAN 2016-2020

continued

#	PLACE OBJECTIVES AND ACTIONS	YEAR 1	YEARS 2-5
8.2	*Identify Future Needs for Jobs-ready Industrial and Employment Lands*		
	• Implement the existing work of the Regional Industrial Site Readiness, Lands for Jobs and Regional Large Site Industrial Recruitment Strategy.	X	
	• Develop protocols to keep site data updated to share with prospects, key partners in business development and local economic development professionals.	X	
	• Maintain an up-to-date inventory of the region's brownfield sites and their development needs to market through GPG initiatives with prospective foreign investors.	X	
	• Develop a regional inventory of permitting and site development best practices to assist local governments in adopting and transitioning to responsive, streamlined, timely and efficient permitting protocols for businesses. Develop regional best practices for jurisdictions to provide business incentives and develop prepared sites.		X
	• Identify and pursue projects that leverage Greater Portland's freight infrastructure through ports, airports and rail for international trade over the long term.		X
	• Continue to study and market the advantages of Greater Portland's access to water.		X
	• Pursue opportunities to increase competitive fiber capacity and connectivity throughout the region.		X
8.3	*Address the Regional Housing Supply and Affordability*		
	• Develop a region-wide housing plan.	X	
	• Ensure an adequate supply of workforce housing that is both affordable for middle-income workers and accessible from middle-income job sites.	X	
	• Create a plan that also addresses the regional availability of affordable housing for low-income workers.	X	
8.4	*Plan for Greater Portland's Economic Resiliency*		
	• Develop the regional capacity to deploy support, make quick decisions and chart a new path in the face of major vulnerabilities to the regional economy.	X	
	• Through BRE and GPG intelligence, identify regional businesses' primary international and domestic markets, major infrastructure resources and other information so in the face of internal/external disaster, firms can be quickly contacted for support and assistance in developing alternatives and accessing capital	X	
	• Gather emergency preparedness plans for Greater Portland's communities, counties, Metro and major assets (like Port of Portland and Port of Vancouver), and aggregate the response to businesses at the regional level.		X
	• Through existing business data gathered at the local level, identify barriers to businesses' adoption of disaster preparedness plans and protocols.		X
	• Work with state and local officials to develop mitigation, preparedness, financial, response and outreach tools for businesses that can be activated in the event of a disaster.		X

PERFORMANCE MEASURES

To record meaningful economic development, a set of measurements have been established to determine whether the regional economy is growing as planned by meeting the goals and objectives of the strategy. The strategy will be assessed by the performance measures and allow for modifications to reflect the changing economy. The measures will be accessible on the Greater Portland Pulse website (portlandpulse.org) and within annual GPEDD reports to EDA.

PEOPLE

ACTION 1.1
Advance Career Technical Education by Activating Industry in Education

1. Number of school districts covered by cradle-to-career collective impact initiative
2. Percent of public school enrollees covered by a cradle-to-career collective impact initiative
3. Share of students engaged in career pathway program
4. Number of businesses engaged in career pathway education programs and curricula
5. Members of community college workforce alliance
6. Number of businesses in “idea and action lab”
7. Number of higher education institutions in “idea and action lab”

ACTION 2.1
Own, Practice and Perfect Divsersity

1. Number of people of color and international residents engaged in leadership development programs
2. Number of signees to Greater Portland diversity and equity charter
3. Number of employers engaged in international talent recruitment
4. Number of national/international news stories about Greater Portland’s value of diverse talent
5. Percent of in-migrants who are not white and non-Hispanic

ACTION 3.1
Close the Income Gap in Underrepresented, Disadvantaged Populations

1. Percent unemployed
2. Percent of personal income derived from wages
3. Percent of adults 25 and over with postsecondary degree (associates or higher)
4. Median household income
5. Continuing education rate/percent going to college for high school seniors
6. Poverty rate
7. PCI in communities of color as a % or PCI in white, non-Hispanic
8. Postsecondary degree attainment for adults 25 and over in communities of color (aggregated)
9. Dollar amount companies investing in training new employees

ACTION 3.1a
Build a Framework for Access to Economic Opportunities and Identify/Eliminate Hurdles to Quality Employment

1. Percent of transit riders with at least one-hour commute to work
2. Number and type of short-term actions executed and/or developed into projects
3. Number of expanded/added transit routes to connect more workers to jobs

BUSINESS

ACTION 4.1
Execute a Regional Approach to Industries

1. Total employment
2. Employment by industry
3. Productivity (gross metro product) per worker

PERFORMANCE MEASURES
continued

ACTION 5.1
Make Greater Portland a Top Location for Global Trade and Investment

1. Dollar amount of foreign exports per worker
2. Port of Portland exports minus pass through
3. Port of Vancouver exports minus pass through

ACTION 6.1
Sharpen the Region's Competitiveness for Jobs and Investment from Target Sectors

1. Employment in identified target traded sectors
2. Productivity in identified target sectors

ACTION 7.1
Connect Entrepreneurial Support Initiatives and Networks

1. Number of new startups in high-tech industry
2. Number of commercialization licenses

ACTION 7.2
Develop a Regional Public-Private Higher Education Innovation Network

1. Total higher education R&D expenditures
2. Startups spun off from university technologies
3. Percent of startups spun off from university technologies that locate in the region

PLACE

ACTION 8.1
Improve Greater Portland's Transportation Capabilities

1. Annual PDX air freight cargo (lbs.)
2. Port of Portland exports
3. Port of Vancouver exports
4. Port of Portland value of exports
5. Port of Vancouver value of exports
6. Port of Portland leakage
7. Port of Vancouver leakage
8. PDX retention of nonstop flight destinations
9. PDX international travel – time to market
10. PDX air passengers
11. Aggregate congestion costs
12. Commute time
13. Volume of vehicles between Vancouver and Portland
14. Number and type of short-term tactics executed and/or developed into projects

ACTION 8.2
Identify Future Needs for Jobs-ready Industrial and Employment Lands

1. Number and type of short-term tactics executed and/or developed into projects

ACTION 8.3
Address the Regional Housing Supply and Affordability

1. Housing affordability index
2. Renters spending 30% or more of income on rent

ACTION 8.4
Plan for Greater Portland's Economic Resiliency

1. Grant funding proposals developed and grants received
2. Establishment of emergency preparedness plan for businesses

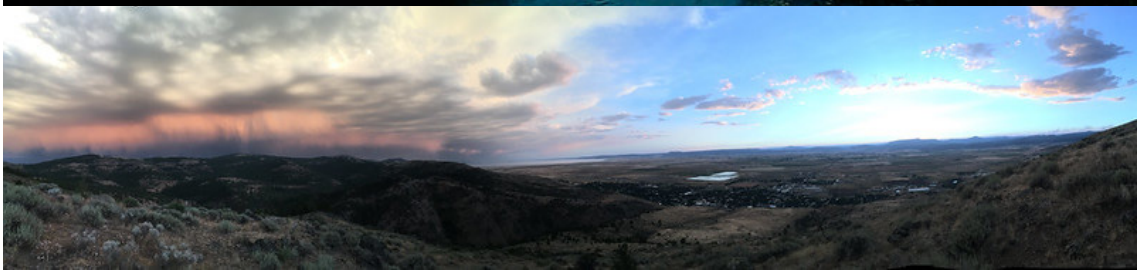
ODOT State Revenue Forecast



Oregon Department of Transportation

Transportation Development Division
State Revenue Forecast
October 2019

Foreword

This summary report presents a selection of State Other Funds Revenue forecasts for the Oregon Department of Transportation. It is published twice a year to assist in financial planning, the formulation of transportation budgets, and to support other decision-making activities. The forecast is consistent with the Department of Administrative Services' Oregon Economic & Revenue Forecast (Vol. XXXIX, No. 3, September 2019) and the associated baseline macroeconomic forecast from IHS Markit.

This document is also available at: https://www.oregon.gov/ODOT/Data/Pages/Revenue-Forecasts.aspx and scroll down to the "Most Recent Forecast."

Questions and comments should be directed to:

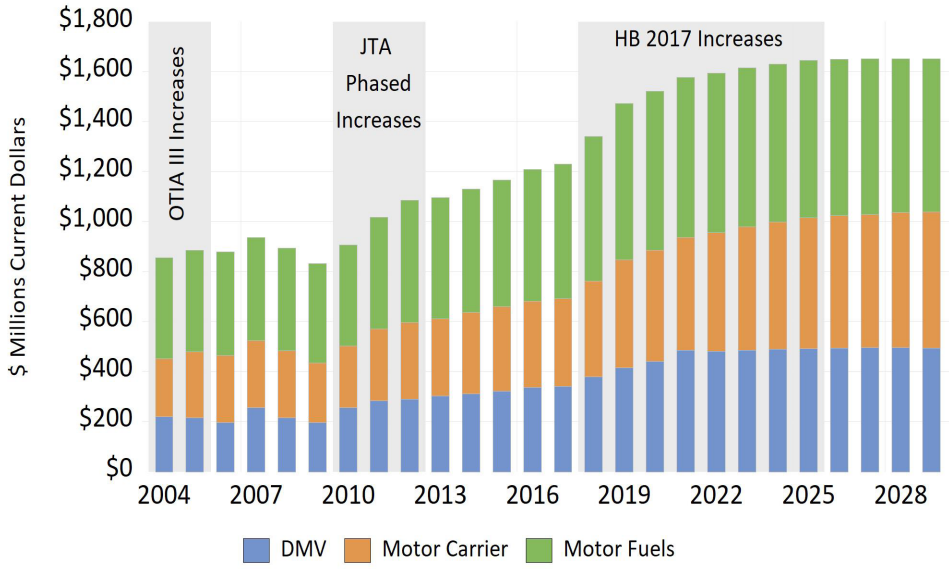
Forecast Summary

Overall, State Highway Fund revenues continue to grow as a result of the tax increases from HB 2017, but compared to the prior forecast growth is weaker due to a larger than anticipated slowdown in new vehicle sales, trucking activity, and fuel sales.

As expected, HB 2017 is providing a large increase in overall State Highway revenues.

The first round of tax and fee increases by HB 2017 from the 2017 Legislative Session have been effective since January 1, 2018. The next phase of increases are scheduled to take effect in January of 2020, which will increase DMV fees, weight-mile tax rates and motor fuel tax rates if certain conditions are met. Tables 6-8 in the main body of this forecast report include only the guaranteed motor fuels tax increases. The appendix at the end of the report presents alternative Tables 6A-8A, which include the conditional six cents in future fuels tax increases.

Overall, the economic backdrop has not changed much since the last forecast. Employment growth is expected to continue slowing but remain above one percent through 2021. Oregon's population growth rate is lower than in the prior forecast. Part of this change is due to a drop in the net natural increase in population and another part is due to lower net-migration numbers. The current population forecast now calls for deaths to exceed births in the latter 2020's. This will place the entire burden for any population growth on net migration, which is a key factor for growth in transportation revenues.



Motor Fuels revenue growth finished state fiscal year 2019 up 7.5 percent due to the tax rate change in January of 2018. This rate is 0.6 percentage points lower than the prior forecast. Absent any tax changes, revenues grow through fiscal year 2021 before declining through the remainder of the forecast. If the conditions are met enabling the additional $0.02 per gallon rate to take effect in calendar years 2020, 2022 and 2024, revenue growth will increase through fiscal year 2025.

Motor Carrier revenue, led by weight-mile collections, finished state fiscal year 2019 with growth of 14.2 percent, due to the tax rate changes. This rate is 1.9 percentage points lower than the prior forecast, as weight-mile revenue came in weaker than previously anticipated. HB 2017 increased weight-mile rates in a phased approach every two years beginning in January of 2018. Looking ahead, significant revenue growth is expected through fiscal year 2025 as the rates increase. However, the slowing economy is expected to lead to overall slower growth if the rates were held constant.

Like Motor Fuels and Motor Carrier, DMV revenues finished state fiscal year 2019 significantly higher, increasing 9.7 percent. Motor Carrier and Motor Fuels, DMV revenues for fiscal year 2019 were lower than previously forecasted as well. HB 2017 increased fees for most registration and title transactions beginning in January of 2018, and phasing some increases in 2020 and 2022. Absent the fee changes, transaction growth has been buoyed by strong in-migration. Going forward, transaction growth is expected to slow as in-migration growth slows. However, revenue should continue growing at a higher rate over the next several fiscal years as the fee increases from HB 2017 are implemented.

Figure 1. Total Gross State Highway Revenue by Fiscal Year

Revenue growth will continue through FY 2025 as the tax and fee increases are phased in from HB 2017.

Source: October 2019 ODOT State Revenue Forecast

On a fiscal year basis, total gross revenues show a sharp increase year over year beginning in FY 2018, continuing through FY 2025, with the largest increases coming in FY 2018 and FY 2019. On a biennial basis, compared to the prior forecast gross revenues are down over the forecast period, with the gap increasing in the outer forecast years. Net revenues follow a similar pattern but display a larger gap between forecasts as costs are anticipated to rise faster than in the prior forecast.

Table 1. Change in Revenues from the December 2018 Forecast

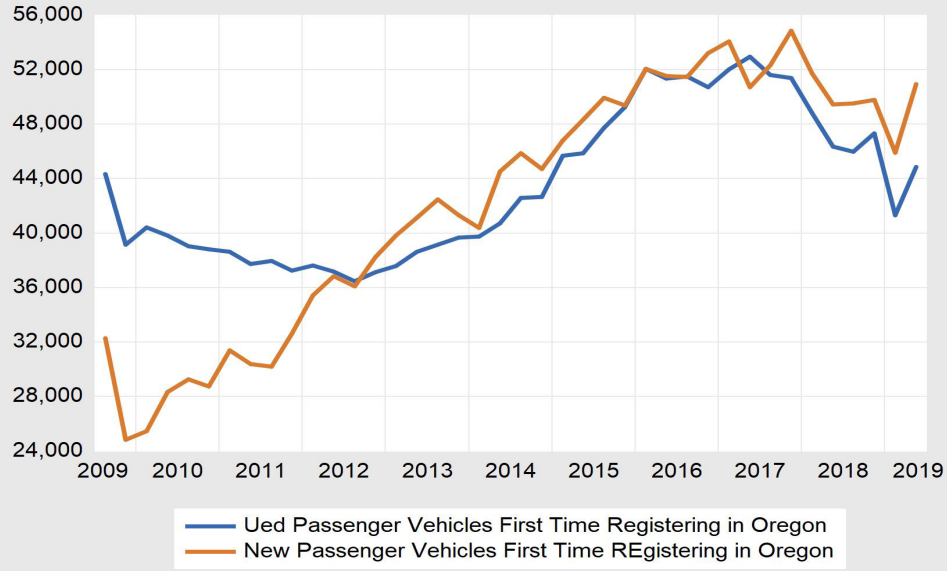
($ Millions)	2017-19	2019-21	2021-23	2023-25	2025-27
Motor Fuels (w/ triggered increases)					
Gross	$(14.2)	$(2.3)	$(18.7)	$(40.6)	$(59.6)
Net Apportionable	$(14.5)	$(3.1)	$(19.6)	$(41.5)	$(60.5)
Motor Fuels (w/o triggered increases)					
Gross	$(14.2)	$(2.2)	$(16.9)	$(34.8)	$(50.6)
Net Apportionable	$(14.5)	$(5.2)	$(22.9)	$(44.1)	$(60.8)
Motor Carrier					
Gross	$(1.8)	$(14.2)	$(8.0)	$(11.1)	$(10.5)
Net Apportionable	$(1.8)	$(13.9)	$(7.8)	$(10.9)	$(10.3)
DMV					
Gross	$(7.3)	$14.3	$(1.3)	$(5.2)	$(3.6)
Net Apportionable	$(7.3)	$2.4	$(16.9)	$(19.0)	$(16.7)
Total (w/ triggered increases)					
Gross	$(23.3)	$(2.1)	$(28.0)	$(56.9)	$(73.8)
Net Apportionable	$(23.7)	$(14.6)	$(44.3)	$(71.4)	$(87.5)
Total (w/o triggered increases)					
Gross	$(23.3)	$(2.0)	$(26.2)	$(51.1)	$(64.8)
Net Apportionable	$(23.7)	$(16.7)	$(47.7)	$(74.0)	$(87.8)

A penny increase in the motor fuels tax will yield about $29.2 million in net revenue with the heavy equivalent included.

Forecast yields have changed with this forecast, decreasing into the outer years of the forecast. On average, we estimate a penny increase in the motor fuel tax rate will yield $17.6 million in net revenue per year without the weight-mile tax and $29.2 million in net revenue per year with the weight-mile tax included through fiscal year 2029. Net motor fuel tax revenue is defined as gross revenue minus collection costs and the non-highway fuel tax transfers for the fuel used in non-highway sources, like ATV's and lawnmowers. The amount of the non-highway transfers is based on the tax rate. Assuming consumption does not change, it will increase as the tax rate increases.

Transportation Backdrop

Slowing economic growth will act as a drag on transportation transaction growth.



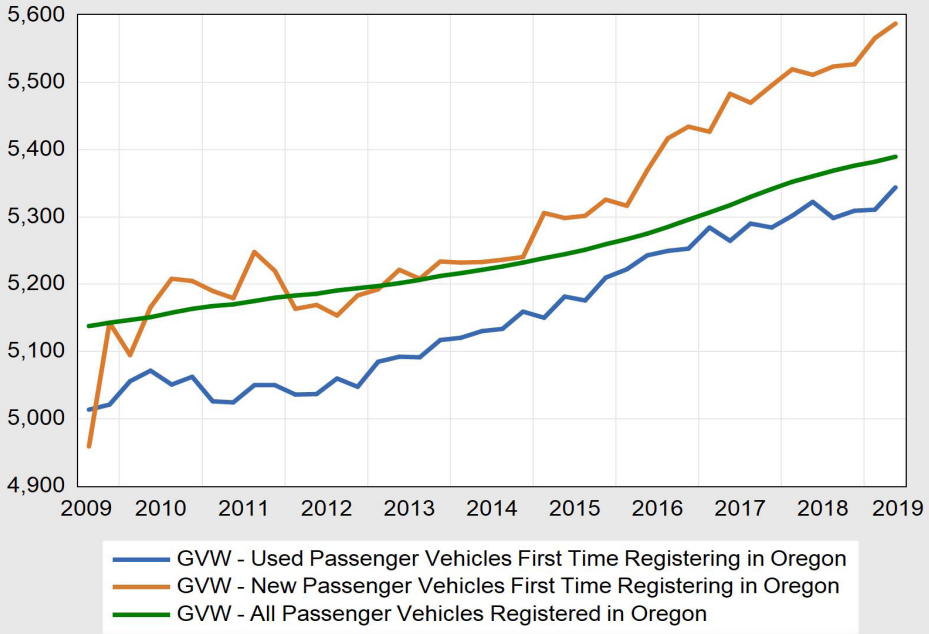
The current outlook for Oregon's economy has not changed much compared to the previous forecast provided by the Office of Economic Analysis, Oregon Department of Administrative Services. The general expectation is that the economy will continue growing, but at slowing rates (Table 2). As our growth slows, we are no longer outpacing the nation, which likely is contributing to slowing net migration. While income growth remains strong, this is no longer translating into new vehicle sales or increased fuel consumption.

A full discussion of the state and national economic forecasts can be found on Oregon Office of Economic Analysis website located here. http://www.oregon.gov/DAS/OEA/Pages/index.aspx

Overall, the number of passenger vehicles entering Oregon's fleet has been declining in the last few years, indicative of a slowing economy. Data for the first two quarters of 2019 is a bit misleading because of the DMV data system migration that happened in January of 2019. The proportion of new vehicles entering the fleet is slightly above the proportion of used vehicles first time registering in Oregon (Figure 2). The proportion of new vehicles entering the fleet typically declines during the recessions.

Figure 2. New and Used Passenger Vehicles First Time Registering in Oregon (quarterly frequency – seasonally adjusted)

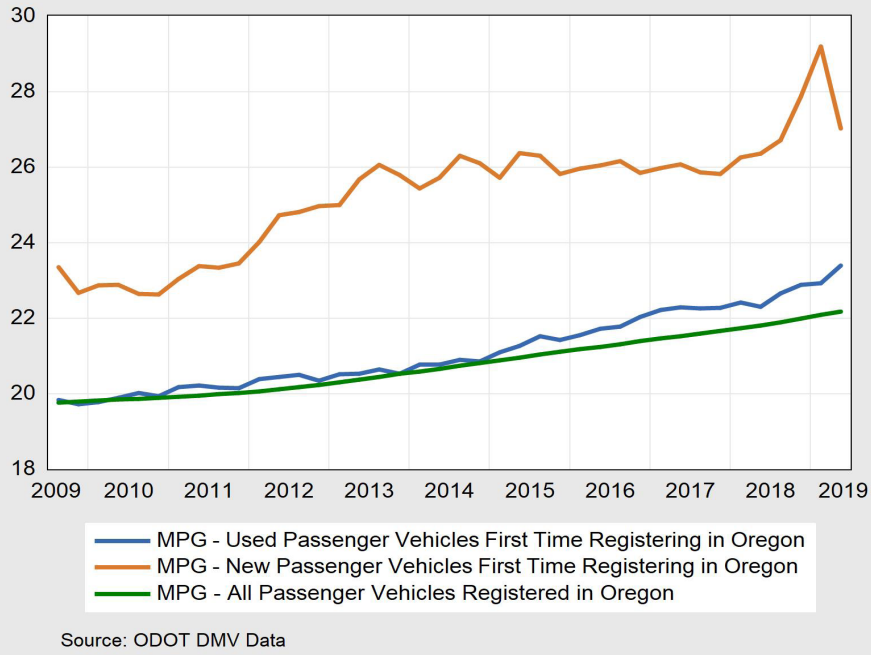
The number of used vehicles entering the fleet is about the same as the number of new vehicles entering the fleet.



Source: ODOT DMV Data

There are some interesting differences between new vehicles first time registering and used vehicles first time registering in Oregon. Used vehicles on average have a lower gross vehicle weight (GVW). Most of these vehicles likely belong to people who just moved to Oregon from another state. Another interesting fact is that people moving from other states on average have lighter vehicles compared to all passenger vehicles currently registered in Oregon (Figure 3). The other pattern that has emerged in the past three years is the rapid increase in average GVW for new vehicles, which explains the recent pattern of slower growth in fuel efficiency of Oregon's fleet.

Figure 3. Gross Vehicle Weight (GVW) of New and Used Passenger Vehicles First Time Registering in Oregon



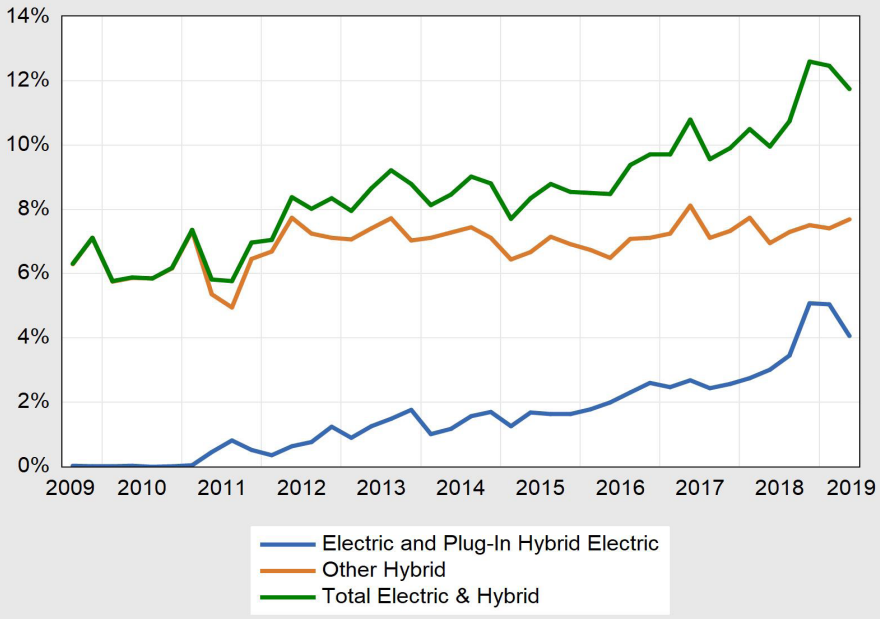
The average GVW has been increasing over time.

Source: ODOT DMV Data

The overall average fuel efficiency of new passenger vehicles entering the fleet is higher than the average fuel efficiency of all currently registered passenger vehicles in Oregon. This contributes positively to overall improvements in fuel efficiency of the entire fleet (Figure 4).

Figure 4. Fuel Efficiency, Miles per Gallon (MPG), of New and Used Passenger Vehicles First Time Registering in Oregon

Source: ODOT DMV Data



The average MPG of new vehicles was stagnant for a while. It has jumped in the last two years, due to increased share of electric vehicle sales.

The share of electric and hybrid vehicles entering the fleet has been steadily increasing (Figure 5). The proportion of Electric vehicles is growing rapidly, reflective of government policies, such as: Oregon's Electric Vehicle Rebate program administered by DEQ, investments in charging station infrastructure, zero emission vehicle (ZEV) sale mandate imposed on dealers, and other policies promoting the adoption of electric vehicles.

Figure 5. Share of New Electric and Hybrid Passenger Vehicles Entering the Fleet

The share of electric and hybrid vehicles entering the fleet has been steadily increasing.

Source: ODOT DMV Data

Table 3 highlights changes for some of the most important revenue generating variables in the ODOT state highway revenue forecast. Growth across DMV, Motor Carrier and Motor Fuels peaked in 2015-2016. Growth has slowed through 2017 and in some cases has turned negative into 2018. Looking ahead, with a continual slowdown in the economy expected, transportation transactions face significant headwinds to growth.

DMV

The Driver and Motor Vehicle Services Division (DMV) is responsible for administration of driver and motor vehicle related activities. Revenues collected from the fees charged for the various DMV activities flow into the State Highway Fund, the Transportation Operating Fund and into other funds administered by ODOT divisions such as Public Transit and Passenger Rail. Additionally some fees net of costs are transferred to outside entities. For example, RV-related fees are transferred to the Oregon Parks and Recreation Department. Lastly, revenues remaining after deducting transfers and costs are apportioned to cities and counties statewide for local road repair, maintenance and construction.

The DMV forecast is produced at the transaction level and aggregated to the summary level. The transactions are grouped into three different business lines: Vehicle, Driver, and Business Regulation. The Vehicle program area contains the transactions related to legal ownership and operation of a vehicle, including titling, plates, registrations and permits. The Driver program contains the transactions related to the legal right to operate a vehicle, including permits, licenses, endorsements and the associated tests to obtain these rights to drive. The Business Regulation program is tasked with ensuring the businesses that sell vehicles in Oregon are properly licensed along with those that dismantle and transport vehicles.

DMV has the largest number of transactions to forecast but only a handful have significant impacts on revenue.

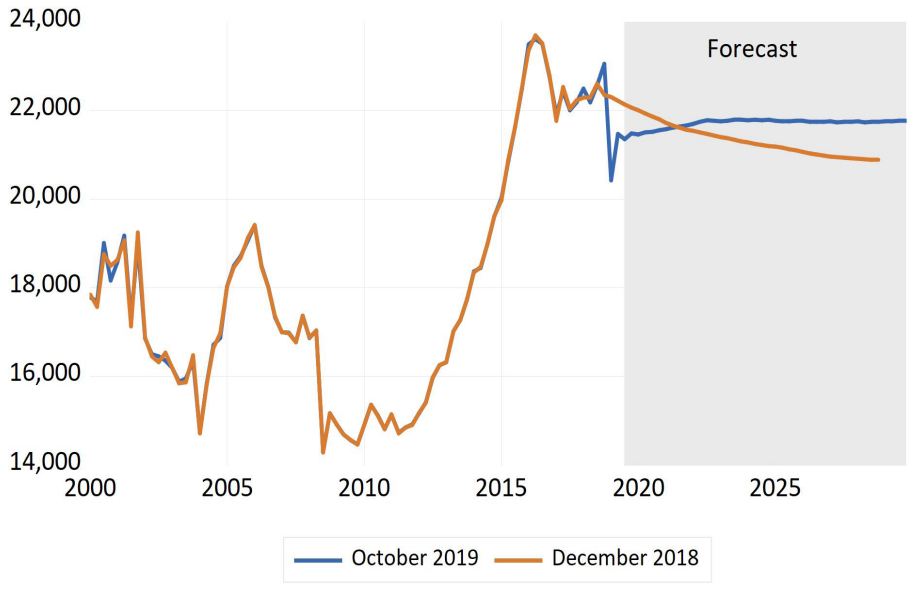
In total the DMV forecast contains over 240 individual product transactions and over 100 different forecast equations. However, most of these transactions have little significant impact on the

overall forecast as their volumes and fee levels are small. In FY 2019, of the total number of transactions, about 80 percent of the revenue was collected by about 10 DMV transactions. Passenger vehicle registrations alone accounted for almost 47 percent of all revenue collected by DMV. Other significant contributors are truck and light trailer registrations, light vehicle trip permits, light title transactions, plate manufacturing fees, vehicle and driver related record fees and class C non-commercial licenses and renewals.

DMV provides the gateway to access Oregon's transportation system and is heavily influenced by changes in population.

DMV activities are affected by various economic and demographic variables and provide a reflection of broad undercurrents in the state. The impacts from changes in population, employment, migration, and economic production are readily evident in many of the DMV data series. In general, DMV activities are more strongly affected by demographic than economic changes, and as such are generally more immune to cyclical swings typical with economic variables. Of the three business lines in DMV, the Vehicle and Business Regulation programs are most susceptible to economic influences, especially related to new vehicle titles.

Currently DMV is in a transition period; after several years of strong growth DMV is likely headed toward several years of slow growth. While the economy is still expanding, the rate is slowing. U.S. economic expansion generally means jobs are plentiful and

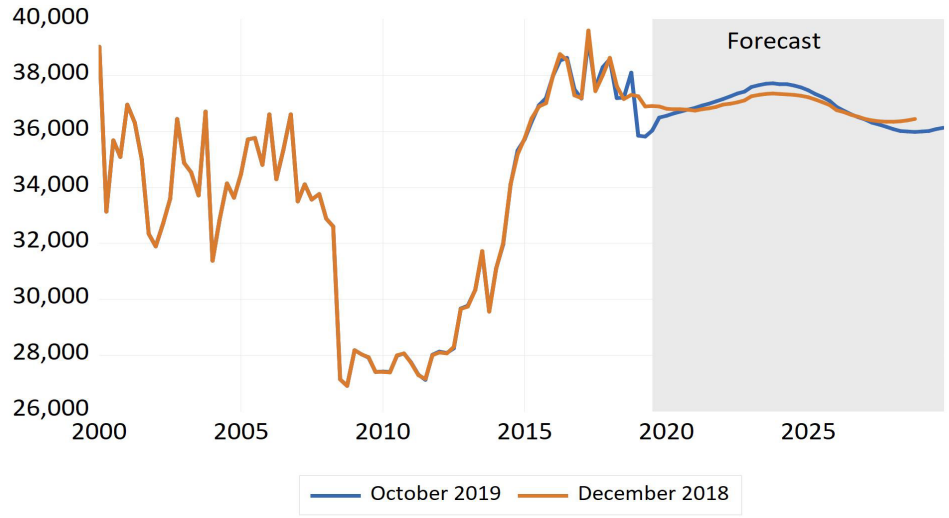


movement across state borders is easier. States with higher quality of lives see increases in in-migration during these periods. As Oregon enjoys a high standard of living, its population is currently increasing, which impacts both the Driver and Vehicle programs in DMV.

A surrendered license transaction occurs when a person moves to Oregon from another state surrendering their out-of-state license to DMV. This is the first contact with DMV for this group of people. Unfortunately, we lack additional information about who these people are, such as their age and location to which they are moving. Regardless, it is a valuable statistic that influences other DMV transactions. Figure 6 compares the surrendered license forecast to the prior outlook. Data shows that growth peaked at the end of 2016 and the rate has dropped a bit. The current outlook is for the rate to stay stable.

The impact that surrendered licenses has on other DMV transactions begins first with non-commercial class C licenses. As

Figure 6. Out-of-State Surrendered License – Forecast Comparison (quarterly frequency – seasonally adjusted)



The number of out-of-state surrendered licenses peaked in 2016.

Source: October 2019 ODOT Forecast

an individual moves to Oregon and surrenders their old license, they get a new Oregon issued license. Figure 7 compares the current forecast to the prior one. The license sales bottomed out in 2011 with about 110,000 licenses sold that year before growing rapidly in a very similar pattern to the surrendered licenses. Following the pattern in surrendered licenses, growth seems to have peaked in 2016 at over 152,000 sold.

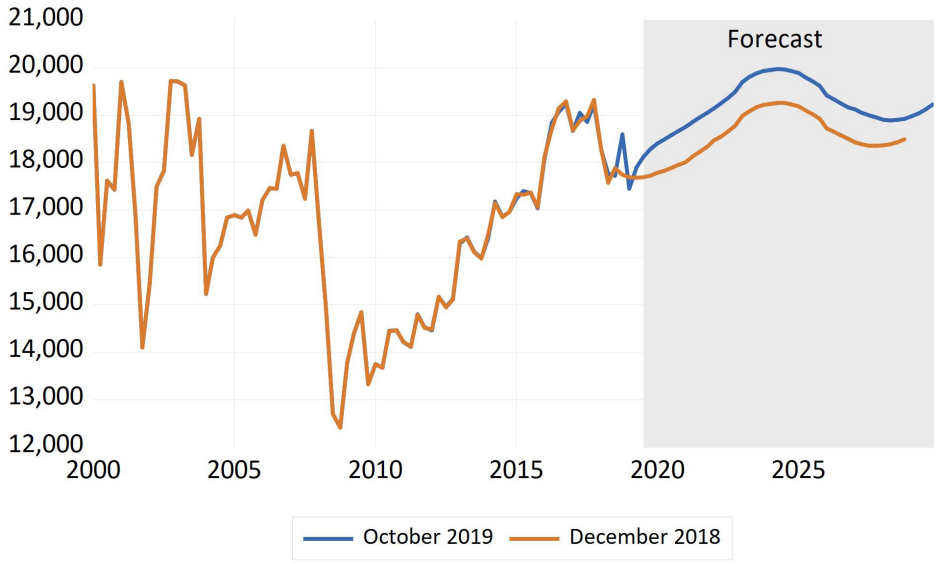


Figure 7. Original Class C Non-Commercial License – Forecast Comparison (quarterly frequency – seasonally adjusted)

Source: October 2019 ODOT Forecast

The other factor influencing the growth in driver licenses is instructional permits. Beginning in March of 2000, young adults under the age of 18 looking to obtain their driver license must first get their permit and complete 50 hours of certified driving experience. Prior to this, the instruction permit was only required for drivers under 16. As Figure 8 shows, the recession and stricter documentation requirements had a negative impact on permit sales. As the economy recovered so did the permit sales, with growth peaking toward the end of 2016. Fast forward several months and a lot of these permittees will be applying for an original class C driver license, which helps explain the jump in license sales. This increased workload from in-migration and from existing

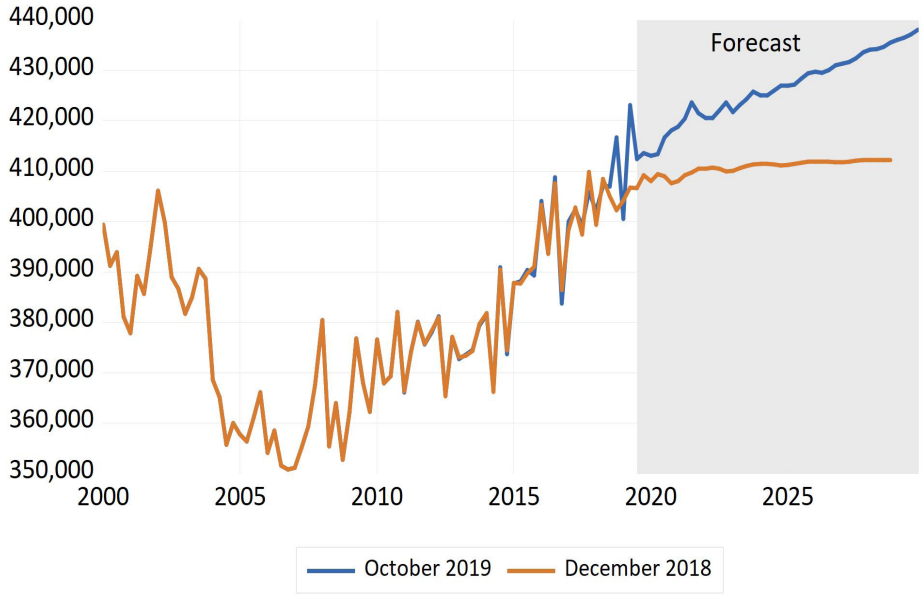

Figure 8. Non-Commercial Instructional Permits – Forecast Comparison (quarterly frequency – seasonally adjusted)

Source: October 2019 ODOD Forecast

Oregon residents impacts the Vehicle program as well. When someone surrenders their license they likely have a vehicle they want to legally title and register in Oregon. While having an Oregon title provides documented ownership of a vehicle, to be driven legally on the road the vehicle needs to be registered. New vehicles are eligible to register for a four year period, while used vehicles brought into the state or vehicles already registered in Oregon renewing their registration will typically register for two years. The forecast for two year registrations is primarily impacted by the existing fleet as it renews, but strong in-migration is also causing a pronounced increase in registrations (Figure 9).

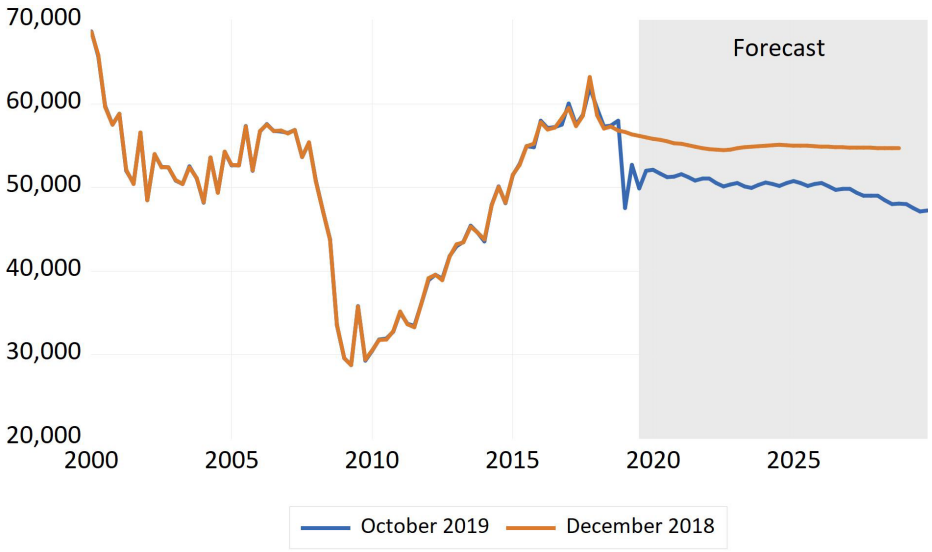

Figure 9. Two-Year Passenger Vehicle Registrations – Forecast Comparison (quarterly frequency – seasonally adjusted)

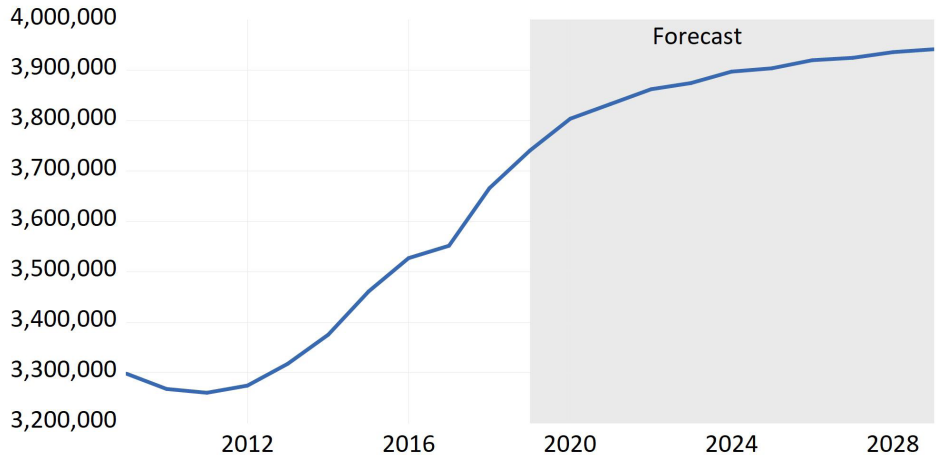
Source: October 2019 ODOD Forecast

The recession created pent-up demand for new vehicle sales, leading to consistent growth between 2012 and 2015 in light vehicle sales (Figure 10). Sales peaked in 2017 and now are gradually declining.

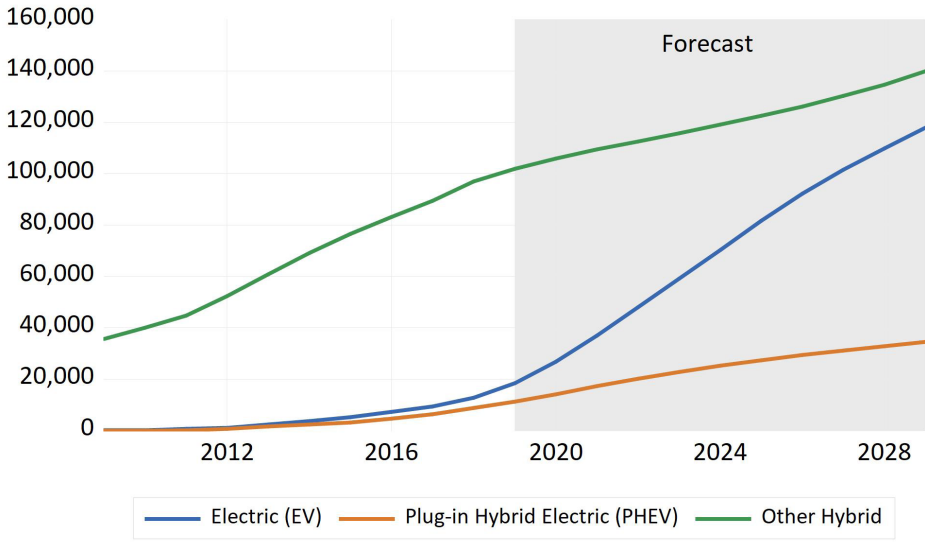
Figure 10. New New Light Vehicle Titles – Forecast Comparison (quarterly frequency – seasonally adjusted)



Source: October 2019 ODOT Forecast

As of July 2019, there were 3,707,100 registered passenger vehicles in Oregon (Figure 11). The number will continue to grow for the forecast horizon, but the growth rates are expected to slow down because of declining new vehicle sales. The proportion of hybrid and electric vehicles in the stock is expected to grow fairly rapidly as more consumer options become available and the infrastructure grows (Figure 12). This forecast is a baseline projection of what we expect to happen if current policies remained unchanged. The stock forecasts are developed based on vehicle in and out flow. The flow in is projected based on Energy Information Agency (EIA) reference scenario forecast from 2019 Annual Energy Outlook. The flow out is projected utilizing survival analysis of Oregon's historic vehicle registration data.

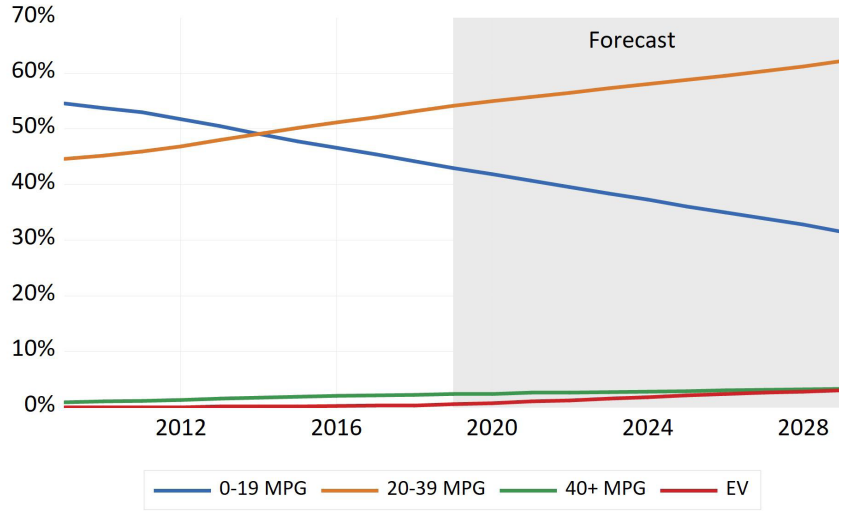
Figure 11. Registered Passenger Vehicles Stock Forecast



Total number of registered passenger vehicles will continue to grow but at a slower rate.

Source: October 2019 ODOT Forecast

Figure 12. Electric and Hybrid Vehicle Stock Forecast



Electric vehicle stock grows the fastest compared to other vehicle stocks.

Source: October 2019 ODOT Forecast

Overshadowing the impact of population and economic changes are the increases related to HB 2017. This bill significantly increases most light vehicle registration and title fees along with trip permits. The most significant increases in terms of revenue are in passenger registrations and light titles. In both cases fees are increased in stages, beginning in January of 2018 with subsequent increases in January of 2020 and 2022. In addition to increased fees over time the bill also creates varying fee structures for both passenger registrations and light titles based on the EPA fuel efficiency rating of the vehicle, beginning with the increases in 2020. Under this structure a higher rated vehicle pays more in registration and title fees. The tiered schedule is created to address the issue of user equity (Figure 13). Because our current taxation is based on gas/diesel consumption, more efficient light vehicles end up not paying their fair share of road usage compared to their lower efficient counterparts. While the tiered fee structure is not user based it does attempt to address this equity concern.

Figure 13. Passenger Stock Shares by MPG Tier

Source: October 2019 ODOT Forecast

Tiered fee schedule will help to maintain equity among highway system users.

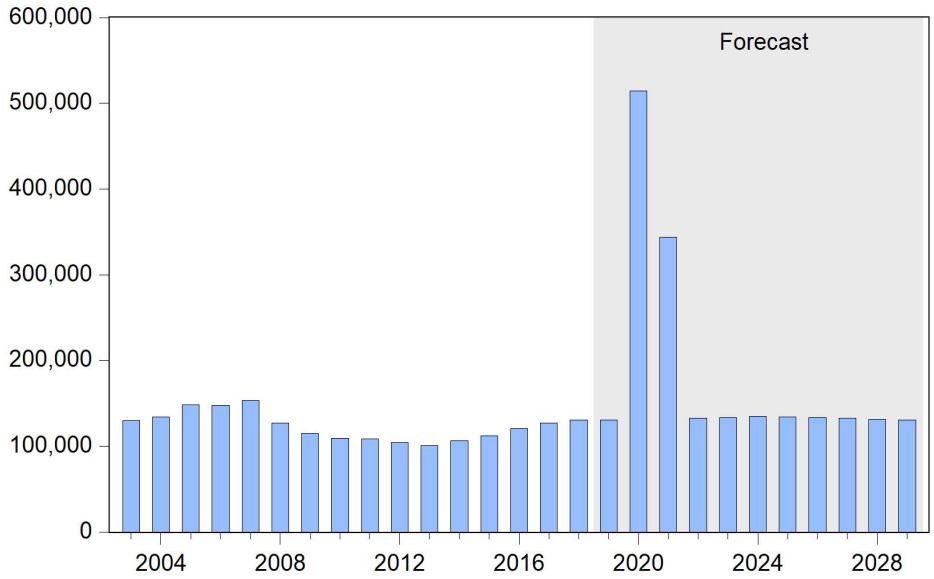


Table 4 shows DMV revenues based on forecasted transaction volumes. The gross revenue portion of Table 4 is grouped into three major components reflecting the primary revenue sources: vehicle registrations, driver licenses, and vehicle titles. Row one and three contain the Vehicle program revenue which is dominated by light vehicle title transfer and passenger vehicle registration revenue.

Driver revenue includes original issuance, renewal, and replacement of commercial and non-commercial licenses and permits, testing fees and other associated fees. Gross revenues are shown in row 2 of Table 4. There are two policy changes that will have an impact on a number of driver related transactions. First, is the implementation of Real ID: as of October 2020, Oregon residents would have to have Real ID compliant driver licenses/ID cards to be able to travel to other states. DMV will start issuing Real ID compliant cards in July of 2020. This will create a significant increase in replacement card transactions as well as an increase in early renewals (drivers are allowed to renew their cards within 12 months of expiration date). Second, is the implementation of HB 2015, where undocumented immigrants will be able to get driver licenses, permits, and ID cards. These impacts were added to ODOT's October 2019 baseline forecast.

As a result, driver revenues increased by 29% for 2019-21 biennium compared to the previous forecast, and 12% for 2021-23 biennium.

Implementation of Real ID will nearly triple replacement card transactions for 2019-21 biennium.

Figure 14. Replacement Driver Licenses

Source: October 2019 ODOT Forecast

Row 5 of Table 4 summarizes the change in gross revenues from the previous forecast. FY19 to FY23 show a negative change from the last forecast.

Rows 6 through 11 and 13 through 15 of Table 4 give the costs associated with administration of DMV and transfers of the DMV revenues to support JTA and OTIA projects and for other statutory purposes.

DMV program costs primarily change when personal services costs change or programs are phased in or phased out. ODOT's approved budget for 2017-19 includes expenditure authorization for DMV computer system modernization project. This project replaces a system created in the 1960's with one using current technologies, and is estimated to cost $90 million over 10 years. Below is the updated schedule for project expenses:

	Actual	Forecast				Project Total
Biennium	**2015-17**	**2017-19**	**2019-21**	**2021-23**	**2023-25**	**2015-2025**
Estimated Total Expenses (in millions)	$12.0	$35.0	$30.0	$10.0	$3.0	$90.0

Net DMV revenues, as represented in row 12 of Table 4, show the impact of the DMV projects on revenue growth as well as general inflation impacts on DMV programs.

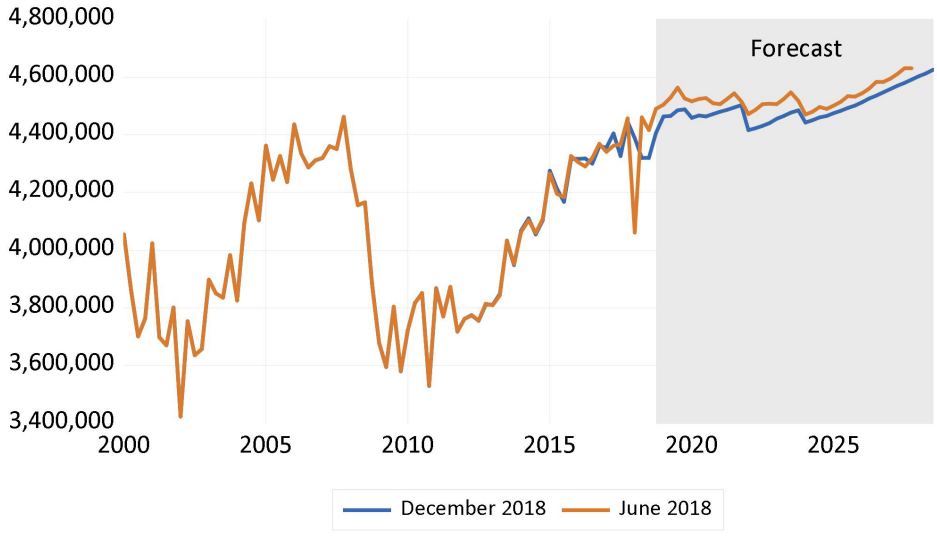
Motor Carrier

Trucking activity and the freight industry contribute to the State Highway Fund through the weight-mile tax, heavy vehicle registration fees, and other Motor Carrier fees. Changes in economic conditions within Oregon and the nation as a whole influence each of these revenue sources. State and federal legislation can also impact trucking activity.

The weight-mile tax was created in 1933 based on loaded weight and number of miles traveled each year.

The weight-mile tax is the largest source of trucking-related revenue. This highway use tax applies to trucks with a gross weight over 26,000 pounds. The tax paid by a motor carrier varies with the weight of the vehicle, the number of miles traveled, and the axle configuration. The carriers generally have the option of paying on a monthly or quarterly schedule, but in some cases will pay by the trip. Certain qualifying motor carriers, such as those transporting logs, wood chips and sand/gravel, may pay the highway use tax based on a flat monthly fee. The weight-mile revenue and transaction totals discussed in this report include the trip based, monthly, quarterly and flat fee revenue, as well as revenues from a small number of other trip-related fees.

An estimate of weight-mile "transactions" provides the basis for the current forecast of weight-mile revenues. This methodology, also used for prior forecasts, constructs a measure of weight-mile transactions by normalizing revenue by the tax rate paid for a typical heavy vehicle. The forecasting model regresses the normalized weight-mile transactions on Oregon construction and durable goods employment, real consumer spending on durable goods, and industrial production and sales of heavy trucks in order to estimate weight-mile transactions. The variables in the model that have the most significant impact on the forecast are real consumer spending on durable goods and Oregon construction employment. Afer several years of strong growth, construction employment growth slowed some in 2018 with a couple weak quarters. It is set to slow considerably further in 2019 and beyond, slowing to rates under 1 percent by 2022. Real consumer spending on durable goods is also expected



to see slower growth over the forecast as the overall economy cools.

In addition to the economic changes, the weight-mile tax rates increase in 2018, 2020, 2022 and 2024 for a total of 53 percent over the 2017 rates. These significant rate increases will also have an impact on trucking activity as businesses look for ways to minimize the impact of these higher rates.

Combined, these variables produce the forecast shown below in Figure 15. Compared to the prior forecast, the drop in transactions in the first quarter of 2019 was unexpected. However, overall growth has stalled and at the end of 2018 turned negative. After consultation with Motor Carrier staff, they are concerned that trucking firms are struggling to find qualified drivers and that some firms are moving to smaller trucks for local deliveries. Both of these would negatively affect and limit growth in trucking activity. Looking ahead, the drops in the future, shown in 2020, 2022 and 2024 are the result of the coming tax increases.

Figure 15. Weight-Mile Transactions Forecast Comparison

While weight-mile is expected to grow in the coming years, the business cycle will influence the shape of the forecast.

Source: December 2018 ODOT State Revenue Forecast

Row 1 of Table 5 shows the amount of weight-mile and flat fee revenues collected each fiscal year. In 2019, weight-mile and flat-fee revenue totaled $374.6 million, increasing 14.2 percent over 2018. This strong growth is from the HB 2017 rate increases.

Row 2 of Table 5 shows heavy vehicle registration fee revenues. It includes both International Registration Plan (IRP) registration fees paid by interstate carriers and the Commercial registration fees paid by intrastate carriers. Together these heavy vehicle registration fees totaled $48.1 million in fiscal year 2019. Historically, revenues have been consistent for these sources. However, recently IRP revenue has been growing as firms register more trucks. Unfortunately, this increase is not reflected in the weight-mile data and Motor Carrier staff believe these additional trucks are ultimately not being driven in Oregon. Going forward, revenues are expected to maintain the historical consistency, staying around $47 million per year.

HB 2592 from the 2019 Session eliminated the weight receipt fee, a loss of about $4.5 million per year in gross revenue.

Row 3 shows the revenues from Road Use Assessment Fees (RUAF), permits, passes, and credentials such as weight receipts and cab cards. This row also includes OTIA III Local Fund fee in¬crements from the commercial driver permits, licenses, and tests, along with weight receipts. Overall, total revenue from these heavy vehicle sources increased slightly as the rates were increased for a few of these transactions as part of HB 2017. However, HB 4059 passed in the 2018 Legislative Session rolled back some of these rate increases effective January 2020. In addition, HB 2592 passed during the 2019 Legislative Session eliminated the weight receipt. This was effective October of 2019, and is responsible for the drop in revenue from FY19 to FY20, as it averaged about $4.5 million per year.

Row 4 reports the total gross revenues for the Motor Carrier Division and row 5 shows the change from the prior forecast. Overall, the differences between the two forecasts are primarily due to the elimination of the weight receipt.

Row 9 reports the revenues net of collection costs. Rows 10 through 13 highlight the amounts Motor Carrier contributes to the OTIA, JTA and HB 2017 programs.

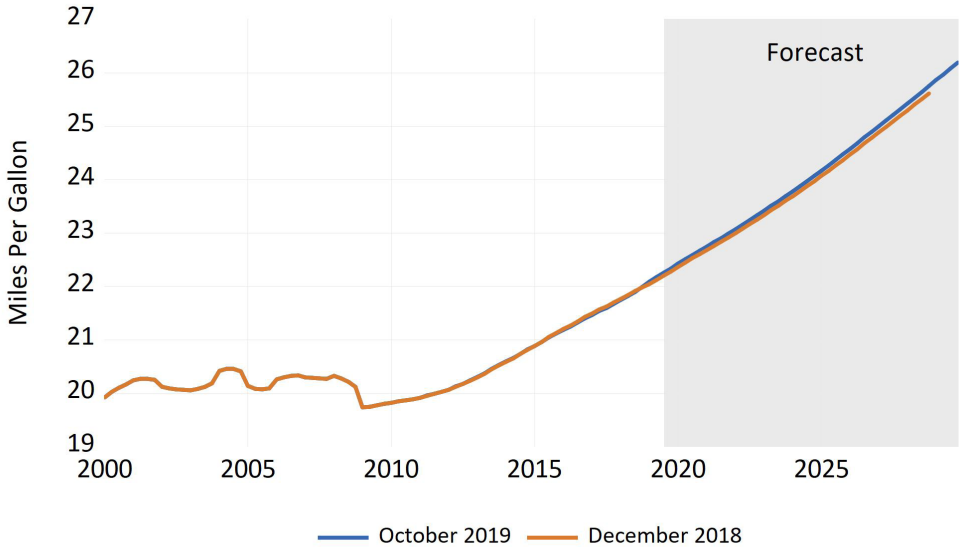
Motor Fuels

Oregon implemented the nation's first gasoline tax in 1919 at 1 cent per gallon.

Motor Fuels revenue is derived from the tax paid on the sale of both motor vehicle fuels (gasoline) and use fuels (predominately diesel). The distinction is important because the tax is collected in different parts of the supply chain. Gasoline is taxed at the point of first sale, when the dealer or distributor purchases the fuel from the terminal. Diesel on the other hand is taxed later in the supply chain, at the retail level. This gives retailers like card lock stations the option of not imposing the tax for heavy trucks that pay the weight-mile tax instead of the motor fuels tax. The separation between when a vehicle pays the fuels tax or pays the weight-mile tax is at a weight of 26,000 pounds. Generally a vehicle up to 26,000 pounds will pay the fuels tax and register their vehicle through DMV, while vehicles over this weight will pay the weight-mile tax and register their vehicle through Motor Carrier. Gasoline comprises the largest share of taxable fuel at roughly 90 percent, while diesel comprises the remaining 10 percent. This has not always been the case: in the past, taxable diesel represented as low as one percent of sales back in 1980. However as more vehicles required to pay the fuels tax switch to diesel, it has been steadily increasing its share. Since about 2014, diesel's share has leveled out at just over 10 percent.

As more vehicles that pay the fuels tax have diesel engines, diesel's share has grown steadily over the years.

Weighing on the future viability of the motor fuels tax as a stable revenue source is the fuel efficiency of the vehicles paying the fuels tax. For many years through the 1990's and early 2000's the fuel efficiency of the light vehicle fleet did not significantly change, as fuel prices remained low and vehicle manufacturers had no real incentive to improve the fuel economy of the vehicles they produced. However, in 2007 legislation was passed establishing new fuel efficiency standards for light vehicles in a



two phase approach. Phase 1 affected model year 2012-2016 vehicles setting a fuel efficiency target of 34.1 miles per gallon (MPG) by model year 2016. Phase 2 builds on this by continuing to expect improvements with each model year reaching a model year 2025 target of 54.5 MPG. The actual standard is expected to be 49.6 MPG by 2025, with the remaining 5 MPG equivalent reached through improvements in vehicle air conditioners. As the 54.5 MPG target is only required under ideal test con-ditions not fully representative of all driving conditions, the actual on-road average is expected to be closer to 38 MPG. Still, at a minimum this is an improvement of over 10 miles per gallon compared to the previous standards.

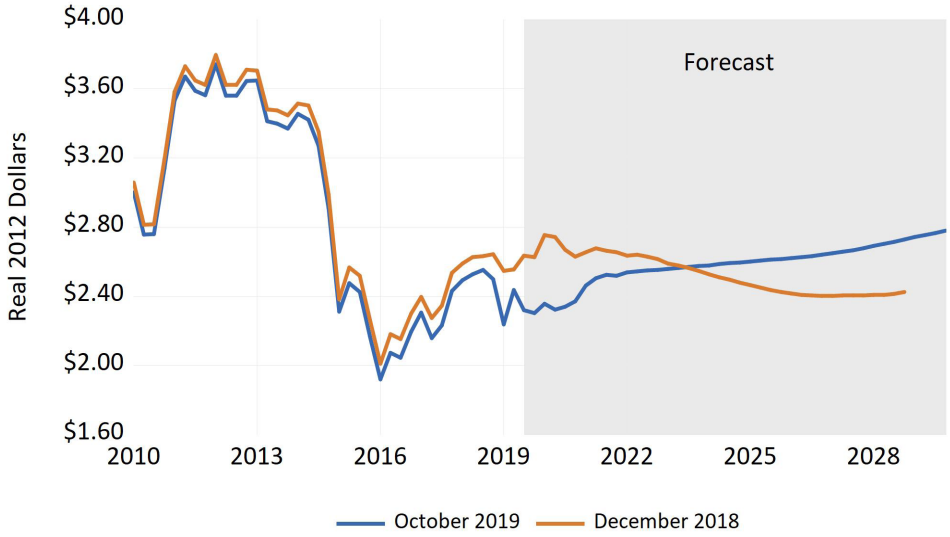
Recently there has been movement to modify the current standards. However, nothing is final as of this publication date, and until final rules are passed we will continue to assume the standards laid out above will remain in effect.

While the new vehicle fuel economy is expected to increase rapidly over the next 10 years, stock fuel efficiency will grow much more slowly. Oregon has 3.7 million registered passenger vehicles, and only about 180,000 new model year registrations a year. This coupled with an average vehicle age of almost 13 years, means it will take quite some time for these new higher efficient vehicles to replace the older less fuel efficient ones. Additionally, the health of the economy impacts vehicle purchase decisions. Prior to the recession the average vehicle age was only 10 years, but during and after the recession people have hung onto their vehicles for longer. This also could be due to the increased durability of
newer cars. When people do replace their older vehicles, the type of replacement vehicle will impact the overall fleet fuel economy. In recent years Oregon has been experiencing an increase in heavier less efficient vehicle sales, which mutes the impact of fuel efficiency growth.

The current fuel efficiency forecast is almost identical to the prior forecast (Figure 16). The slight increase in the current forecast is due to stronger than expected growth in the last few quarters.

Figure 16. Light Duty Stock Fuel Efficiency Forecast Comparison

Source: October 2019 ODOT State Revenue Forecast



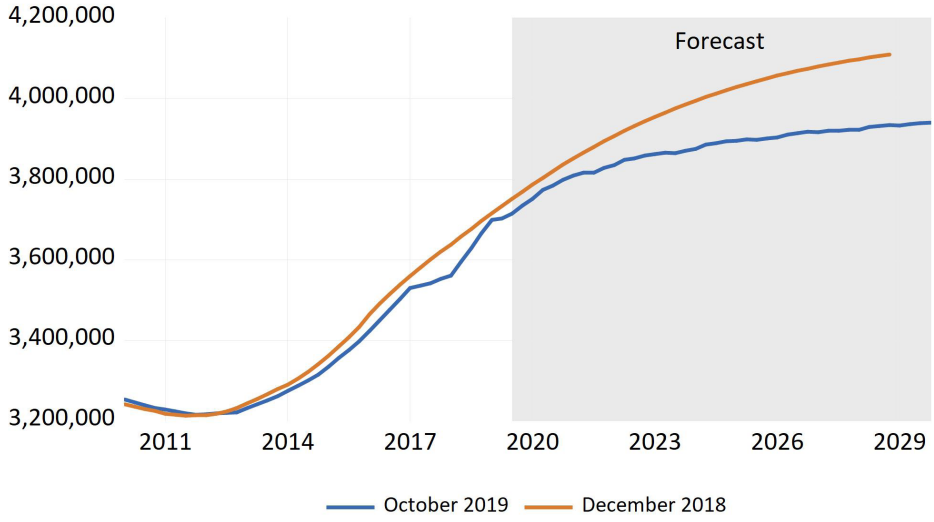
Current CAFE standards aimed at reducing emissions will lead to light vehicles getting increasingly better fuel economy.

Consumption of motor vehicle fuel is generally considered a means to an end rather than an end itself. Because of this, the price of fuel is not as significant a consideration of whether a person will choose to drive as other considerations. However, at higher price levels, price of fuel has a greater impact on a decision to drive than at lower price levels, as it impacts households disposable income more noticeably.

Fuel prices have experienced a lot of volatility over the last decade compared to the stability of prior decades. This is due mainly to the run up in oil prices beginning in 2004, peaking in the summer of 2008. After falling briefly during the recession, oil and fuel prices rose again and sustained elevated levels through the summer of 2014 before falling through most of 2017. However, through much of 2018 tightening oil supplies pushed oil prices back up again, albeit to lower levels than prior peaks. Looking into the future, abundant crude oil stocks and production, coupled with a slowing global economy, are expected to keep fuel prices under $3.00 per gallon in real dollars as shown in Figure 17.

Figure 17. Real Gasoline Price Forecast Comparison

Robust oil inventories and mild global demand have allowed oil prices to remain low and are expected to stay low over the forecast period.



Source: October 2019 ODOT State Revenue Forecast

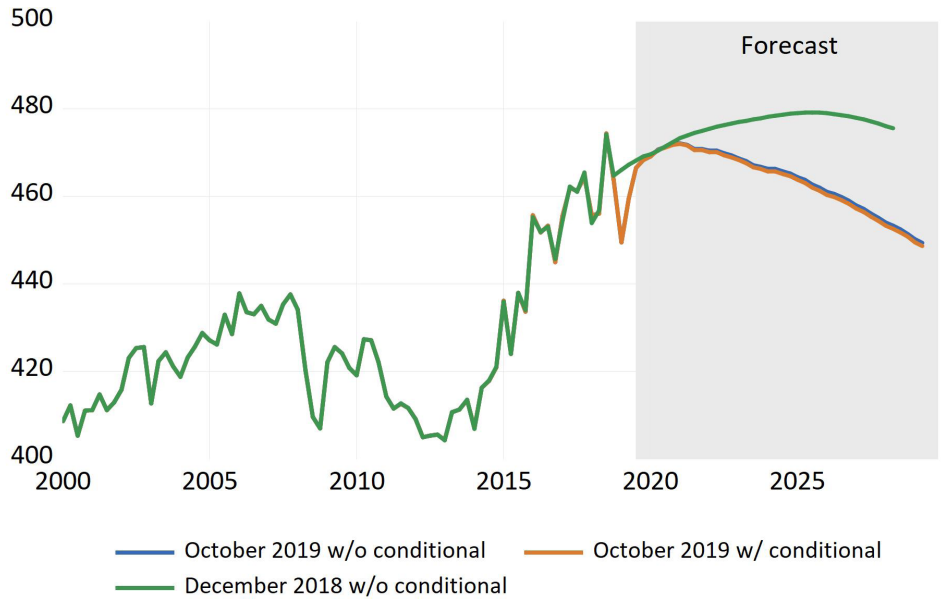
How much fuel a vehicle consumes is not only a function of the fuel efficiency and fuel price, but also by the stock of vehicles. Of the total number of registered vehicles that consume taxable fuel in Oregon, about 94 percent of them are passenger vehicles. As the total size of the passenger vehicle fleet increases, so does the taxable fuel sales assuming all other factors are held constant. Figure 18 below, contrasts the current forecast of the passenger stock to the prior forecast. With the updated passenger stock model the current forecast has slower growth in the passenger stock compared to the prior forecast.

Table 6 shows the results of the motor fuels forecast. The current forecast model combines the use fuel and motor vehicle fuel to produce one forecast including both sources. Model variables include fuel efficiency, total Oregon nonfarm employment, stock of registered passenger vehicles in Oregon and the real price of gasoline. The model forecasts the quantity of taxable fuel consumed and is multiplied by the fuels tax rate to arrive at the gross revenues reported in row 1.

Figure 18. Passenger Stock Forecast Comparison

Of the total number of vehicles registered in oregon that use taxable gasoline and diesel, about 94% are passenger vehicles.

Source: October 2019 ODOT State Revenue Forecast



As discussed above, the fuel efficiency variable is expected to have a significant impact on fuel sales in the future. The increasing CAFE standards will slowly increase the overall fleet fuel efficiency, enabling drivers to go further on the same amount of fuel. In a static environment holding all else constant, a ten percent increase in the fuel efficiency roughly equates to a nine percent decrease in consumption. However, there is a rebound effect associated with fuel efficiency where miles driven increase as fuel economy increases. This effect has been measured in the short-run at around 0.2 to 0.4 percent for a one percent increase in fuel efficiency. Adjusting for the rebound effect yields an estimated decrease in consumption of between five and seven percent for a ten percent increase in fuel efficiency.

The sensitivity of the fuel efficiency variable over the estimation sample interval is estimated to be -0.57 with respect to fuel consumption. That means a one percent increase in fuel efficiency leads to a 0.57 decrease in consumption. For a ten percent increase in fuel efficiency this leads to a 5.7 percent decrease in fuel consumption, falling into the middle of the expected range above.

Figure 19 below, shows the current forecast compared to the prior forecast. Overall, the forecast is predicting decreased fuel sales compared to the prior forecast. There are three main reasons for this drop. First, the model variables are either all virtually unchanged from the prior forecast or changed in a way that would act as a drag on taxable fuel sales. Second, calendar year 2019 has not started off well for sales, where the first quarter in particular was abnormally low. Third, the lower passenger stock forecast reduces the number of vehicles in the fleet, which translates into fewer gallons sold. By itself this change accounts for about half of the drop in the motor fuel taxable gallons forecast compared to the prior forecast.

The negative impact of steadily increasing fuel efficiency on fuel consumption is dragging the motor fuel forecast down in the slow growth economic environment Oregon is projected to be heading towards.

Figure 19. Gallons of Taxable Motor Fuels Forecast Comparison

Source: October 2019 ODOT State Revenue Forecast

Lastly, as noted earlier in the report, HB 2017 included guaranteed and conditional fuels tax rate increases. Since the bill only guarantees the first four cent tax rate increase, this necessitates creating a forecast where we assume all the conditions are met and the full ten cents in increases are implemented, and one where only what is guaranteed is implemented. For now, only the first four cents are included in the guaranteed version. The chart above includes both forecasts.

Since consumption is not very sensitive to price changes, the impact of the six cent increase is very minor.

Row 2 of Table 6 shows the total gross revenue from the motor fuels taxes. Fiscal year 2019 finished with $625 million in gross revenues growing at a 7.7 percent rate, which includes the first full year of new revenue from HB 2017. Going forward, the economic and passenger stock growth overcomes the increasing fuel efficiency through fiscal year 2021, but beyond that point the weak economic growth and slower passenger stock growth is not enough to offset the increasing fuel economy, leading to declining tax revenue.

Row 3 shows the change from the prior forecast. The abnormally low first quarter of calendar year 2019 along with the slower than anticipated second quarter brought down taxable sales in fiscal year 2019 by $10.9 million.

The fuels tax program is very efficient. Collection costs are only about 0.3% of total revenue collected.

Rows 4 through 13 list the costs associated with the Fuels Tax program and the statutory transfers that occur prior to apportionment. Row 14 is a special memo row to show the impact of the B20 biofuels tax exemption program. Since the B20 fuel is tax exempt, it is not included in the gross revenue above and is included as a memo item only for tracking purposes. This exemption is currently set to sunset at the end of calendar year 2019.

Rows 16 through 19 highlight the amounts that the motor fuels tax contributes to the OTIA, JTA and HB 2017 programs, either as a portion of the OTIA I set-aside shown in row 10 or as the incremental revenues from the OTIA III, JTA and HB 2017 programs shown in rows 17 through 19. Note that the OTIA III legislation did not increase the motor fuels tax rate so the incremental amount is zero.

Highway Revenue Forecast Summary

The forecasted revenue is based on current law tax and fee rates. While it is likely that sometime in the near future rates will increase, this forecast is based only on what is enrolled in the current Oregon revised Statutes.

Aside from the tax and fee increases from HB 2017, we are now fully into a transition period from the 2015-2017 years of robust growth into a much slower growth environment. However, the influx in revenue from HB 2017 changes this outlook dramatically and should provide growth into the middle 2020's as the fee and tax increases are implemented over time. Compared to the prior forecast, cumulative changes in gross revenue from FY19 through FY28 are significant. A loss of $4.5 million per year due to the elimination of the weight receipt is a large part of it. In addition, the drop in the motor fuels forecast is the other significant component of this change.

Row 5 of Table 7 sums all the collection and program costs for DMV, Motor Carrier, and Motor Fuels, and the pre-apportionment transfers. It also includes the incremental revenues from the OTIA III, JTA and HB 2017 programs. Row 6 is the total gross revenue minus the amount in row 5.

Rows 7 through 19 are memo items creating summaries of different bill components related to forecast revenues. Note that HB 2017 created not only new revenues but also included some dedicated funds prior to apportionment and new bonding potential. Row 17 includes a placeholder for bonds to support the projects from Section 71 of the bill. The 2019 Legislature authorized the sale of these bonds, with the anticipated sale during the spring of 2021.

Rows 20 through 26 summarize the net revenue for each OTIA, JTA and HB 2017 program disaggregated by amounts to the local governments or to the state. Row 27 represents the total net revenue for distribution by summing rows 20 through 26 plus row 6.

Table 8 separates the total from row 22 in Table 7 into county, city and state apportionments by apportionment formula, whether it is pre-OTIA, OTIA I&II, OTIA III, JTA or HB 2017.

A separate monthly forecast of the County/City Apportionments is available under "Highway Revenue Apportionment Forecasts" at http://www.oregon.gov/ODOT/Data/Pages/Revenue-Forecasts.aspx

Appendix – Alternative Conditional Motor Fuel Forecast

If we assume the conditions are met triggering the three two cent increases in the motor fuels tax rate in January's of 2020, 2022, and 2024, this will significantly increases motor fuels tax revenue in these years. As of now, we are on course to meet the requirements for the 2020 increase. Below are updated tables 6A, 7A and 8A where these conditional tax increases are included. In addition to generating revenue for the State Highway Fund and apportionable revenue to share with local governments, it also increases the revenue transferred for the non-highway fuel uses. This is shown in Table 6A rows 6 through 13.

Tables 6A-8A (Includes All Conditional Rate Increases)

Table 6A. Highway Fund Revenue Collected by FSB (Millions of Dollars) (Includes all Conditional Fuels Tax Increases - Currently an Additional 6 Cents)

Multnomah County 2017 Carbon Emissions and Trends

We are in a climate crisis. July 2019 was the hottest month in recorded history with scorching heat in Europe and massive wildfires in Siberia and Alaska. According to the World Meteorological Organization, "July 2019 has rewritten climate history, with dozens of new temperature records at the local, national and global level[1]."

In the Pacific Northwest, the region has warmed substantially, nearly 2°F since 1900[2]. This temperature rise is leading to warmer winters, decreasing snowpacks, hotter summers, and heavier storms. Scientific models predict increasing the risk of both flooding and drought, water scarcity, large wildfires, warmer stream temperatures, harmful algae blooms, life-cycle impacts for salmon, damage to recreational tourism economies, and negative human health impacts from poor air quality and heat.

Despite 26 years of climate planning and mitigation in Portland, local carbon emission reductions have started to plateau around 15% below 1990 levels, see Figure 1. This is both a success story, and a warning. The reductions to date are impressive given we've welcomed 38% more people and 34% more jobs during the same time. Collectively we have reduced per person emissions in Multnomah County by 38% since 1990, although these reductions have slowed. Despite our successes, our emission reduction efforts clearly need to rapidly accelerate.

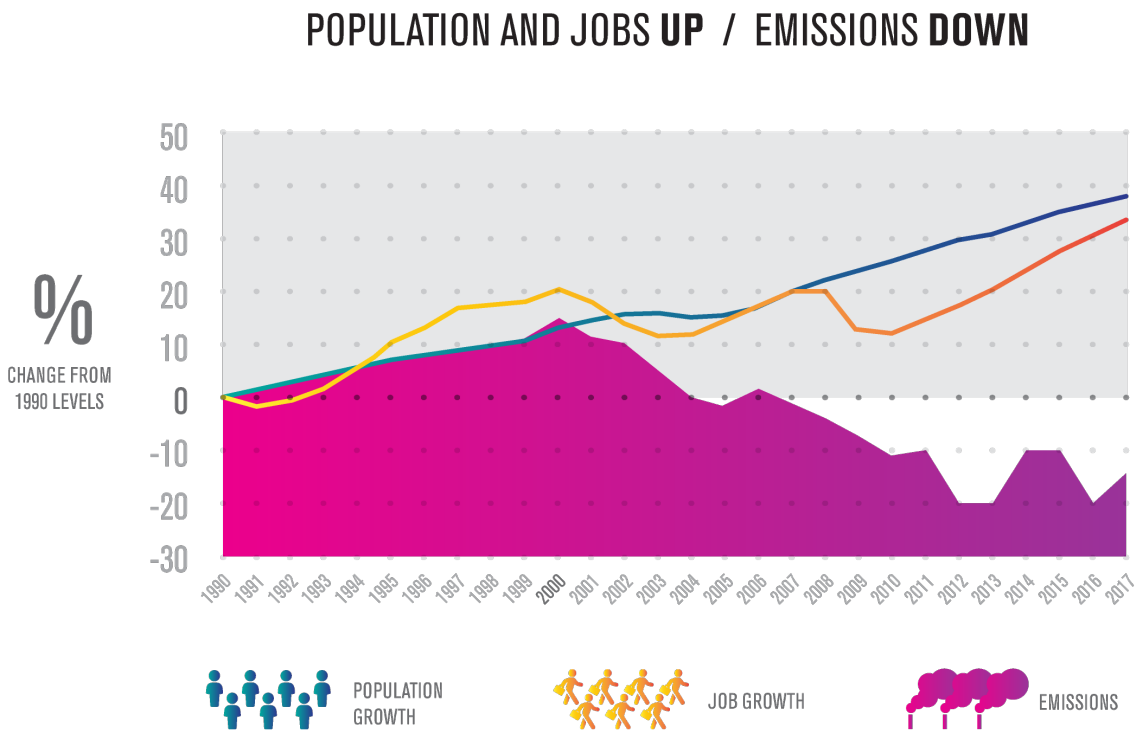

Figure 1: Emissions continue to decline from their peak in 2000, despite significant population growth and increase in jobs. Portland has maintined the decoupling of emissions from growth. However, reductions have reached a plateau in recent years.

Transportation sector emissions are increasing dramatically, currently 8% over 1990 levels, and 14% over their lowest levels in 2012. Portland has experienced year over year increases in transportation related emissions for the past five years, with transportation emissions growing faster than population growth over the same period.

The United Nations International Panel on Climate Change (IPCC) released a special report in October 2018[3] that reiterated the need to limit global warming to 1.5°C to avoid the worst impacts of climate change, including the risk of severe weather events, reduced heat-related mortality, reduced water scarcity, prevent sea level rise that could render delta and low-coastal regions uninhabitable, where two-thirds of the world's population live. IPCC projects that limiting warming to the 1.5°C will require an unprecedented transformation of every sector of the global economy to achieve a 50% reduction in carbon emissions by 2030 and net-zero carbon emissions by 2050. To achieve this Portland must reduce our local emissions by an additional 35% in the next 11 years, a daunting task.

This white paper presents Portland's carbon emission inventory, including sources and trends for the years 1990 to 2017 for Multnomah County. The intent of this paper is to provide information about the pressing challenge to uphold Portland's share of the Paris Climate Agreement. Portland conducts annual emissions inventories to inform policy and planning to reduce emissions. The inventory shows where to focus mitigation efforts and whether we are on track with emission reduction goals. Households and businesses can also assess their own carbon emissions by using free online tools, like the Cool Climate Network's calculators:

- Households - https://coolclimate.berkeley.edu/calculator
- Businesses - https://coolclimate.berkeley.edu/business-calculator

Emissions overview from 2017

Portland and Multnomah County have been tracking local carbon emissions for nearly 30 years using an annual sector-based emissions inventory. This sector-based carbon emissions inventory is widely used by local, state and national governments and meets the Global Protocol for Community-scale GHG Emission Inventories (GPC).

A conventional sector-based carbon emissions inventory shows emissions resulting from four primary categories: fuel use in transportation (e.g. gasoline, diesel, and propane) and energy use in homes, commercial buildings, and industrial facilities (e.g. natural gas for heating, electricity, industrial process fuels), see Figure 2. The City maintains an annual inventory of countywide emissions from these sources, together with landfilled solid waste, wastewater treatment, and other fugitive emissions.

Fugitive emissions *are emissions of gases or vapors from pressurized equipment that escape due to leaks and other unintended releases of gases. These leaks occur during gas extraction from the ground, gas distribution to end users, or gas that escapes from equipment like air conditioning or refrigeration units. Fugitive emissions contribute to air pollution and climate change.*

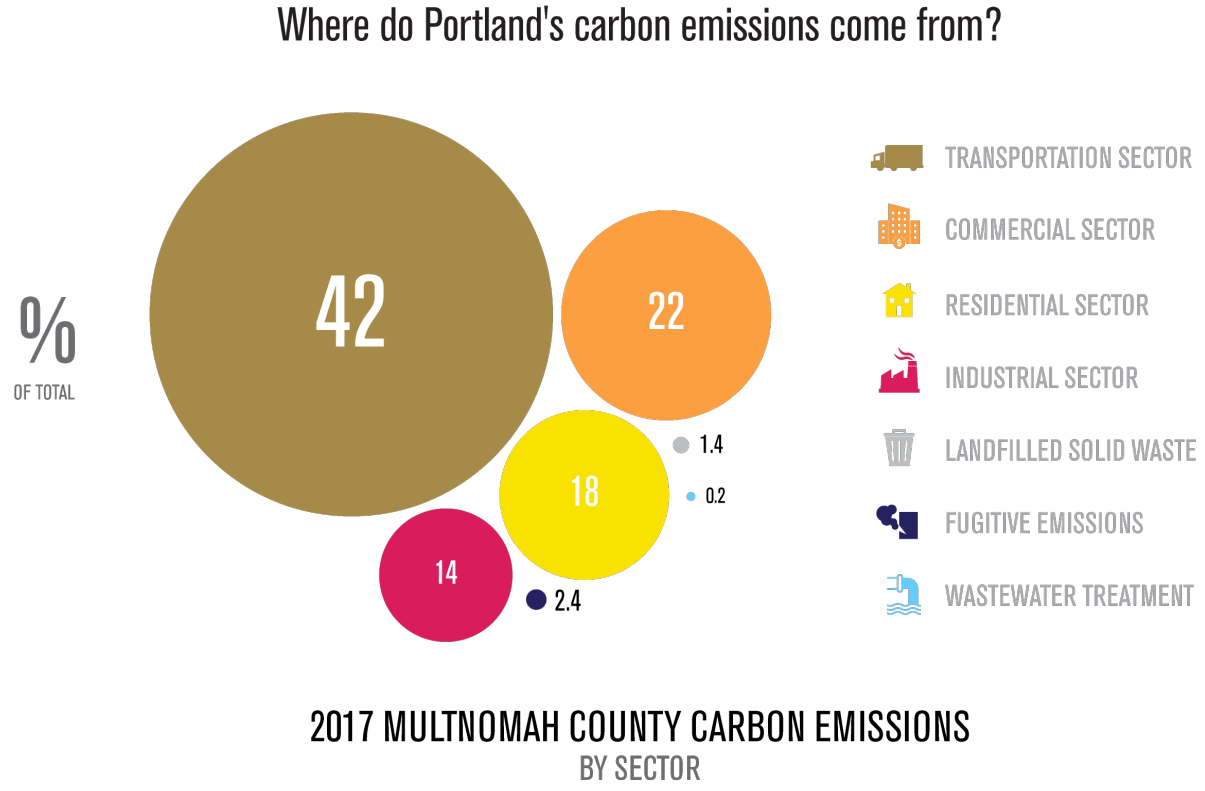

Figure 2: 40 percent of local emissions come from the energy used to run, heat and cool our homes and businesses, and over 40 percent come from transporting people and goods. These proportions have changed as the transportation sector share of local emissions has increased significantly since 2013, when they only accounted for 38 percent of emissions.

This inventory method allocates carbon emissions across the residential, commercial, industrial and transportation sectors based on fuel and energy use in those sectors. It also assigns emissions to solid waste disposal based on the tonnage and type of materials hauled to regional landfills, local wastewater treatment practices, and estimates of fugitive emissions generated in Multnomah County based on population.

Two primary factors influence the emissions trends over time:

1. The amount of energy used in the different sectors (e.g. residential, commercial, industrial, transportation).
2. The carbon-intensity (carbon emissions per unit of energy) of the different energy sources (e.g., electricity, natural gas, gasoline, diesel).

The carbon intensity of energy used in Multnomah County has declined substantially, carbon emissions per unit of energy were 21% lower in 2017 than in 1990. This results in overall reduction in carbon emissions even as the total amount of energy use has increased 8% since 1990.

Today, carbon emissions from Multnomah County total 7,702,000 Metric tons of carbon dioxide equivalents (MT CO2e), which is a 15% reduction from 1990 levels, see figure 5. This decline reflects the continued growth of renewable energy resources like wind and solar in the Pacific Northwest, investments in transit and bike infrastructure, dense and walkable neighborhoods, renewable transportation fuels, as well as the transition from fuel oil to natural gas for heating. These efforts combined have reduced per-person emissions in Multnomah County to 38% below 1990 levels, see Figure 3. This means that a person living in Portland today produces 38% fewer carbon emissions than they would have in 1990.

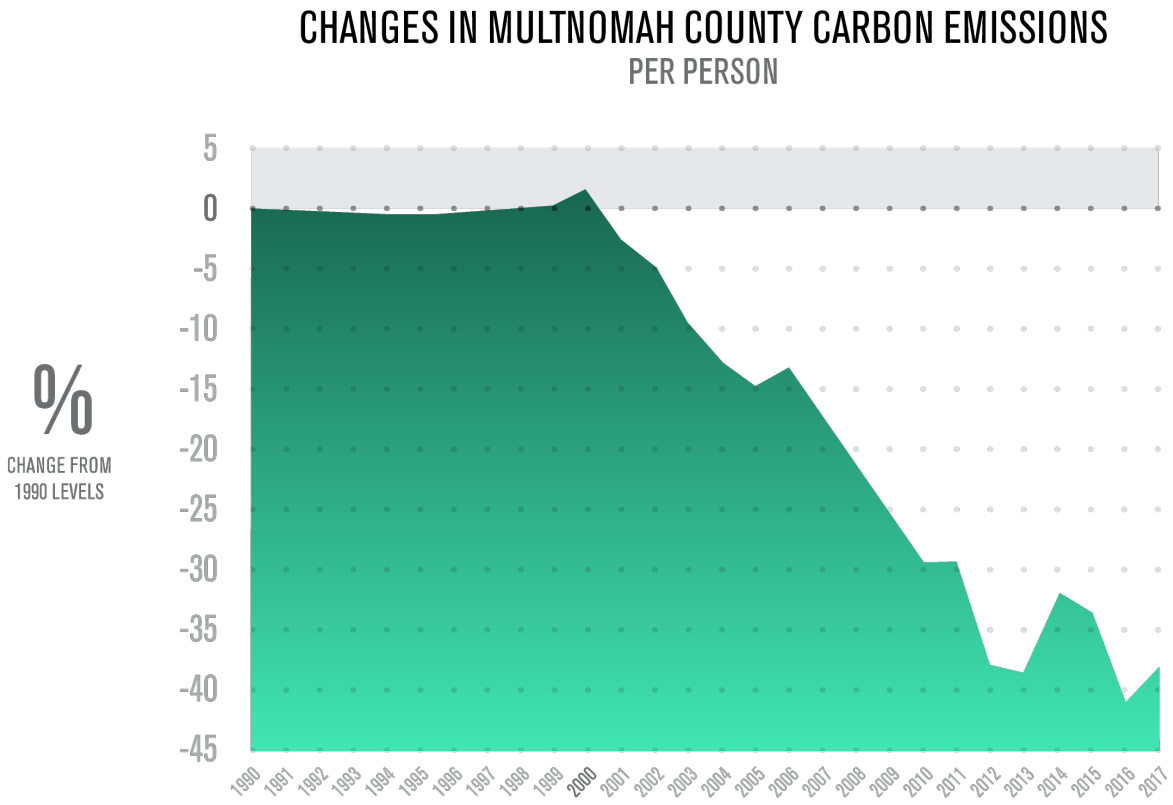

Figure 3: Multnomah County per person carbon emissions have fallen significantly, currently 38% below 1990 levels.

Electricity generation is the single largest source of local carbon emissions, 28%, see Figure 4. These emissions are the result of the carbon intensity of coal and natural gas burned to produce the electricity that powers Multnomah County households and businesses.

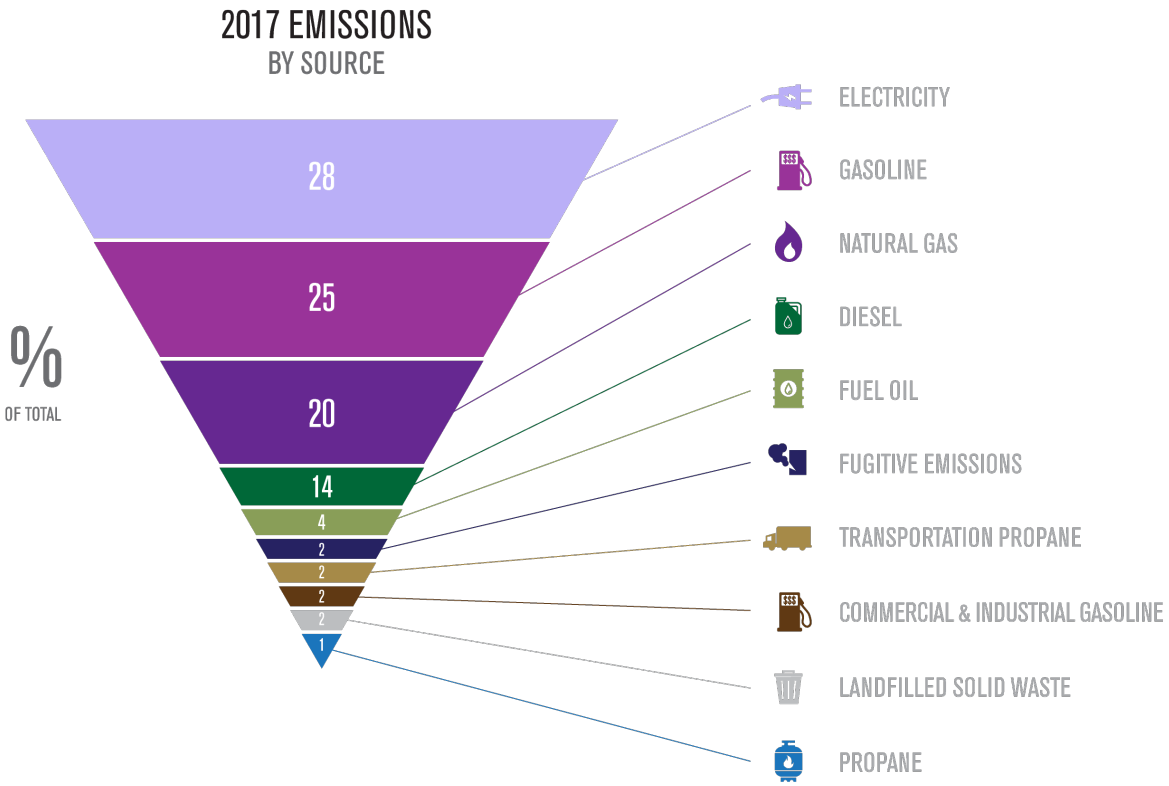

Figure 4: Nearly all of Multnomah County's carbon emissions come from four sources - electricity, gasoline, natural gas, and diesel fuel. Emissions from electricity are the single largest source of local carbon emissions. Additional emissions not shown on chart include wastewater treatment, kerosene, and residual fuel oil -- less than 1% of total emissions.

All transportation fuels (gasoline, diesel, propane, ethanol, biodiesel) combined account for 42% of carbon emissions. These emissions are the result of driving vehicles powered by gasoline, diesel and propane, the transportation of goods, off road vehicles and equipment used for construction, and a transit system dominated by diesel buses.

Direct use of natural gas, primarily used to heat buildings, water, and in industrial processes, is the third major source, at 20%.

Emissions trends

Over time, emissions fluctuate depending on numerous complex factors like the economy, weather, population growth, and local individual behavior. For instance, from 2016 to 2017 emissions increased 6%, due primarily to a very cold winter and increased use of transportation fuels. Due to the complex interaction of numerous factors, this year-to-year change is less significant than the overall trend. Tracking emissions with the same methodology since 1990 allows us to focus on the main sources of carbon emissions and track our overall trajectory towards long-range goals.

The emissions trend, in Figure 5, shows that since 2010 emissions have varied substantially from year to year, due to the carbon intensity of the electric grid and variations in weather. This inventory uses eGRID emission factors for the Northwest Power Pool, which includes Washington, Oregon and most of Montana, Idaho, Wyoming, Nevada, and Utah, and cannot be disaggregated by State. These factors are based on data collected every other year and are heavily affected by weather patterns, as the Northwest Power Pool is dominated by hydroelectric power from Pacific Northwest dams. When there are high rainfall years, hydroelectric dams generate more power, reducing the carbon emissions that result from electricity generation. In dryer years, emissions increase, causing up to 10% variation in emissions. However, if we look through the annual variations from 2010-2017, at the larger trend, we see that emission reductions have reached a plateau.

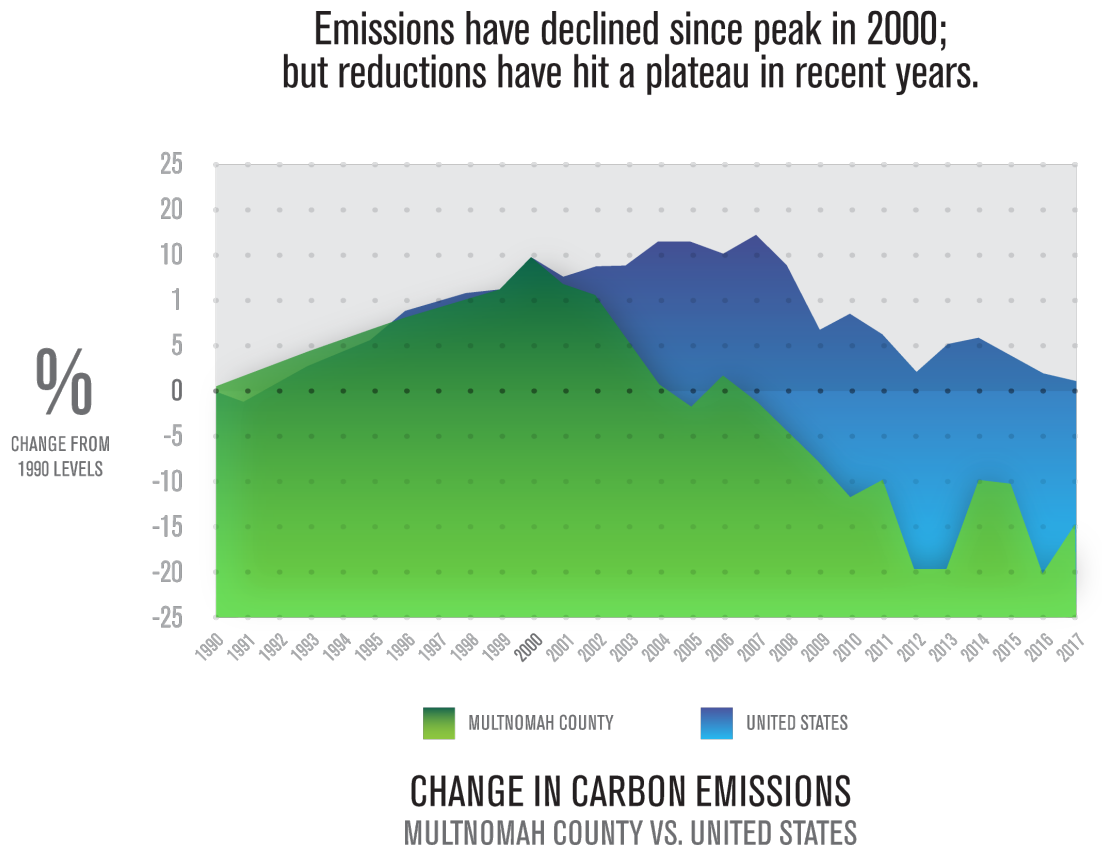

Figure 5: Total carbon emissions in 2017 were 15 percent below 1990 levels. There was a 6 % increase in emissions from 2016 to 2017, mostly the result of winter heating and increased transportation fuel use.

Emissions resulting from residential and multifamily energy use have declined 19% below 1990 levels, a per-person decrease of 41%. This is primarily a result of the improved efficiency of appliances and lighting, weatherization retrofits of homes, the transition from oil to natural gas as a home heating fuel, and the increased use of renewable energy by utilities.

Emissions from energy use in the commercial sector have declined by 10% since 1990. Over the same period, emissions from the industrial sector have declined by 42%, while the total number of jobs has increased by 34%. This is the result of improved efficiency and shifts toward lower-carbon fuels, both in direct consumer use and by electric utilities. For the industrial sector, there remains strong demand for industrial jobs and industrial land, indicating that the reductions are the result in a decrease in the carbon-intensity of industrial jobs, as opposed to a loss of industrial sector jobs[4]. There has also been a shift from energy intensive manufacturing, like aluminum smelting to less energy intensive manufacturing activities.

While emissions are down in other sectors, the reverse is true for transportation, see Figure 6. Over the last six years, transportation sector emissions have climbed above 1990 levels, a 14% increase from their lowest level in 2012. Transportation sector emissions are not as high as they would have been without a 2% decrease in the carbon intensity of transportation fuels. This was largely achieved by the increased use of biofuels in Oregon, including a statewide Renewable Fuel Standard that requires diesel to be blended with a minimum of 5% biodiesel and gasoline to be blended with a minimum of 10% ethanol for fuels sold in Oregon.

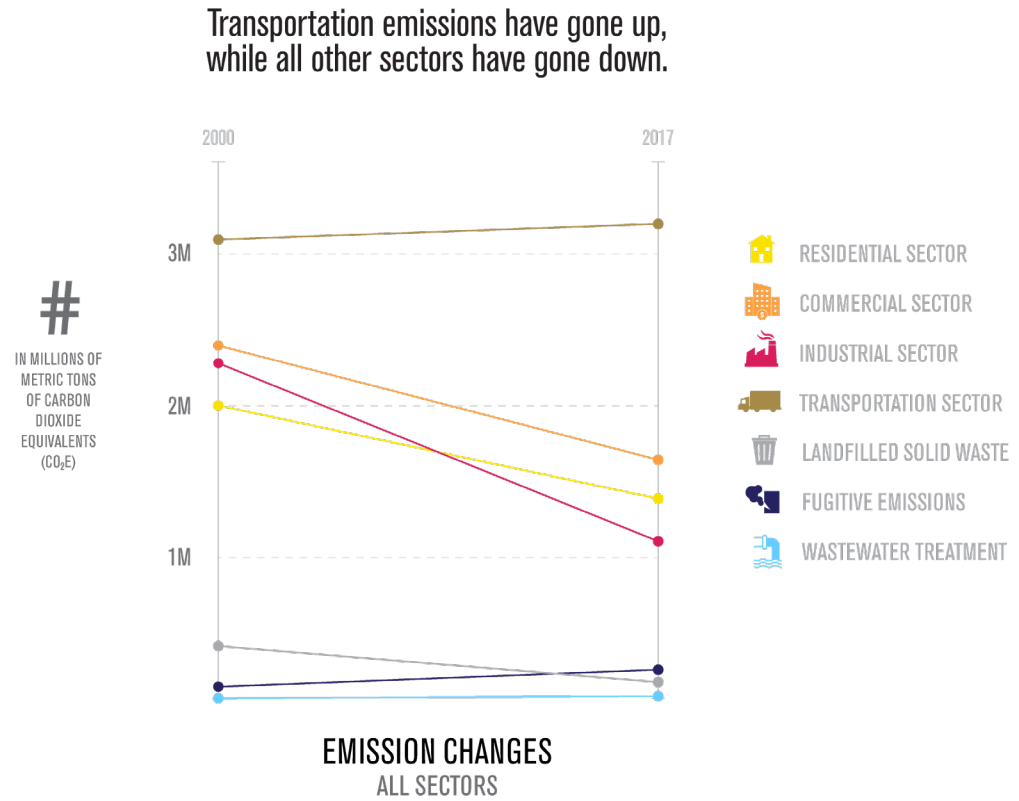

Figure 6: Since peak emissions in 2000, emissions have declined across all sectors, except for transportation which is currently 3% over 2000 levels. Due to the limited availability of data, fugitive emissions are estimated based on population and will therefore increase annually with population growth.

The following sections explore our primary emissions sources in more detail – transportation fuels, natural gas, and electricity.

Deep dive on transportation sector data

As discussed above, transportation sector emissions have increased in recent years. The increase in transportation emissions has tracked closely with recovery from the 2009 recession and are currently 8% above 1990 levels.

Transportation sector emissions come from use of transportation fuels (gasoline, diesel, propane, ethanol, biodiesel) and estimated vehicle miles travelled. These emissions are the result of driving vehicles powered by gasoline, diesel and propane, the transportation of goods, off road vehicles and equipment used for construction, and a transit system dominated by diesel buses. In recent years there have been more electric vehicles on the road, but because these vehicles are fueled with electricity – charged in people's homes and businesses without metering - the emissions are allocated to the buildings sector.

According to Metro, per person daily vehicle miles travelled (VMT) have remained relatively flat across the region since 2010, despite significant population growth. More Portlanders are on the road driving, but they aren't driving longer distances.

This section focuses on gasoline sales, see Figure 7 below, because gasoline data is the most accurate transportation fuel source at the local level. Total gasoline sales in Multnomah County in 2017 were 2% below 1990 levels, notable given the 38% increase in population over the same period.

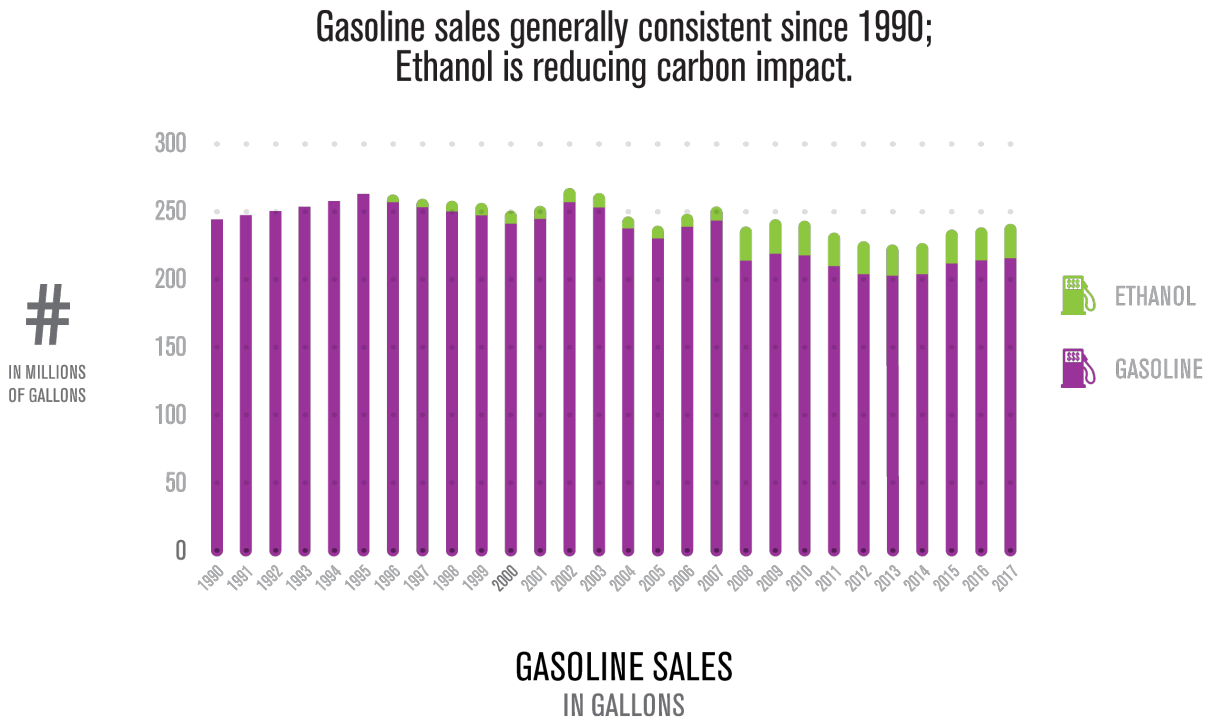

Figure 7: Gasoline sales have remained generally consistent since 1990. We've reduced the carbon emissions per unit of gasoline sold through Portland and Oregon's Renewable Fuel Standards, which require 10% ethanol in every gallon of gasoline. Gasoline sales data is available at the County level, reported by the Oregon Department of Transportation as fuel tax revenue is distributed by County.

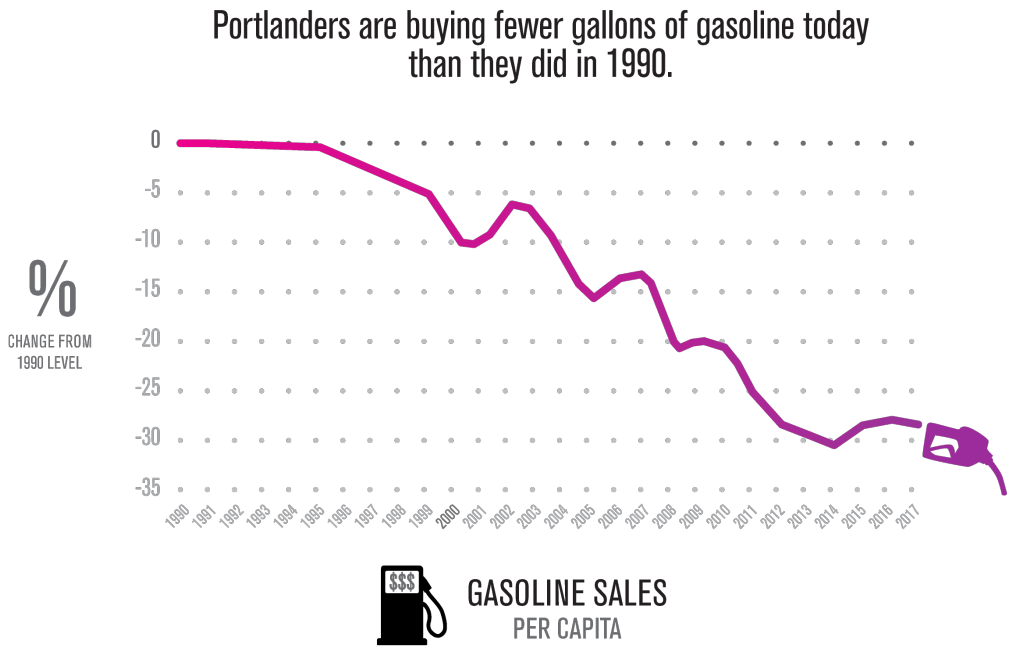

Figure 8: Since 1990 sales of gasoline per person have declined rapidly, the result of more efficient vehicles and more complete and connected neighborhoods that enable better walking, biking, and access to public transit.

Per-person gasoline sales are down 28% below 1990 levels, see Figure 8. This is the result of increasingly complete and connected neighborhoods, regional transit system investments, shifts from driving to walking and bicycling, improved vehicle fuel efficiency and use of lower-carbon fuels such as biodiesel, ethanol and electricity.

The increase in total transportation sector emissions is largely the result of more people moving to Portland and driving vehicles on our roads.

Deep dive on natural gas

Natural gas is one of the primary sources for carbon emissions in Multnomah County. Natural gas is used for heating buildings, heating water, and used in industrial processes. Natural gas accounts for 20% of total Multnomah County carbon emissions. Both the City of Portland and Multnomah County have adopted resolutions establishing a goal of 100 percent renewable energy to replace natural gas communitywide by 2050.

Since 1990, natural gas has largely replaced fuel oil for home heating and associated carbon emissions have declined as a result. Historically, natural gas has been used as a transition fuel, as it is cleaner burning fuel than fuel oil. Fuel oil sales in Portland have declined 80% since 1990. Today in Portland, only 4% of housing units are heated with fuel oil and 51% are heated with natural gas. Natural gas is the primary heating source for Portland's single-family, owner-occupied housing, see Table 1. The challenge of decarbonizing home heating will require extensive private investment and public policies to switch to lower carbon energy sources.

Table 1: Portland's owner-occupied housing stock is primarily heated by natural gas. The renter occupied housing stock is primarily heated with electricity, making these units easier to decarbonize as the electricity grid becomes more renewable. According to the US Census, 1% of Portland housing units, or nearly 2,000 units, do not have heat.

Source: U.S. Census Bureau, 2013-2017 American Community Survey 5-Year Estimates

House Heating Fuel	Number of Occupied Units	Percent Total Occupied Units	Percent of Owner-Occupied units	Percent of Renter-Occupied Units
Natural Gas	134,280	51%	71%	29%
Propane Gas	3,001	1%	1%	1%
Electricity	107,116	41%	20%	65%
Fuel Oil	10,462	4%	6%	2%
All other	4,277	2%	2%	1%
No fuel	1,813	1%	0%	1%
	260,949			

In addition, national studies have demonstrated that lifecycle emissions from natural gas extraction and distribution systems are greater than previously understood. Fortunately, NW Natural's Portland-area distribution system for natural gas is one of the best in the nation, with 100% of its cast iron and bare steel pipes having been replaced. There are still opportunities for property owners to upgrade natural gas pipes on their properties to further reduce these fugitive emissions from escaping the natural gas distribution system. Portland's emissions inventory includes federally reported fugitive emissions from the natural gas distribution system.

In 2017 NW Natural logged their highest-ever sales of natural gas in Multnomah County, 6% over the previous peak in 2000, see Figure 9 below. In 2017, compared to 2016, there was a 27% increase in residential usage and a 22% increase in commercial usage.

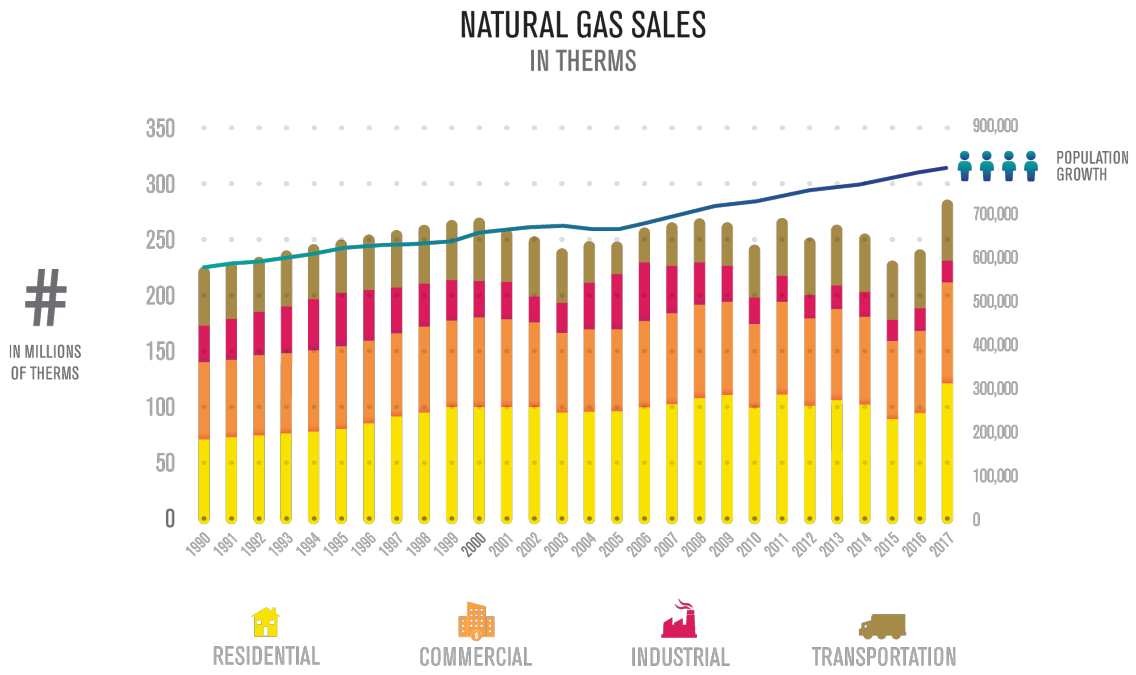

Figure 9: Natural gas sales, primarily used for heating, track with weather patterns. 2017 was an unusually cold winter, resulting in higher than average natural gas use in the residential and commercial sectors. 2017 had the highest ever natural gas sales for NW Natural in Portland, 6 percent over the previous peak in 2000. As Portland is growing we have become more efficient in the use of natural gas, reducing per person natural gas usage, primarily because buildings owners have upgraded gas furnaces and water heaters to more efficient models. Data reported by NW Natural.

This increase was not the result of new construction of gas heated units or new people moving to Portland, but the result of an unusually cold winter. Winter heating days in 2017 were higher than normal levels. 2017 was the coldest winter heating season since 2008 and 1985 before that. To provide context, natural gas usage in 2008 was 153 therms per person. In 2017 natural gas usage per person was lower, down to 150 therms per person. Therefore, even with colder temperatures, our use of natural gas today is more efficient than a decade ago. Given this, we expect natural gas emissions to decline for 2018 with a return to more normal winter heating.

Deep Dive on Electricity

Electricity is our single largest local source of carbon emissions. Electricity is used for power in all sectors. Electricity grid mix must become more renewable over time. This is even more important as electrification of our transportation system, homes, and businesses play a key role in decarbonizing the local economy. Unfortunately, the grid is not as green as we think, see figure 10. For our local utilities, Portland General Electric (PGE) and Pacific Power (PAC), 63% of electricity is still sourced from fossil fuels.

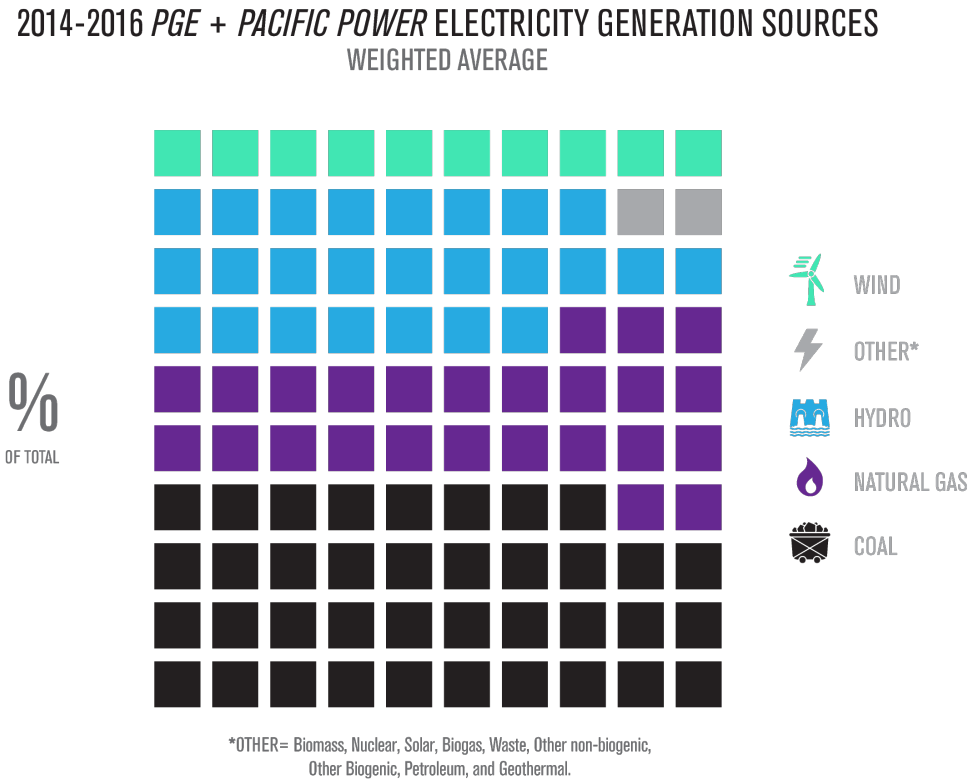

Figure 10: Weighted three-year average of electric generation sources for Portland's two electric utilities, based on data from the Oregon Department of Energy, including direct generation and grid power purchases. The data shows that 63% of Portland's electrical grid mix is sourced from fossil fuels that contribute to climate change.

PGE provides 75% of electricity purchases in Multnomah County. According to the Oregon Department of Energy[5] three-year weighted average. PGE generates or purchases electricity sourced from 28% natural gas and 29% coal. PGE generates 80% of their power and purchases 20% from the Northwest Power Pool, an organization of major utility providers in the Northern US and lower Canada.

PAC provides 25% of electricity purchases in Multnomah County. 63% of their electricity is directly generated from coal and 17% is from natural gas. PAC purchases 10% of their power from the Northwest Power Pool.

Emissions included in this paper are based on the Northwest Power Pool, with emission factors published by eGRID, for compliance with international reporting and protocols. The City of Portland also reviews emissions using utility specific emission factors on an annual basis. Using emission factors for PGE and PAC, the trends track very closely to the Northwest Power Pool emission factors, except that

PGE and PAC emissions are higher due to the lack of hydroelectric generation, as compared to the Pacific Northwest grid as a whole.

As we seek to move more sources to electricity, we must also work to reduce the carbon intensity of the grid. Currently a 50% reduction is required by the Oregon Renewable Portfolio Standard by 2040, but only 15 to 20% is renewable today. Both the City of Portland and Multnomah County have adopted resolutions establishing a goal of 100 percent renewable electricity communitywide by 2035.

As shown in Figure 11, electricity purchases peaked in 2000 and have generally declined since. Currently grid power purchases (excluding voluntary green power) are down 5% below 1990 levels, even with a 38% increase in population over the same period. Figure 11 shows grid electricity purchases by sector. The slow reduction in energy use speaks to the need to accelerate energy efficiency investments to reduce per person electricity use. The figure also shows the share of electricity purchases for voluntary green power, which have helped to reduce overall emissions from electricity.

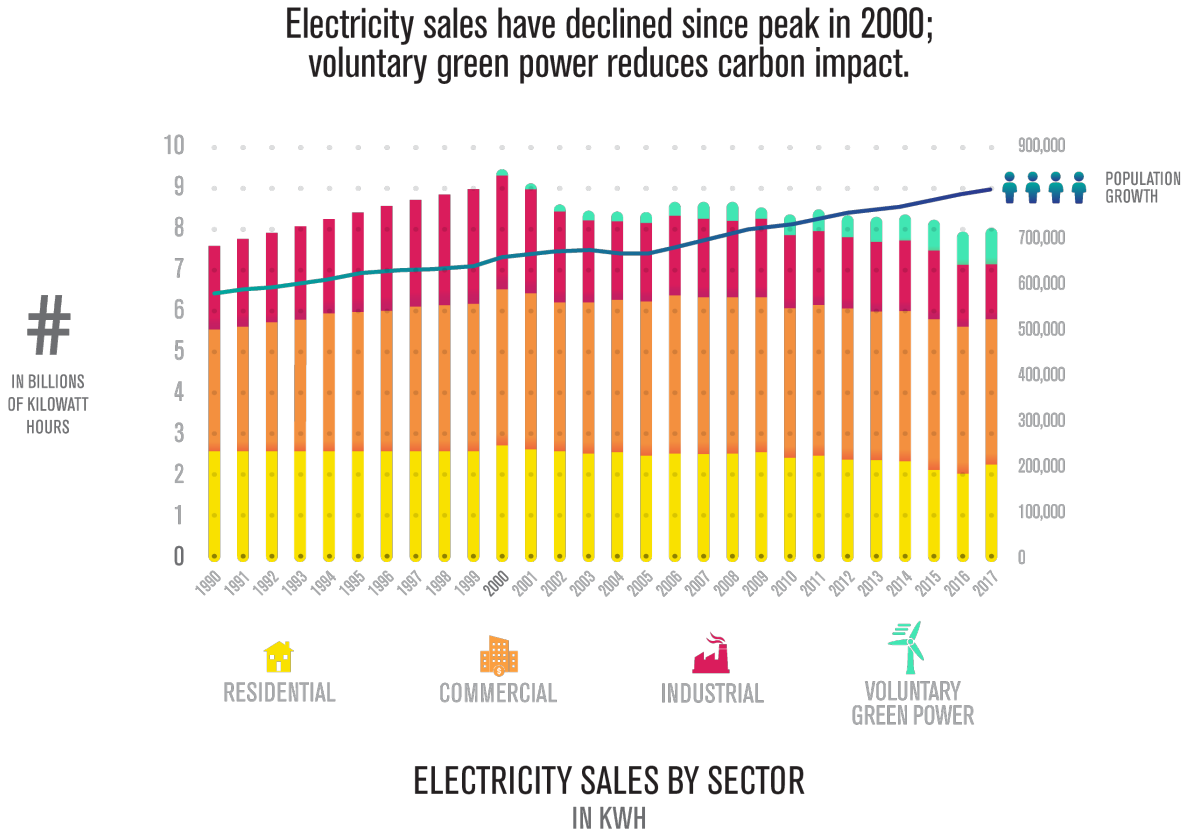

Figure 11: Electricity sales for Portland General Electric and Pacific Power have declined from their peak in 2000, even with significantly more people in Multnomah County. Electricity is primarily used to power lighting and electronics. Although 41% of Portland's housing units are heated with electricity, mostly in multifamily buildings. Half of all electricity use is from the commercial sector, primarily used to power lighting, water heating, refrigeration, air conditioning and ventilation. Voluntary green power purchases by utility customers have helped to reduce carbon emissions that result from electricity generation. Data reported by Portland General Electric and Pacific Power.

Voluntary green power purchases are electricity purchases where the customer has selected to pay a higher rate for green power. These voluntary green power purchases require utilities to procure more renewable energy and do not count towards State Renewable Portfolio Standard targets. Voluntary

green power purchases have increased year over year since 2000, see Figure 12. These purchases help reduce overall emissions from electricity generation. Portland has one of the highest participation rates in voluntary green power programs in the country, with participants accounting for more than ten percent of all electricity purchases.

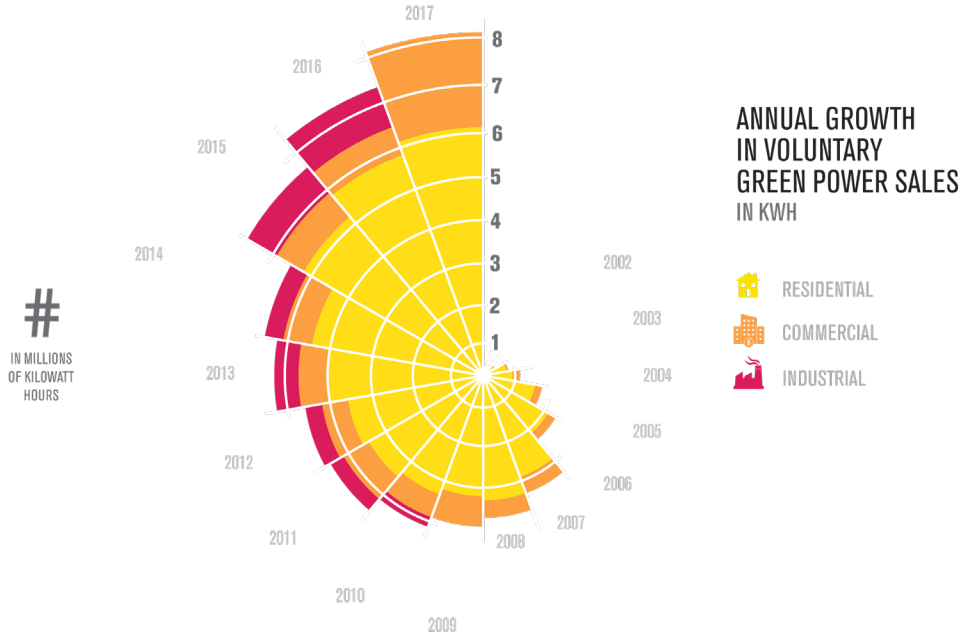

Figure 12: Both of Portland's electric utilities have been nationally recognized for their successful voluntary green power programs. These programs have seen year-over-year growth and currently account for 10% of all electricity sales. Data reported by Portland General Electric and Pacific Power.

Over the same period, Portlanders have invested in solar photovoltaic panels, or solar panels. Solar panel installs have continued to grow, even with reduced State and Federal incentives, see figure 13. Collectively, Portlanders have installed more than 4,600 solar systems, generating 34 MW of power annually. In terms of carbon emissions, that's the equivalent of driving 62 million miles per year.

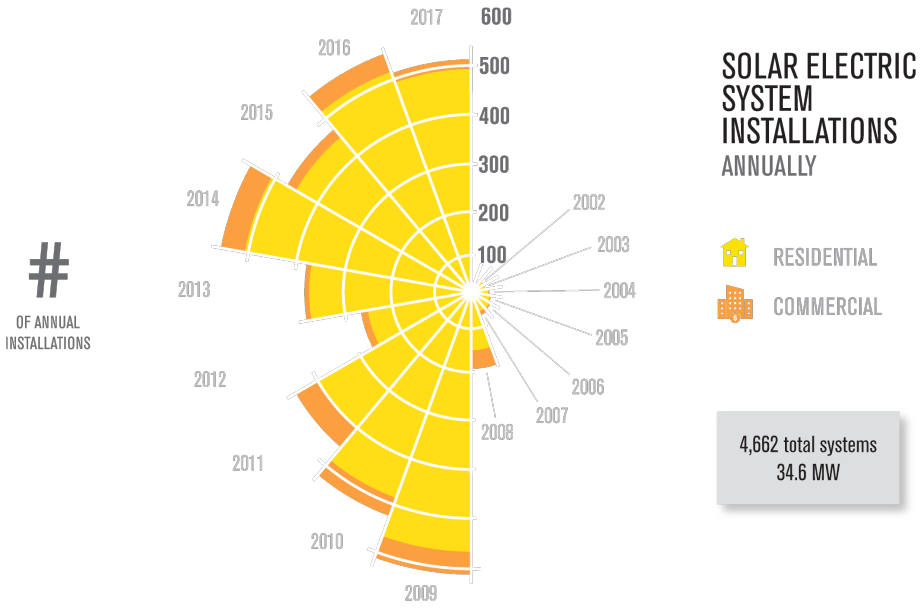

Figure 13: Solar installs in Portland remain strong, even with declining state and federal incentives. There is much more opportunity for cost effective large-scale solar systems on commercial and industrial facilities. The State's new community solar program should enable more Portlanders to benefit from renewable solar energy. Data reported by Energy Trust of Oregon.

Solar electric systems are an important part of our overall grid mix and a pathway to decarbonize our energy supply by 2050. Solar electric systems are challenging at a small scale, however, and not every home can accommodate solar panels. Opportunities exist to focus investment on larger utility scale solar facilities, these could include commercial and industrial solar installs, or community solar.

> ***"Community solar"*** *means solar photovoltaic energy systems that provide owners and subscribers the opportunity to share the costs and benefits associated with the generation of electricity. Subscribers receive credits on their utility bill for a share of the solar electricity generated by a community solar project.*

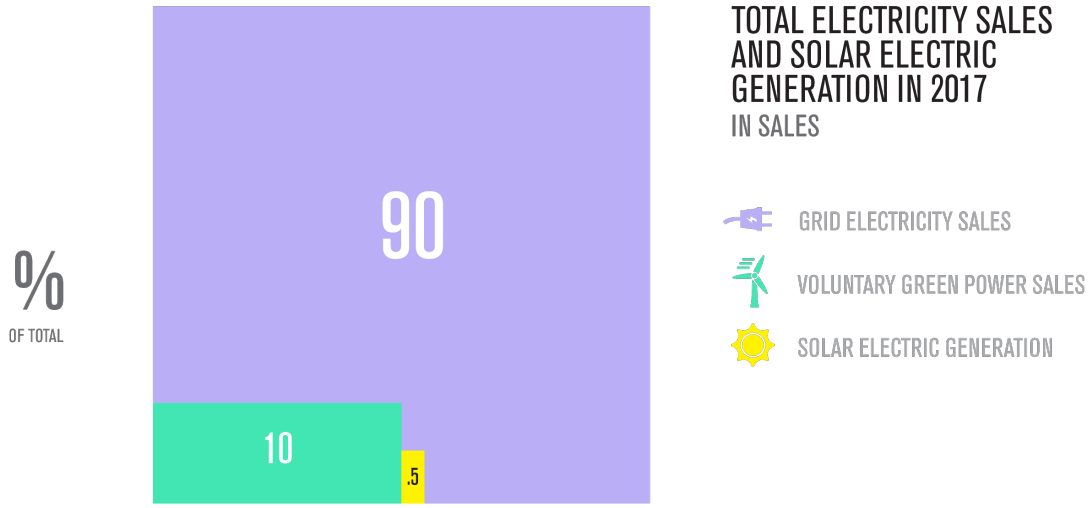

Figure 14: Portland's total electricity use is offset partially by voluntary green power purchases (10% of electricity used) and solar electric systems (.5% of electricity used) installed on Portland's homes and businesses. Data reported by Portland General Electric, Pacific Power, and Energy Trust of Oregon.

Investments in voluntary green power purchases remain an important way to reduce carbon emissions from electricity purchases, see figure 14. In addition, PGE is now offering a green tariff – Green Future Impact program - that provides customers with bundled renewable energy certificates. To strengthen its renewable energy commitment, the City of Portland infrastructure bureaus enrolled in PGE's Green Future Impact program. Starting in 2021, the City will receive 46,600 annual megawatt-hours – approximately 40 percent of its annual PGE electricity load- from a new solar facility in Central Oregon.

Renewable energy certificates (RECs) *are tradeable, market-based instruments that represent the legal property rights to the environmental attributes of one megawatt-hour (MWh) of renewable electricity generation. A REC is issued for every MWh of electricity generated and delivered to the electric grid from a renewable energy resource. Electricity cannot be considered renewable without a REC.*

Unbundled Renewable Energy Certificates (RECs) refer to RECs that are sold, delivered, or purchased separately from electricity. RECs provide no physical delivery of electricity to customers and as such the customer is purchasing power from a separate entity than the one selling them the REC. A bundled REC is when the customer is purchasing the electricity and the REC together from the same utility.

Inventory methodology changes

Portland tracks carbon emissions annually. Since the 2017 Progress report, staff have worked to update emissions inventories in accordance with the new Global Protocol for Community-scale GHG Emission Inventories to stay in alignment with Paris Agreement (limiting global warming to 1.5 degrees Celsius).

Protocols

By updating protocols, Portland stays in alignment with other cities around the world, enabling better tracking against long range goals with greater confidence. Updating protocols is a challenge for cities and can create discrepancies with previously reported emissions. For example, to move to the global reporting protocol, Portland had to update accounting methods for emissions from landfilled waste, wastewater treatment, and fugitive emissions. This required finding new data sources all the way back to the 1990 baseline to consistently compare data year over year.

The City of Portland utilizes multiple emission protocols to compare results and better refine estimates of emissions produced locally. By reviewing data using different protocols, Portland can make up for gaps in individual methodologies. For example, Portland reports electricity sector emissions by greenhouse gas, a level of detail only available for the Northwest Power Pool, although as discussed above, those emissions are lower than the emissions from Portland's two electric utilities. Therefore, the use of multiple protocols allows Portland to better understand what's happening locally.

The time required to find and evaluate new data sets for a protocol change delays the frequency of emissions inventory reporting. Changes to protocols that affect data collection and carbon accounting limit comparability with previously reported data using older methodologies. With a baseline year of 1990, protocol changes create substantial new work as more than 20 years of inventories need to be consistently updated.

Changes in data sources

This 2017 inventory includes a variety of new data sources and emission factors that have been applied back to the 1990 baseline. New data sources increase annual emissions as they are added to the inventory. These changes help improve the accuracy of the emissions inventory but can negate comparability with previously published emissions.

New data sources include:

- New eGRID electricity emission factors for 2014 and 2016, (US EPA)
- Waste incineration, (Oregon DEQ)
- Improved estimates of propane use, (US EIA)
- Better accounting of emissions from wastewater treatment and septic tanks, (Oregon DEQ)
- Better accounting of fugitive emissions (NW Natural, US EPA, Oregon DEQ)

Reporting carbon emission data

Portland reports emissions annually through the Carbon Disclosure Project for compliance with international agreements, like the Covenant of Mayors and C40's Deadline 2020. Portland will continue to monitor and report on annual carbon emissions, noting when changes are made to methodologies that limit comparability with previously reported data. When data is fully updated, the emission data are released publicly through Climate Action Plans, Progress Reports, or periodic publications like this one.

Liquid Storage Tanks at the Critical Energy Infrastructure (CEI) Hub

Seismic Assessment of Tank Inventory

May 2019

ACKNOWLEDGEMENTS

This report was written for the city of Portland's Bureau of Emergency Management (PBEM). The work was conducted though a collaboration between Mapleaf LLC and Portland State University.

Appreciation is extended to Anne Castleton, Ph.D., Emergency Management Coordinator with the Bureau of Development Services, City of Portland, for her insightful questions and perspectives.

REPORT SUMMARY

Seismic vulnerability of the Critical Energy Infrastructure (CEI) hub in Portland has been recently highlighted in several regional resiliency assessments. This report focuses on the liquid fuel storage tanks located at the CEI hub due to the adverse consequences of failure. General structural and geotechnical damage of similar facilities were identified by reviewing the seismic performance of liquid fuel storage tanks during past earthquakes. Data was then gathered on the storage tanks at the CEI hub and analyzed in an effort to quantitatively assess the tank inventory. There are nine different companies with hundreds of in-service tanks holding various forms of liquid products that have a potential storage capacity of over 8.6 million barrels. Over 95% of this capacity can be stored in large tanks that are 25ft in diameter or larger. The majority of the large tanks were built prior to 1970s and the vast majority prior to 1990s, eras when regional seismicity and seismic design were not fully appreciated or developed. Consequently, the structural and geotechnical issues revealed in tanks from past earthquakes are likely to manifest at the CEI hub unless mitigation steps are taken to minimize the risk. A conceptual order of magnitude cost of seismic mitigation for the large capacity tanks was estimated to exceed $300 million. This estimate made gross assumptions on soil mitigation, structural anchoring and design/permitting costs and did not consider fuel distribution past the tanks. Based on the findings and associated limitations of this study, recommendations are made for next steps that would fill gaps in existing data and generate new critical knowledge to better quantify and mitigate the seismic risk of this critical facility.

INTRODUCTION

BRIEF BACKGROUND

The six-mile stretch of industrial land along the west shore of the Willamette River in Northwest Portland is often referred to as the Critical Energy Infrastructure (CEI) hub. Energy facilities in the CEI hub include liquid fuel port terminals, storage tanks, pipelines and transfer stations, natural gas transmission and storage, electrical substations, and high voltage transmission lines. There are no petrochemical refinery operations in Oregon, so all of Oregon's liquid fuel is imported and over 90% is stored at fuel storage facilities in the CEI hub. This includes gas and diesel for the Portland metro area and all of the jet fuel for the Portland International Airport. These liquid fuel storage facilities are located along the river with the original intent for ships to import the fuel through port terminals. Now, most of the liquid fuel is brought in and out through pipelines. Numerous reports have highlighted the criticality of the CEI hub, the interconnectivity and the general earthquake risk to Portland and to the State (DOGAMI 2012, Bureau of Planning and Sustainability 2012, OSSPAC 2015, City Club of Portland 2017).

PURPOSE OF STUDY

The purpose of this study was to focus on the liquid fuel storage aspect of the CEI hub and more specifically the storage tanks that hold the fuel. The storage tanks were chosen because they are some of the most visible aspects of the hub and pose the greatest risk if the tanks were to fail. The risk includes not only the regions inability to access fuel following a major earthquake, but also health and environmental concerns should failure occur.

This report summarizes the findings of the study, which had three main goals:

- Review past earthquake experiences from available literature of liquid fuel storage facilities in order to identify common vulnerabilities and key factors leading to tank damage and failure.
- Gather data from publicly available sources to identify the quantity and characteristics of the tanks and the supporting soil at the CEI hub. Contrast the information with past earthquake observations in order to gain a better appreciation of the expectations for seismic performance of the fuel storage tanks at the hub.
- Review potential mitigation options that aim to enhance the seismic performance of liquid storage tanks and estimate order-of-magnitude costs for implementing the mitigations.

The subsequent sections of the report address the above goals in a similar chronological order.

EARTHQUAKE DAMAGE TO LIQUID FUEL STORAGE TANKS

OVERVIEW FROM PAST EARTHQUAKES

Liquid petroleum products are commonly held in cylindrical, above-ground storage tanks. These are relatively simple structures comprised of a soil supported base-plate, a welded or riveted steel wall supported on a ring reinforced concrete foundation and a roof. The tanks are often categorized by their roof type; floating or fixed. To store liquids with low vapor pressures, such as propane, butane, or kerosene, a fixed roof tank is required to maintain pressure. For liquids that do not need to be pressurized for storage, floating roof tanks are utilized. As liquid is drained from a floating roof tank, the roof descends with the liquids surface and prevents the buildup of vapors that would otherwise form in the void of a fixed roof tank. Floating roof tanks are desirable for products such as crude oil, gasoline and diesel. The presence or absence of a floating roof in a large tank can influence the dynamic behavior when shaken by an earthquake.

Above ground storage tanks are well known to be vulnerable to seismic events. Since their simple design has been relatively unchanged for over a century, their seismic reliability has been tested numerous times. Previous earthquakes involving documented cases of tank damage are listed in Table 1. Selected examples from these earthquakes are used in the following sections to highlight some of the common vulnerabilities and the resulting damage.

Table 1: Earthquakes with Documented Significant Damage to Fuel Storage Tanks

Location	Magnitude	Date
Tokyo, Japan	8.3	September 1, 1923
Long Beach, California	6.4	March 10, 1933
Kern County, California	7.3	July 21, 1952
Prince William Sound, Alaska	9.2	March 27, 1964
Niigata, Japan	7.6	June 16, 1964
San Fernando, California	6.5	February 9, 1971
Managua, Nicaragua	6.3	December 23, 1972
Miyagi-Ken-Oki, Japan	7.7	June 12, 1978
Imperial County, California	6.5	October 15, 1979
Greenville, California	5.9	January 24, 1980
Central Greece	6.7	February 24, 1981
Coalinga, California	6.2	May 2, 1983
Loma Prieta, California	6.9	October 17, 1989
Marmara, Turkey	7.6	August 17, 1999
Tōhoku, Japan	9.0	March 11, 2011

STRUCTURAL DAMAGE

Although there are some references to an event in 1923 in Tokyo, the first reasonably well-documented case of damage to oil storage tanks followed the 1933 earthquake in Long Beach, California. The earthquake affected an industrial area that produced, refined, and stored petroleum. Complete tank failures were reported at three different locations, all less than 30 miles from the epicenter of the magnitude M6.4 earthquake. Peak ground acceleration (PGA) of 0.19g recorded at stations with similar distance from the epicenter were thought to be representative of those at the storage tanks (Housner 1952). Many tanks exhibited distortion, elongation, strain in riveted joints and buckling of the roof plates. Two of the tanks' riveted joints failed and while the tanks did not collapse as a result, the oil leaked. In one group of tanks, three partially full tanks sustained no damage while a full tank experienced total failure. The lost oil overcame the firewall and damaged neighboring buildings over 300 ft away (Nielsen & Kiremidjian 1986). There were other failures including overtopping where the roof was found 200 ft from the failed tank as shown in Figure 1. Other tanks did not necessarily fail in their structure, but were not anchored and separated from the inlet/outlet (I/O), resulting in loss of the oil. All failed tanks were of riveted construction and their structural failures were due to damage in the tank shell. The behavior of riveted shell wall tanks differs from the newer, welded shells construction. The long beach earthquake demonstrated that structural vulnerabilities of tanks relate to the riveted shell construction, to how full the tank is and to the connectivity of the I/O piping.

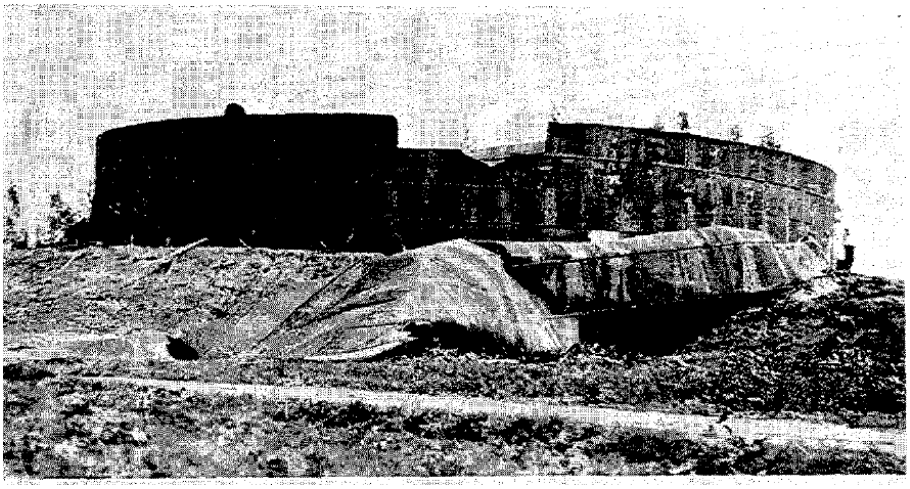

Figure 1: Failed Tank following 1933 Long Beach Earthquake (Cooper 1997)

The Great Alaskan earthquake of 1964 significantly influenced numerous aspects of earthquake engineering and also highlighted the vulnerability of petroleum storage tanks. The magnitude M9.2 subduction zone earthquake is the most powerful earthquake on record in North America. At the time of the earthquake,

the petroleum industry was Alaska's largest mineral industry and damage to petroleum storage facilities was reported in the cities of Valdez, Whittier, Seward, Anchorage, and Nikiska. Direct structural damage to fuel storage tanks included: shell buckling near the bottom of the tank, buckling of cone roofs and top courses of shells, damage to floating roofs and accessories, and damage to I/O connecting piping (Rinne 1967). These were the result from liquid sloshing induced deformations, hydrodynamic pressure acting on the tank walls, shear force and overturning moment acting at the base of the tank, the buckling strength of tanks and, uplift on the axial stresses acting on the tank wall in contact with the ground. Sloshing can damage the top of the tank and can also result in roof damage. Buckling of the steel shell near the bottom of the tank is referred to as elephant-foot buckling. An example of roof damage and elephant-foot buckling is photographed in Figure 2. This type of damage usually occurs in tanks with a low height to radius ratio. Many tanks experienced elephant-foot buckling in this earthquake, all of them were near full capacity. Extreme elephant-foot buckling had resulted in leakage and also complete collapse. Sudden loss of oil from a leak can produce suction that implodes the roof of a tank. The structural damage to fuel storage tanks following the Great Alaskan earthquake exposed vulnerabilities even when the tank shells were welded.

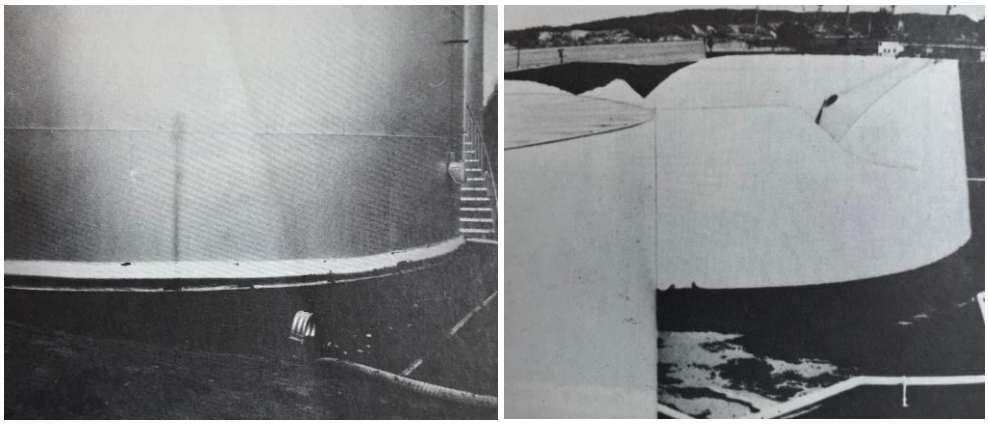

Figure 2: Elephant Foot Buckling (left) and Roof Collapse (right) following 1964 Great Alaskan Earthquake (Hanson 1973)

In 1978, a magnitude M7.4 earthquake occurred of the east coast of Japan with the epicenter approximately 95 km to 120 km from several oil storage or refineries. The peak ground acceleration near Sendai City was thought to have exceeded 0.25 g. The complex of over 87 fixed and floating roof tanks containing various petroleum products was constructed in 1971 and had been designed with reasonable seismic criteria. All piping as well as the tanks were anchored, where the tank anchors were located around the perimeter and embedded into a concrete pad (NBS 1980). Stretched anchor bolts indicated that tank uplift was limited to approximately 6 inches. Three crude oil tanks failed and the contents spilled. The

tanks were surrounded by a reinforced concrete dike, but the volume of spilled oil exceed the capacity of the dike and the oil escaped as shown by the dark areas in Figure 3. The top of the fixed roof tank buckled inward due to low pressure caused by rapid evacuation of the oil through the ruptured connection of the base and wall of the tank. While containment areas in the form of dikes or walls are common, the consequence of failure of fuel storage tanks can extend beyond these containment areas due to overtopping following multiple tank failures or due to potential earthquake damage to the walls themselves.

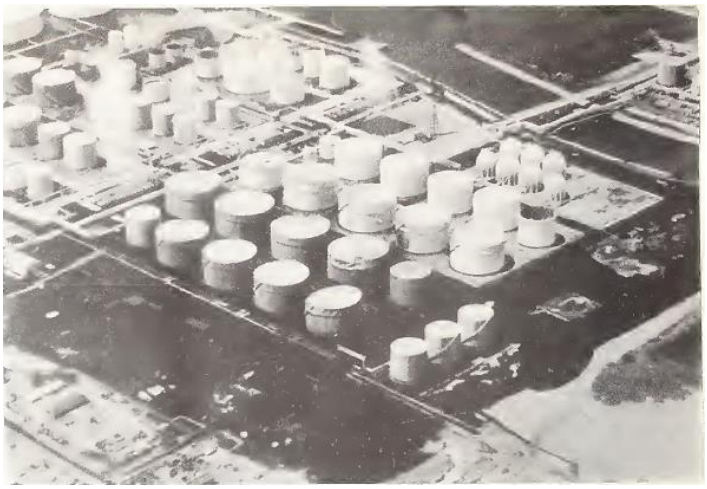

Figure 3: Spilled Oil Past the Containment Dikes following 1978 Earthquake in Japan (NBS 1980)

SOIL INDUCED DAMAGE

There are two major aspects of soil behavior during an earthquake that can influence the overall damage to the fuel storage tanks; amplification and liquefaction. Amplification of the ground motion has been recognized and documented for soft soils in numerous earthquakes, including the iconic 1985 Mexico City and 1989 Loma Prieta. The resulting accelerations manifest in the severity of the above discussed structural damage. Liquefaction of the ground on the other hand, can result in additional damage that is related to permanent settlement of the ground or to lateral soil movement referred to as lateral spreading.

The Great Alaskan earthquake of 1964 resulted in numerous examples of damage caused by liquefaction. Another 1964 earthquake occurred in Japan and was a magnitude 7.6 near the city of Niigata. Two oil refineries were located near a river and had liquid fuel storage tanks built on loose sandy ground. Settlements due to liquefaction were observed to be 8 to 12 inches on compacted ground and up to 20 inches of unequal settlement in uncompacted sand. These resulted in many damaged tanks in both refineries. In contrast, newly built tanks constructed

on compacted soil at the refineries settled uniformly, and approximately 1 in. These tanks exhibited minimal to no damage and remained operational, while surrounding tanks were severely damaged from large ground settlement (Watanabe 1966).

Liquefaction induced lateral spreading can move entire tanks or cause relative ground deformations of the tank. During the 2011 Tohoku subduction zone earthquake, surrounding soil spread and caused uplift on the side of a tank of approximately 20 inches, resulting in the tank cracking and the contents leaking out (Zama et al 2012). An example of tank settlement and of lateral spreading induced uplift is photographed in Figure 4. In addition to damaging the tank itself, liquefaction can sever I/O connectivity. These examples underscore that minimizing the effects of liquefaction can minimize the risk of damage to liquid fuel storage facilities.

Figure 4: Liquefaction Induced Settlement following 1964 Niigata and 2011 Tohoku Earthquakes in Japan (Watanabe 1966, Zama et al 2012)

FIRE

While fire can be thought of as a secondary effect resulting from the damage caused by the earthquake, it is particularly relevant given the volatile contents of the tanks. Numerous instances of fires at liquid fuel storage facilities following an earthquake have been reported, with examples provided in Figure 5. Approximately 37 miles from the epicenter of the Great Alaskan earthquake, oil storage tanks were constructed in the port city of Whittier on fill that consisted of delta deposits and glacial outwash. All of the storage tanks were completely destroyed by a fire that broke out and burned for three days. The fire, and subsequent tsunami, destroyed the evidence and the cause of the fire was never determined. Two possible causes included a live power line that was snapped during the earthquake, or fuel from a leaking tank could have spilled into an operating boiler (Kachadoorian, 1965).

A refinery was located approximately 19 km from the epicenter of magnitude 7.4 earthquake near Istanbul, Turkey. Constructed in 1961 and expanded in 1974 and

1983, the facility had a large tank farm with over 100 unanchored, aboveground liquid storage tanks. The tanks were designed by American contractors adhering to seismic design code of California in 1961 (Sezen & Whittaker 2004). The damage at the refinery is thought to have been largely overlooked due to the extensive damage in more populated areas. The majority of the damage was caused by a fire that was ignited by sparks created from the collision of a metallic floating roof seal against the tank wall. The tanks contained naphtha, a highly volatile and flammable petroleum product. A total of 6 tanks of diameter 33ft to 82 ft, completely burned down. The fire spread to other tanks and 30 of the 45 floating roof tanks were damaged (Yazici and Cili 2008). More recent examples of fire at fuel storage was also observed in 2011 Tohoku, Japan in different refineries built in 1963 and 1971. The fire was attributed in different instances to damage to the tanks themselves or to leaks in the surrounding pipes. In these examples, fire remains a threat to fuel storage facilities despite construction practices that had at least some awareness of the associated earthquake risk.

Figure 5: Fire Caused by Tank Damage following 1999 Turkey (left) and 2011 Tohoku Earthquakes (right) (French Ministry of Ecology, Sustainable Development and Energy, 2013)

LIQUID FUEL STORAGE TANKS AT THE CEI HUB

OPERATING COMPANIES

While the CEI Hub is generally referred to as a singular area, the liquid storage tanks are actually clustered in a few distinct locations and are owned by different operating companies. Map with relative locations of the various companies between U.S. Route 30 and the Willamette River is shown in Figure 6. The majority of the fuel storage facilities are either near the Linnton neighborhood to the north or within the Northwest Industrial Area to the south.

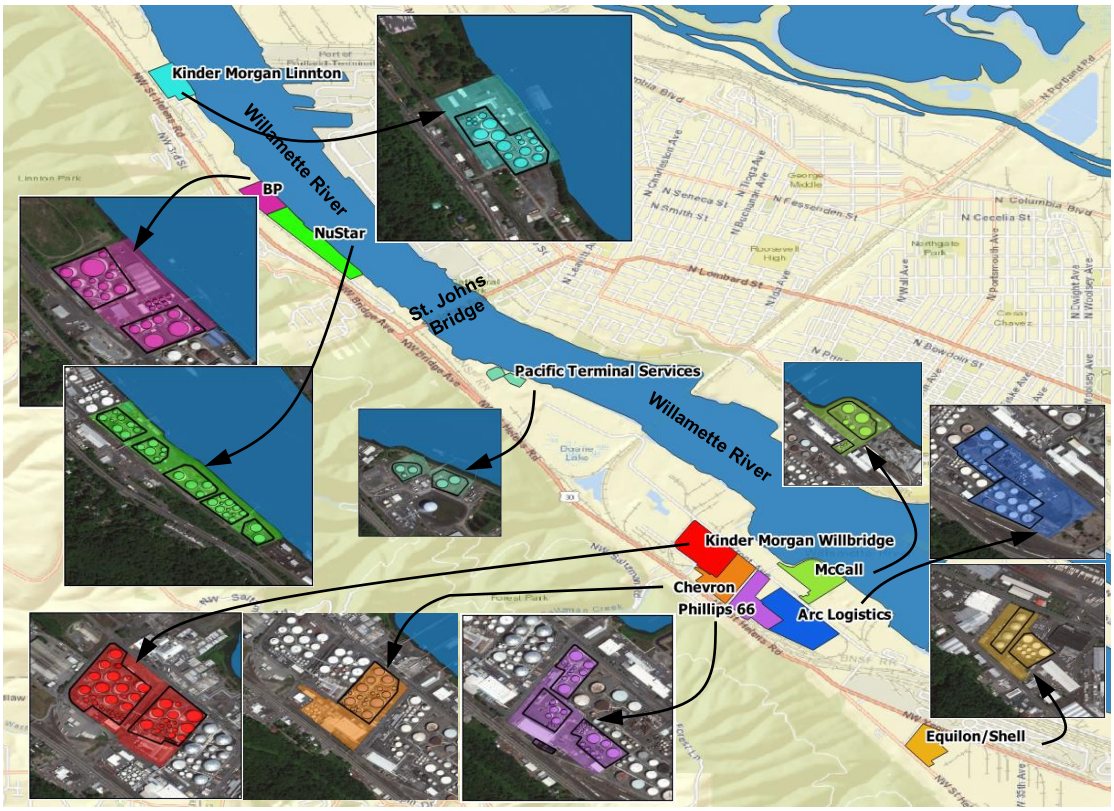

Figure 6: Companies with Liquid Fuel Facilities at the CEI Hub (background Google Maps)

The petroleum storage tank owners are required to submit an oil spill contingency plan to the Department of Environmental Quality (DEQ). In 2015 Oregon Public Broadcasting (OPB) made a public records request and attained records from seven owners of liquid fuel storage tanks (Schick 2015). These included BP, Chevron, Kinder Morgan, McCall, NuStar, Pacific Terminal Services and Phillips 66. Further queries into the City of Portland permits

database indicated that no additional fuel storage tanks were constructed since 2015, making the data set relevant to date. In addition to this dataset, two additional companies were identified through review of The City of Portland Bureau of Planning and Sustainability documentation from 2016 (Bureau of Planning and Sustainability 2016). These companies were Arc Logistics and Shell/Equilon.

In all, there were 10 properties with liquid fuel storage tanks, owned by 9 different companies. Within each property, large tanks appear to be collocated within shared secondary containment areas that are built to contain potential spillage or leaks. These containment areas are typically intended to contain the volume of the largest tank in the group and are constructed using soil dikes or structural walls. No data was found related to the secondary containment aspect of the facilities in any of the properties, so the areas were manually traced and acreage calculated based on satellite imagery. The resulting tank locations and associated containment areas are depicted in Figure 6 via zoomed in details for each property. The acreage and the number of storage tanks are summarized in Table 2 for each company. To help parse the data when available, the tanks were grouped into tank diameters that were 25 ft and larger or smaller than 25 ft.

Table 2: Total Area and Fuel Storage Overview

Company	**Site Area** (acres)	**Secondary Containment** No.	(acres)	**No. of Storage Tanks** ≥ 25ft	< 25ft	**Tank Capacity** (million Gallons) ≥ 25ft	< 25ft
Kinder Morgan							
Linnton Terminal	13	1	5.5	19	14	20.4	0.3
Willbridge Terminal	33	2	17.0	46	88	70.0	1.5
BP	18	2	5.6	26	6	23.9	0.0
NuStar	22	5	11.8	31	4	53.4	0.1
Pacific Terminal Services	2	2	3.2	5	2	11.6	0.0
Chevron	21	1	8.5	35	109	47.4	3.0
Phillips 66	21	4	10.8	36	61	29.3	1.1
McCall	19	2	10.0	10	16	40.0	0.5
Arc Logistics	39	2	14.0	25		61.6	
Equilon/Shell	38	2	6.8	13		16.8	

TANK TYPE AND QUANTITY

The records for seven of the companies list a total of 514 tanks, of which 146 were tagged to be out-of-service (O.O.S). While it is unclear if O.O.S. tanks could be brought back to service, examination of aerial photographs of some of the known locations of large O.O.S. tanks show visual signs of tank deterioration that make that possibility less likely. The data for each tank include the storage capacity, substance, and year built for each tank. Tank type is also included, although this identification is not consistent across the different companies.

Phillips 66 reported container type as welded or riveted steel while the others reported container type by the roof characteristics (e.g. floating roof, fixed roof, cone roof, vertical fixed roof). There were no tank details available for Shell/Equilon and Arc Logistics, so the additional 38 tanks were estimated from satellite imagery. The number of tanks breakdown along with the fuel storage capacity for each of the companies is summarized in Figure 7. Given that floating roof tanks can exhibit different dynamic behavior to fixed roof under earthquake motion, the tank types are differentiated where known.

Discounting the O.O.S. tanks, there are at least 362 tanks with a total capacity of 8.64 million barrels (362.9 million gallons) of liquid product of various types. Despite approximately 40% of the tanks being 25 ft in diameter or larger, they can hold over 95% of the total volume capacity. The total volume is not present on site at any given time because the tanks are not always full. The average fill varies, nonetheless there is a significant amount of liquid fuel products stored in above ground storage tanks at the CEI Hub. There also appear to be a wide spectrum of tank types. The tank construction includes riveted and welded, as well as fixed and floating roof. The variability in construction and tank type make relevant all of the aforementioned structural damage vulnerabilities exposed by past earthquakes.

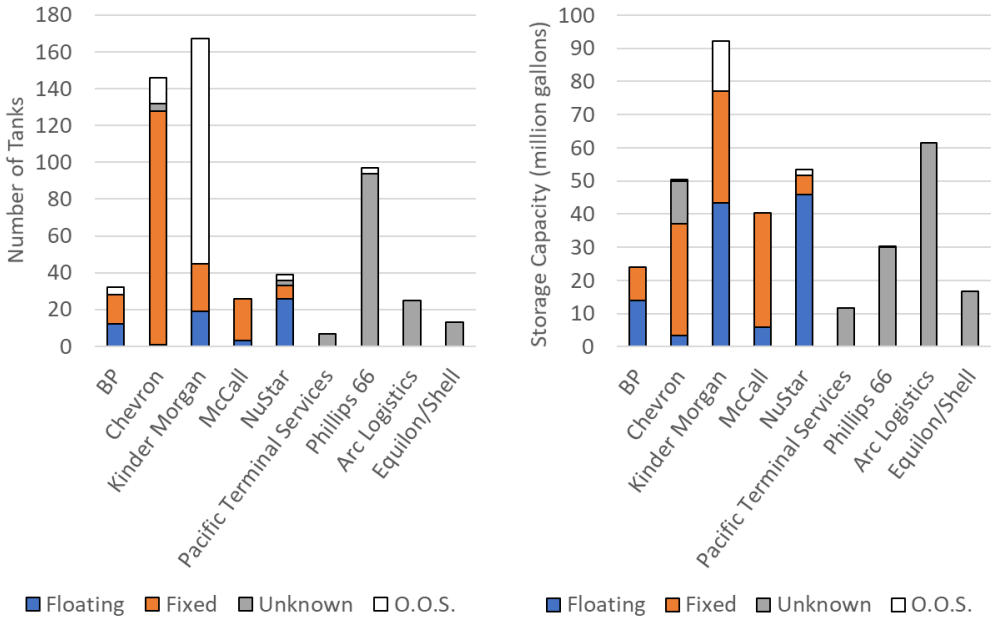

Figure 7: Number of Tanks (left) and Total Storage Capacity (right) by Company

TANK AGE AND SIZE

Knowledge about a seismic hazard evolves over time. In Oregon, our understanding of the threat of the looming Cascadia Subduction Zone (CSZ) has only come to light in the last 20 years. Design standards follow and therefore the age of any structure is often a strong indicator of the potential vulnerability. To get a sense of the age of the tank inventory at the CEI Hub, the tank age is summarized in Figure 8 by showing the number of in-operation storage tanks built within a particular decade. Within each decade, the number of tanks are binned by the tank diameter in increments of 20 ft. This allows for a visual representation of the physical size of the tank and indirectly the volume of fuel capacity. The tank diameters were only provided for approximately half of the tanks. Regression model based on the tank volume and the known tank diameters was developed and used to estimate the tanks for which diameters information was not available.

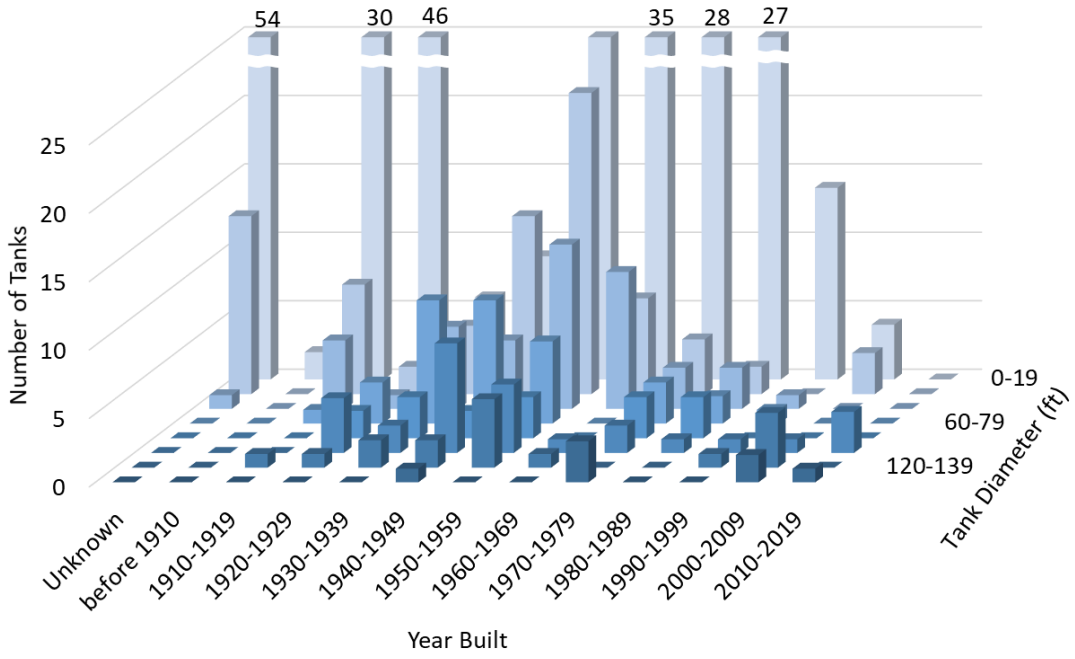

Figure 8: Distribution of In-operation Tank Age and Size

There are numerous in-service large tanks built prior to 1930s. Most significantly, majority of the tanks and majority of the fuel capacity within the hub has been built prior to 1960s. Even if the designers were fully aware of the seismic hazard, this time frame is prior to any design and performance lessons learned from the damaging Great Alaskan earthquake of 1964 and the many other

documented earthquakes that followed. The next construction active period in the CEI hub spanned 1970s-1980s, with only a few large tanks built in the last couple of decades.

The industry standard for the design of petroleum storage tanks is published by the American Petroleum Institute (API); API Standard 650 establishes the minimum design requirements for welded tanks. It is unclear what standards were used for the design of the tanks as the City of Portland had not been overseeing these non-building structures. Even so, the seismic load requirements in Portland have significantly increased for buildings during the 1990s, reflecting the state of science of the regions seismicity. Regardless of the design standards followed, the vast majority of the tanks were constructed with minimal, if any, considerations of seismic loading given their vintage.

SOIL CHARACTERIZATION

Detailed subsurface information at CEI hub in general is very limited. Based on the available information, loose to medium dense silty sand lie below the groundwater table and the soil is susceptible to liquefaction (Beaty et al 2014). There is also a possibility of landslides from the nearby slope entering the area. Raster data that included permanent ground deformations from liquefaction was made available by the Oregon Department of Geology and Mineral Industries (DOGAMI 2012) and was overlaid on the fuel storage facilities as shown in Figure 9. Because of the proximity to the river, the permanent ground deformations due to liquefaction and lateral spreading is expected to be very high at all fuel storage tank locations. The underlying raster data is a high level assessment and serves only as an indicator for liquefaction risk at any particular location within the hub. More detailed geotechnical assessment would be needed to quantify the severity, nonetheless, liquefaction clearly poses a significant risk for all of the liquid fuel tanks in the CEI Hub. If left unmitigated, the seismically induced damage observed in past earthquakes is likely to manifest.

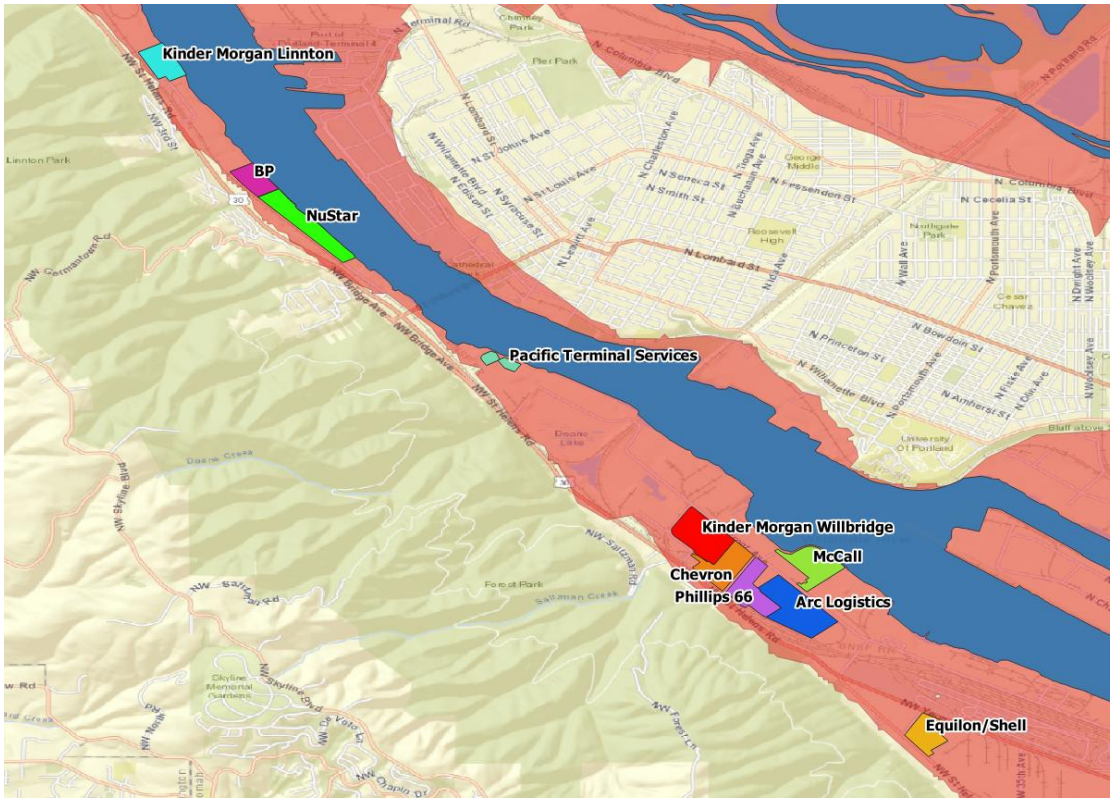

Figure 9: Areas of High Permanent Ground Deformations (shaded red) following CSZ Earthquake (background Google Maps)

POTENTIAL SEISMIC HAZARD MITIGATIONS

SEISMIC HAZARD

Factors contributing to seismic performance of above ground storage tanks include the amount of shaking, the existence of anchorage, subsurface soil condition and the amount filled at the time of the earthquake. The amount of shaking relates to the seismic risk characteristics and for Portland and Oregon, the CSZ is one of the more significant considerations. The expected severity of the shaking is represented by the 5% critically damped spectral acceleration plot in Figure 10 and includes a probabilistic hazard of a 500 year return and 1000 year return earthquake as well as the anticipated full rupture of the CSZ. These values consider the location of the CEI hub relative to the earthquake as well as a relatively soft soil (Vs_{30}=270 m/s). The expected accelerations ranging between 0.2g and 0.56g are well within the range of accelerations where structural tank damage as well as soil liquefaction were reported in past earthquakes. The level of shaking is therefore expected to be significant and have the potential to cause damage or failure to vulnerable fuel storage tanks.

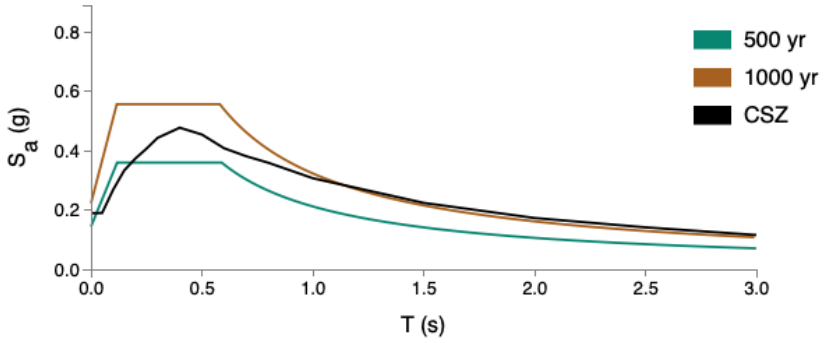

Figure 10: Spectral Acceleration for Portland's CEI Hub

The stresses generated on the tank can be correlated to the amount of fuel in the tank. Performance during past earthquakes have indicated a lower susceptibility to damage for tanks that are partially filled. One potential mitigation of the risk of damage can therefore employ practices that at maximum only partially fill any vulnerable tank.

STRUCTURAL MITIGATION

The large diameter fuel storage tanks are typically above-ground and constructed with flexible floors and steel perimeter shell that is supported on a reinforced

concrete ring foundation. Smaller diameter tanks are likely to be supported by a reinforced concrete slab on grade. In either case, anchorage for the tanks have the potential to limit or minimize the uplift of the walls of the tank as the liquid imposes stresses on the tank walls. Effectiveness of anchoring storage tanks has been demonstrated in past earthquakes and would most likely be implemented for any new tank construction. Tanks in the CEI hub are unlikely to be anchored and would need to be retrofitted. As with most seismic retrofit cases, mitigating existing structures is more challenging than starting with a blank site. The anchorage would need to be implemented around the perimeter, connecting the steel shell with the foundation. The details of the connectivity will need to be evaluated depending on the individual tank as additional challenges may arise from having the ability to attach to the tank wall or the foundation. Issues with welding ranging from the steel vintage to shell thickness need to evaluated as is the ability of the foundation to resist the anchorage forces.

SOIL MITIGATION

For storage tanks located further away from the edge of the river, lateral spreading may not necessarily be as great a concern. However, liquefaction settlement and bearing capacity failures could result in damage to the tanks. To mitigate liquefaction settlement, the ring foundations could be mitigated by installing sheet piles or compaction grout columns around the perimeter. Sheet piling consists of installing steel interlocking sheets around the perimeter. Compaction grouting displaces and densifies loose granular soils by staged injection of fluid grout. These sub surface columns would support the tank shell and potentially the I/O connections, but the centers of the tanks could still settle. Site specific studies would be necessary to assess the differential.

To mitigate lateral spreading in addition to settlement, jet grout columns could be installed under the tanks. Jet grouting is a hydrodynamic jet process that breaks up and loosen the ground, and mixes fluid grout with the soil. The jet grouting can be inserted at an angle, potentially reaching and mitigating soil under the tank as well as the perimeter. For large diameter tanks the jet grouting might require the tanks to be drained and cut open so that low-overhead equipment can work from within the tank.

Alternatively and less conventionally, instead of treating the soil, the water table could be lowered because without water, no liquefaction of the soil can occur. An example of this was implemented in three sites in Japan in 1970s. Underground cutoff wall was constructed using the slurry wall technique with soil/bentonite backfill. The cutoff wall surrounded a group of tanks and the water table was lowered. The refinery reported that these tanks had no damage after the 2011 Tohoku Earthquake.

CONCEPTUAL ESTIMATION OF SEISMIC MITIGATION COSTS

In order to get a sense of the magnitude of costs required to mitigate the major vulnerabilities of the liquid fuel storage tanks at the CEI hub, a high level cost estimation was made based on the tank data available. Three components of the mitigation costs were estimated; soil mitigation, structural anchoring and associated design/permitting. These were estimated as follows:

- Soil mitigation – in order to address both liquefaction induced settlement as well as lateral spreading, jet grouting was selected for estimating the cost. Jet grouting estimates were obtained from one of the major national geotechnical construction contractors. The calculated cost include an initial mobilization of $100K/tank plus the cost of the grouting procedure. While economies of scale could be employed to lower the mobilization costs, there is much uncertainty at this conceptual stage to be fine-tuned. The grouting procedure costs were estimated at $400/cubic yard of grout, 35% grouted mixing for 40ft depth under the entire area of the tank. This cost was calculated for each 25ft diameter or larger tank, each rounded to the nearest $100K. The resulting cost aims to represent the material and labor cost of soil mitigation implementation for the larger tanks.

- Tank anchoring – as an initial estimate, mobilization cost of $50K/tank was used plus an additional $1K/ft of the tank perimeter. This cost was calculated for each 25ft diameter or larger tank, each rounded to the nearest $100K. The resulting cost aims to represent the material and labor cost of implementation for the larger tanks.

- Design and permitting – in order to implement the above mitigation, engineering assessment, design and permitting needs to be conducted. This cost was simply estimated as 10% percent of the total cost for both soil and structural mitigation implementation combined.

The calculated cost is summarized in Figure 11. Values are separated for floating tanks and other because floating tanks on average have larger diameters and at a future date could also include the cost of installation of fire suppression measures, which at this time were not estimated. The total cost for implementing these conceptual mitigation measures to storage tanks of 25 ft diameter and larger is estimated to exceed $300 million. Over one third of the cost is for floating roof tanks alone. Unsurprisingly, the cost of soil remediation dominates the overall cost for all tanks, especially for floating roof tanks that tend to have a higher ratio of area to perimeter given their general larger size. The cost of mitigating storage tanks smaller than 25 ft in diameter is expected to only incrementally add to the overall cost as the mitigation measures would more likely be associated with structural anchoring rather than deep soil mitigation.

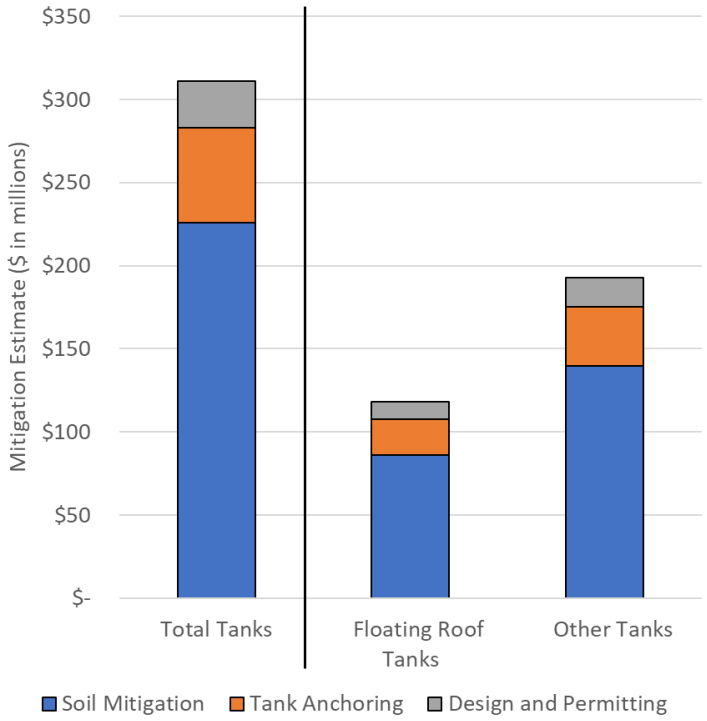

Figure 11: Conceptual Seismic Mitigation Cost Estimates for Tanks 25ft in Diameter and Larger

The conceptual cost estimate was intended as a first pass order of magnitude number for mitigating the damage and failure of only the tanks. No cost consideration was given to maintaining integrity of the fuel distribution system, support mechanical systems, secondary containment areas or the shore terminals that are also located on the site. And, the aim of the remediation measures for the tanks was to minimize the potential for failure that would result in loss of fuel. Much more detailed analyses would need to be conducted to estimate each property ability to operate following a major earthquake event.

RECOMMENDATIONS FOR NEXT STEPS

This study provided a closer look at the seismic vulnerability of the CEI hub by assessing more quantitatively the available inventory of fuel storage tanks at the site. The recommended next steps aim to build on this work to fill information gaps and generate new critical knowledge with the overarching goal of quantifiable assessment and mitigation of seismic risk.

- Develop seismic performance criteria for storage tanks at the CEI hub:

  The philosophy behind majority of design standards and codes is to prevent catastrophic failure. Given the criticality of the fuel, specific seismic performance criteria for the storage tanks in the CEI hub need to be developed. The criteria need to address the input earthquake motion as well as the desired output performance goals, such as tank collapse, prevention of leakage, access to fuel or continued operations. Having established criteria will provide basis for evaluation and eventual design. The decisions made in establishing the criteria can significantly affect the mitigation costs and if adhered to, the associated performance level of post-earthquake performance.

- Quantify tank seismic fragility:

  Seismic fragility describes the anticipated performance for a particular ground motion input parameter. For example, the potential for tank wall collapse given the earthquake peak ground acceleration. Limited literature exists on the topic, quantifying liquid storage tank fragility difficult. To address this shortcoming, archetype tanks should be defined that represent different storage sizes, roof types, structural as well as soil characteristics. Numerical models of the archetypes need to be analyzed to determine their seismic fragility. This new knowledge would be used to inform the seismic loss assessment process and provide a tool to quantify the effectiveness of particular mitigation measures. For example, the amount of fuel fill in the tank can be used as a variable in the analyses to determine the seismic performance benefit gained by lowering the amount of fuel stored. The fragility is useful on individual tank basis, can be applied across the tank inventory and can be used to better understand cost/benefit.

- Investigate mitigation options for fuel distribution:

  The focus of the study has been on the storage tank inventory, but aspects related to connectivity and distribution of the fuel are also important. Pipelines, support mechanical systems and access terminals need to be better understood, existing condition assessed and mitigation options investigated.

- Conduct subsurface geotechnical investigations:

  All of the sites are located close to the river and have been generally identified as susceptible to liquefaction. Detail survey of the properties of the soil at depth are needed. This information could then be used to estimate soil amplification of ground motion, the amount of settlement as well as lateral spread from liquefaction, and be used to refine the cost of the extent of the soil remediation required.

- Obtain detailed structural tank information:

  The current tank data set is incomplete and basic information that was inferred needs to obtained, including missing tank diameters, tank roof types and physical locations. Additional structural data currently not available needs to be gathered. Details of existing foundation size, tank to foundation anchorage, tank wall thickness, roof support and I/O connectivity. Some of this information can be gathered through site visits while other would require more direct tank owner cooperation.

- Prioritize fuel storage tanks:

  From the hundreds of tanks identified, certain types of fuel and certain size of tanks are likely to be more critical to post-earthquake recovery than others. Prioritization of the tanks based on post-earthquake needs and consequences of failure should be conducted. Having prioritized tanks would help focus the associated assessment and mitigation efforts.

1. INTRODUCTION

During summer 2018, city of Portland's Bureau of Emergency Management (PBEM) requested that Oregon Solutions conduct an assessment to determine potential avenues for collaborative action that might increase resiliency of the Critical Energy Infrastructure (CEI) hub located in northwest Portland. This request came after several meetings between members of the Portland City Club's Earthquake Resiliency Advocacy Committee (CCERAC) and staff from the Governor's Office, Oregon Solutions, and PBEM. According to a February 14, 2017, Portland City Club report, "approximately 90 percent of the liquid fuel for the entire state of Oregon and 100 percent of the jet fuel for Portland's airport comes through the CEI hub." But the tanks on this site are vulnerable to a Cascadia Subduction Zone event (CZE) given their age and that they were constructed on seismically vulnerable soils susceptible to liquefaction, which could potentially cause the tanks to "sink, split, tilt or leak." Additionally, risks to the environment, life, safety, and property at and near the site from a CZE are unclear.

PBEM requested Oregon Solutions conduct an assessment focused on determining potential avenues for collaborative action that might increase resiliency of the hub. Specifically, this assessment looked at the following areas of inquiry:

- What ideas could reduce the risks associated with seismic activity impacting fuel storage facilities in northwest Portland at the CEI hub?
- What are the long- or short-term incentives, regulations, agreements, or other creative approaches that could be identified in order to bring all relevant parties to a collaborative table to improve resiliency?

The goal of this assessment interview process was to determine if there was enough substantive interest from stakeholders to work in a neutral process, such as an Oregon Solutions process, to look for ways to improve

ABOUT OREGON SOLUTIONS

Oregon Solutions is the state of Oregon's program to help communities address community-based problems and opportunities through sustainable solutions. We do this by creating a neutral forum for collaboration where businesses, governments, nonprofits, community-based organizations, sovereigns, and other stakeholders can align resources and pool efforts to achieve desired results.

OREGON SOLUTIONS PROCESS

Oregon Solutions' engagement starts with an assessment. When invited, Oregon Solutions begins an assessment to explore whether and how a collaborative approach might be structured to address a particular community issue. The assessment is composed of a series of one-on-one or small group interviews. If an assessment finds there is a project that can be conducted by Oregon Solutions, it will go before the governor for consideration of a designation as an Oregon Solutions project.

seismic resiliency at the CEI Hub. This report reflects the findings from our assessment interviews.

1.1. Methods

This assessment report is the product of interviews conducted by Oregon Solutions with parties and stakeholders representing key interests related to the CEI hub. Between July 2018 and January 2019, Oregon Solutions interviewed thirty-two individuals representing city, county, state, and federal government, as well as civic groups, energy associations, and the energy sector. Initial interviews for this assessment were conducted from July 2018 through January 2019. The overarching purpose of our assessment is to gauge stakeholder interest in a collaborative approach, such as an Oregon Solutions process, to address identified issues.

The team was not able to interview everyone with an interest in the CEI hub. Some requests that Oregon Solutions staff made for assessment interviews went unanswered even though several attempts were made over several months. We made every effort to reach out to stakeholders with an interest in the seismic resiliency of the hub. Our goal with assessment interviews is to have all interested parties feel their perspectives and interests will be represented by those interviewed. A list of those interviewed and their affiliations can be found in appendix A.

Most interviews were held in person—a few by phone. Before each interview, individuals were briefed about the purpose of the assessment. All interviews were voluntary and lasted approximately one to one-and-a-half hours. Interviewees were informed that the final report would aggregate responses into key issues without individual attribution.

1.2. Intent of this report

This report is ***not*** intended to be a comprehensive review of all issues published, reported on, or discussed about the hub. Instead, this assessment report reflects what Oregon Solutions heard from interviewees at a single point in time, and it is an overview for stakeholders and policy makers about the key topics of interest to parties engaged in the hub.

2. BACKGROUND

2.1. History

The state of Oregon and the greater Pacific Northwest are vulnerable to an earthly force little understood until the end of the twentieth century: powerful subduction zone earthquakes and coastal tsunamis that occur with periodic frequency along the Juan de Fuqua and North American plates.

In the past, both the Huu-ay-aht First Nation peoples and the Makah tribe shared similar stories of lost land and peoples as a result of these earthquakes and tsunamis. But as recounted in a 2015 *The New Yorker* article, their stories were long overlooked as fact until scientific research paired Japanese tsunami records with on-the-ground geologic field

research to reconstruct the Cascadia earthquake of 1700.[1] What this research unveiled was that subduction zone earthquakes have occurred along the Pacific Northwest with relative regularity over the last 10,000 years, and if averages from past events are predictive, the region could be overdue for another powerful subduction zone earthquake. [2]

2.2. Critical infrastructure and community resiliency

Many of the region's buildings and critical infrastructure were built before the region's seismic exposure was widely understood.[3] This infrastructure includes Oregon's primary liquid fuel storage facility, the CEI hub. This hub is located in northwest Portland and receives 90 percent of the state's liquid fuel supply either via pipe or marine vessel.[4] One interviewee for this assessment noted that roughly 70 percent of the fuel arrives by pipe and another 30 percent arrives by tanker barge.

The CEI hub is considered by many experts to be vulnerable to failure in the event of a CZE event. A 2012 Oregon Department of Geology and Mineral Industries (DOGAMI) study notes that the hub has a "significant portion of Oregon's electricity, natural gas, and fuel oil infrastructure."[5] Specific to the liquid fuel, DOGAMI's high-level findings spelled out the following areas of vulnerability:

- *General.* The facilities on the site range in age from a handful of years old up to one hundred years old; consequently, they range from "[infrastructure] built to no or very antiquated standards to new infrastructure built to the current state-of-practice standards."
- *General.* "Current building codes do not adequately address the seismic deficiencies in existing CEI hub facilities."
- *Liquid fuel pipeline.* "Liquid fuel pipeline was largely constructed in the 1960s when the regional seismic hazards were unknown and state-of-practice construction techniques at that time did not include any reference to seismic standards."
- *Marine terminals.* "All of the port facilities in the CEI hub have significant seismic risks due to liquefaction, lateral spreading, and seiches." Also, some "older piers were constructed without any seismic protection, have deteriorated, and are likely to fail in even a moderate earthquake."
- *Fuel supply.* At the time when the report was published, only "three existing tanks [were] known to have addressed liquefaction vulnerabilities." Moreover, the hub

> has on average a "three to five day supply… for regular unleaded and diesel fuel," with premium gasoline subject to daily delivery.[6]

A 2013 Oregon Resilience Plan echoed concerns from the DOGAMI report raising questions about the sturdiness of facilities constructed on soils susceptible to liquefaction, and infrastructure not built to current standards given the hub's age-range of structures. [7]

These vulnerabilities mean that in the event of a CZE, Oregon communities dependent on fuel to respond to a disaster could struggle for adequate supply, and environmental and safety risks would be likely for people and natural places near the hub. Further, if the hub was majorly damaged, "operations could be degraded for months or years, with complete repairs and equipment replacement potentially taking many years."[8]

In recent years, a great deal of research has been conducted into how crises or disasters (e.g., earthquake, hurricane, tsunami, and terrorism) are made worse by a failure or disruption of critical infrastructure.[9] Pescaroli and Alexander researched how a breakdown in one critical sector, like energy, "can rapidly create much broader effects by cascading throughout the network and possibly…over into other networks…which may cause great harm and may become full-blown transboundary catastrophes."[10] They use the 2003 power outage in Italy and Switzerland to illustrate their point:

> On the night of 28 September 2003, electricity was being imported into Italy from Switzerland via three routes. A short circuit occurred when one transmission line overheated and touched the branch of a tree. Transmission automatically switched to the other two lines and then shut itself down to prevent them from overheating too. A series of blackouts propagated from the Swiss–Italian border progressively as far as Sicily and Geneva, affecting 56 million people. Trains were marooned in tunnels, and people were trapped in elevators. Civil aviation was briefly shut down…transportation, health systems, the Internet and building maintenance were affected, and lack of refrigeration put foodstuffs at risk.[11]

This real word example shows how a "very localized fault" can "rapidly spread to the level of international system-wide effects."[12]

Professor Stephanie Chang, another leading researcher in disaster preparedness and community resilience says today's "infrastructure services are so ingrained in modern life," they are "both ubiquitous and taken for granted." Because these systems are "highly interdependent," damage and ensuing losses from outages are often substantial and disproportionately large. A community's ability to manage the severity of impacts of a disaster also depends "not only upon the occurrence and duration of infrastructure loss but also upon preparedness and response actions undertaken by governments and individuals." To that end, she says "reducing the likelihood of damage through pre-disaster mitigation, reducing the duration of outage through rapid restoration, and enhancing the capacity of people and businesses to withstand outage disruption through preparedness and emergency response planning will all enhance disaster resilience."[13]

These and other examples speak to the importance of shoring up critical infrastructure, understanding how interdependent critical infrastructure is as part of emergency preparedness planning, and preparing communities to be as resilient as possible in case of a disaster that impacts essential services.

3. FINDINGS

3.1 Introduction

This section details findings from assessment interviews. **Note:** Findings do *not* reflect a point of view of the National Policy Consensus Center or any of our team members. Instead, findings reflect what we heard from interviewees.

We asked interviewees their perspectives on a variety of substantive issues during these interviews, including ideas to mitigate risk at the hub, perceived challenges that need to be addressed, thoughts on incentives and a distributed system of hubs, and interest in a collaborative approach to work through these issues. Interviewees were also asked to identify and consider how to overcome perceived challenges to collaboration. Interview questions can be found in appendix C.

Many ***substantive issues*** or themes emerged, which the assessment team saw as being related to the key assessment questions. These themes were described explicitly and implicitly by many interviewees. We have incorporated content from interviews, and these responses are listed in no particular order. We did not include comments that were not germane to the scope of this assessment. We note areas where lack of shared knowledge may currently impact individual perceptions about how a sector works and/or its capacity. We have also listed brainstormed ideas offered by interviewees related to incentives, and general interest in an Oregon Solutions-like collaborative process that could identify mitigation approaches.

3.2. Substantive findings

3.2.1. Likelihood of CZE event well understood

We found most interviewees had a good understanding of the risks associated with a CZE event, the potential risks to the hub, and the larger systems that the hub relies on (e.g., pipelines, docks, roads, bridges, and highways). This was significant since some interviewees noted that knowledge of a potential CZE event was not well understood—across sectors—even a handful of years ago.

There is also confidence that, in the event of an accident involving a single tank or a few tanks, emergency responders could respond well. But when it comes to a worst-case disaster like a CZE event, we found little clarity for how an emergency response would work. We found there to be speculation about what resources the public and private sectors have when it comes to a worst-case scenario event.

3.2.2. Shoring up the hub versus moving it

One of the main areas of interest for CCERAC and PBEM was to find out what people thought about the possibility of moving the hub from its current site to a more seismically-resilient location. With a few exceptions, most interviewees felt that moving the hub was not feasible because it would cost billions of dollars and it was unclear if there was a better location. Some interviewees noted a hub would still need to be accessed by river, proximate to existing pipeline infrastructure, and relatively close to the population center to have a rational product distribution mechanism. In light of that, some interviewees also questioned what other stretch of river would be safer for siting a hub facility.

We note a few interviewees felt a hub could be moved to eastern Oregon. These interviewees said an eastern Oregon hub would be safer and less exposed to earthquake east of the Cascades. In this example, other interviewees who were not as interested in moving the hub said, depending on the proposed location, new pipelines would likely need to go on tribal and public lands, which could be controversial. Oil would also still come via the traditional delivery methods of pipe, barge, rail, and truck—and river and pipeline access would remain essential.

The majority of interviewees felt that shoring up the existing site and mitigating for a CZE event was the best approach. Some even said a few other sites for oil storage inside and outside the Portland area should be considered. But a wholesale move of the hub was not seen as practical.

3.2.3. Long- or short-term incentives, regulations, agreements, and other approaches

Another main area of interest for CCERAC and PBEM was what, if any, *incentives* might bring parties to the table to work on the hub's resilience. When asked about incentives, we found interviewees to be creative and inventive. Interviewees saw incentives not simply as cash (although that was brought up as an important option). The following is a compiled list of the multitude of ideas offered in the spirit of brainstorming. We did not screen or vet them with subject matter experts as to the merit and feasibility of these ideas. Rather, we

share the ideas we heard as an illustration of the creativity of interviewees and potential for many good ideas for consideration as part of any collaborative effort:

- Be open to options for some kind of cost recovery models like those seen with regulated utilities under Public Utility Commission purview.
- Look at state and federal regulations for incentives or flexibility.
- Look at permitting issues for incentives or flexibility. For example, consider allowing an entity to submit a twenty-year plan for retrofitting that, if approved with measures for seismic resiliency, would allow for easing of the permitting process. (Changes to permitting processes could be made legislatively, by contract, or both.)
- Offer tax credits to a company that moves tanks or builds more seismically-sound tanks.
- Explore public/private partnerships as a way to set up infrastructure with shared ownership and responsibility.
- For improvements in Portland, be open to increasing capacity for storage to help pay for new facilities that are seismically sound.
- Increase funds for seismic improvements by considering expanding Oregon Department of State Land's moorage fees to include companies that are exempt.
- Offer back-up generators to oil companies located at the hub.
- Use tank consolidation as a "carrot" and regulations as a "stick."
- Provide financing for facilities.
- Look at other properties in the region where tanks could be located to gain seismic improvements; exhaust private- and publicly-owned properties.
- Consider a business license tax.
- Create a seismic resiliency fund at Business Oregon that could be used by facilities like the hub.
- Create incentives for storage of a cache of usable fuel around the state. (Industry would need to advise how to do this strategically.)
- Look at ideas from other states like Florida, which is studying the possible construction of additional petroleum distribution centers around the state as a way to improve access to fuel during large-scale emergencies. (Florida's Legislative Office of Program Policy Analysis and Government Accountability is conducting the research.)
- Look at flexibility related to the low carbon fuel standard.
- Look at who should have authority over seismic issues to rationalize how critical infrastructure is regulated and managed.

Some interviewees also felt that for incentives to be viable at the end of any collaborative process, the support of elected officials at the local and state levels (mayors, councils, legislators, etc.) will be needed. Also, other interviewees felt strongly that a collaborative process that looked at incentives would be seen as positive and a high priority for industry in order to help balance out long-term return on investments.

3.2.4. Importance of defining regulatory authorities

Several interviewees noted state agencies have limited regulatory authority over liquid fuel hubs, and that what exists is not well understood. Some interviewees report they know of no authority to make fuel companies mitigate for a CZE event. They offered ideas on regulation as a potential task/incentive for a collaborative effort. The following is a compilation of the suggestions interviewees presented during our interviews:

- Some interviewees felt that if it's not already being done, a collaborative process could work to clarify regulators' road map and oversight. For example, a process could work through the difference between the scope of federal, state, and local regulations, and programs, including the Oregon Department of Environmental Quality's oil spill program, the Oregon State Fire Marshal's inspections of tank farms, and the Oregon Public Utilities Commission's oversight of regulated utilities.
- An interviewee felt collaborative process could include a review of the scope of the Oregon Seismic Safety Policy Advisory Commission to better understand how it could help on mitigation issues specific to a hub.
- Any process could explore recommended changes to federal, state, or local regulations. Some interviewees stressed any proposed regulatory change should be clear-eyed about what it does, how it works, how it fits, who owns it, and do its best to consider unintended consequences.

3.2.5. Need to address gaps in emergency response, recovery planning, and coordination

Interviewees felt a collaborative table across sectors could be a helpful place to work on gaps of knowledge across sectors related to emergency response, recovery planning, and coordination at the hub. For example, while interviewees understand that industry and emergency responders train for traditional events, there is no clear understanding how a coordinated emergency response would work at the hub in a worst-case CZE scenario. Interviewees questioned whether entities are even prepared: what is the plan, who needs it, and, if there is no plan, how can a plan be achieved?

Some interviewees said they are concerned industry and emergency responders cannot provide the necessary response to a worst-case CZE. An example was given related to the six fire stations around the CEI hub. These are traditional fire stations designed to respond to their fire management area. We were told they would likely respond to their management area for triage in a CZE event. Some interviewees expressed interest in developing a fire brigade model around the CEI hub for response during a CZE-like event.[14]

14. For an example of a fire brigade model, see http://www.iturri.com/en/solutions/fire-fighting-solutions/fire-fighting-solutions-in-industrial-plants.

Portland International Airport Fire Department was shared as another fire house model for structuring day-to-day work.[15]

Some interviewees were specifically unclear what provisions industry could bring to respond during a worst-case scenario. Other felt assumptions are being made on how quickly industry could recover from a CZE. For example, some interviewees feel there is an assumption they could recover quickly, while others said depending on damage, it could take months or years. There is also concern about the maritime damage from a CZE event that could hinder river travel and delay recovery. Some suggested that wildland interface protection of nearby Forest Park needs to be part of any discussion about reducing the risks of a CZE to the hub. Finally, some suggested a process to address incorporating concepts of Shake Alert (earthquake early warning system) to provide facility managers more time to implement quick prevention measures in case of near-term incident.

3.2.6. Conversation needed on mitigation

Interviewees said they need a better picture of the overall capacity to do specific mitigation projects, resources to do mitigation work at the site, and gaps that could prevent work on mitigation from happening. Some said that recent ideas implemented in singularity, such as providing industry with portable generators, which is appreciated, does not represent a robust mitigation effort. They hoped for more global conversations to outline mitigation needs of the hub.

3.2.7. Need for shared information across sectors

On a related topic, interviewees said there is a lack of a general knowledge about the basic interworkings of a sector. This has led to a sense that there are misperceptions and poor information, and in some instances mistrust, between sectors. For example, we heard a concern that since sectors are not sharing emergency response plans with one another, it is creating a "we don't know what we don't know" climate. Others say there is limited understanding in Oregon of how the macro fuel sector works and limited awareness of infrastructure improvements already completed at the hub.

To confront this information issue, there is an interest in educating relevant parties on these issues to create a shared base of knowledge and better understanding of the unique challenges facing each sector. Examples of misperceptions shared by interviewees include the belief that industry has "limitless pockets," or that public sector emergency responders already have resources to protect the hub. There is awareness between sectors that misperceptions are out there. We found that many interviewees have a genuine interest to learn more about other sectors and share information from their sector at a collaborative table. This was seen as a way to build knowledge, verify information, and build trust.

15. Port of Portland website, https://www.portofportland.com/PublicSafety/Firedepartment.

3.2.8. General support for a collaborative effort

The primary purpose of an assessment like this one is to determine what would be needed for a productive, collaborative process to succeed. This section outlines what we heard from interviewees directly.

We did find that interviewees generally felt a neutral, non-political process, such as an Oregon Solutions process, would be a good way to get parties to the table to layout issues and to begin relationship building seen as critical to successfully implementing solutions. This was seen as potentially helping with trust issues, gaps of knowledge, and general understanding of how sectors work.

3.2.8.1. On the political climate

Some told us they prefer a third-party collaborative effort where all key parties are at the table working collaboratively instead of a political body taking the lead. The presumption is that it would lead to better outcomes. There was a general concern from most interviewees that the current politic climate related to liquid fuel vs. a greener economy has had an unintended consequence of introducing high political risk for efforts to mitigate the seismic risks of the CEI hub. Put another way, the need to improve safety of the hub site is seen as having statewide significance, but the politics of liquid fuel is a challenging environment for emergency responders to navigate. Some are concerned that political actions involving the hub could be seen by industry as burdensome.[16] There is also a concern that any exploration of a diverse array of potential incentives as a way to improve seismic resiliency would be frowned upon by some political jurisdictions. Even with these challenges, interviewees see value in participating in a collaborative process to proactively work on this significant infrastructure challenge.

3.2.8.2. On the focus of a collaborative effort

We heard that any process should keep to a specific agenda focused on resiliency and mitigation for the hub in preparation for a CZE event. Some interviewees told us that focusing beyond liquid fuels could be unwieldy for the group and of no interest to industry. Interviewees also expressed interest in being clear what success looks like for minimizing environmental disaster, creating structurally-sound infrastructure that can withstand a CZE, planning properly for sequenced infrastructure improvements, and creating clarity on needs for resources and response during a CZE. A few interviewees also said that, while their organization might not play a lead role at a collaborative table, their organization would want to participate nonetheless.

3.2.8.3. On teeing up a process and what it would take to bring people together

We heard that taking the time to set up any neutral process would be essential. *Process development* in this case would be complex, and all stakeholders would want to confer on the structure of a process. Any actual process should also be well-framed, well-timed, and well-structured. Also, a process should not be rushed. We found from our interviews that

16. Note: Industry has been wary of participating in past stakeholder research efforts as those efforts were perceived as adversarial.

interviewees feel investing front-end time in building trust, relationships, and shared knowledge would give any process a better chance for long-term success on mitigation and infrastructure improvements.

We also note that some interviewees said no one wants to throw good money after bad in a process that is not well thought out or infrastructure investments that are not strategic. Some also said if lawyers were involved, conversations might not be frank.

3.2.8.4. On potential activities for a neutral process

Some interviewees began to brainstorm approaches for consideration by a collaborative, neutral table during our interviews. For example, some interviewees said it would be important to develop a group agreement on what the hazards and threats are in order to establish a baseline on mitigation. Another interviewee mused that a group could work on a phased approach to make infrastructure improvements based on the hub-based experts' estimate of a CZE event occurring in a fifty-year horizon. Such an approach could have immediate approaches (one to ten years, focus on trust building, resiliency, education, research, planning, infrastructure improvements, and drills), intermediate approaches (ten to twenty years, focus on mitigation, next-phase infrastructure improvements, research, and drills), and long-term approaches (for twenty to thirty years, focus on next-phase infrastructure improvements, research, and drills).

Other interviewees said it could be helpful to get an agreement among parties on geotechnical studies and their findings as a way to advance shoring up the hub. This is considered important because there is perception that research conducted by a party considered a stakeholder would be discounted by other parties or stakeholders regardless of the quality of the research. Finally, some interviewees also said a group could consider going through the recommendations in the Oregon Resilience Plan (2013) to identify actionable items.

3.2.8.5. On potential obstacles to a collaborative process

A number of potential obstacles were identified. The following is a list of what we heard:

- Some expressed the need for a place in a process where they could freely speak to express points of view without attribution. Some worried that if comments were attributed to them before they could run them by their organizations, it could stymie their involvement. These interviewees said having comments attributed to them out of context could hurt their relationships with peers and within their sector.
- Interviewees said there is a perception that additional fuel infrastructure is never a good thing. Related to this, some interviewees said Portland's limitation on tankage is politically charged for some and could be an obstacle.
- Many interviewees said that in the past, industry has said that antitrust regulations prevent them from participating in work related to CZE resiliency efforts; this

concern would need to be addressed as part of any new effort going forward if industry is to participate.

- Clarifying the regulatory roadmap at the outset of a process was also seen as helpful because it has been an obstacle to past efforts. For example, some are concerned there is no state agency with direct regulatory authority or oversight of a liquid fuel storage facility like the CEI hub. Others are more specifically concerned that the lack of clarity about the current regulatory roadmap has created misperceptions and misunderstandings about current authorities that public entities have today.
- One final obstacle that was raised was lack of clarity how the Portland Harbor Superfund cleanup might impact CEI hub mitigation work. No one had a resolution for this obstacle, but many were mindful that is an overlay to any work at the hub in the future.

3.2.9. Other considerations of note raised by interviewees

The following considerations did not fit neatly into other categories; so they are listed here in an effort to comprehensively capture what we heard:

- It is unclear what impact increasingly fuel-efficient vehicles and alternative fuel vehicles will have, if any. These vehicles could result in less oil coming to the region and may mean less revenue for seismic improvements.
- Even if markets shift to renewables, the oil industry has all of the existing infrastructure that could serve that market.
- Interviewees noted that industry staff live here, too, and felt they (individually and at the corporate level) want to do the right thing.
- Pump stations for the pipeline are at the hub; a critical item could also be work on pump stations and preparation of the system that connects to Eugene.
- The CEI hub has other gathering lines from other terminals that should be strengthened—doing so would help the overall state system.
- We were told it is important not to lump industry together as a monolith; each company operates differently and some said trade associations don't necessarily represent individual company perspectives.
- We were told by some interviewees that industry is interested in having safer assets.
- Some experts told us they believe the pipeline system will do well during a CZE event in existing soils; the system will float during a CZE and oil lost from pipes will be more recoverable because the steel pipes have been replaced with cast iron. (Uncoated older steel was brittle.)
- Many interviewees said it is unlikely that oil will not be an important energy source over the next 50 years—even with current efforts to transition to alternative fuel

sources. Therefore, resiliency of the hub remains important and any investments to shore up the infrastructure for seismic resiliency would not be in vain.

- That utilities and emergency response entities will need access to liquid fuel during a disaster is on the top of the list of needs in order to respond to a CZE event.
- Fuel associations are stepping up outreach on the importance of resiliency planning.

3. ASSESSMENT RECOMMENDATIONS FOR AN OREGON SOLUTIONS/COLLABORATIVE PROCESS

Oregon Solutions found that among those we were able to interview there is significant interest in proceeding with a collaborative process, convened by a neutral third party, to explore mitigation, trust building, education, and incentives discussed in this report.

3.1. Recommendation one: Continue to engage critical parties

Despite the interest in collaboration, we did not find conditions exist at this time for a collaborative effort based on the scope.[17] ***Specifically, we were unable to secure enough responses from critical parties who have a direct interest in the hub to recommend going forward with a collaborative process as outlined in the scope at this time***. We found some of our requests for assessment interviews were met with silence, confusion, and even mistrust, because of sensitivities surrounding the hub. Even so, we do believe ***a collaborative table is within reach***. With more time, efforts to engage those parties could be successful.

3.2. Recommendation two: Convene an education-focused collaborative table

We did, however, find other areas where we feel it would be beneficial to begin a collaborative process now. Given the consistent concerns voiced about lack of trust and need for relationship building, we find one way to begin testing the waters for working together would best be focused around information sharing and mutual education. Some of the ideas generated during our interviews included the following:

- Do cross-sector education on how each sector works. Work through worst case scenario emergency response planning across sectors for a CZE event. As part of this effort, identify gaps of knowledge across sectors related to emergency response, resources that currently exist that could help a response effort. Outline recovery planning and coordination at the hub.
- Clarify regulatory authority and oversight of hubs, either through ongoing work through state commissions, and/or through work of a collaborative table. For example, a process could work through the difference between the scope of federal,

[17] 1) What ideas could reduce the risks associated with seismic activity impacting fuel storage facilities in northwest Portland at the CEI hub? 2) What are the long- or short-term incentives, regulations, agreements, or other creative approaches that could be identified in order to bring all relevant parties to a collaborative table to improve resiliency?

state, and local regulations as it relates to the hub. This effort could also explore programs at the Oregon Department of Environmental Quality's oil spill program, the Oregon State Fire Marshal's inspections of tank farms, the Oregon Public Utilities Commission's oversight of regulated utilities, and a review of the scope of the Oregon Seismic Safety Policy Advisory Commission to better understand how it could help on mitigation issues specific to a hub.

- Identify initial mitigation options, resources, and gaps in order to protect human and natural resources beyond the hub; longer-term planning could be part of this effort if there is ***adequate participation across sectors.***

These ideas could start a conversation, but we emphasize that part of the convening effort would be for the convened group to identify areas where to start with sector education.

3.3. Recommendation three: Convene to explore incentives

As a second phase building off of an education-focused effort, we do believe a collaborative table effort, working on an exploration of incentives, would be beneficial. We found those we interviewed to be creative when asked to provide off-the-cuff ideas, and we think a collaborative table could further explore and vet more ideas. We also think, if such a table proves beneficial, it could attract those entities that did not respond to our request for interviews as part of this assessment process, and could lead to the needed level of engagement on mitigation efforts.

3. FINAL COMMENTS

We acknowledge that securing the interviews we did for this assessment took significantly more time than we anticipated from the outset. We appreciate that the city of Portland team gave us more time to make additional attempts to secure interviews for this assessment report.

Finally, we want to recognize and acknowledge the support of the staff at the City of Portland and the representatives of the Portland City Club in this effort. City emergency response staff, in particular, has been invaluable in ensuring that the hard work to ensure the issue of seismic preparedness of the CEI hub remains on the forefront of policymakers' and industry leaders' agendas. This assessment process, while not leading to an immediate recommendation for an Oregon Solutions process at this time, demonstrated the strong interest in a collaborative effort to improve seismic resiliency of the CEI hub. This was unclear prior to this assessment process.

Oregon Fuel Association
Community groups
Utilities
Port of Portland

APPENDIX C: OREGON SOLUTIONS ASSESSMENT INTERVIEW QUESTIONS

QUESTIONS PART A

- What has been your level of involvement in this issue?
    - If not at all, what information would you need in order to effectively engage in a process to improve resiliency at the hub?
- From your perspective, what could be done to minimize the risk at the CEI hub from a Cascadia Subduction Zone event; (e.g., replacing, retrofitting, or consolidating of tanks, barriers, building code changes, pipelines crossing the river, liquefaction, general public's available knowledge of risk, etc.)?
    - Of these, what is your *highest priority*?
- Are there external factors that could impact the need for the hub in the mid-term future (e.g., transition to alternative fuels/energy, unforeseen decommissioning of tanks)?
- Would a distributed system of hubs be possible in the future to minimize risk?
    - If yes, what would need to be done to move a hub? What barriers do you foresee?

QUESTIONS PART B

- From your perspective, where might there be an opportunity to work together to impact this issue?
- What unforeseen *opposition* or *conflict* might there be for a project like this?
- What unforeseen *support* might there be for a project like this?
- What incentives are needed to *get the parties together* to work on improving resiliency at the CEI hub (e.g., from funding to backup generators for tanks that currently do not have them)?
- Are there (other) critical issues/challenges/hurdles that might need to be resolved in order to bring people to the table? How would you suggest going about addressing these challenges/issues/hurdles?
- Who are the *critical* players in relation to this issue (e.g., federal, state, local, private)

- How willing do you think they would be to engage in an Oregon Solutions process focused on incentives to improve the resiliency of the CEI hub?

- How might you/your organization be willing to participate in an Oregon Solutions process?

- Who else would you recommend be interviewed for this assessment?

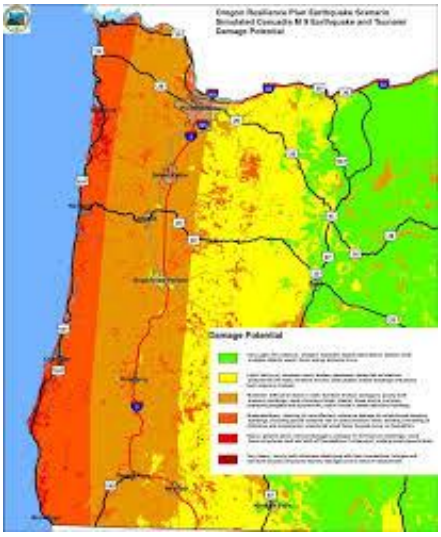
- If an Oregon Solutions project moves forward, who do you think has the credibility and gravitas to be a convener who could engage diverse partners to accomplish a project like this?

- Is there anything else you want to address that wasn't addressed already?

APPENDIX D: OREGON FUEL REPORT, LIQUID FUEL INFRASTRUCTURE

The following is an excerpt from "Earthquake Risk Study for Oregon's Critical Energy Infrastructure Hub," August 1, 2012, by Yumei Wang, Steven F. Bartlett, and Scott B. Miles of the State of Oregon Department of Geology and Mineral Industries.

PLANNING BASIS: WORST CASE SCENARIO

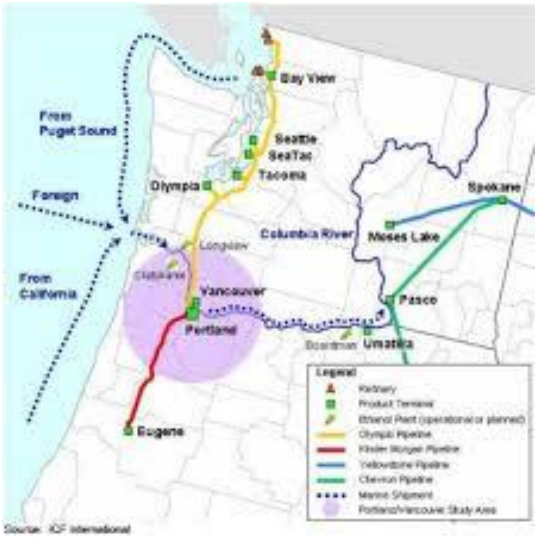


The Pacific Northwest region's most likely catastrophic event is the 9.0 Cascadia Subduction Zone (CSZ) earthquake and tsunami. Expected impacts include ground shaking for 4 – 6 minutes causing massive critical infrastructure damage along with a tsunami reaching some parts of the Oregon coast within 15 minutes of the quake.

The Federal Emergency Management Agency (FEMA) anticipates up to 25,000 fatalities, tens of thousands of people in need of shelter, and $30+ billion in economic losses.

Oregon counties in the high impact areas along the coast include: Clatsop, Tillamook, Lincoln, Lane, Douglas, Coos, and Curry counties. Mid-range impacted areas include the Portland metropolitan area with Washington, Multnomah, and Clackamas counties. Additional counties west of the Cascades in the mid-range impact areas include: Columbia, Yamhill, Polk, Marion, Benton, Linn, Jackson, and Josephine counties.

This event would devastate the region's petroleum supply and distribution system. Oregon can expect to lose most of the normal incoming supply of fuel. The Oregon Department of Geology and Mineral Industries (DOGAMI) 2013 Seismic Study found that the region's refineries and petroleum distribution terminals are expected to sustain moderate to significant damage. The facilities will have tank farm failures, marine dock failures, pipeline system breaks, hazardous material spills, fires, and structural damages onsite. Restoring the region's petroleum infrastructure would likely take months if not longer. In addition, the Olympic Pipeline that transports the majority of gasoline, diesel, and jet fuel to Oregon is projected to suffer as many as 250 breaks and 82 leaks.



ODOE has no regulatory authority to require its private sector partners to make seismic upgrades to their fuel tank farms, pipeline systems, marine docks, or other facilities. However, ODOE is responsible for ensuring the state can

respond to a catastrophic event whenever it may happen and is prepared to address the impacts to the fuel infrastructure in its current state with all of its vulnerabilities.

OREGON PETROLEUM INFRASTRUCTURE

Oregon does not have refining capabilities and imports 100 percent of the refined petroleum products used in the state. That is an estimated three billion gallons of fuel each year or roughly 250 million gallons each month.

Gasoline & Diesel Supply and Distribution System

More than 90 percent of the refined petroleum product used in Oregon come from four refineries located in the Puget Sound area of Washington State. Product is transported from the refineries in Washington to Oregon via the 400 mile Olympic Pipeline (est. 90 percent) and barges (est. 10 percent) entering the state at the Port of Portland where seven petroleum distribution terminals are located in what is called the Portland Fuel Hub.

Oregon receives the remaining less than 10 percent of the state's refined petroleum products from refineries in Salt Lake City, Utah and the California Bay Area. From Salt Lake City, the refineries transport product via Tesoro's Salt Lake Products Pipeline System to a distribution terminal in Pasco, Washington. From the Pasco facility, fuel is trucked into Oregon to service eastern Oregon communities. California Bay Area refineries supply minimal quantities of fuel to a Chico, California terminal and then product is trucked into Oregon to supply southern Oregon communities.

Portland Distribution Terminals (Fuel Hub)—From the Portland Fuel Hub, product is distributed throughout Oregon by:

- Two Pipelines—Kinder Morgan's pipelines link petroleum terminals in the Portland Fuel Hub with the petroleum distribution terminal in Eugene, Oregon and provide jet fuel to the Portland International Airport.

- Barges—Product is loaded onto barges from the BP, Chevron, and Phillips 66 marine docks and delivered up the Columbia River to Pasco to service eastern Oregon communities.

- Tanker Trucks—An estimated 1,500 tanker trucks deliver fuel throughout the state to about 2,400 fueling locations.

Jet Fuel and Aviation Gas Supply & Distribution System

Oregon imports about 15 million gallons of jet fuel each month (about 180 million gallons of jet fuel annually) from the refineries in Washington State. An estimated 90 percent of the jet fuel is transported via the Olympic Pipeline to the petroleum distribution terminals located at the Port of Portland Fuel Hub. The remaining estimated 10 percent of the jet fuel is transported by ship or barge directly to the Port of Portland.

From the Fuel Hub, the Kinder Morgan Pipeline transports the bulk of the jet fuel to the Portland International Airport. Jet fuel is delivered by truck to other airports and air fields in the state from the Fuel Hub.

Oregon also imports up to 170,000 gallons of aviation gasoline (AVGAS) each month (just over two million gallons annually) from Canada and Texas. AVGAS is transported by rail to the Chevron and Kinder Morgan terminals in the Fuel Hub then trucked to airports and airfields throughout Oregon.

Constraints and Limitations

The petroleum industry exercises a "just in time" business strategy. Refineries and distribution terminals maintain adequate supplies to meet expected demands under normal conditions. Because of this, a significant increase in demand regardless of the cause will likely result in a fuel disruption or shortage.

Crude Supply in Alaska—At any given time, there is less than one week of crude oil available at the Alaska Terminal that supplies Washington's four refineries.

Refineries in Washington—Refineries located in the Puget Sound area of Washington State also have about a one week supply of product on hand. These refineries have been operating above 90 percent capacity for decades. The refineries have no plans to increase capacity and cannot accommodate a dramatic demand increase.

Portland Petroleum Distribution Terminals—The seven terminals located in the Fuel Hub in Portland are on a six-day refueling cycle. At any given time, the Fuel Hub has only a one week supply of refined gasoline and diesel reserves on hand.

Retail Service Stations—Depending on the storage capacity and refueling cycles, retail service stations throughout the state have about a two to three day supply on site.

PETROLEUM SECTOR INTERDEPENDENCIES

The rapid recovery of the region's petroleum supply and distribution system is heavily dependent on other critical lifeline services. The fuel sector is reliant on other ESFs to gain situational awareness; conduct damage assessment; obtain and transport fuel to priority users; and support recovery operations in the aftermath of a Cascadia earthquake. These interdependencies include:

ESF 1: Transportation—Viable roads, highways, bridges, and waterways are essential to supporting fuel deliveries to priority users.

ESF 2: Communications—Viable communications are essential to ODOE's ability to: 1) assess impacts to the petroleum supply and distribution system; 2) work with USDOE and petroleum industry partners to obtain fuel from outside the region and transport it into Oregon; 3) facilitate emergency fuel requests and deliveries to priority users; 4) provide fuel sector situational awareness to key federal, state, and local emergency response agencies and other critical stakeholders; and 5) provide emergency information and instructions regarding critical fuel conservation measures to the news media and public.

ESF 12: Energy (Electricity) —Operators at the petroleum terminals need electricity to conduct damage assessments to the facilities, tanks, equipment, and systems. Power is essential to getting the fuel out of the storage tanks into delivery trucks. Electricity is also needed at designated fuel distribution points and emergency fueling locations for responders to fuel up their response vehicles. Electric power is also required for pipeline operation.

State of Oregon Department of Environmental Quality

Electric Vehicles in Oregon – End of 2018

Updated: April 19, 2019
Contact: Cory-Ann Wind, wind.cory@deq.state.or.us

This document provides data on the electric vehicles registered in Oregon. DEQ compiles this report quarterly based on Oregon vehicle registration records provided by the Oregon Department of Motor Vehicles (DMV). This information is used for many purposes, including:

- To measure Oregon's progress towards Governor Brown's Executive Order 17-21 to have 50,000 electric vehicles registered in the state by the end of 2020;
- To implement two of DEQ's regulatory programs: the Zero Emissions Vehicle (ZEV) mandate and the Clean Fuels Program (CFP) and
- To provide information to the many stakeholders interested in transportation electrification.

Table 1 shows the number of electric vehicles registered in Oregon through the end of 2018.

Battery Electric Vehicles (BEVs)	Plug-in Hybrid Electric Vehicles (PHEVs)	Total Electric Vehicles (EVs)
12,951	9,094	22,045

Figure 1 shows the growth in BEV, PHEV and total EV registrations since 2013.

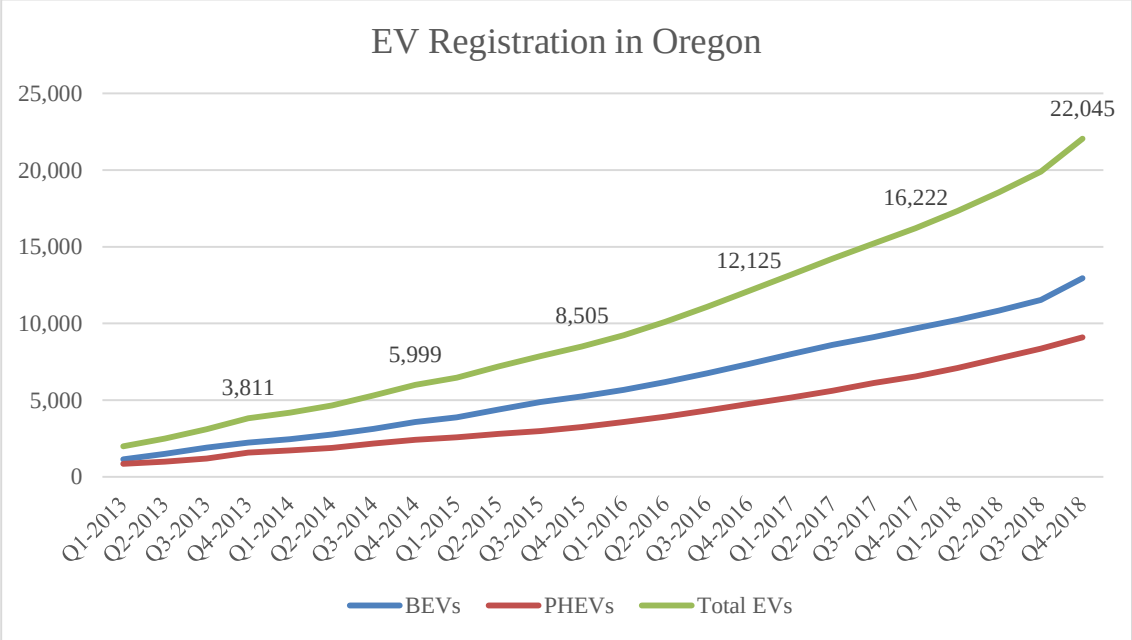


Table 2 shows the number of BEV, PHEV and total EVs registered by county, including registrations per capita and changes in registrations since the end of June 2018.

	End of Dec 2018						Changes since June 2018			
County	BEVs	PHEVs	EVs	% Registered in County	Population	Registrations per capita	BEVs	PHEVs	EVs	% change
Baker	5	8	13	0.06%	15,980	0.08%	(2)	1	(1)	-7.69%
Benton	370	266	636	3.06%	88,249	0.76%	132	39	171	26.89%
Clackamas	1,846	1,116	2,962	14.58%	399,962	0.80%	566	163	729	24.61%
Clatsop	48	61	109	0.56%	38,021	0.32%	18	15	33	30.28%
Columbia	83	102	185	0.89%	50,207	0.39%	18	11	29	15.68%
Coos	57	69	126	0.61%	62,921	0.21%	14	9	23	18.25%
Crook	16	23	39	0.18%	21,717	0.18%	7	4	11	28.21%
Curry	35	40	75	0.35%	22,377	0.34%	19	8	27	36.00%
Deschutes	464	326	790	3.89%	175,321	0.49%	166	68	234	29.62%

Oregon Fuel Action Plan

Oregon Seismic Safety Policy Advisory Commission

Deanna Henry
Emergency Preparedness Manager

January 8, 2019

OREGON DEPARTMENT OF ENERGY

Emergency Powers: Fuel

State Declared Emergency – Management of Resources (ORS 401.188)

- ✓ Control, restrict, and regulate the use of food, feed, **fuel**, clothing, and other commodities, materials, goods, and services

Oregon Department of Energy (ODOE) Authority – (ORS 176.750-785)

- ✓ Develop and maintain a statewide contingency plan in response to petroleum shortages that impact Oregon
- ✓ Provide adequate fuel supplies to maintain emergency services, transportation, and the operation of the economy to ensure the health, safety, and welfare of the residents of the State of Oregon while an emergency exists

Fuel Executive Order

- ✓ Authorizes ODOE to implement the strategies in the Oregon Fuel Action Plan in response to a Cascadia Subduction Zone Earthquake and Tsunami

HISTORY: Energy Assurance & Resiliency

Awards Grants to 50 States – Fall 2009

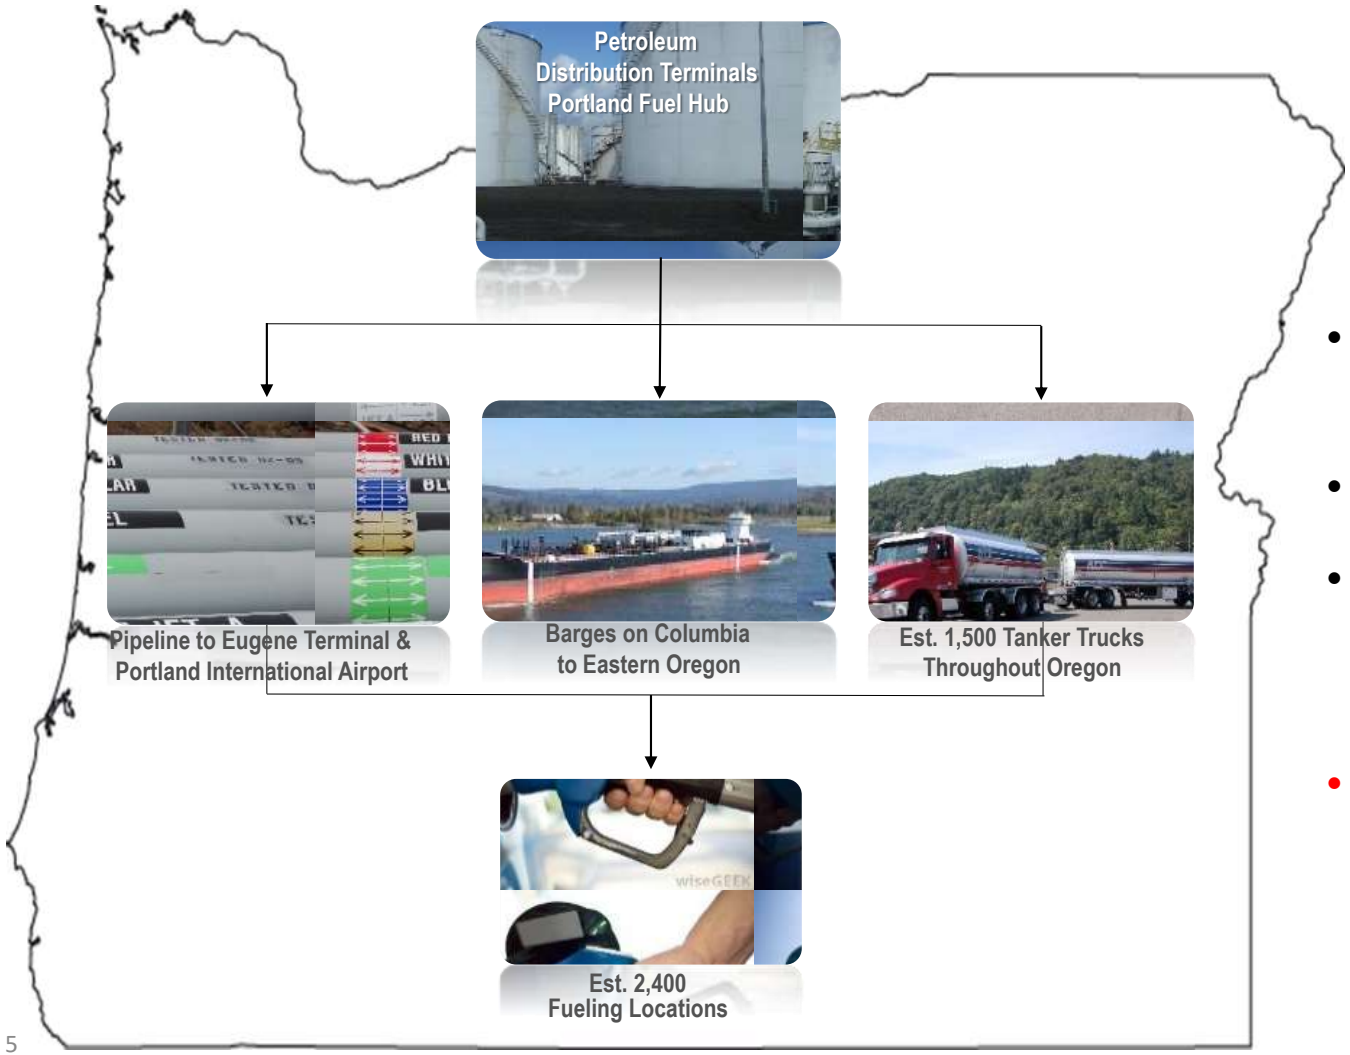
To enhance state government energy assurance and resiliency

Oregon Department of Energy (ODOE)

- Partnered with the Oregon Public Utility Commission (OPUC) and the Oregon Department of Geology and Mineral Industries (DOGAMI)
- Assessed seismic vulnerabilities and earthquake impacts on critical energy infrastructure from a 9.0 Cascadia Subduction Zone (CSZ) earthquake
- Coincided with the state's development of the Oregon Resilience Plan

USDOE Definition: Resilience

"The ability of the energy critical infrastructure to absorb, adapt to, and/or rapidly recover from a potentially severe and disruptive event"



Oregon Imports 100 Percent of the State's Refined Petroleum Products

- Washington refineries supply more than 90 percent
  - ✓ About 75 percent by Olympic Pipeline to Oregon
  - ✓ Remaining product by tanker ships to Oregon
  - ✓ Portland Fuel Hub – located on liquefiable soils *anticipate significant fuel supply loss*
- Utah refineries supply less than 5 percent to eastern Oregon communities
- California refineries supply less than 5 percent to southern Oregon communities

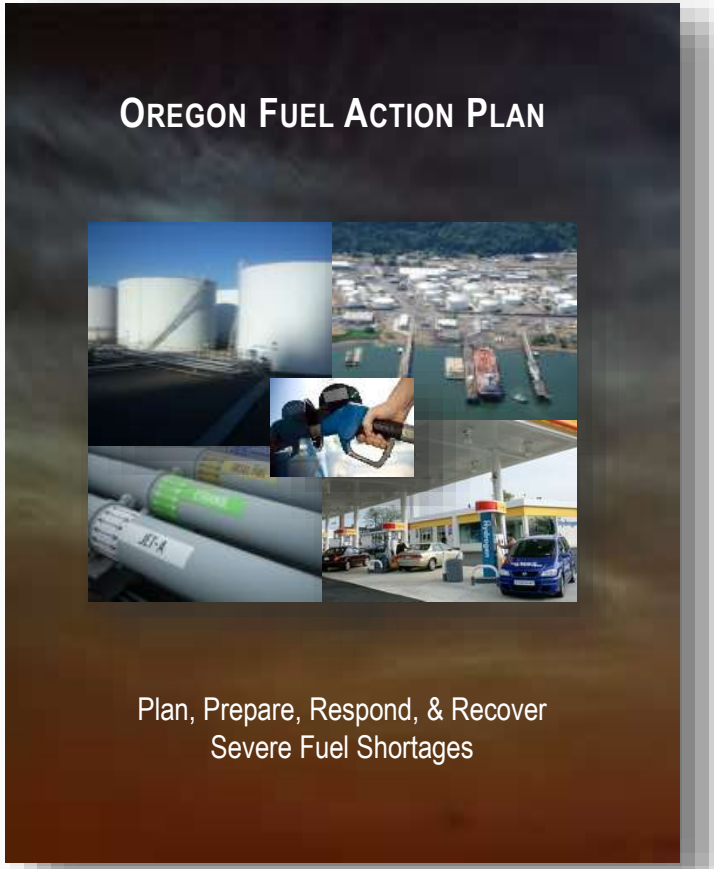
OREGON DEPARTMENT OF ENERGY

Oregon Fuel Supply & Distribution System

- Annual fuel imports estimated at three billion gallons
- Six day fuel delivery cycle
- Product delivered throughout Oregon by pipeline, barges, and tanker trucks
- Anticipate significant impacts to distribution system post Cascadia

OREGON DEPARTMENT OF ENERGY

DOGAMI Study Sites Aging Petroleum Infrastructure



Olympic Pipeline built in the 1960s without seismic design standards

Only 3 of the hundreds of fuel tanks at the Portland fuel hub likely to survive Cascadia

Marine docks receiving fuel will be damaged with moderate earthquake

OREGON DEPARTMENT OF ENERGY

Oregon Fuel Action Plan

- Identifies ODOE authority and responsibilities to control and direct the state's overall response to petroleum emergencies
- Provides coordination structure for federal, state, county, tribal, and petroleum industry partners
- Provides structure for fuel allocation that identifies pre-approved priority users of fuel and user responsibilities
- Identifies state and county priority lifeline routes to support fuel deliveries
- Pre-designates Fuel Points of Distribution (FPOD) for receiving emergency fuel
- Plan on ODOE website - ***www./Oregon.gov/ENERGY***

Oregon Fuel Action Plan: 9 Priority Actions

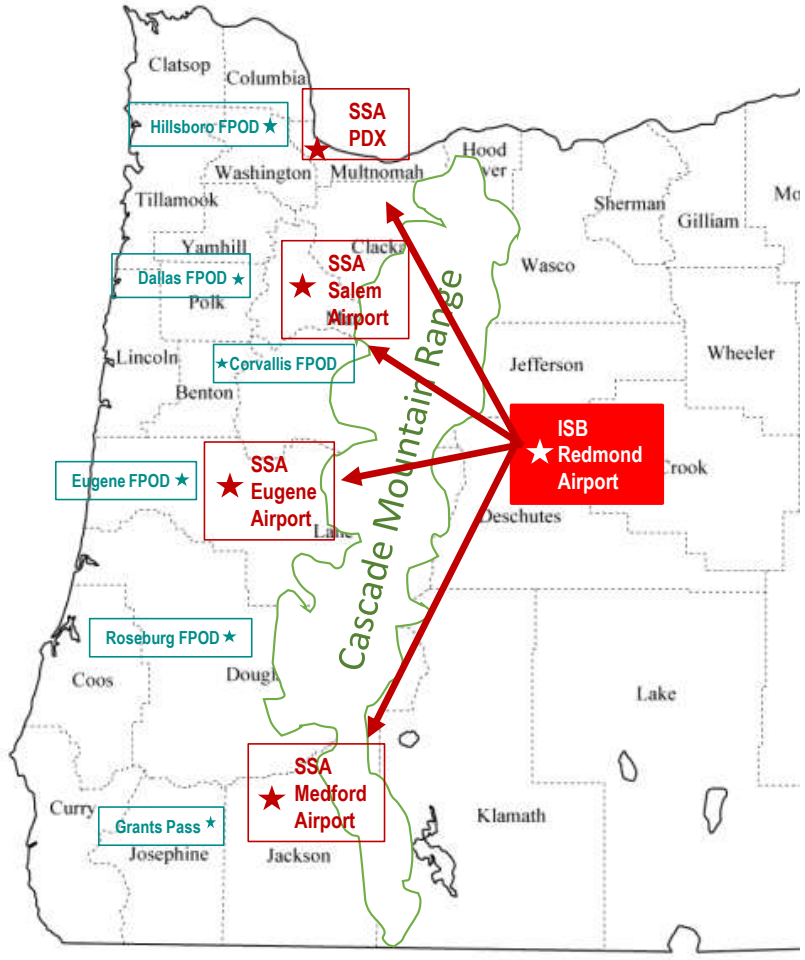
OREGON DEPARTMENT OF ENERGY

Action 1	Action 2	Action 3	Action 4	Action 5	Action 6	Action 7	Action 8	Actions 9
Notification Activation and Authorities	**Public Information**	**Damage Assessment**	**Assess Fuel Needs & Determine Priorities**	**Outside Assistance: Fuel Supply**	**Fuel Conservation Measures**	**Temporary Waivers**	**Fuel Allocation**	**Recovery**
- Initial Notifications - Activate ODOE AOC - Succession & Authorities	- ODOE Fuel Emergency Outlook Web Page - Public Information Campaign – social media - News conferences - Telephone Information Center	- Assess impacts to petroleum infrastructure - Estimate timeline for repairs - Provide fuel sector info & status updates	- Assess fuel availability in Oregon - Assess 18 state ESFs, counties, and tribal fuel needs - Determine state & regional fuel priorities - Governor's Disaster Cabinet	- Identify & obtain fuel source - Identify viable fuel delivery options into Oregon - Identify viable options for dispensing fuel	- Issue voluntary fuel conservation measures - Issue mandatory fuel conservation measures	- Obtain temporary environmental operational, and safety waivers as needed to ensure the timely delivery of fuel	- Review & approve/deny fuel requests *(ESF Primary State Agencies, counties & tribes)* - Allocate fuel to approved state agencies, counties & tribes - Odd/Even Fuel Allocation - ***Fuel Request Form Provided***	- Allocate fuel to support recovery activities - State Recovery Coordinating Team - Governor's Recovery Cabinet - Terminate fuel recovery activities as appropriate

Fuel Allocation: All Hazards

Saving Lives and Restoring Critical Lifelines & Services

OREGON DEPARTMENT OF ENERGY



Challenge – Allocating fuel to emergency and essential service providers in the state involves 120 state agencies, 36 counties, 240 cities, and 9 federally-recognized tribes

Standardized Structure – Identifies three categories of priority fuel users:

- 18 ESF Primary State Agencies
- 36 Counties
- 9 Federally-Recognized Tribes

Fuel Strategy: Air Response

INITIAL AIR RESPONSE ACTIVITIES

Required Support: Federal, Military, and Industry

Bulk Fuel Source – Outside Region

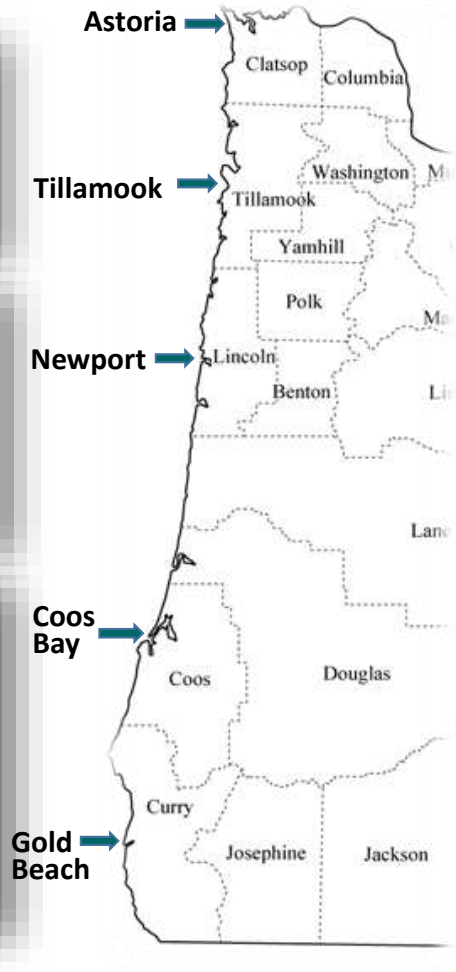
- Bulk fuel "pushed" into the federal Incident Support Base - Redmond Municipal Airport
- Initial daily bulk fuel push into Oregon
  - Unleaded gasoline – est. 75,000 gallons
  - Diesel – est. 400,000 gallons
- ODOE directs fuel movement from federal ISB to State Staging Areas and to the pre-designated fuel points in the impacted communities

Fuel Strategy: State & Local Lifeline Routes

Oregon Department of Transportation (ODOT)

- **State Lifeline Routes** – Guide initial repairs on the transportation, power, and communication systems to support fuel delivery
- **County Lifeline Routes** – Counties to identify local priority routes that connect to state lifeline routes
- **Fuel Points of Distribution (FPOD)** – Counties pre-designate FPODs to receive emergency fuel supplies

- **Marion County Example:**
  - Identified Tier 1 priority routes connecting to state lifeline routes
  - Pre-designated 9 FPODs to receive emergency bulk fuel supplies



ODOE has fuel data from 26 of 36 counties

Fuel Strategy: Oregon Coast

U.S. MARITIME ADMINISTRATION (MARAD) ASSETS

Fuel Source: Outside Region

Maritime Assets – Deliver bulk fuel and operate portable fueling points along the Oregon Coast

- Ready Reserve Force ships out 7 – 10 days of notification
- Larger MARAD vessels ship out within 30 days of notification

Foreign Vessels – Lift Jones Act to allow foreign vessels to deliver bulk fuel to Oregon ports

- Superstorm Sandy – Foreign vessels shipped 115 million gallons of fuel to ports in New York and New Jersey

Fuel Strategy: Central & Eastern Oregon

OREGON DEPARTMENT OF ENERGY

VIABLE CRITICAL INFRASTRUCTURE

Working Transportation, Power & Communications Systems

Fuel Source: Pasco Distribution Terminal-Petroleum Industry

- Reliant on petroleum industry to meet fuel demands
- Obtain temporary waivers to ensure timely fuel movement
- Implement voluntary/mandatory fuel conservation measures
- Implement Odd/Even Fuel Allocation Program if needed
- Implement public information campaign to reduce fuel consumption

Oregon Fuel Action Plan: In Progress

JANUARY 25, 2018 FUELING ANXIETY TABLETOP: GAP IDENTIFIED

- Need for ODOE to assist counties with developing local fuel management plans
- ODOE works with the Oregon Fuels Association and member companies to identify strategies for local fuel management *(acquisition, storage, distribution)* post - Cascadia
  - Presented Oregon Fuel Action Plan at OFA Conference *(July 2018)*
  - Survey completed of OFA member companies *(November 2018)*
- ODOE to review survey results
- ODOE to facilitate meetings between counties and fuel distributors as appropriate to assist in local fuel management plan development

Partnership With OFA & Members

Alternate Fuel Hub: Post Cascadia

JANUARY 25, 2018 FUELING ANXIETY TABLETOP: GAP IDENTIFIED

- Need to identify an alternate location for a Fuel Hub if industry determines the existing location is unsalvageable post - Cascadia

- Industry Requirements for Alternate Fuel Hub:
  - Upriver on stable soils within close proximity to current location
  - Access to waterway
  - Access to rail systems
  - Government support

Oregon Only As Resilient as the Region's Fuel Infrastructure

- Washington Refineries Resilience
  - ✓ Anticipate moderate/significant damage – inoperable for months if not longer
- Olympic Pipeline Resilience
  - ✓ Anticipate widespread damage *(est. 250 breaks/82 leaks)* – inoperable for months if not longer
- Oregon Fuel Sector Resilience (CEI Hub)
  - ✓ No seismic assessments or risk mitigation plans have been conducted by fuel companies
  - ✓ Need to identify alternate CEI Hub post - Cascadia
  - ✓ Challenge remains getting fuel to the impacted communities with compromised roads and bridges

Oregon Fuel Action Plan

[1]Includes waste coal.
[2]These values represent the energy obtained from uranium when it is used in light water reactors. The total energy content of uranium is much larger, but alternative processes are required to take advantage of it.
[3]Includes grid-connected electricity from wood and wood waste; biomass, such as corn, used for liquid fuels production; and non-electric energy demand from wood. Refer to Table A17 for details.
[4]Includes grid-connected electricity from landfill gas; biogenic municipal waste; wind; photovoltaic and solar thermal sources; and non-electric energy from renewable sources, such as active and passive solar systems. Excludes electricity imports using renewable sources and nonmarketed renewable energy. See Table A17 for selected nonmarketed residential and commercial renewable energy data.
[5]Includes non-biogenic municipal waste, liquid hydrogen, methanol, and some domestic inputs to refineries.
[6]Includes imports of finished petroleum products, unfinished oils, alcohols, ethers, blending components, and renewable fuels such as ethanol.
[7]Includes coal, coal coke (net), and electricity (net). Excludes imports of fuel used in nuclear power plants.
[8]Includes crude oil, petroleum products, ethanol, and biodiesel.
[9]Balancing item. Includes unaccounted for supply, losses, gains, and net storage withdrawals.
[10]Estimated consumption. Includes petroleum-derived fuels and non-petroleum derived fuels, such as ethanol and biodiesel, and coal-based synthetic liquids. Petroleum coke, which is a solid, is included. Also included are hydrocarbon gas liquids and crude oil consumed as a fuel. Refer to Table A17 for detailed renewable liquid fuels consumption.
[11]Excludes coal converted to coal-based synthetic liquids and natural gas.
[12]Includes grid-connected electricity from wood and wood waste, non-electric energy from wood, and biofuels heat and coproducts used in the production of liquid fuels, but excludes the energy content of the liquid fuels.
[13]Includes non-biogenic municipal waste, liquid hydrogen, and net electricity imports.
[14]Includes reported prices for both open market and captive mines. Prices weighted by production, which differs from average minemouth prices published in EIA data reports where it is weighted by reported sales.
[15]Prices weighted by consumption; weighted average excludes export free-alongside-ship (f.a.s.) prices.
Btu = British thermal unit.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

[1]Includes residential use of kerosene.
[2]Includes wood used for residential heating. See Table A4 and/or Table A17 for estimates of nonmarketed renewable energy consumption for geothermal heat pumps, solar thermal water heating, and electricity generation from wind and solar photovoltaic sources.
[3]Includes ethanol and ethers blended into gasoline.
[4]Excludes ethanol. Includes commercial sector consumption of wood and wood waste, landfill gas, municipal waste, and other biomass for combined heat and power. See Table A5 and/or Table A17 for estimates of nonmarketed renewable energy consumption for solar thermal water heating and electricity generation from wind and solar photovoltaic sources.
[5]Includes energy for combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[6]Includes ethane, natural gasoline, and refinery olefins.
[7]Includes petroleum coke, asphalt, road oil, lubricants, still gas, and miscellaneous petroleum products.
[8]Represents natural gas used in well, field, and lease operations, and in natural gas processing plant machinery.
[9]Fuel used in facilities that liquefy natural gas for export.
[10]Includes consumption of energy produced from hydroelectric, wood and wood waste, municipal waste, and other biomass sources. Excludes ethanol in motor gasoline.
[11]E85 refers to a blend of 85 percent ethanol (renewable) and 15 percent motor gasoline (nonrenewable). To address cold starting issues, the percentage of ethanol varies seasonally. The annual average ethanol content of 74 percent is used for these projections.
[12]Includes only kerosene type.
[13]Diesel fuel for on- and off- road use.
[14]Includes aviation gasoline and lubricants.
[15]Represents consumption unattributed to the sectors above.
[16]Does not include residential use of kerosene.
[17]Includes aviation gasoline, petroleum coke, asphalt, road oil, lubricants, still gas, and miscellaneous petroleum products.
[18]Includes electricity generated for sale to the grid and for own use from renewable sources, and non-electric energy from renewable sources. Excludes ethanol and nonmarketed renewable energy consumption for geothermal heat pumps, buildings photovoltaic systems, and solar thermal water heaters.
[19]Includes consumption of energy by electricity-only and combined heat and power plants that have a regulatory status.
[20]These values represent the energy obtained from uranium when it is used in light water reactors. The total energy content of uranium is much larger, but alternative processes are required to take advantage of it.
[21]Includes conventional hydroelectric, geothermal, wood and wood waste, biogenic municipal waste, other biomass, wind, photovoltaic, and solar thermal sources. Excludes net electricity imports.
[22]Includes conventional hydroelectric, geothermal, wood and wood waste, biogenic municipal waste, other biomass, wind, photovoltaic, and solar thermal sources. Excludes ethanol, net electricity imports, and nonmarketed renewable energy consumption for geothermal heat pumps, buildings photovoltaic systems, and solar thermal water heaters.
Btu = British thermal unit.
- - = Not applicable.
Note: Includes estimated consumption for petroleum and other liquids. Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.
Sources: 2017 consumption based on: U.S. Energy Information Administration (EIA), *Monthly Energy Review*, September 2018. 2017 and 2018 population and gross domestic product: IHS Markit, Macroeconomic model, August 2018. 2017 carbon dioxide emissions and emission factors: EIA, *Monthly Energy Review*, September 2018. 2018: EIA, *Short-Term Energy Outlook*, October 2018 and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. **Projections:** EIA, AEO2019 National Energy Modeling System run ref2019.d111618a.

[1]Includes energy for combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[2]Excludes use for lease and plant fuel and fuel used for liquefaction in export facilities.
[3]E85 refers to a blend of 85 percent ethanol (renewable) and 15 percent motor gasoline (nonrenewable). To address cold starting issues, the percentage of ethanol varies seasonally. The annual average ethanol content of 74 percent is used for these projections.
[4]Sales weighted-average price for all grades. Includes Federal, State, and local taxes.
[5]Kerosene-type jet fuel. Includes Federal and State taxes while excluding county and local taxes.
[6]Diesel fuel for on-road use. Includes Federal and State taxes while excluding county and local taxes.
[7]Natural gas used as fuel in motor vehicles, trains, and ships. Includes estimated motor vehicle fuel taxes and estimated dispensing costs or charges.
[8]Includes electricity-only and combined heat and power plants that have a regulatory status.
[9]Weighted averages of end-use fuel prices are derived from the prices shown in each sector and the corresponding sectoral consumption.
Btu = British thermal unit.
- - = Not applicable.
Note: Data for 2017 are model results and may differ from official EIA data reports.
Sources: 2017 prices for motor gasoline, distillate fuel oil, and jet fuel are based on prices in the U.S. Energy Information Administration (EIA), *Petroleum Marketing Monthly*, July 2018. 2017 residential and commercial natural gas delivered prices: EIA, *Natural Gas Monthly*, July 2018. 2017 industrial natural gas delivered prices derived on: EIA, *Manufacturing Energy Consumption Survey*, 2002-2014. 2017 transportation sector natural gas delivered prices are model results. 2017 electric power sector distillate and residual fuel oil prices: EIA, *Monthly Energy Review*, September 2018. 2017 electric power sector natural gas prices: EIA, *Electric Power Monthly*, July 2018, and EIA, *State Energy Data Report 2016*. 2017 coal prices based on: EIA, *Quarterly Coal Report, October-December 2017* and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. 2017 electricity prices: EIA, *Monthly Energy Review*, September 2018. 2017 E85 prices derived from monthly prices in the Clean Cities Alternative Fuel Price Report. 2018: EIA, *Short-Term Energy Outlook*, October 2018 and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. **Projections:** EIA, AEO2019 National Energy Modeling System run ref2019.d111618a.

[1]Does not include water heating portion of load.
[2]Includes televisions, set-top boxes, home theater systems, DVD players, and video game consoles.
[3]Includes desktop and laptop computers, monitors, and networking equipment.
[4]Includes small electric devices, heating elements, and motors not listed above. Electric vehicles are included in the transportation sector.
[5]Includes such appliances as outdoor grills, natural gas-fueled lights, pool heaters, spa heaters, and backup electricity generators.
[6]Includes kerosene use.
[7]Includes such appliances as pool heaters, spa heaters, and backup electricity generators.
[8]Includes wood used for primary and secondary heating in wood stoves or fireplaces as reported in the *Residential Energy Consumption Survey*.
[9]Includes small electric devices, heating elements, outdoor grills, natural gas-fueled lights, pool heaters, spa heaters, backup electricity generators, and motors not listed above. Electric vehicles are included in the transportation sector.
[10]Consumption determined by using the average electric power sector fossil-fuels net heat rate.
[11]See Table A5 for regional detail.
Btu = British thermal unit.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

Coal	0.15	0.15	0.13	0.11	0.10	0.09	0.08	-1.9%
Renewable fuels[7]	0.33	0.31	0.30	0.29	0.28	0.27	0.25	-0.7%
Purchased electricity	0.43	0.42	0.42	0.40	0.38	0.36	0.32	-0.8%
Delivered energy	**3.37**	**3.38**	**3.28**	**3.14**	**2.97**	**2.84**	**2.56**	**-0.9%**
Industrial combined heat and power[1]								
Capacity (gigawatts)	25.3	25.9	28.6	30.0	31.8	33.8	39.2	1.3%
Generation (billion kilowatthours)	140	147	164	172	181	192	221	1.3%

[1]Includes combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[2]Includes ethane, natural gasoline, and refinery olefins.
[3]Includes lubricants and miscellaneous petroleum products.
[4]Represents natural gas used in well, field, and lease operations, and in natural gas processing plant machinery.
[5]Fuel used in facilities that liquefy natural gas for export.
[6]Includes net coal coke imports.
[7]Includes consumption of energy produced from hydroelectric, wood and wood waste, municipal waste, and other biomass sources.
Btu = British thermal unit.
- - = Not applicable.
Note: Includes estimated consumption for petroleum and other liquids. Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.
Sources: 2017 prices for motor gasoline and distillate fuel oil are based on: U.S. Energy Information Administration (EIA), *Petroleum Marketing Monthly*, July 2018. 2017 petrochemical feedstock and asphalt and road oil prices are based on: EIA, *State Energy Data Report 2016*. 2017 coal prices are based on: EIA, *Quarterly Coal Report, October-December 2017* and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. 2017 electricity prices: EIA, *Monthly Energy Review*, September 2018. 2017 natural gas prices: *Natural Gas Monthly*, July 2018. 2017 refining consumption based on: *Petroleum Supply Annual 2017*, and EIA, *Refinery Capacity Report*, June 2017. Other 2017 consumption values are based on: EIA, *Monthly Energy Review*, September 2018. 2017 shipments: IHS Markit, Industry model, May 2018. 2018: EIA, *Short-Term Energy Outlook*, October 2018 and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. **Projections:** EIA, AEO2019 National Energy Modeling System run ref2019.d111618a.

[1]Net summer capacity is the steady hourly output that generating equipment is expected to supply to system load (exclusive of auxiliary power), as demonstrated by tests during summer peak demand.
[2]Includes electricity-only and combined heat and power plants that have a regulatory status.
[3]Includes plants that only produce electricity and that have a regulatory status. Includes capacity increases (uprates) at existing units.
[4]Total coal and oil and natural gas steam capacity account for the conversion of coal capacity to gas steam capacity, but the conversions are not included explicitly as additions or retirements. No planned conversions are assumed. The totals may reflect any conversions projected by the model.
[5]Includes oil-, gas-, and dual-fired capacity.
[6]Nuclear capacity includes 3.0 gigawatts of uprates.
[7]Includes conventional hydroelectric, geothermal, wood, wood waste, all municipal waste, landfill gas, other biomass, solar, and wind power. Facilities co-firing biomass and coal are classified as coal.
[8]Primarily peak load capacity fueled by natural gas.
[9]Includes combined heat and power plants whose primary business is to sell electricity and heat to the public (i.e., those that report North American Industry Classification System code 22 or that have a regulatory status).
[10]Cumulative additions after December 31, 2018.
[11]Cumulative retirements after December 31, 2018.
[12]Includes combined heat and power plants and electricity-only plants in the commercial and industrial sectors that have a non-regulatory status; and small on-site generating systems in the residential, commercial, and industrial sectors used primarily for own-use generation, but which may also sell some power to the grid.
[13]Includes refinery gas and still gas.
[14]Includes batteries, chemicals, hydrogen, pitch, purchased steam, sulfur, and miscellaneous technologies.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.
Sources: 2017 capacity and projected planned additions: U.S. Energy Information Administration (EIA), Form EIA-860, "Annual Electric Generator Report" (preliminary). 2018: EIA, *Short-Term Energy Outlook*, October 2018 and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. **Projections:** EIA, AEO2019 National Energy Modeling System run ref2019.d111618a.

Economy	7.0	10.2	9.1	9.1	9.1	9.1	9.1	-0.4%
Total	**9.4**	**10.2**	**9.1**	**9.1**	**9.1**	**9.1**	**9.1**	**-0.4%**

- - = Not applicable.

Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports. Firm power sales are capacity sales, meaning the delivery of the power is scheduled as part of the normal operating conditions of the affected electric systems. Economy sales are subject to curtailment or cessation of delivery by the supplier in accordance with prior agreements or under specified conditions.

Table A11. Petroleum and other liquids supply and disposition (continued)
(million barrels per day, unless otherwise noted)

Supply and disposition	Reference case							Annual growth 2018-2050 (percent)
	2017	2018	2025	2030	2035	2040	2050	
Domestic refinery distillation capacity[18]	18.6	18.6	19.0	19.0	19.0	19.0	19.0	0.1%
Capacity utilization rate (percent)[19]	91.1	92.6	91.6	91.2	90.7	90.5	91.0	-0.1%
Total gross imports	10.14	10.18	7.78	6.77	7.02	7.76	9.67	-0.2%
Total gross exports	6.37	7.82	10.16	10.17	10.65	11.01	9.63	0.7%
Total net imports	3.76	2.37	-2.38	-3.39	-3.63	-3.25	0.04	-12.1%
Net import share of product supplied (percent)	18.9	11.7	-12.0	-17.6	-19.1	-16.9	0.2	-12.1%
Expenditures for imported crude oil and petroleum products (billion 2018 dollars)	138	170	174	172	195	227	290	1.7%

[1]Includes lease condensate.
[2]Strategic petroleum reserve stock additions plus unaccounted for crude oil and crude oil stock withdrawals.
[3]Includes other hydrocarbons and alcohols.
[4]The volumetric amount by which total output is greater than input due to the processing of crude oil into products which, in total, have a lower specific gravity than the crude oil processed.
[5]Includes pyrolysis oils, biomass-derived Fischer-Tropsch liquids, biobutanol, and renewable feedstocks used for the on-site production of diesel and gasoline.
[6]Includes domestic sources of other blending components, other hydrocarbons, and ethers.
[7]Total crude supply, net product imports, refinery processing gain, product stock withdrawal, natural gas plant liquids, supply from renewable sources, liquids from gas, liquids from coal, and other supply.
[8]Includes ethane, natural gasoline, and refinery olefins.
[9]Includes ethanol and ethers blended into gasoline.
[10]E85 refers to a blend of 85 percent ethanol (renewable) and 15 percent motor gasoline (nonrenewable). To address cold starting issues, the percentage of ethanol varies seasonally. The annual average ethanol content of 74 percent is used for these projections.
[11]Includes only kerosene type.
[12]Includes distillate fuel oil from petroleum and biomass feedstocks and kerosene use in the residential sector.
[13]Includes aviation gasoline, petrochemical feedstocks, lubricants, waxes, asphalt, road oil, still gas, special naphthas, petroleum coke, crude oil product supplied, methanol, miscellaneous petroleum products, and kerosene not used in the residential sector.
[14]Includes energy for combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[15]Includes consumption of energy by electricity-only and combined heat and power plants that have a regulatory status.
[16]Represents consumption unattributed to the sectors above.
[17]Balancing item. Includes unaccounted for supply, losses, and gains.
[18]End-of-year operable capacity.
[19]Rate is calculated by dividing the gross annual input to atmospheric crude oil distillation units by their operable refining capacity in barrels per calendar day.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

[1]Marketed production (wet) minus extraction losses.
[2]Synthetic natural gas, propane air, coke oven gas, refinery gas, biomass gas, air injected for Btu stabilization, and manufactured gas commingled and distributed with natural gas.
[3]Natural gas imported to and exported from Canada and Mexico.
[4]Includes energy for combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[5]Represents natural gas used in well, field, and lease operations, and in natural gas processing plant machinery.
[6]Fuel used in facilities that liquefy natural gas for export.
[7]Includes any natural gas used in the process of converting natural gas to liquid fuel that is not actually converted.
[8]Includes any natural gas converted into liquid fuel.
[9]Includes consumption of energy by electricity-only and combined heat and power plants that have a regulatory status.
[10]Balancing item. Natural gas lost as a result of converting flow data measured at varying temperatures and pressures to a standard temperature and pressure and the merger of different data reporting systems which vary in scope, format, definition, and respondent type. In addition, 2017 values include net storage injections.
[11]Excludes use for lease and plant fuel and fuel used for liquefaction in export facilities. Includes energy for combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[12]Natural gas used as fuel in motor vehicles, trains, and ships. Price includes estimated motor vehicle fuel taxes and estimated dispensing costs or charges.
[13]Weighted average prices. Weights used are the sectoral consumption values excluding lease, plant, pipeline and distribution fuel, and fuel used for liquefaction in export facilities.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

(nominal dollars per short ton)	39.1	40.5	50.1	56.8	63.0	71.3	90.6	2.5%
(nominal dollars per million Btu)	2.05	2.11	2.58	2.95	3.27	3.69	4.67	2.5%
Average	**42.3**	**45.0**	**55.2**	**62.7**	**70.1**	**79.4**	**100.9**	**2.6%**
Exports[10]	77.3	94.0	105.2	112.0	118.0	125.4	151.6	1.5%

[1]Includes anthracite, bituminous coal, subbituminous coal, and lignite.
[2]Includes waste coal consumed by the electric power and industrial sectors. Waste coal supplied is counted as a supply-side item to balance the same amount of waste coal included in the consumption data.
[3]Excludes imports to Puerto Rico and the U.S. Virgin Islands.
[4]Production plus waste coal supplied plus net imports.
[5]Includes consumption for combined heat and power plants that have a non-regulatory status, and small on-site generating systems. Excludes all coal use in the coal-to-liquids process.
[6]Includes all electricity-only and combined heat and power plants that have a regulatory status.
[7]Balancing item: the sum of production, net imports, and waste coal supplied minus total consumption.
[8]Includes reported prices for both open market and captive mines. Prices weighted by production, which differs from average minemouth prices published in EIA data reports where it is weighted by reported sales.
[9]Prices weighted by consumption; weighted average excludes commercial and institutional prices, and export free-alongside-ship prices.
[10]Free-alongside-ship price at U.S. port of exit.
- - = Not applicable.
Btu = British thermal unit.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

Wind	254.5	273.4	364.9	369.7	373.0	381.5	428.9	1.4%
Total generation, all sectors	**710.0**	**734.2**	**1,014.6**	**1,100.0**	**1,199.5**	**1,356.2**	**1,695.9**	**2.7%**

[1]Includes electricity-only and combined heat and power plants that have a regulatory status.
[2]Includes both hydrothermal resources (hot water and steam) and near-field enhanced geothermal systems (EGS). Near-field EGS potential occurs on known hydrothermal sites, however this potential requires the addition of external fluids for electricity generation and is only available after 2025.
[3]Includes municipal waste, landfill gas, and municipal sewage sludge. Incremental growth is assumed to be for landfill gas facilities. All municipal waste is included, although a portion of the municipal waste stream contains petroleum-derived plastics and other non-renewable sources.
[4]Facilities co-firing biomass and coal are classified as coal.
[5]Does not include off-grid photovoltaics.
[6]Includes biogenic municipal waste, landfill gas, and municipal sewage sludge. Incremental growth is assumed to be for landfill gas facilities.
[7]Includes combined heat and power plants and electricity-only plants in the commercial and industrial sectors that have a non-regulatory status; and small on-site generating systems in the residential, commercial, and industrial sectors used primarily for own-use generation, but which may also sell some power to the grid.
[8]Includes municipal waste, landfill gas, and municipal sewage sludge. All municipal waste is included, although a portion of the municipal waste stream contains petroleum-derived plastics and other non-renewable sources.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.
Sources: 2017 capacity: U.S. Energy Information Administration (EIA), Form EIA-860, "Annual Electric Generator Report" (preliminary). 2017 generation: EIA, *Monthly Energy Review*, September 2018. 2018: EIA, *Short-Term Energy Outlook*, October 2018 and EIA, AEO2019 National Energy Modeling System run ref2019.d111618a. **Projections:** EIA, AEO2019 National Energy Modeling System run ref2019.d111618a.

Wind	0.01	0.01	0.01	0.01	0.01	0.01	0.02	3.4%

[1]Includes nonelectric renewable energy groups for which the energy source is bought and sold in the marketplace, although all transactions may not necessarily be marketed, and renewable energy inputs for electricity entering the marketplace on the electric power grid. Excludes electricity imports; see Table A2. Actual heat rates used to determine fuel consumption for all renewable fuels except hydroelectric, geothermal, solar, and wind. Consumption at hydroelectric, geothermal, solar, and wind facilities is determined by using the average electric power sector fossil-fuels net heat rate.
[2]Includes combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[3]Includes municipal waste, landfill gas, and municipal sewage sludge. All municipal waste is included, although a portion of the municipal waste stream contains petroleum-derived plastics and other non-renewable sources.
[4]Excludes motor gasoline component of E85. E85 refers to a blend of 85 percent ethanol (renewable) and 15 percent motor gasoline (nonrenewable). To address cold starting issues, the percentage of ethanol varies seasonally. The annual average ethanol content of 74 percent is used for these projections.
[5]Renewable feedstocks for the on-site production of diesel and gasoline.
[6]Includes consumption of energy by electricity-only and combined heat and power plants that have a regulatory status.
[7]Includes biogenic municipal waste, landfill gas, and municipal sewage sludge. Incremental growth is assumed to be for landfill gas facilities.
[8]Includes selected renewable energy consumption data for which the energy is not bought or sold, either directly or indirectly as an input to marketed energy. The U.S. Energy Information Administration does not estimate or project total consumption of nonmarketed renewable energy.
- - = Not applicable.
Btu = British thermal unit.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

[1]Emissions from the electric power sector are distributed to the end-use sectors.
[2]Includes combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[3]Includes lease and plant fuel.
[4]This includes carbon dioxide from international bunker fuels, both civilian and military, which are excluded from the accounting of carbon dioxide emissions under the United Nations convention.
[5]Includes pipeline and distribution fuel natural gas and natural gas used as fuel in motor vehicles, trains, and ships.
[6]Includes electricity-only and combined heat and power plants that have a regulatory status.
[7]Includes emissions from geothermal power and nonbiogenic emissions from municipal waste.

Note: By convention, the direct emissions from biogenic energy sources are excluded from energy-related carbon dioxide emissions. The release of carbon from these sources is assumed to be balanced by the uptake of carbon when the feedstock is grown, resulting in zero net emissions over some period of time. If, however, increased use of biomass energy results in a decline in terrestrial carbon stocks, a net positive release of carbon may occur. See Table A19, "Energy-Related Carbon Dioxide Emissions by End Use", for the emissions from biogenic energy sources as an indication of the potential net release of carbon dioxide in the absence of offsetting sequestration. Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

[1]Does not include water heating portion of load.
[2]Includes televisions, set-top boxes, home theater systems, DVD players, and video game consoles.
[3]Includes desktop and laptop computers, monitors, and networking equipment.
[4]Includes small electric devices, heating elements, outdoor grills, natural gas-fueled lights, pool heaters, spa heaters, backup electricity generators, and motors not listed above. Electric vehicles are included in the transportation sector.
[5]Represents differences between total emissions by end-use and total emissions by fuel as reported in Table A18. Emissions by fuel may reflect benchmarking and other modeling adjustments to energy use and the associated emissions that are not assigned to specific end uses.
[6]Includes emissions related to fuel consumption for district services.
[7]Includes emissions related to (but not limited to) miscellaneous uses such as transformers, medical imaging and other medical equipment, elevators, escalators, off-road electric vehicles, laboratory fume hoods, laundry equipment, coffee brewers, water services, emergency generators, combined heat and power in commercial buildings, manufacturing performed in commercial buildings, and cooking (distillate), plus residual fuel oil, propane, coal, motor gasoline, kerosene, and marketed renewable fuels (biomass).
[8]Includes combined heat and power plants that have a non-regulatory status, and small on-site generating systems.
[9]Commercial trucks 8,501 to 10,000 pounds gross vehicle weight rating.
[10]By convention, the direct emissions from biogenic energy sources are excluded from energy-related carbon dioxide emissions. The release of carbon from these sources is assumed to be balanced by the uptake of carbon when the feedstock is grown, resulting in zero net emissions over some period of time. If, however, increased use of biomass energy results in a decline in terrestrial carbon stocks, a net positive release of carbon may occur. Accordingly, the emissions from biogenic energy sources are reported here as an indication of the potential net release of carbon dioxide in the absence of offsetting sequestration.
- - = Not applicable.
Note: Totals may not equal sum of components due to independent rounding. Data for 2017 are model results and may differ from official EIA data reports.

2019 Fuel Supply Forecast

Background

Oregon Revised Statutes (2017) Chapter 750, Section 163[1] authorizes the Office of Economic Analysis (OEA), with substantial assistance from the Department of Environmental Quality, to produce annually a forecast regarding deficits and credits owing to fossil and alternative fuel consumption, as well as the availability of fossil and alternative fuels in Oregon. In particular, the forecast is to determine whether fuel supply will be sufficient to generate alternative fuel (ethanol, electricity, and diesel substitutes - including biodiesel, renewable diesel, natural gas, and propane) credits to meet the scheduled applicable low carbon fuel standards for the compliance period. The forecast report is required to include an assessment of banked deficits and credits at the beginning of the compliance period.

In preparing the forecast, the Office of Economic Analysis has formed a Clean Fuels Forecast Advisory Committee comprised of relevant experts and stakeholders to assist in reviewing methodological considerations and various data sources. A membership list can be found in Appendix A.

Data Sources

The forecast uses available public and program data to develop the estimates of low-carbon fuels available to Oregon and estimated consumption of fossil and alternative fuels in Oregon. The sources of this data include:

- Oregon Clean Fuels Program (CFP) Online System
- Fuel Pathway Codes (carbon intensity values) approved in Oregon and California
- Oregon Department of Transportation's (ODOT) Revenue Forecast
- Oregon DMV vehicle registration data
- Annual Energy Outlook from the US Energy Information Administration
- Trade associations (Renewable Fuels Association and the National Biodiesel Board) on their members' production capacity

Methodology

The current methodology was developed by ICF Incorporated for the 2017 Clean Fuels Forecast and is based on the following components: a fuel demand component, a fuel supply component, and a carbon intensity component.

Demand Inputs

- Vehicle stocks – OEA uses Oregon DMV vehicle registration data to analyze for which vehicle types are currently registered as well as historical trends.
- Fuel consumption – OEA uses a combination of the ODOT Revenue Forecast and the EIA Annual Energy Outlook to analyze for projected and historical trends in fuel consumption.

Fuel Supply

[1] https://olis.leg.state.or.us/liz/2017R1/Downloads/MeasureDocument/HB2017/Enrolled

- Fuels and associated feedstocks - OEA reviews data regarding the supply of gasoline, diesel, ethanol, biodiesel, renewable diesel, natural gas, propane and electricity.
- Regional fuel supply – OEA primarily uses data reported to CFP to analyze the volumes and types of fuels facilities are supplying fuels to Oregon. If needed, this information can be supplemented by information from California or British Columbia to demonstrate what fuels are broadly available to the West Coast.

Carbon Intensity

- Oregon and California-approved values – OEA looks at individual carbon intensity values to facilities that have been approved by either itself or by the California Air Resources Board.

Numerous issues were raised during the development of the 2019 forecast. For the 2020 forecast cycle, the Office of Economic Analysis will form a technical advisory committee to consider modifications to the existing methodology, as well as the incorporation of additional data sources not factored into the current methodology. In addition, much of the data underlying the clean fuels forecast has only recently begun to be collected. To the degree that the passage of time will generate longitudinal time series more amenable to the econometric techniques that are the cornerstone of OEA's forecasting processes, better projections will avail themselves over time.

Deficit Generation from Fossil Fuel Consumption – Credits Needed

The amount of credits needed to comply with the 2019 clean fuel standards is based on assumptions about the consumption of fossil fuels that generate deficits.

Gasoline Consumption

1,626 million gallons of gasoline, including ethanol, were consumed in 2017, the most recent year of data collected. Growth projections exhibited in the Oregon Department of Transportation's June 2018 forecast equal -1.7 percent growth for calendar year 2018 and 0.2 percent growth for calendar year 2019. CFP data shows that gasoline is being blended with ethanol statewide at 10.3 percent of the gasoline pool. As presented in Table 1, this results in a projected 1,436 million gallons of CBOB gasoline blendstock in 2019. In comparison, AEO estimates -0.3 percent growth in 2018 and -0.5 percent growth in 2019 for the Pacific Region. Furthermore, projected deficit generation assumes a CBOB energy density of 122.5 and a carbon intensity differential of -3.6 (a projected actual value of 97.2 minus a target value of 100.8. This results in an expected deficit generation equaling 634,994 deficits.

Diesel Consumption

According to CFP reported data, 750 million gallons of diesel, including bio- and renewable diesel, were consumed in 2017, the most recent year of data collected. Growth projections from the Department of Transportation's June 2018 forecast indicate 1.4 percent growth for calendar year 2018 and1.0 percent growth for calendar year 2019. AEO estimates -1.0 percent growth in 2018 and 1.1 percent growth for 2019 for the Pacific Region. The diesel pool has a greater variance in the amount of biodiesel and renewable diesel being blended with clear diesel blendstock. Therefore, OEA and DEQ developed a low and high case of diesel consumption based on low and high scenarios for biodiesel and renewable diesel blend rates. Both cases assume an energy density of 134.5 and a carbon intensity differential of -3.6 (a projected actual value of 98.1 minus a target value of 101.7). The low fossil diesel demand case forecasts 2019 diesel consumption at 642 million gallons by assuming blending 10 percent biodiesel and 6.5 percent renewable diesel into the diesel pool, resulting in 304,536 deficits generated in 2019. The high fossil diesel

demand case forecasts 2019 diesel consumption at 705 million gallons by blending 6.9 percent biodiesel and 1.3 percent renewable diesel into the diesel pool, resulting in 334,808 deficits generated in 2019.

Table 1: Fossil Fuel Consumption and Deficits

Fuel	2019 Projected Consumption		Energy Density/ (Carbon Intensity Differential)	Deficits	
Gas Blendstock (CBOB)	1,436 million gallons (Ethanol blend = 10.3%)		122.48/(100.8-97.2)	634,994	
Diesel Blendstock	705 mil. gallons BR = 8.2%	642 mil. gallons BR = 16.5%	134.48/(101.7-98.1)	334,808	304,536

Credit Generation from Gasoline Substitutes and Alternatives

Credits can be generated by supplying transportation fuels that are lower in carbon intensity than the higher carbon fuels they replace. For gasoline, the most likely substitutes and alternatives are ethanol and electricity.

Ethanol Consumption

In order to estimate the number of credits that may be generated from the ethanol available to Oregon, the volume and carbon intensities must be estimated. 164 million gallons of ethanol are estimated to be consumed in 2019, based on the gasoline consumption forecast discussed above and a blend rate assumption of 10.3 percent.

For carbon intensities, OEA reviewed facilities that have Oregon-approved carbon intensity values, and focused on four of which are mostly like to deliver their ethanol to Oregon. They have a combined production capacity of 342 million gallons of ethanol, well in excess of the 164 million gallons needed, and are:

Table 2: Ethanol Producers and Capacity

Facility	Location	Production Capacity	Carbon Intensity
Pacific Ethanol Columbia	Boardman, OR	40 mil. gallons	53.81 gCO2e/MJ
Guardian Energy Janesville	Janesville, MN	110 mil. gallons	62.40 gCO2e/MJ
Guardian Energy Hankinson	Hankinson, ND	132 mil. gallons	60.11 gCO2e/MJ
Pacific Ethanol Magic Valley	Burley, ID	60 mil. gallons	54.00 gCO2e/MJ
Totals/Average		342 mil. gallons	61.6 gCO2e/MJ

CFP data shows that the average ethanol carbon intensity exhibited in 2017 was 62.7 gCO2e/MJ, which is the basis for the low credit scenario. The high credit scenario is based on the observed 61.6 carbon intensity for the supply that is assumed available to Oregon (see Table 2). The resulting ethanol credits projected for 2019 range from 490,763 and 560,412.

Electricity Consumption

In order to estimate the number of credits that may be generated from electricity used in light-duty vehicles, three factors must be considered: 1) the number of electric vehicles registered in Oregon, 2) the average amount of electricity consumed per vehicle, and 3) the carbon intensity of electricity.

Oregon DMV vehicle registration data shows that about 10,107 battery electric vehicles (BEVs) and 7,786 plug-in hybrid electric vehicles (PEVs) were registered in Oregon in June 2018. OEA projects that those numbers will rise to 11,366 BEVs and 9,050 PEVs by the end of 2018. Further, growth rates assumed for 2019 are based on historical quarterly year-over-year growth rates and variance in growth over time to produce 95 percent confidence interval of 22.5 percent (low) to 33.6 percent (high). The resulting projections put the number of electric vehicles in use in 2019 at between approximately 23,105 and 25,207.

Using assumptions that electricity consumption per vehicle is 10 kWh/day (or roughly 30 miles per day) and that the average electric vehicle is driven 347 days per year, the average electricity consumption per vehicle is 3,470 kWh of charging per year. The statewide electric mix carbon intensity is 120.27 gCO2e/MJ, although when adjusted to reflect the energy efficiency ratio of 3.4 the intensity comparable to gasoline is 35.4 gCO2e/MJ. This results in between 60,632 and 66,150 credits projected for 2019. Also, note that some charging of electric vehicles will occur in places where the carbon intensity electricity is less than the statewide mix, but this was not factored into the forecast.

Credit Generation from Diesel Substitutes and Alternatives

Credits can be generated by supplying transportation fuels that are lower in carbon intensity than the higher carbon fuels they replace. For diesel, the most likely substitutes and alternatives are biodiesel, renewable diesel, natural gas, propane and electricity.

Biodiesel Consumption

In order to estimate the number of credits that may be generated from the biodiesels available to Oregon, the volume and carbon intensities must be estimated. For biodiesel, the blend rate varies between 6.9 percent and 10 percent, as shown above in the diesel consumption discussion. The committee discussed these assumptions and noted that blend rates could range as high as 20 percent in 2019. OEA chose to go with the historical range, resulting in a range of 52 – 75 million gallons of biodiesel demand.

For carbon intensities, OEA reviewed facilities that are mostly like to deliver biodiesel to Oregon. They have a combined production capacity of 125 million gallons of biodiesel, well in excess of the gallons needed (see Forecast Risks later in the report), and are:

Table 3: Biodiesel Suppliers and Capacity

Facility	Location	Production Capacity	Carbon Intensity
SeQuential Biodiesel	Salem, OR	15 million gallons	14.62 gCO2e/MJ
REG Grays Harbor-Canola	Grays Harbor, WA	100 million gallons	52.87 gCO2e/MJ
REG Grays Harbor-UCO	Grays Harbor, WA		18.26 gCO2e/MJ
General Biodiesel	Seattle, WA	10 million gallons	28.59 gCO2e/MJ
Totals/Average		125 million gallons	33.86 gCO2e/MJ

CFP data shows that average biodiesel carbon intensity was 47.1 gCO2e/MJ in 2017. Assuming the same CI in 2019 and incorporating the projected range of biodiesel consumption, the forecast for credits in 2019 ranges from 341,203 to 494,498.

Renewable Diesel Consumption

In order to estimate the number of credits that may be generated from renewable diesel available to Oregon, the volume and carbon intensities must be estimated. In 2016, approximately 5 million gallons of renewable diesel were supplied to Oregon based on a DEQ survey. Renewable diesel consumption volumes were first reported to the CFP for the fourth quarter 2017. Since fuel consumption exhibits a significant degree of seasonality, the first full year of data on renewable diesel consumption in Oregon will be calendar year 2018.

Table 4: Renewable Diesel Capacity

Feedstock	Potential Supply to Oregon (Low/High)	Carbon Intensity
Tallow	0 gallons/12.2 million gallons	34.48gCO2e/MJ
Soy	10 million gallons/12.2 million gallons	55.25 gCO2e/MJ
UCO	0 gallons/12.2 million gallons	20.97 gCO2e/MJ
Corn oil	0 gallons/12.2 million gallons	34.32 gCO2e/MJ
Totals/Average	10 million gallons/48.8 million gallons	36.25 gCO2e/MJ

Additionally, EIA data shows that 198.6 million gallons of renewable diesel was supplied to the West Coast in 2017 and OEA projects that between 10.0 – 48.8 million of those gallons are available to be supplied to Oregon, which would be between 1.3 - 6.5 percent of the state's diesel pool. The energy density of renewable diesel is 129.65 MJ/gallon. For carbon intensities, OEA assumed weighted average carbon intensities for available feedstocks supplied to Oregon with a range of 34.32 – 55.25 gCO2e/MJ. Those volumes and carbon intensities would result in between 55,512 – 400,545 credits generated in 2019.

Natural Gas and Propane Consumption

In order to estimate the number of credits that may be generated from natural gas used in medium and heavy-duty vehicles, OEA reviewed Oregon DMV vehicle registration data and volumes reported to CFP to date. OEA estimates that between 4 - 14 million diesel gallon equivalents of natural gas will be consumed in Oregon in 2019. Additionally, by reviewing data reported to Oregon and California, OEA estimates that 60 – 80 percent of the natural gas consumption will be in the form of renewable natural gas. The carbon intensities of renewable natural gas can vary greatly, from manure digesters, wastewater treatment plants and landfills. For the forecast, OEA assumed carbon intensity in the range of 44.0 to 53.0 gCO2e/MJ based on the assumed blend rate of biogas. Those volumes and carbon intensities would result in between 24,286 and 101,919 credits generated in 2019.

In order to estimate the number of credits that may be generated from propane used in medium and heavy-duty vehicles, DEQ reviewed Oregon DMV vehicle registration data and volumes reported to CFP to date. OEA estimates that between 0.8 - 1.3 million gasoline gallon equivalents of propane will be consumed in Oregon in 2019. The statewide carbon intensity value for propane is 83.1 gCO2e/MJ, which results in between 1,336 - 2,171 credits projected for 2019.

Electricity Consumption

For electricity used in public transit, ICF estimated credit generation from light rail, street cars, and aerial tram in their 2017 Additional Electrification memo. ICF estimated that 20,300 credits would be generated in 2018. This credit value is carried forward into 2019 as explicit data on non-road consumption of transportation electricity are just being collected by the CFP program. In addition, electricity used in public transit buses were not included in the forecast but credits will be generated in 2018 for this category. Also note that some charging of electric vehicles will occur in places where the carbon intensity electricity is less than the statewide mix, but this was not factored into the forecast.

Table 5: Alternative Fuels Consumption and Credits

Fuel Type	Consumption Forecast	Energy Density/CI Diff.	Credits Generated
Ethanol	165 mil. gallons	81.5/(97.2 – 62.7/56.4)	490,763 – 560,412
Electricity	2.4 – 2.6 mil. gallons	3.6/(97.2 - 35.4)	60,632 – 66,150
Biodiesel	52 – 75 mil. gallons	126.1/(98.1 – 47.1)	341,203 – 494,498
Renewable Diesel	10 – 49 mil. gallons	129.65/(98.1 – 39.5)	55,512 – 400,545
Natural Gas	4 – 14 mil. gallons.	78.8/(98.1 – 49.4)	3,914 – 6,849
Biogas	2.4 – 11.2 mil. gallons	134.5/(98.1 – 35.0)	20,372 – 95,070
Propane	0.8 – 1.3 mil. gallons	89.6/(97.2 – 83.1)	1,336 – 2,171

Banked Credits

The number of credits is taken from the CFP Online System. The number of gross credits registered through the end of calendar year 2017 equaled 1.76 million, while the number of deficits recorded amounted to 1.33 million. The net credits banked equaled 423,379. OEA projects that another 222,784 credits will be banked during calendar year 2018. It is important to note that credits were not generated for residential electric vehicle charging in 2016 and 2017 but will be retroactively generated as per recent changes to the regulation, these credits are not included in that bank.

Table 6: Summary of actual and projected net banked credits

Year	Deficits	Credits	Net Banked Credits
2016	617,071	830,714	213,643
2017	715.057	924,793	209,736
2018 (Projected)	814,395	1,037,179	222,784
Total	2,146,523	2,792,686	646,163

Data Summary

The table below summarizes the forecast for deficit generation and credit generation:

Table 7: Summary of Deficits and Credits

	Credit / Deficit Summary		
Deficits	RBOB (Gasoline)	-634,994	
	Diesel	-334,808	-304,536
		Low	**High**
Credits	Ethanol	490,763	560,412
	Biodiesel	341,203	494,498
	Renewable Diesel	55,512	400,545
	Electricity, on-road	60,632	66,150
	Electricity, off-road	20,300	20,300
	Natural Gas	24,286	101,919
	Propane	1,336	2,171
2019 Net Credits/Deficits		**24,232**	**706,464**
2018 Banked Credits/Deficits		**646,163**	**646,163**
Total Net Credits/Deficits		**670,395**	**1,352,627**
Percent of Credits Needed		**69.1%**	**144.0%**

Forecasted Fuel Supply Deferral Analysis & Determination

If OEA forecasts a shortfall in clean fuel credits greater than five percent of the credits that are estimated to be needed for compliance, then the forecasted fuel supply deferral is triggered. House Bill 2017 changed

the calculation to include projected banked credits. As shown above, neither scenario results in an expected deferral.

Forecast Risks

There are a number of potential risks to this 2019 Clean Fuels Forecast. A risk is defined as a deviation from one or more assumptions that would alter the conclusion outlined in the previous section. They are:

(a) The most fundamental risk to the forecast amounts to potential deviations from the assumptions highlighted in each fuel type discussion. Further, there is risk that the actuals used as the basis for consumption predictions in 2019 are not completely accurate to one degree or another, given that they are reported figures rather than direct counts (e.g., tax collections and prison beds). More detailed descriptions of these types of error are described below.

(b) The forecasting model developed by ICF uses historical carbon intensities with the assumption that projected carbon intensities will not increase (no backsliding). However, many members of the committee expressed concern that this was a significantly conservative assumption given that new technologies have been reducing carbon intensities over time. As the CFP data increase in historical coverage, more advanced longitudinal and statistical techniques become possible to better produce unbiased estimates of future carbon intensities.

(c) There is a significant discrepancy between the diesel consumption numbers in the Clean Fuels Program data and the number generated by ODOT's Weight Mile Tax program, with the former being higher than the latter. This forecast uses the CFP consumption numbers for 2017, but inflates them using the growth rates exhibited in the ODOT June 2018 forecast. To the degree that the actual diesel consumption for 2017 is more similar to the ODOT numbers, the net credits figures in Table 7 would skew more positive, potentially even eliminating the small likelihood of deferral. In addition, CFP data indicate a 2.9 percent decrease in diesel consumption for 2017, whereas the ODOT data result in a growth rate of 6.7 percent. If the ODOT growth forecast is higher than actually transpires, diesel deficits would be lower and the net credits would skew even higher. Bottom line, this issue is only a "risk" in the sense that net credits might deviate significantly outside the range presented in Table 7.

(d) House Bill 2017 (2017 Legislative Session) created a rebate for sales of electric vehicles in Oregon. The Oregon Supreme Court upheld that this component of the bill was constitutional. The electric vehicle forecast underlying the credit projections for electricity consumption do not explicitly account for the potential impact of this rebate. To the degree that electric vehicle sales skew higher than expected herein, net credits would be even higher than exhibited in table 7, constituting an upside risk to the forecast.

(e) The ethanol availability presented above does not include other potential sources, such as sugarcane ethanol imported from Brazil. To the degree that available ethanol in Oregon exceeds the amount indicated, the likelihood that capacity impinges on consumption is even less, thus reinforcing the credit generation from ethanol presented in Table 7. This mirrors the characterization of risk for diesel consumption in section (b).

(f) Forklifts, aviation fuels, and certain other fuel types not currently included in the Clean Fuels Program are being considered for inclusion in 2019. To the degree that this would increase deficits, the probability for deferral would be higher that exhibited in this forecast.

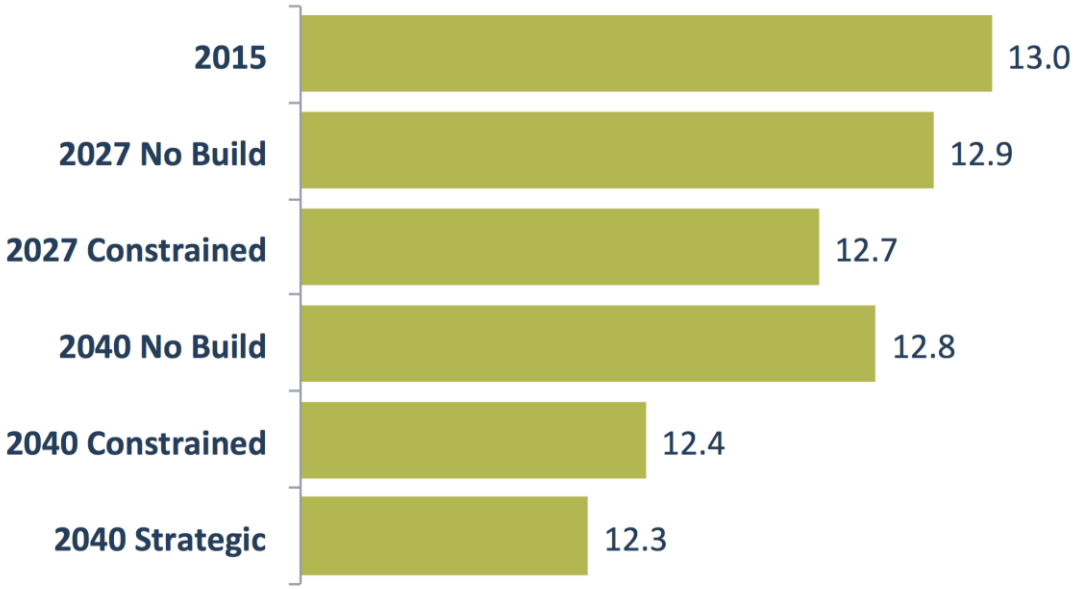
7.4.1 Multimodal travel

Data source: Metro travel forecast model

Description: System-wide number of miles traveled (total and share of overall travel) within the Metropolitan Planning Area Boundary (MPA) by different modes of travel.



- Person miles traveled *(total and per capita)*
- Vehicle miles traveled (VMT) *(total, per capita, per employee)*
- Transit miles traveled *(total, per capita, per employee)*
- Bicycle miles traveled *(total, per capita, per employee)*
- Pedestrian miles traveled *(total, per capita, per employee)*
- Freight miles traveled *(total)*

Target or desired direction: By 2040, reduce vehicle miles traveled per person by 10% compared to 2015.

Findings: Overall travel (person miles traveled – all modes) per capita is increasing in future strategies while vehicle miles traveled per capita decreases over 5 percent between 2015 and the 2040 Constrained strategies – making progress towards the target but not reaching it. That means that other modes such as transit and bicycling are increasing. In the 2040 Constrained strategies transit miles traveled per person increases by 82 percent from 1.1 to 2.0, and bicycle miles travel per person increases by 20 percent, from 0.50 to 0.60 between 2015 and 2040. Miles traveled by any mode are higher per employee than per capita.

Equity findings: Not included in transportation equity analysis.

7.4.2 Mode share

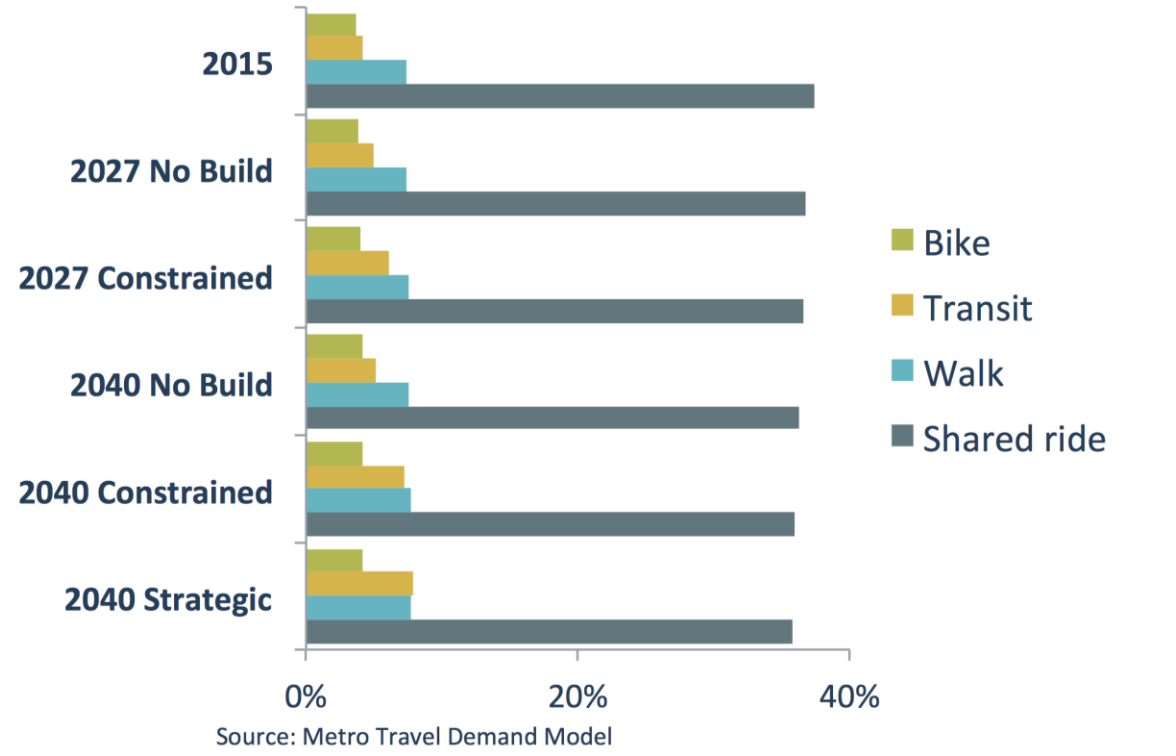
Data source: Metro travel forecast model

Description: Evaluates percent of non-drive alone trips (daily walking, bicycling, transit and shared ride trips) at multiple geographies (system wide, sub region, mobility corridor, and 2040 design type). The data is categorized by 'trips to, from within'. '.

Target or desired direction: Increase non-drive alone mode share at all geographic levels. Triple walking, biking and transit region wide by 2040 compared to 2015 levels.

Findings: Findings for mode share are provided below for region-wide, sub-regions, centers and other 2040 design types, and mobility corridors.

Equity findings: Not included in transportation equity analysis



Region-wide (within MPA boundary)
Plan does not meet target of tripling walking, biking, shared ride and transit within the MPA between 2015 and 2040.

Table 7.10 Regional mode share (within the MPA)

Travel Mode	2015 Base Year	2027 No Build	2027 Constrained	2040 No Build	2040 Constrained	2040 Strategic
Walk	7	7	8	8	8	8
Bike	4	4	4	4	4	4
Transit	4	5	6	5	7	8
Shared ride	37	37	37	36	36	36
Drive alone	45	45	43	45	43	43

Note: For all trips to, from and within the metropolitan planning area boundary, except school bus trips. Values have been rounded.

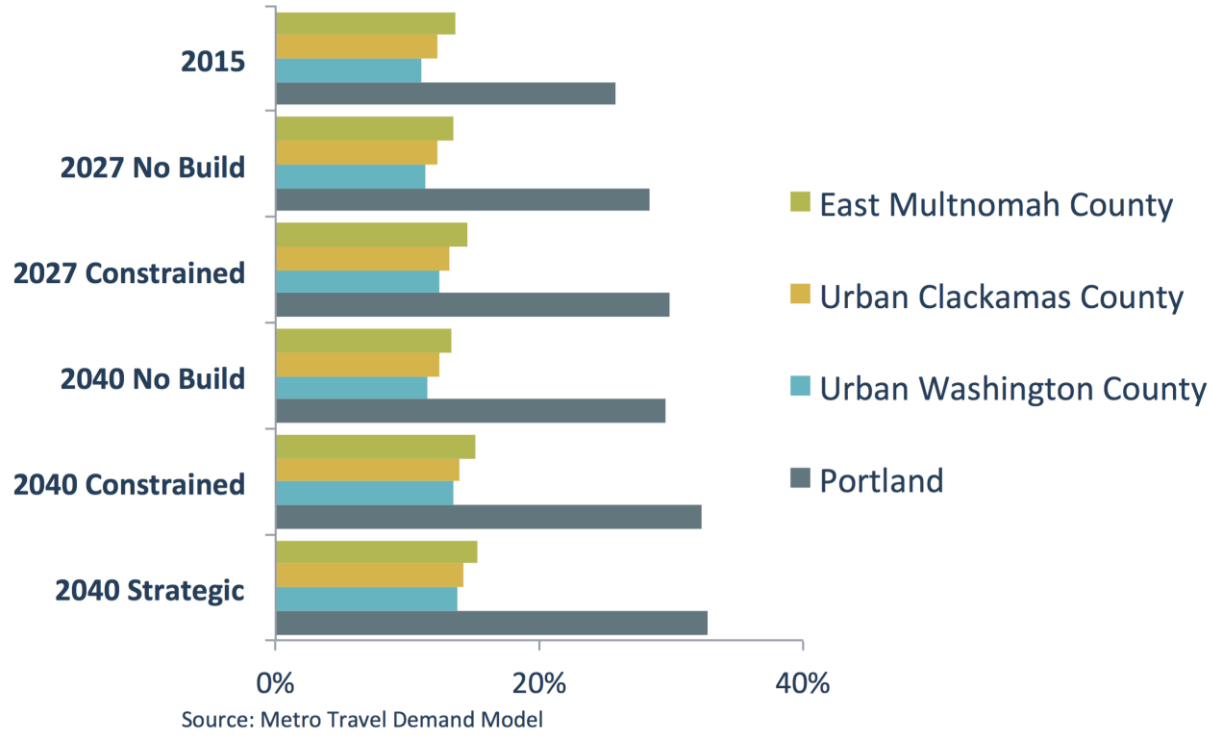


Figure 7.4 Non driving mode share within the MPA

Sub-region non-drive alone mode share

As the figure below shows, there are relatively large increase in walking, bike, shared ride and transit from 2015 to 2040 Constrained for travel within the City of Portland (from 26 percent to 32 percent) and urban Washington County (from 11 percent to 14 percent), with more moderate increases within other sub-regions. However, non-drive alone mode share does not triple for any sub-region.

Figure 7.5 Non-drive alone mode share by sub-region

Urban Washington County	52	52	53	52	54	54

Note: For all walking, biking, transit and shared ride trips to, from and within each sub-regio. Does not include school bus trips. Values are rounded.

Centers and other 2040 land use design types

Shown in Table 7.12, centers across the region display relatively large increases in non-SOV mode share (transit, biking, walking and shared ride) between 2015 and 2040 demonstrating the RTP continues to comply with Section 0035(5) of the Oregon Transportation Planning Rule.

First adopted in the 2000 RTP and approved by the Land Conservation and Development Commission in 2001, the RTP targets shown in Tables 7.12 and 7.13 reflect the non-SOV mode share needed to comply with Section 0035(5). Section 0035(5) allows the RTP to include an "alternative standard" to measure progress in reducing reliance on the automobile in place of the requirement to achieve a specific reduction in per capita vehicle miles traveled. Cities and counties are responsible for identifying actions that will result in progress towards achieving these targets as they develop local transportation system plans, as required in Section 3.08.230 of the Regional Transportation Functional Plan. Progress toward achieving the targets is monitored through scheduled updates to the RTP.

7.4.12 Climate change

Data source: The on-road vehicle emissions estimates for the 2018 RTP were produced within a software framework that combines the regional transportation model with EPA's emissions projection MOVES model, version MOVES2014a. A newer version of MOVES (MOVES2014b) has since been released, but it should be noted that the improvements incorporated into this update pertain almost exclusively to estimates of non-road emissions and are, therefore, not relevant to this analysis.

Description: Evaluates projected mobile source emissions of carbon dioxide (CO2) a primary greenhouse gas pollutant to determine mobile source greenhouse gas emissions in the base year and for 2027 and 2040 to determine if mobile source greenhouse gas emissions are declining as a whole and on a per capita basis.

Metro's current implementation of MOVES was developed for air quality conformity purposes in accordance with all pertinent EPA guidance included in the document, "Using MOVES to Prepare Emission Inventories in State Implementation Plans and Transportation Conformity: Technical Guidance for MOVES2010, 2010a and 2010b" (April 2012).

Metro estimates future mobile source greenhouse gas emissions by using existing and proposed transportation project information and inputting the project information into the travel demand model to understand the travel behavior in the region with and without proposed investments at key times in the future (2027 and 2040). Key travel behavior outputs include trip generated, mode split (i.e. percentage of trips taken by different transportation modes), trip distances, and vehicles miles traveled. This information is then taken into the MOVES2014a emissions model to estimate projected greenhouse gas emissions with and without the proposed transportation investments for the Portland airshed in 2027 and 2040. Then the total vehicle emissions are divided by projected population estimate to understand emissions per capita and ultimately the reduction level from the base year of 2015. Detailed information about the fleet and technology assumptions used in the 2018 RTP on-road vehicle emissions analysis and a comparative assessment of VisionEval and MOVES emissions estimation methodologies is provided in Appendix J.

Target or desired direction: The target adopted in the 2014 Climate Smart Strategy is to reduce per capita greenhouse gas emissions from cars and small trucks by 29 percent by 2035 and 25 percent by 2040, compared to 2005 levels. The Climate Smart Strategy performance measures and monitoring targets were adopted with an acknowledgement that they will be reviewed during development of the 2018 Regional Transportation Plan to address new information, such as federal transportation performance-based planning rulemaking. At the time of adoption, Metro also anticipated transitioning from using ODOT's GreenSTEP software tool (VisionEval) to the Environmental Protection Agency's MOVES model for forecasting on-road mobile source greenhouse gas emissions in the region. This transition was anticipated because Metro maintains and implements MOVES to conduct federally-required air quality and other on-road vehicle emissions analysis, and does not have the expertise nor the resources necessary to maintain and implement VisionEval on an on-going basis. Further, significant methodological differences in how

VisionEval and MOVES estimate on-road vehicle emissions do not allow for direct comparison of forecasted on-road vehicle emissions results.

To assess progress towards the targets, the region's Climate Smart Strategy calls for the implementation of nine key land use and transportation policies to reduce greenhouse gas emissions. Monitoring targets are used to track progress. One of the most significant transportation strategies outlined in the Climate Smart Strategy is increasing transit service hours. The Climate Smart Strategy called for 9,400 transit service revenue hours (excluding C-TRAN) within the metropolitan planning area boundary by 2035 to meet the region's greenhouse gas reduction target. Refer to Appendix J for details on the monitoring targets and other performance outcomes.

Findings: The 2018 Regional Transportation makes satisfactory progress towards implementing the Climate Smart Strategy and, if fully funded and implemented, can reasonably be expected to meet the state-mandated targets for reducing per capita greenhouse gas emissions from cars and small trucks (light-duty vehicles) for 2035 and 2040.

- By 2040, the plan, together with advancements in fleet and technology, is expected to reduce total annual greenhouse gas emissions from all on-road vehicles by 19 percent (compared to 2015 levels) and annual per capita greenhouse gas emissions from all on-road vehicles by 40 percent (compared to 2015 levels).
- By 2040, the plan, together with advancements in fleet and technology, is expected to reduce total annual greenhouse gas emissions from passenger cars and passenger trucks by 27 percent (compared to 2015 levels) and reduce annual per capita greenhouse gas emissions from passenger cars and passenger trucks by 46 percent (compared to 2015 levels).

Due to differences in emissions analysis tools, the 2018 RTP greenhouse gas emissions estimates are not directly comparable to the state-mandated greenhouse gas emissions reduction targets that were set using VisionEval. However, the findings above and in Appendix J demonstrate the region is making satisfactory progress implementing the Climate Smart Strategy.

The findings also demonstrate that more investment, actions and resources will be needed to ensure the region achieves the mandated greenhouse gas emissions reductions defined in OAR 660-044-0060. In particular, additional funding and prioritization of Climate Smart Strategy investments and policies will be needed.

Equity findings: Not included in transportation equity analysis.

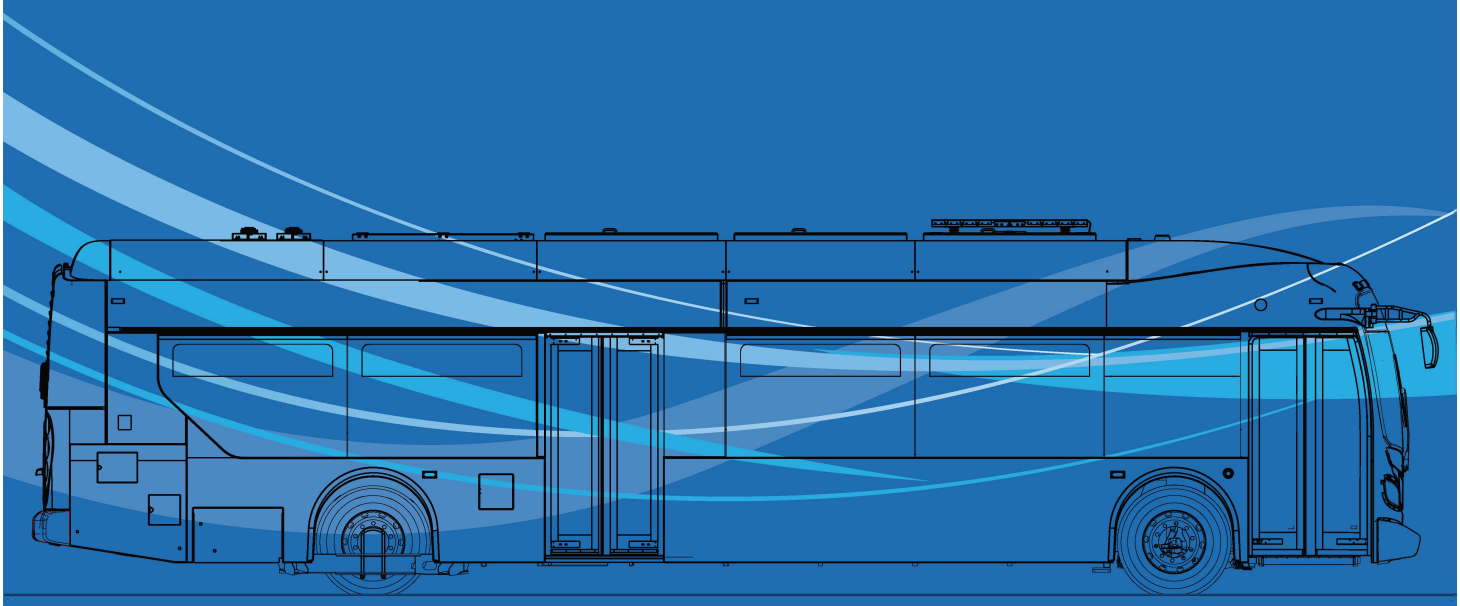
7.4.13 Clean air

Data source: The on-road vehicle emissions estimates for the 2018 RTP were produced within a software framework that combines the regional transportation model with EPA's emissions projection MOVES model, version MOVES2014a. A newer version of MOVES (MOVES2014b) has since been released, but it should be noted that the improvements incorporated into this update pertain almost exclusively to estimates of non-road emissions and are, therefore, not relevant to this analysis.

Description: Evaluates projected mobile source emissions of criteria pollutants: carbon monoxide (CO), nitrogen oxide (NO_X), volatile organic compounds (VOC), and particulate matter (PM_{10} and $PM_{2.5}$) and transportation-related air toxics identified with guidance from the Oregon Department of Environmental Quality.[9]



Metro estimates future mobile source emissions by using existing and proposed transportation project information and inputting the project information into the travel demand model to understand the travel behavior in the region with and without proposed investments at key times

[9] Nitrogen oxide and volatile organic compounds are precursors to Ozone. Transportation-related air toxics are: Acrolein, Arsenic, Benzene, 1,3-Butadiene, Chromium 6, Diesel particulate matter plus diesel exhaust organic gases (Diesel PM), Formaldehyde, Naphthalene, Polycyclic organic matter

TRIMET

Non-Diesel Bus Plan

September 2018

Introduction

TriMet has long been a leader in the Portland region's efforts to reduce air pollution. In the 1970s, expansion of the TriMet system played an important role in reducing the region's chronic smog. In more recent years, the agency has invested heavily in clean diesel technology, incorporated biodiesel into its fuel and switched to ultra-low sulfur diesel to reduce bus emissions significantly while continuing to expand service.

Expanded and improved transit service is central to achieving the region's climate change goals. By reducing the number of single-occupancy car trips and encouraging compact, walkable neighborhoods, TriMet services reduce the level of global climate change-inducing carbon emissions by an estimated 21,000 metric tons per year. TriMet's MAX Light Rail system, powered with lower carbon intensity electricity, today provides one-third of all transit trips in the system.

In the coming years, TriMet expects to significantly expand service — particularly to unserved and underserved areas – increase frequency, add evening and weekend service and speed transit travel times. These improvements will help promote additional transit use, reduce auto trips, help alleviate congestion and promote a more compact land use pattern – all of which reduce our collective carbon footprint.

TriMet's bus fleet, while diesel powered, is being rapidly modernized to high efficiency, low emissions models. Today 65 percent of TriMet's fleet has post-2012 emissions technology, employing cleaner-burning diesel engines and selective catalytic reduction (SCR) technology, which scrubs nitrogen oxides and particulates from the exhaust. TriMet uses a biodiesel blend to further reduce its carbon footprint.

Although TriMet's existing service delivers extensive benefits to the environment and supports efforts to reduce carbon emission, we also recognize that more can and should be done to reduce the environmental impact of the region's transportation sector. Moving away from diesel buses, combined with expansion of service, will provide a double win: reducing emissions by expanding transit use while using vehicles that themselves emit less carbon. TriMet does not believe a one-sided strategy that sacrifices additional service to achieve low emissions or providing only more service without embarking on the transition to a non-diesel fleet will best serve the community. The following plan seeks to achieve the twin goals of expanded service with cleaner technology.

Chapter 1: Context

TriMet has the 11th largest bus fleet in the United States. TriMet operates 658 buses, the vast majority of which (97 percent) are standard 40-foot diesel buses. The average bus is 7.4 years old. The oldest bus is 19 years old. The fleet also contains 22 smaller, 30-foot buses. Today, 65 percent of TriMet's fleet has post-2012 emissions technology, employing cleaner-burning diesel engines and SCR technology, which scrubs nitrogen oxides and particulates from the exhaust. Seventy percent of TriMet's fleet has 2007 or better emissions technologies and TriMet began using biodiesel fuel blends in 2006.

Diesel buses are a tried and true technology. Historically, they have been cost-effective and reliable. On a full tank of fuel, they have sufficient range for any typical service route and can be refueled easily and

safely within a matter of minutes. Mechanics have been servicing them for decades, original equipment manufacturers (OEMs) have honed the technology and established trusted relationships with transit agencies. Lifecycle statistics regarding reliability and maintenance costs also are well documented.

On the other hand, even low-emission buses running on a biodiesel blended fuel still rely on fossil fuels that generate emissions, contributing to climate change. Although TriMet's total carbon emissions are low relative to the entire transportation sector, TriMet is Oregon's largest single consumer of diesel fuel, and – with anticipated growth in TriMet services – its consumption of diesel will continue to increase unless alternatives are developed.

State, regional and local governments have adopted legislative and policy direction to address climate change. The Oregon State Legislature established a goal, through House Bill 3543, of reducing greenhouse gas emissions 10 percent below 1990 levels by 2020 and 75 percent below 1990 levels by 2050. To support these goals and improve sustainable transportation infrastructure in the state, the Oregon Legislature passed House Bill 2017 (HB 2017) to fund public transportation and other transportation improvements through a variety of revenue sources. This bill establishes a Statewide Transportation Improvement Fund (STIF) for public transit, which can be used for the purchase of electric or natural gas buses.

The Metro Council has adopted the Climate Smart Strategy, which fulfills a 2009 mandate by the Oregon Legislature requiring Metro to develop and implement a strategy to reduce the region's per capita greenhouse gas emissions from cars and light trucks at least 20 percent by 2035. One specific action recommended as part of this strategy is to lead by example by increasing the number of alternative-fuel vehicles in public sector fleets.

The City of Portland and Multnomah County have also created a joint Climate Action Plan, which calls for transition to 100 percent clean energy by the year 2050 and provides a roadmap to achieve an 80 percent reduction in carbon emissions by 2050, with an interim goal of a 40 percent reduction by 2030. This plan also includes a public transit system electrification strategy. Similarly, in 2017, both the City of Portland and Multnomah County adopted a 100 percent renewable energy resolution that calls for collaboration between Portland, Multnomah County, Metro and TriMet to expand service, reduce fares for those with a low income and complete a rapid transition to an electric fleet.[1]

While progress has been made in a number of areas toward meeting the state, regional and local emissions reduction goals, achieving progress in the transportation sector has been more challenging. In the past two reporting years, greenhouse gas emissions in the transportation sector have actually risen in Oregon, either due to increased economic activity or vehicle miles traveled. A TriMet transition to non-diesel buses would begin to contribute to reversing this trend in Oregon and achieving relevant state, regional and local climate goals.

Fortuitously, improving technology and decreasing costs of non-diesel buses, combined with credit programs and new funding from HB 2017, provide an opportunity to begin the process of transitioning away from diesel buses.

[1] https://multco.us/file/100-renewable-resolution-finaldoc.

Chapter 2: Evaluation Process

This report summarizes the results of an assessment of whether TriMet should transition from a primarily diesel bus fleet to a non-diesel fleet, and, if so, how. The assessment is based on four interrelated analyses.

Industry Review of Non-Diesel Bus Technology: Several non-diesel bus technologies are in operation or development, each with its unique set of advantages and disadvantages; and the technologies are rapidly evolving. It was concluded that a preferred technology should be selected for testing prior to fully committing to a specific technology. To make this choice, as discussed in Chapter 3, TriMet assessed the performance, operations, cost-efficiency and challenges of alternative non-diesel bus options based on industry reports and discussions with industry officials. As explained in Chapter 5, as a result of this assessment, battery electric buses (BEBs) is recommended as the preferred option for testing. However, it is also recommended that continued assessment of two other technologies (renewable natural gas and hydrogen fuel cells) is warranted during the testing period.

Net Present Value Analysis of Transitioning to a BEB Fleet: While BEBs' initial capital costs are greater than diesel buses, industry reports indicate they may be less expensive to operate than diesel over the long term. In addition, BEBs generate less air and noise emissions, which are societal costs that can be measured in monetary terms. Generally a BEB fleet would be more expensive than a diesel fleet in the early years of the transition and less expensive in the later years, taking into account the total cost to TriMet and the societal costs. Net present value (NPV) analysis is a traditional methodology to compare differing cost streams. It addresses the monetary value of time by applying discount rates to the year-by-year costs of both the BEB fleet scenario and diesel bus scenario, and then totaling the discounted values. While the totaled discounted values are not actual costs, a comparison of these values shows, as described in Chapter 4, that the BEB fleet is less expensive than diesel, i.e., most cost-efficient, given the value of time.

Recommendation for Short- and Long-Range Strategy: Chapter 5 of the report recommends a two-step approach for converting the TriMet fleet to a non-diesel system. The long-range strategy is to adopt a goal of converting the entire TriMet fleet to non-diesel vehicles by the year 2040 or before. While this strategy will require the identification of additional resources to be successful, TriMet believes it is important to signal its commitment to achieving this important goal. The plan also suggests a short-term strategy for testing BEBs as the initial step in this long-term strategy. The test period will involve purchasing 80 BEBs over the next five years.

Fiscal Analysis of Transitioning to a BEB Fleet: Where the NPV analysis focuses on which fleet scenario is most cost efficient in relative terms, the fiscal analysis addresses the actual cost that would be incurred by TriMet in implementing the short- and long-term strategies – assuming BEB is the technology for all diesel bus replacements and expansions. Instead of using discounted present values, the fiscal analysis focuses on the anticipated year-by-year costs in year-of-expenditure (inflated) dollars. It does not consider the societal costs (air and noise emissions), only the capital and operating costs to be paid by TriMet, minus tax credits. The analysis considered the use of a portion of the state funding made available by HB 2017 to offset a portion of the added costs of BEBs, but notes the need for added funding for a full fleet conversion. The results are shown in Chapter 5.

Chapter 3: Industry Review of Non-Diesel Bus Technology

In evaluating potential non-diesel bus technologies, TriMet seeks to find a technology that has the fewest negative impacts on current operations and customer service. This approach helps to ensure that the community gains the benefits of reduced emissions without sacrificing good customer service and the efficiencies gained from an experienced and expert maintenance staff.

While BEBs are the non-diesel bus technology that is being deployed most widely today, there are other zero- (or near zero) emission technologies in use or under development. In addition to non-diesel technologies, many transit agencies have sought to reduce their emissions through the use of hybrid-electric buses that get greater fuel efficiency through the use of regenerative breaking and other features. Many others have transitioned some or all of their fleets to compressed natural gas (CNG), which produces much less particulate matter and other pollutants but, depending on a number of variables such as sourcing and pipeline leakage, can vary in the amount of greenhouse gas emissions. The technologies that were evaluated as part of this analysis are as follows.

Battery-Electric Buses (BEBs)
BEBs have a number of benefits that make them an appealing technology for transit agencies. They emit zero point source pollution and lifecycle emissions are related to the emissions from associated power generation. In Portland General Electric's (PGE) service area,[2] an overall reduction in emissions of 57 percent is estimated with the current mix of electrical generation.[3] As PGE implements strategies to integrate more renewable electric energy sources this is expected to improve. BEBs also have significant noise-related benefits relative to traditional diesel buses.

However, BEBs also come with challenges and limitations at this point in their development. Purchase prices are currently much higher for BEBs than for comparable diesel buses (nearly twice as expensive). BEBs also require additional infrastructure to accommodate electric charging. While these capital costs have been declining in recent years, they are expected to remain higher than those of equivalent diesel buses for the foreseeable future.

In addition, in the United States, experience with BEB technology is relatively limited. Most U.S. transit agencies would need to learn to operate and maintain this type of vehicle. A growing number of transit providers are conducting trials with BEBs, so in the coming years there will be more peer experience to share about practical performance, maintenance techniques and operational best practices.

One vulnerability of BEBs is the potential for electric outages that could prevent buses from being charged. TriMet is working with PGE to understand strategies for preventing outages, such as redundant feeders and hardening against cyber intrusion, and contingency options should outages occur. Generally, TriMet's maintenance facilities are near major PGE substations and transmission facilities.

[2] Although there are two electric utilities serving the Portland area, this analysis examined only PGE energy supply characteristics because TriMet's three existing bus maintenance facilities are located in PGE service territory. Given the depot-based charging technology recommended in this report, it anticipated that all battery recharging during the initial phases of BEB adoption will occur at PGE-served facilities.

[3] This reduction reflects PGE's current generation portfolio. However, PGE has adopted plans to reduce greenhouse gas emissions by more than 80 percent by 2050, including transitioning away from coal-fired power generation by 2035. As these transitions take place, the emissions savings from transitioning to BEBs will also increase.

During outages, these are typically the first equipment restored, so even if outages occur they tend to be for shorter periods.

One question that remains to be answered is the projected useful life of BEB batteries. Many BEB manufacturers are currently projecting a 14-year lifespan,[4] which is a standard retirement age for many transit properties in the U.S. However, TriMet keeps its buses for an average of 16 years to reduce the cost of vehicles. The longevity of the vehicle plays an important role in its overall lifecycle costs. Achieving a 16-year lifespan for BEBs will be an important factor in implementing a long-term BEB adoption strategy.

Depot-Based and On-Route Opportunity Charging

There are two dominant varieties of BEBs: depot-based charging and on-route opportunity charging vehicles. Depot-based charging involves charging vehicles at the bus depot during a midday layover or overnight. Their large batteries hold more energy than the smaller batters in on-route opportunity charging buses but require between one and four hours to charge, depending on battery capacity and charger type. On-route opportunity-charging vehicles, on the other hand, can charge during the course of their scheduled service using chargers at layover terminals. Opportunity charging batteries hold a smaller amount of energy, but only require several minutes to fully charge. Each of these technologies comes with tradeoffs related to neighborhood impacts, TriMet's scheduling, maintenance, operations and costs.

On-route opportunity-charging technology is quickly developing, and some manufacturers currently advertise nominal ranges of 50-70 miles between charges. However, based on a review of King County Metro's experience with opportunity charging technology, a "real-world" range of 25 miles is considered most realistic to allow for variations in topography, traffic congestion and use of heating and air conditioning, among other factors. A planned pilot of BEBs on TriMet's Line 62-Murray Blvd will provide a more precise understanding of how opportunity-charging technology performs locally.

The challenges related to opportunity charging are primarily associated with the need for distributed charging infrastructure located along transit routes. To use the infrastructure efficiently, charging locations should be sited where they can serve multiple routes, and ideally up to six to eight buses per hour. These locations would require approval of the appropriate local municipalities and property owners. Additionally, schedule revisions also might be needed to ensure adequate charging time between bus trips, and the costly location of on-route charging equipment does not easily allow for route changes.

Sufficient power supplies may not be available at all potential opportunity charging locations, and daytime charging means that buses are charging when electricity rates tend to be higher. Lastly, and importantly, opportunity chargers are significantly more expensive than depot chargers, and more of them may be needed depending on configuration at layover locations. In 2018, one depot charger costs approximately $69,000, whereas one opportunity charger costs approximately $584,000. This can make a difference in whether an agency BEB plan is financially viable or not.

Depot-charging technology is also developing rapidly. Again, taking account of real world factors such as traffic congestion, varying topography and use of heating and cooling systems, it is estimated that

[4] Projected lifespans assume one battery replacement. This is similar to diesel buses, which typically have at least one major engine rebuild during their lifespan.

today's depot-charging buses can reliably travel up to 150 miles on a single charge This is not sufficient to support all of TriMet's current routes. This issue can be addressed by deploying the first generations of depot-charging buses on shorter routes. Battery ranges are growing steadily as battery technology is developing, and 300-mile ranges on a single charge, comparable to a full tank of fuel in a diesel bus, are generally expected in the coming years. As battery ranges expand, the universe of routes within TriMet's system that could be served by BEBs will grow.

Depot-charging buses also have tradeoffs related to the space the charging infrastructure consumes at depots. Installation of new charging infrastructure would require reconfiguration of bus depot space used for storage and fueling. Overall this would cause a net reduction in storage capacity, on the order of 12-17 percent, depending on site configuration. In addition, while these buses would not need to be fueled as part of the normal bus intake process, they would need to be plugged in during their midday and overnight layovers, requiring attendant attention at this point in the daily schedule.

A number of transit agencies are buying and testing on-route opportunity charging buses (including TriMet's purchase of five opportunity charging buses using Federal Transit Administration (FTA) Low-No funding), and there are uses for which this is the preferred technology. However, because they perform more like a traditional diesel bus, have lower charging infrastructure costs and fewer community impacts, the trend among transit agencies planning for a full transition to BEBs is to assume the use of all depot-charging technology.

Lastly, while 40-foot BEBs are in relatively widespread deployment, 60-foot BEBs (articulated buses) are still relatively new to market. While some agencies such as LA Metro and King County Metro are currently testing 60-foot BEBs, many agencies are still waiting for early-adopting agencies to more extensively report on their experiences with them. Although TriMet does not currently operate any 60-foot buses, it will begin doing so with the opening of the Division Transit Project and is interested in deploying 60-foot vehicles on other high ridership routes in the future.

For both depot-charging and on-route opportunity charging technologies, it will be important for the electric utilities to work with TriMet to ensure that adequate service is available at the necessary locations and that major facilities, such as maintenance depots, have redundant service to ensure TriMet's ability to serve its customers in the event of natural disasters.

Fuel Cells

Hydrogen fuel cell buses currently are less widely deployed than BEBs. This technology uses on-board liquid hydrogen as fuel, and tailpipe emissions include only water vapor and warm air. Lifecycle emissions depend on the type of power used to generate the hydrogen, but in many cases it is generated using clean, renewable energy sources.

Hydrogen fuel is still comparatively expensive and distribution networks are limited. Hydrogen cost ranges from $5–$8/kilogram at the three California transit fueling sites, which is approximately $0.71–$1.14/mile (compared to a diesel fuel cost of approximately $0.67 per mile). As more buses are deployed, the increased fuel demand is expected to lower the price of hydrogen on a per-mile basis and lead to a more robust distribution network.[5] The fuel cell vehicles themselves also are at least as expensive as BEBs. The Orange County Transportation Authority (OCTA) announced in February that it

[5] https://cafcp.org/sites/default/files/CHBC-CaFCP-Fuel-Cell-Electric-Bus-Fact-Sheet.pdf.

will purchase 10 fuel cell buses for approximately $12 million.[6] The National Renewable Energy Laboratory cites an industry goal of reducing the average cost of a fuel cell bus to approximately $1 million in coming years. Maintenance costs for fuel cell buses also have preliminarily been shown to be higher than for diesel or CNG buses at this stage of technological development.[7]

The advantages of a fuel cell bus are that it can be operated more like a diesel bus than a BEB, as it relates to fueling and operating range. Hydrogen bus refueling can be done in a matter of minutes at a refueling station, providing operational efficiency and reducing the space impacts associated with BEB charging. Hydrogen buses are reporting operating ranges of between 280 and 530 miles between refueling, which is also comparable to a traditional diesel bus.[8] Buses with these ranges could serve all of TriMet's existing routes.

While some OEMs are offering fuel cell passenger cars, fuel cells are more ideally suited for large vehicles that need to refuel quickly and store a large amount of on-board energy. For example, long-haul trucking operations may be more suited to fuel cells than battery technology. While some transit agencies are purchasing fuel cell buses, more agencies by far are purchasing BEBs. Alameda-Contra Costa Transit District (AC Transit); SunLine Transit Agency in Palm Springs; and the University of California, Irvine have purchased hydrogen fuel cell buses.

Renewable Natural Gas (RNG)

While CNG is in relatively widespread use as an alternative fuel for transit buses and produces significantly less particulate pollution, it does not produce a notable reduction in carbon dioxide ($CO_{2)}$ compared to diesel and produces significantly more carbon monoxide. In terms of point source pollution, CNG and RNG are identical. However, the benefit of RNG as an alternative fuel can be seen in a lifecycle carbon intensity comparison. RNG, or biomethane, is sourced from gases released by decomposing organic matter such as can be found in landfills, wastewater facilities and agricultural waste. If left uncaptured, this matter decomposes to release methane into the atmosphere, which has

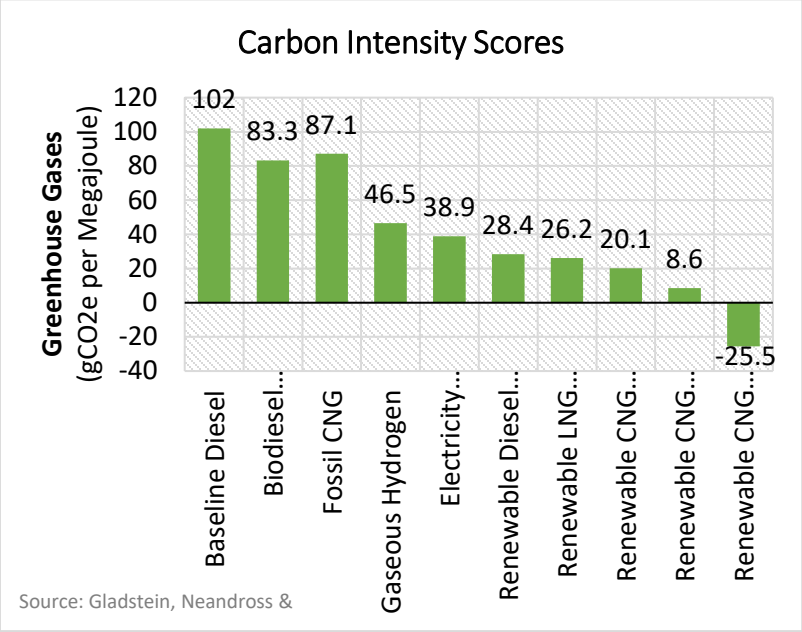


Figure 1. Comparative Carbon Intensity Scores. Source: https://www.trilliumcng.com/en/fueling-solutions/renewable-natural-gas

[6] https://www.ocregister.com/2018/02/07/octa-to-purchase-10-hydrogen-fuel-electric-buses-at-cost-of-about-12-million/.

[7] https://www.nrel.gov/docs/fy18osti/70075.pdf.

[8] http://www.gppq.fct.pt/h2020/_docs/brochuras/fch-ju/20121029%20urban%20buses,%20alternative%20powertrains%20for%20europe%20-%20final%20report_0.pdf.

been found to have 20–25 times the atmospheric warming effect as does CO_2. Capturing RNG generated by anaerobic digestion, or other means, eliminates almost all harmful emissions and can provide dramatic benefits to the environment. In fact, capturing methane and converting it to RNG can have an overall net negative carbon impact, depending on the source, as shown in the comparative carbon intensity scores in Figure 1. For this reason, it is considered in this evaluation among non-diesel fuel sources.

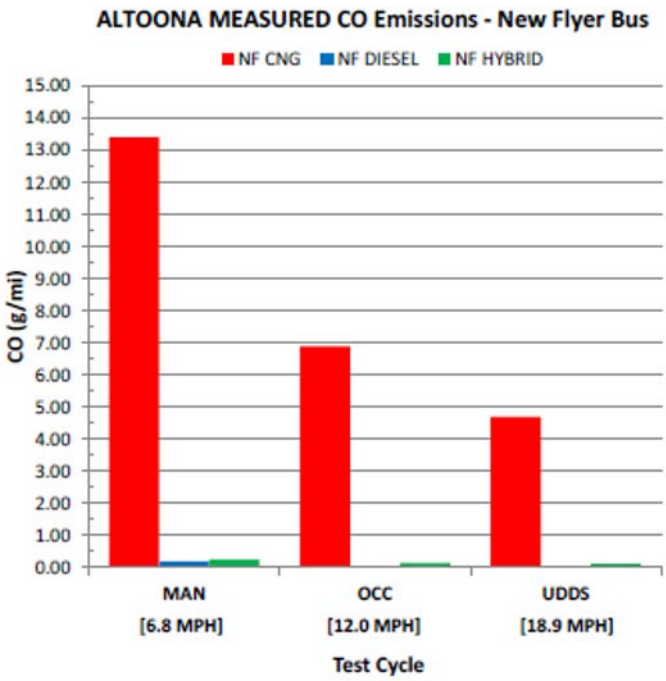

Figure 2. Altoona Measured CO Emissions - New Flyer Bus. Source: https://mjbradley.com/sites/default/files/CNG%20Diesel%20Hybrid%20Comparison%20FINAL%2005nov13.pdf

However, while RNG can have a net negative lifecycle carbon intensity score, it also may not, depending on the source of the methane gas, as shown in Figure 1. And, while particulate and nitrogen oxides (NO_x) pollution with RNG is much reduced, like CNG, carbon monoxide emissions are actually much higher, as shown in Figure 2.

The cost per gallon equivalent for RNG is roughly comparable to the per-gallon cost of diesel, but it can vary by location. Clean Energy Fuels is offering RNG fuel, branded as “Redeem” to transit agencies in California, such as LA Metro and Santa Monica’s Big Blue Bus. It is not yet being provided in Oregon, but an arrangement with Clean Energy Fuels may be possible.

Table 1 below summarizes the key considerations for BEB, fuel cell and RNG buses in relation to existing diesel buses.

Table 1. Comparison of zero or near zero emission technologies

Technology	Cost Relative to Diesel	Emissions Relative to Diesel	Operational Impacts	Status of Deployment in the U.S. Today
Battery-Electric Buses (BEB)	Higher in initial years	Lower	Significant	Peer agencies experience
Fuel Cell Buses	Higher overall	Lower	Minimal	Limited
Renewable Natural Gas (RNG) Buses	Similar	Lower	None	Peer agencies experience

Preferred Technology

After extensive evaluation of available and developing technologies, TriMet's near-term preference is for depot-based charging BEBs. There are several reasons for this choice. Non-diesel fuel cell buses are somewhat less cost effective at this stage of technological development than BEBs, with fuel cell bus vehicle costs at least as much as BEBs but fuel and maintenance costs significantly more than diesel or CNG buses. BEBs, on the other hand, have lower fuel and maintenance costs than diesel or CNG buses, which can help to offset the higher vehicle purchase prices compared to diesel or CNG.

RNG is not preferred over BEBs at this time; however, further exploration of this option is warranted. While CNG buses are currently less costly than BEBs, CNG maintenance costs are projected to be higher than BEBs, they have point source emissions and there are still questions that need to be addressed regarding the supply and characterization of RNG carbon impacts.

Hydrogen, like RNG, appears to hold some promise for meeting the agency's needs, if technological advances and energy supply issues can be addressed. While these technologies are not TriMet's preferred approach at this time, the agency fully intends to continue to investigate the long-term potential of integrating these technologies into its fleet over the coming years. This may include seeking grant funding for acquisition of test vehicles and associated fueling equipment.[9]

Between depot-charging and on-route opportunity charging BEB technologies, depot charging is the preferred agency technology. Depot-charging buses can charge at bus depots with minimal operational impacts. While plugging in buses to charge overnight is a change from the current practice of refueling buses in a matter of minutes and then parking them, the essential experience of being able to send buses out for a full block of service without the need for refueling until they return to the depot would be similar to diesel buses. In addition, eliminating the need for on-route charging equipment will reduce more expensive daytime charging, allow for greater agency flexibility to adjust routes over time and avoid the neighborhood impacts of installing opportunity chargers.

In addition, depot-charging buses are more cost effective at this time than on-route opportunity charging buses, due primarily to the lower cost of charging equipment. Lastly, depot-charging technology would be compatible with more of the existing TriMet service profile. According to an analysis of agency routes, comparing the expected range for BEBs and route lengths, it is estimated that 59 percent of existing service blocks can be served by depot-based charging compared to only 38 percent for opportunity charging technology. It is generally expected that depot-charging technology will improve over the coming years and be sufficient to accommodate virtually all of TriMet routes.

National and International BEB Experience

Internationally, there are almost 400,000 BEBs deployed with approximately 99 percent of those located in China. Within the U.S., at least 38 transit agencies have some experience with BEBs – most with fewer than 10 buses. Within the U.S., most transit agencies with BEBs are in the process of testing the technology and evaluating the desirability of a longer-term commitment to them.

A handful of transit agencies in the U.S. have committed to purchasing only BEBs. Notably, Antelope Valley Transportation Authority in Southern California is anticipating a full transition in 2018, LA Metro

[9] TriMet has determined that due to training, staffing, parts management and infrastructure needs, it would be inefficient and costly to have buses using more than two fuel types at any one maintenance facility. Therefore, the agency intends to house the initial BEB fleet at its Powell Operations Facility.

aims to have a fully electrified fleet by the year 2030 and King County Metro in Washington has committed to a full transition to BEBs but is still testing a number of different OEMs before beginning to purchase BEBs exclusively.

Current Battery Electric Bus Initiative

TriMet is experimenting with on-route opportunity charging with a pilot project deploying five BEBs on Line 62 slated for 2019. TriMet's BEB pilot project is funded jointly by the FTA, TriMet and a partnership with PGE. Some of the project objectives include eliminating vehicle emissions, reducing noise, reducing costs and training the workforce. The pilot will involve training for operators, maintenance team and first responders, as well as a year of revenue service data collection and monitoring. The pilot will use both on-route charging and depot charging to provide the broadest experience. Under a pilot project approved by the Oregon Public Utility Commission (PUC), PGE is assisting by installing, maintaining and designing the necessary charging infrastructure.

Chapter 4: Net Present Value Analysis of Transitioning to a BEB Fleet

A detailed lifecycle cost model was developed to understand the fiscal impact of transitioning to a new BEB fleet. This model evaluates all categories of costs (or credits) that TriMet is projected to experience when purchasing and operating BEBs. The factors included in the analysis are vehicle purchase costs, including assumptions about future price changes due to economies of scale and technology, as well as maintenance, fuel use, electricity use, facility upgrades, charging infrastructure and Clean Fuel Credits. The model also addresses social costs including emissions and noise. All of these costs are calculated for each bus in the transition scenario at each year to measure the full cost of each scenario. The model then compares those costs with an equivalent diesel bus fleet purchase and operations plan.

TriMet replaces buses, on average, at 16 years of age. Each bus in the fleet will reach its retirement age and be replaced with a new bus over the course of an average 16-year lifecycle. Thus, this lifecycle cost model examined a 16-year time period.

The bus purchases in the model are all based on TriMet's Fleet Plan from November 2017.[10] That plan outlines projected fleet replacement needs and fleet growth through 2027. Beyond that point, the model assumes the total fleet grows by 14 buses annually, reflecting historical growth rates.[11] The purchases each year are assigned to replace retiring vehicles and meet the target fleet growth. In the model, diesel buses and BEBs both have a lifetime of 16 years, matching current TriMet experience with diesel buses. As noted earlier, for the lifecycle costs to meet acceptable thresholds for a full conversion to BEBs, TriMet will need to see evidence that suggests such lifecycles are achievable.

The model assigns each bus to one of TriMet's operating facilities. All purchases are assigned to Powell, Center, Merlo, or a new facility that is expected in the coming years. This allows the model to include different service profiles and operating characteristics at the different facilities. It also enables planning for the facilities' capacity levels. Preliminary engineering work at the Powell facility indicates that converting an operating garage to house BEBs results in a capacity reduction of about 17 percent due to space needed for charging equipment and new directional ingress and egress. Anticipating these

[10] Note: Only 40-foot buses are considered as part of this analysis.

[11] To smooth out annual budgets in the lifecycle cost model, occasionally bus lifetimes may be extended as long as 17 years to offset "lumpy" fluctuations in purchase needs.

capacity losses will allow TriMet to plan its facility space to accommodate all of the BEBs for the proposed pilot period.

Cost modeling required making projections concerning many future conditions that involve a number of uncertain variables. The analysis reviewed relevant research findings, manufacturer claims, peer agency experiences and TriMet's own experiences, as well as conducted scenario testing to understand the implications of various assumptions. Initially, the potential conditions were framed as representing optimistic, pessimistic and moderate scenarios. However, because financial planning for multiple scenarios is not practical, after discussions with stakeholders, the model conditions were merged into a single, highest-confidence model scenario.

The key measures that serve as inputs into the highest-confidence model scenario are described below, along with the logic behind their selection.

Vehicle Purchase Costs
Vehicle purchase prices are a crucial variable and a source of significant future uncertainty.

- The base year purchase price of BEBs using depot -based charging is $1,008,794.[12] This is based on averaging quotes from New Flyer and King County Metro's experience with Proterra. Note that this price is "fully loaded" to include vehicle acquisition, warranties, parts, training and after-market features.

- The purchase price of depot-charging BEBs declines relative to equivalent diesel buses (with improvements in technology and economies of scale) and then increases (due to normal inflation) in line with the average of two different scenarios from the California Air Resources Board.[13] Figure 3 below illustrates this trend over the study period.

- The base year purchase price of diesel buses is $532,019. This is based on TriMet's cost for new buses being added in Fiscal Year 2019. Note that this price is also "fully loaded" to include vehicle acquisition, warranties, parts, training and after-market features.

- The purchase price of diesel buses grows by approximately $17,894 annually, in year of expenditure dollars, due largely to inflation. This is based on the average trend of new bus deliveries over the period 2001-2015 as reported in the American Public Transportation Association's 2015 Public Transportation Fact Book. Figure 3 below illustrates this trend over the study period.

- Total costs for both diesel and BEBs also include two types of special equipment requirements particular to TriMet. All new buses require an operator protective enclosure costing $5,000, and all fleet expansion buses (as opposed to replacement buses) require a package of equipment costing approximately $25,000.

[12] Dollar figures are in 2018 dollars unless otherwise noted. Base BEB cost assumptions are based on preliminary quotes for manufacturers and range from approximately $930,000 to approximately $1,087,000.

[13] California Air Resources Board. "5th Innovative Clean Transit Working Group Meeting." June 26, 2017.

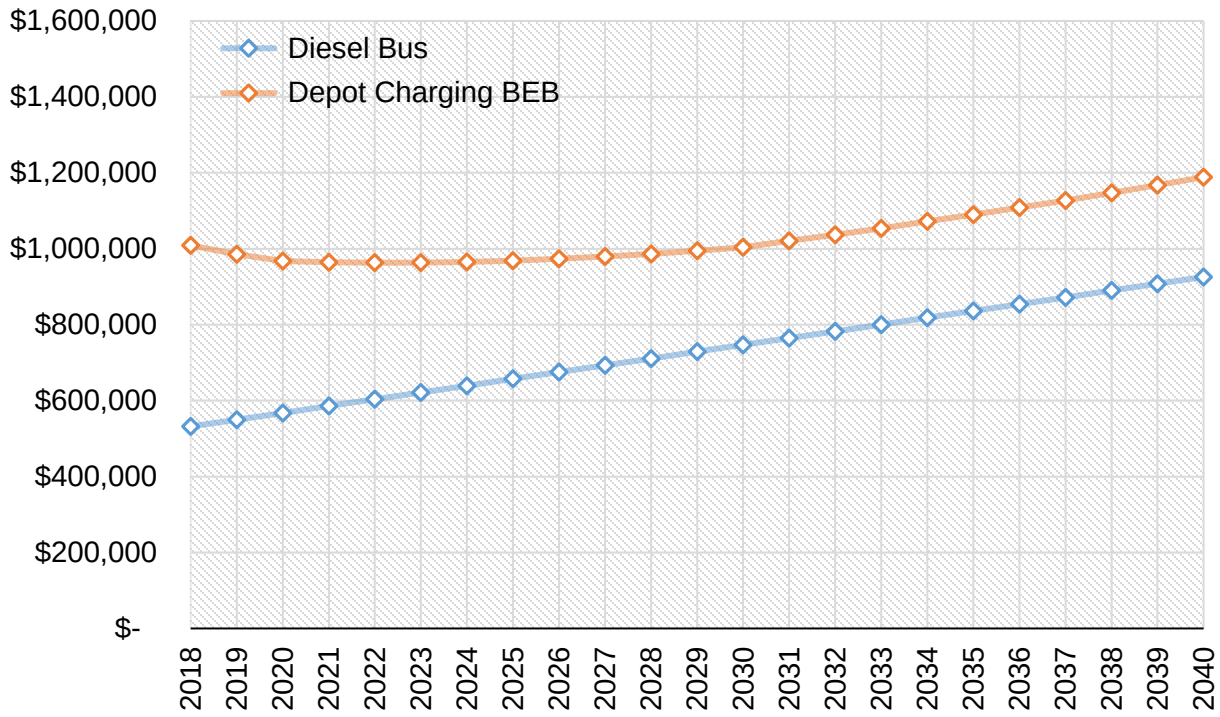

Figure 3. Projected purchases prices for diesel buses and BEBs using depot-based charging.

Maintenance Costs

- The base year cost of diesel bus maintenance is $1.82 per mile based on TriMet's current experience.

- The cost of BEB maintenance is estimated to be 20 percent lower than equivalent diesel buses. Manufacturers highlight that BEBs have fewer parts to maintain and do not require oil and liquid fuels. Savings as large as $151,000 over 12 years have been claimed. Despite these optimistic claims, TriMet seeks to balance its expectations based on experience from other agencies operating electric buses. Due to this technology being relatively new to U.S. transit agencies, full lifecycle maintenance cost trends are not yet available, so a moderate assumption is prudent.

- Actual mileage per bus is determined based on the average of each bus's operating facility.

- Charging equipment also requires maintenance. Based on the King County Metro's Feasibility of Achieving a Carbon-Neutral or Zero-Emission Fleet study,[14] this is estimated at $200 annually for a depot charger in the base year.

Fuel Costs

- The base year price of diesel fuel is $1.95 per gallon based on TriMet's current experience.[15]

[14] https://kingcounty.gov/~/media/elected/executive/constantine/news/documents/Zero_Emission_Fleet.ashx.

[15] Source: TriMet Financial Analyst Timothy Kea.

- The price of diesel fuel is projected to grow by 2 percent annually (inclusive of 1.34 percent inflation). Although there is research suggesting that the price of diesel fuel could grow at faster rates in the future,[16] the 2 percent growth trend aligns with TriMet experience. A faster rate of growth would reflect significant policy or economic shifts. [17]

- Actual gallons of fuel used are determined based on the bus's per-bus average for each operating facility.[18]

Electricity Costs

- For electricity costs that depend on vehicle usage, 2.362 kilowatt hour (kWh) of energy is used per mile. This is based on King County research that is in line with preliminary analysis related to TriMet's BEB pilot.

- Actual mileage per bus is determined based on the average of each bus's operating facility.

- For electricity costs that depend on the peak power draw of facilities, each depot charger is assumed to draw 110 kW. This is the worst case manufacturer specification from Proterra,[19] though manufacturer claims are generally optimistic.

- Pricing of electricity would be provided under PGE's Schedule 85 rate structure. This was confirmed in discussions with PGE. This rate structure applies to large nonresidential customers drawing power in the range of 201 kW to 4,000 kW. The power needs of BEB charging are estimated to fall in this range. The pricing under this schedule varies with the share of charging occurring during PGE's peak period (between 6 a.m. and 10 p.m.). Based on service schedules and the differential pricing, our analysis assumes that 25 percent of charging occurs during the 6 a.m. to 10 p.m. window, and the majority would occur overnight.

Facility Upgrades

- Facility upgrade costs were estimated by developing preliminary engineering plans for the existing TriMet bus depots. These plans considered pavement restriping, electrical wiring, power service and adding a substation.[20] For the planned new bus facility, costing assumes the facility upgrade cost per bus matches the average of the three existing bus bases.

- Facility upgrade costs assume that upgrades are deployed to one-third of a bus facility at a time. Thus, one-third of the facility will be upgraded for the first one-third of its fleet. Facility upgrade costs continue in one-third units as the BEB fleet grows at each bus facility.

[16] Source: National Renewable Energy Laboratory, 2017.

[17] Policy changes, such as federal carbon caps or taxes, could dramatically change the long-range cost of diesel fuel, making it significantly more expensive. Such changes would narrow the gap between the NPV of BEBs versus diesel buses.

[18] Source: September 2017 Bus Maintenance Report.

[19] Source: Catalyst 40-foot bus performance specifications.

[20] Initial facility costs could be reduced if the PUC were to approve a docket expanding on the rule it approved for TriMet's initial five BEBs test and allowing PGE to design, install and maintain charging facilities.

Charger Infrastructure

- The base price for each depot charger is $68,909 to purchase and install. This is based on research from the King County Metro feasibility study and confirmed by manufacturers.[21]

- Based on manufacturer specifications, depot chargers can accommodate two BEBs and have the same lifetime as the associated buses.

Clean Fuel Credits

The Oregon Department of Environmental Quality (DEQ) established a Clean Fuel Credit program that provides credits for BEBs that can be sold in a market. (Its policy currently runs through 2025, beyond which credit distribution is assumed to be static.) The actual value of the credits is subject to market forces.

- The model assumes a value of $100[22] per credit. This approximates the value of similar credits offered in California at the time of writing. While this represents an increase over the current value of the credits in Oregon, it is considered to be a realistic projection of future performance.

Finance Assumptions

The model made the following assumptions regarding finance. All analyses use 2018 dollars, and a discount rate of 3 percent is used to adjust future costs for time value. Second, specific growth rates are assumed for certain categories of costs based on market indexes or TriMet experience: materials and services grow at 3 percent annually and labor costs grow at 1 percent annually. General inflation uses a 10-year average consumer price index value of 1.34 percent. Finally, all financial outputs are presented in constant 2018 dollars.

The overall results of the TriMet fleet replacement net present value (NPV) model through the year 2055 are summarized in Table 2 below.

[21] For purposes of this analysis it is assumed that TriMet will install, own and maintain charging infrastructure. For the purchase of TriMet's first five on-route opportunity charging BEBs, the PUC approved Order No. 18-054, allowing PGE to install, own and maintain the charging infrastructure. If this approach were available for the full implementation of the BEB plan, TriMet's up front capital costs would be reduced significantly.

[22] Source: Approximate current value in California.

Table 2. Comparison of modeled fleet replacement NPV categories between diesel buses and BEB scenarios

	Diesel Fleet Replacement	BEB Fleet Replacement
NPV to TriMet		
Fuel Use	$189,311,600	$40,957,864
Electricity Use	$351,369	$60,394,841
Maintenance	$979,770,749	$829,111,721
Vehicle Purchase	$678,704,440	$877,366,717
Charger Infrastructure	$872,718	$24,432,563
Clean Fuel Credits	-$606,777	-$83,293,920
Facility Upgrades	$226,207	$30,578,032
Total	**$1,848,630,307**	**$1,779,547,818**
Social NPVs		
Emissions (Tailpipe)	$118,967,159	$27,158,828
Emissions (Power)	$169,545	$22,419,826[23]
Noise[24]	$33,183,247	$23,115,102
Total	**$152,319,951**	**$72,693,757**

Under both scenarios, the total of all lifecycle NPVs to TriMet for replacing, expanding and operating its fleet is approximately $1.8 billion. The NPV of choosing the BEB fleet option saves TriMet approximately $69.1 million, or 3.7 percent of the total cost through the year 2055, in 2018 dollars.

Choosing the BEB fleet option also reduces social costs, with a NPV approximately $79.6 million, related to emissions and noise reductions. These benefits accrue to members of the general public and cannot be monetized by TriMet. While some value of emissions reductions are reflected in state emissions credits, the overall contribution that converting to BEBs makes toward meeting climate goals is not a financial resource that TriMet can use to offset the initial cost of purchasing these vehicles and charging infrastructure.

This model also allows us to understand how the NPV is generated over time. Figures 4 and 5 below show that BEB fleet costs are greatest at the beginning of the bus lifecycle when vehicles and infrastructure are being acquired. In the later years, BEB costs related to operations and maintenance are significantly less than diesel buses. In other words, while BEBs cost somewhat more up front than equivalent diesel buses, the benefits in reduced maintenance and operating costs offset the up-front costs in the long term.

Even though the transition to BEBs is expected to save money in the long term, in the short term it requires additional funding sources to facilitate the transition.

As will be noted in the following sections of this report, with an allocation of Statewide Transportation Investment Funds, TriMet is in a position to move forward with a pilot phase of BEB conversion and an aspirational goal of full fleet conversion. However, to achieve the full fleet conversion, significant additional resources will need to be identified beyond those currently available to the agency.

[23] This NPV is based on PGE's current generating portfolio, which includes the coal plant at Boardman. As PGE transitions to a lower-carbon emissions generation portfolio, the social NPV of moving to BEBs will increase above this figure.

[24] A noise reduction of 51 percent is estimated overall.

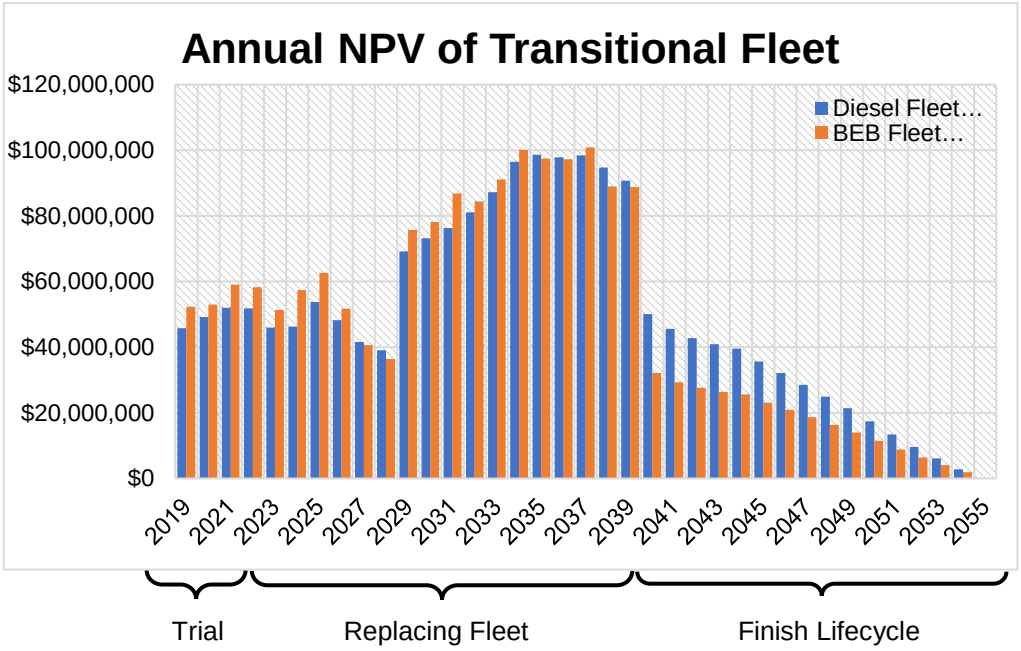

Figure 4. Annual NPV of the transitional fleet

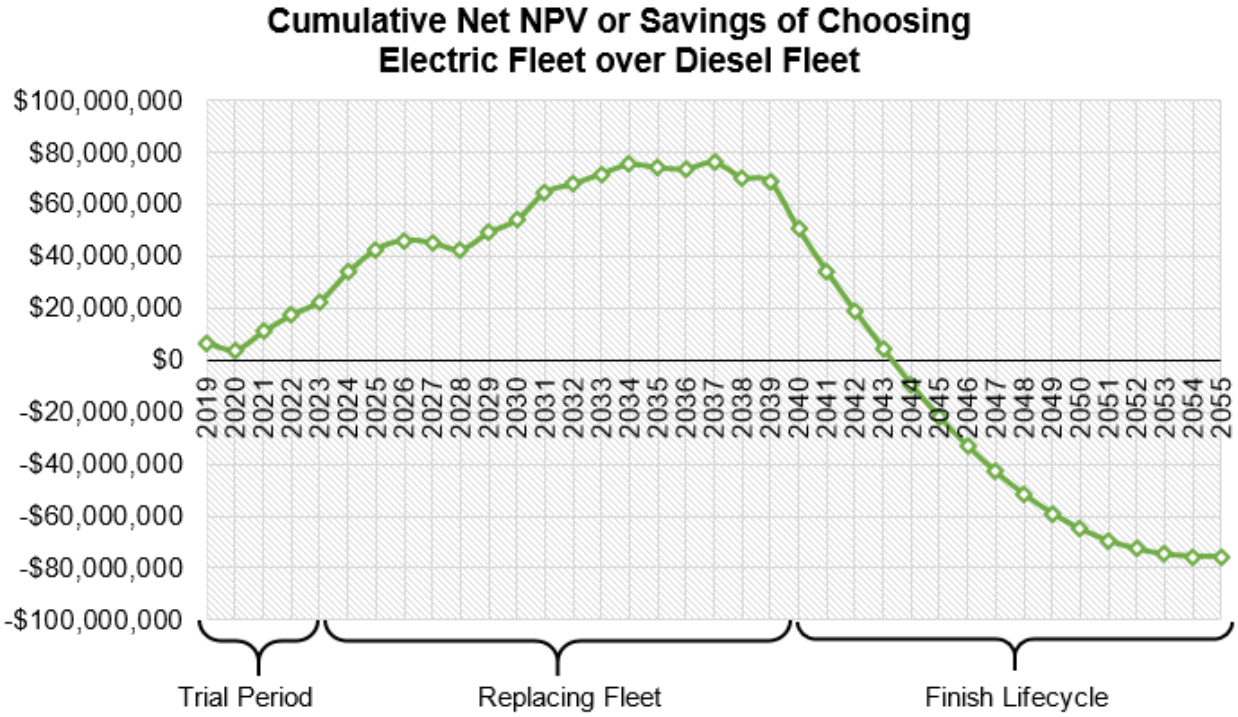

Figure 5. Cumulative NPV or savings of choosing electrical buses over diesel buses for the transitional fleet

Social Costs

Social costs related to emissions were calculated for both tailpipe emissions from diesel buses and from power generation for BEBs. This analysis evaluated the value of the CO_2 and NO_x produced. The social cost per ton of CO_2 is $44.75, while the social cost per ton of NO_x is $8,335.[25] Forty-foot diesel buses emit 2,444 grams of CO_2 per mile and 16.64 grams of NO_x per mile.[26] Thus, a social cost per diesel bus mile can be calculated. Similarly, PGE reports emission rates per megawatt-hour (MWh) of power generated. They report 0.000391 tons of NO_x per MWh and 0.554017 tons of CO_2 per MWh. These statistics can be combined with the energy use per mile to generate a range of social costs per BEB mile.

Social costs related to noise impacts were calculated based on the miles driven for each type of vehicle. The noise costs of diesel buses are 7.6 cents per mile, while the noise costs of BEBs are 4.6 cents per mile.[27] A comparison of total costs of the diesel and BEB transition scenarios, including social costs, are shown in Figure 6 below.

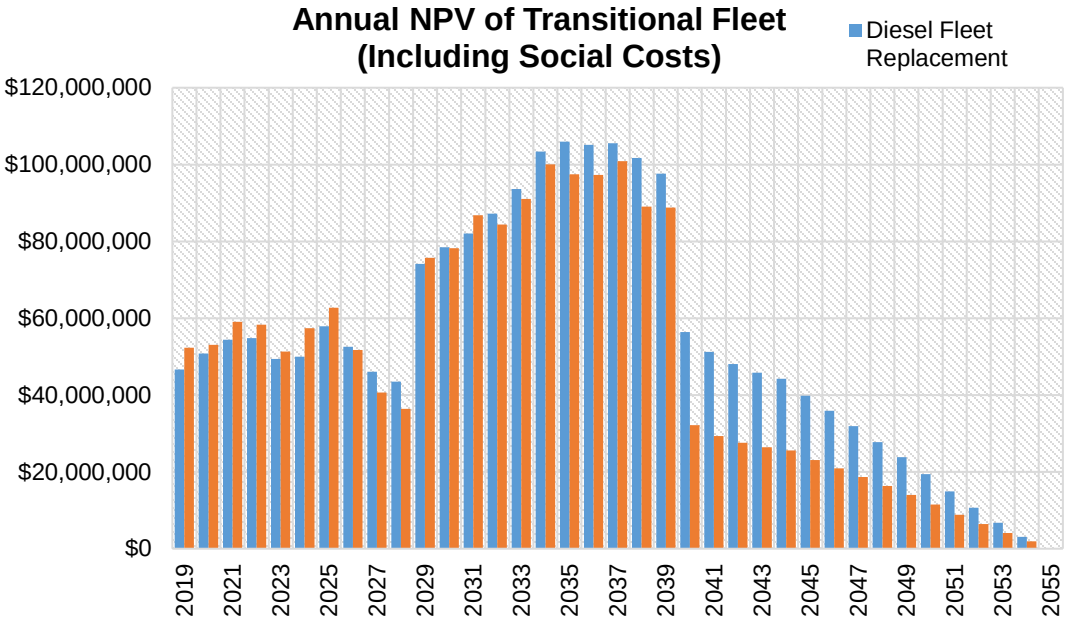

Figure 6. Annual NPV of the transitional fleet, including social costs

Chapter 5: Proposed Implementation Strategy

In order to calculate the year of expenditure costs for converting to a non-diesel fleet, it was necessary to develop a proposed implementation strategy, defining an implementation rate for the purposes of modeling. Based on the findings of the industry review, bus charging type analysis and NPV calculation, TriMet developed the following proposed implementation strategy.

[25] U.S. Environmental Protection Agency.

[26] EMFAC Web Database, California Environmental Protection Agency, Air Resources Board, https://www.arb.ca.gov/emfac/2014/.

[27] Transportation Cost and Benefit Analysis II, Victoria Transport Policy Institute (VTPI), December 2015. Available at: www.vtpi.org/tca/tca0511.pdf.

Trial Period
Because of the uncertainties associated with the current technology, and in an effort to capture the benefits of improving technologies and innovation, TriMet is suggesting a two-step approach to converting to a non-diesel fleet. The first phase will be to incrementally purchase a 65 BEB test fleet over the next four years. The second phase will be to evaluate the performance, cost and reliability of the test fleet and make a determination over the test period whether to either ramp up, maintain or discontinue purchases of BEBs to pursue some other technology altogether. Assuming the BEBs are performing adequately, TriMet would purchase 20 additional BEBs in 2023 as well.

Full Implementation
Assuming successful outcomes during the four-year trial and the identification of new funding needed after the initial STIF allocation, TriMet would discontinue diesel bus purchases in 2023. Following such a strategy, no diesel buses would remain in the TriMet fleet by 2040. A graph of the fleet conversion progression is show in Figure 7.

TriMet's five year BEB purchase plan:

Fiscal Year	No. of BEBs ordered
2019	10[28]
2020	10
2021	20
2022	20
2023	20
Total	80[29]

Trial Phase

1st Year Transition

[28] FTA has approved a Low-No grant to TriMet for the purchase of five depot-based BEBs. In addition, TriMet proposes to purchase an additional 10 BEBs in FY 2019 using STIF funds.

[29] Total BEBs ordered or in use in FY 2023 will be 90 after including the five FTA-funded on-route BEBs approved in FY 2016.

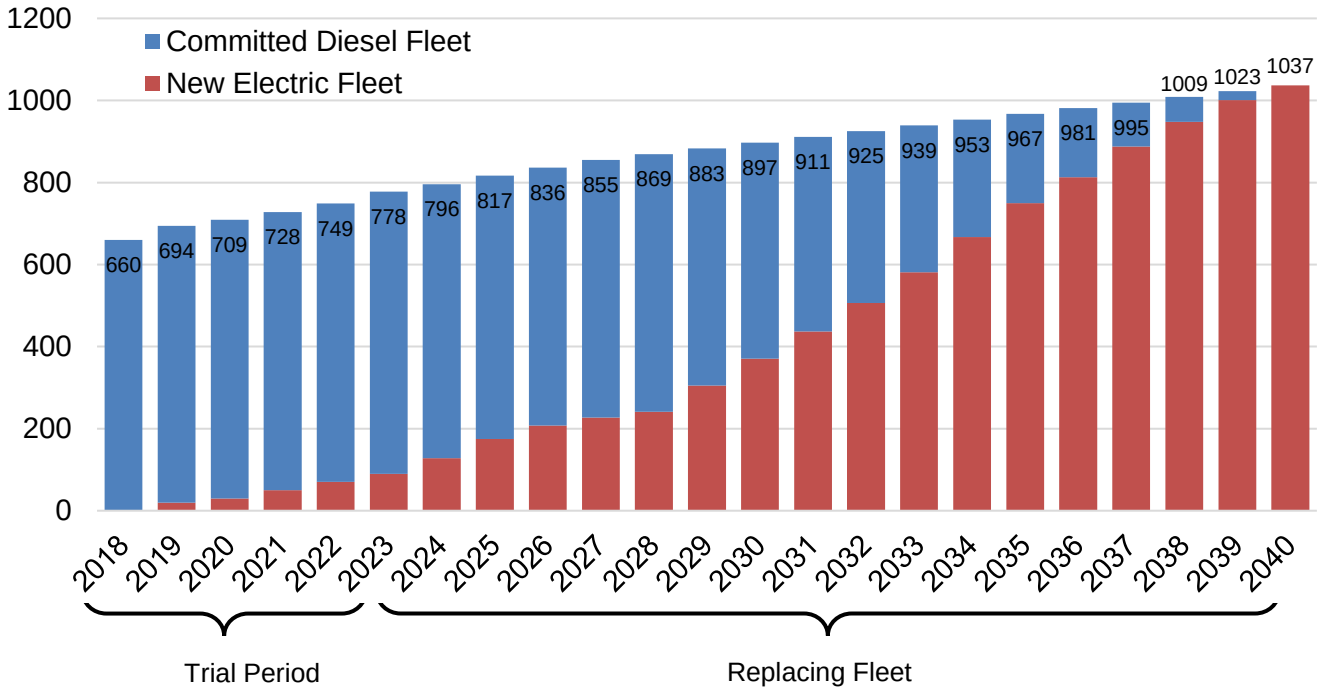

Figure 7. Planned progression of electric fleet to replace diesel fleet by end of 2040. Note: Actual completion of fleet conversion could occur in calendar year 2041 or 2042 depending on manufacturer lead time for construction and delivery of buses.

Long-Term Considerations

During the time required to make the transition to a full BEB or non-diesel fleet, policy, technology and economic considerations are expected to evolve. The following are considerations that will inform either the transition or impact the timeline of such a transition.

- With current battery technology and TriMet's current bus service schedules, it is estimated that approximately 59 percent of bus routes are compatible with depot-charging BEB technology (assuming a "real-world" range of 150 miles). Depot-charging technology will need to improve to accommodate all of TriMet's routes. Some manufacturers already advertise longer ranges and on-the-ground testing over time will evolve the agency's battery range assumptions.

- Future purchase prices of BEBs are uncertain. Some experts argue that prices could decline more than projected in the California Air Resources Board (CARB) model used for this analysis. If purchase prices do not decline at least as much as currently projected in the CARB innovation curve, continued purchase of BEBs may not be feasible. On the other hand, if innovation and economies of scale reduce BEB purchase costs more than projected in the CARB model, less additional funding would be needed to achieve full conversion.[30]

[30] Reducing capital costs do not necessarily speed up the conversion to non-diesel buses because, to manage its bus replacement cycle, TriMet tries to have 1/16th of its bus fleet "age out" each year.

- BEB technology must prove reliable for TriMet's operational needs. If the buses do not perform up to expectations, a full fleet transition may be premature.

- Fuel and maintenance cost savings are currently assumed. If future electricity costs are greater than expected or maintenance costs cannot be reduced to assumed levels, alternative technologies will be explored.

- Although BEBs should eventually cost less than equivalent diesel buses due to lower maintenance and operating costs, TriMet does not have the resources to pay the up-front costs of converting the entire fleet to BEBs. Additional funding, beyond HB 2017, will be needed to support a full transition to BEBs.

- Changes to state and national policies and credit programs may support or detract from BEB viability. Tax credit programs such as Clean Fuel Credits must continue with at least the existing credit value for a transition to BEBs to be viable for TriMet. Policies that increase diesel prices but do not help finance BEB costs, while affecting the NPV calculation, do not make the transition more affordable.

TriMet will continue to monitor and explore alternatives such as hydrogen and RNG during the BEB trial period. If these technologies prove more attractive in terms of cost, emissions, reliability and customer service than BEBs, TriMet may move to pilot those technologies as well. Pilot testing of other technologies will occur at a garage other than Powell, which will have reached its two-fuel type limit with the combined diesel and BEB fleet based there.[31]

Title VI and Equity Considerations

TriMet's commitment to Title VI and equity can be seen across our agency, the transportation system we manage and the community we serve. It is embedded in the policies and practices we develop and implement.

TriMet has established standards and policies for evaluating and addressing equity considerations as set forth in the FTA's Circular 4702.1B. [32] These standards and policies assist in guiding the equitable development and delivery of service in support of TriMet's mission to provide valued transit service that is safe, dependable and easy to use. They also provide benchmarks to ensure that service design and operations practices do not result in discrimination on the basis of race, color or national origin, or place undue burdens on low-income populations. They establish a basis for monitoring and analysis of service delivery, availability and the distribution of amenities and vehicles to determine whether any disparate impacts are evident. In some cases, TriMet has adopted policies that exceed the federal requirements to ensure that its practices meet community expectations regarding equitable allocation of services.

In Oregon and across the U.S., low-income families and people of color are more likely to live in neighborhoods that have high concentrations of air pollution and, as a result, are at higher risk for

[31] TriMet has determined that it cannot support more than two fuel types at any single maintenance facility due to the need for parts, training, equipment and fueling infrastructure. Since diesel buses will remain in service at all TriMet garages for some years to come, each garage will have the capability of housing one alternative fuel bus type.

[32] https://www.transit.dot.gov/sites/fta.dot.gov/files/docs/FTA_Title_VI_FINAL.pdf.

chronic disease and premature death.[33] In alignment with TriMet's commitment to Title VI and equity, one strategy that TriMet can use to help address these impacts is to deploy non-polluting buses to routes that serve minority and low-income areas.

Historically, TriMet's goal for equitably assigning buses has been to ensure that the average age of vehicles that serve minority and low-income populations is no more than the average age of vehicles on routes in non-minority and higher income areas. However, in adopting this plan, TriMet intends to go beyond its historical practices and instead, prioritize the deployment of non-diesel buses to routes serving low-income and minority communities.

In anticipation of TriMet's plan to transition to zero-emission bus technology, staff has developed strategy to prioritize the deployment of non-diesel vehicles throughout the service area utilizing Title VI and environmental justice principles. Decisions about where to deploy BEBs will need to reflect technical and physical feasibility, such as achievable bus range and availability of charging facilities. Locating the initial BEB trial at the Powell Operations Facility will facilitate this effort because the garage already houses many routes serving low-income and minority neighborhoods. TriMet is in the process of upgrading the Powell facility and is incorporating BEB charging infrastructure into the design of these improvements.

Assuming that the initial BEB trial is successful and funding for a full conversion of TriMet's fleet to BEBs is found, TriMet's strategy is to locate BEBs at the Powell facility until that garage has reached capacity (approximately 300 buses) and then deploy BEBs out of other garages. In addition, if no alternative fuel source, such as CNG or hydrogen, proves attractive, the next facility to house BEBs is likely to be TriMet's new maintenance facility, currently being planned for northeast Portland. It is too early to determine which of the two remaining maintenance facilities, Merlo or Center Street, would be the next to receive BEBs. In any case, regardless of which garage is selected as a BEB base, TriMet will prioritize deployment of BEBs to the routes that serve low-income and minority populations and where characteristics route are consistent with the technology.

Chapter 6: Fiscal Analysis of Transitioning to a BEB Fleet

In evaluating the lifecycle costs of diesel buses versus BEB vehicles, it is appropriate to discount all future costs to current dollars. In looking at the year-by-year funding requirements for the purchase of a BEB fleet, it is appropriate to instead look at cost figures in year of expenditure dollars. The following funding requirements take into consideration all of the factors used in the lifecycle analysis: the costs of vehicle purchase, maintenance savings, tax credits and charging infrastructure, converted to year of expenditure figures to better understand the annual funding necessary to successfully accomplish the fleet conversion.

For purposes of this analysis, TriMet is assuming that the purchase of diesel replacement and expansion buses is already funded from existing resources such as the employer payroll tax, STIF and federal formula funds. Therefore, it is the net additional cost of BEBs that is of interest. Using a year of expenditure approach yields the net additional costs of BEB conversion in Table 3.

[33] http://nationalequityatlas.org/indicators/Air_pollution%3A_Unequal_burden.

Table 3. Net BEB premium over equivalent diesel cost in year of expenditure dollars

	Fiscal Year	No. of BEBs Purchased	Equivalent Diesel Bus	Electric Bus	BEB Premium
Phase I	2019	10	$ 5,453,195	$ 19,879,663	$ 14,426,469
	2020	10	$ 5,589,525	$ 10,678,295	$ 5,088,770
	2021	20	$ 11,458,525	$ 21,644,643	$ 10,186,118
	2022	20	$ 11,744,989	$ 21,995,276	$ 10,250,288
Phase II	2023	20	$ 12,038,613	$ 22,383,126	$ 10,344,513
	2024	62	$ 38,252,694	$ 82,071,597	$ 43,818,903
	2025	5	$ 3,162,017	$ 4,186,189	$ 1,024,172
	2026	5	$ 3,241,067	$ 2,625,698	$ (615,369)
	2027	60	$ 39,865,130	$ 81,813,220	$ 41,948,091
	2028	75	$ 51,077,197	$ 89,707,272	$ 38,630,074
	2029	65	$ 45,373,577	$ 97,289,085	$ 51,915,508
	2030	69	$ 49,369,942	$ 83,132,537	$ 33,762,594
	2031	82	$ 60,138,314	$ 129,121,996	$ 68,983,683
	2032	55	$ 41,345,091	$ 65,190,287	$ 23,845,197
	2033	62	$ 47,772,373	$ 75,075,126	$ 27,302,753
	2034	69	$ 54,495,179	$ 116,249,405	$ 61,754,227
	2035	66	$ 53,428,968	$ 82,956,784	$ 29,527,816
	2036	61	$ 50,615,852	$ 75,622,236	$ 25,006,383
	2037	62	$ 52,731,761	$ 102,006,781	$ 49,275,020
	2038	41	$ 35,742,778	$ 42,654,209	$ 6,911,431
	2039	5	$ 4,467,847	$ (21,731,350)	$ (26,199,198)
	2040	5	$ 4,579,543	$ (23,675,627)	$ (28,255,170)

As shown in Table 3, the annual average incremental additional cost of the BEB strategy is about $10 million per year for the period FY 2019 to FY 2023. After that point, the incremental costs increase dramatically due to the larger bus purchases programed for FY 2023 to FY 2027.[34] In those years, the average annual incremental additional cost is approximately $20 million. From FY 2028 to FY 2031, the annual incremental premium jumps to nearly $50 million per year on average.

As noted previously, to pursue a full conversion strategy, significant additional resources would need to be identified or costs would have to decline dramatically.

To begin the conversion process and respond to the legislative direction in HB 2017 (Keep Oregon Moving Act), TriMet approached the STIF advisory committee with the request to allocate a portion of the new regional funding to the Phase I BEB trial and beyond. The advisory committee agreed to consider this request and, subsequently, TriMet included the option of allocating STIF funds to a BEB strategy in its community outreach and engagement process for HB 2017. TriMet anticipates that the STIF committee will allocate both ongoing and one-time STIF resources over the initial five years of the new funding as the agency ramps up expanded services. TriMet suggested the allocation of $5 million in ongoing funding and $28 million in one-time funds. Combined, these resources are sufficient to meet

[34] TriMet's bus replacement schedule shows five buses needed in 2025 and 2026 due to the fact that there are five buses in TriMet's existing fleet that will be reaching 16 years of age in those two years. In all likelihood, TriMet will smooth out bus purchases over these four years, purchasing approximately 30 replacement buses per year in 2024 through 2027. In either case, the average annual premium for BEBs over this period is approximately $20 million per year.

the BEB cost premium for the Phase I trial period and the first year of full fleet conversion in FY 2023. Given current cost projections, this would allow for the purchase of a total 80 BEBs and associated charging infrastructure in addition to the 10 BEBs funded through FTA Low-No grants. After FY 2023, TriMet would have $5 million in ongoing STIF resources to address the premium costs of a full conversion to BEBs; however, additional resources would be needed to address the unfunded portion of the premium.

As of the writing of this report, the STIF advisory committee has made a preliminary allocation of these ongoing and one-time funds. Successful allocation to the BEB trial program will require approval by both the TriMet Board of Directors and the Oregon Transportation Commission (OTC).

TriMet has been successful in securing two federal Low-No grants for the purchase of a total 10 BEBs and associated charging infrastructure. While TriMet will continue to pursue additional grants, these resources are not of a scale to address the bulk of the non-diesel conversion strategy. There are a number of potential sources of funding for the full conversion of the fleet.

- **Carbon cap and invest resources:** If the Oregon Legislature moves forward with a carbon cap and invest program, it could allocate resources in the form of cash or monetizable credits to TriMet to offset BEB premium costs. In addition, it is anticipated that a portion of the new resources generated under a cap and invest bill will fall under the restrictions of Article IX, Section 3 of the Oregon Constitution, requiring that all taxes or fees on motor vehicles or fuel must be used for roads. The state and region could make a policy decision to replace un-flexed federal dollars used for roads with these new cap and invest resources and flex more federal resources to alternative modes, including BEB conversion.

- **Flexible federal transportation funds:** Flexible federal transportation funds are allocated to the Oregon Department of Transportation and a portion of those funds are sub-allocated to the Portland metropolitan region, where the Joint Policy Advisory Committee on Transportation (JPACT) and Metro set funding priorities.

- **Expanded tax credits:** State or federal tax credits that can be earned by virtue of BEB investments that reduce carbon emissions could generate revenue that the agency can use to make the BEB investments. Currently, Oregon has a modest tax credit, which could be expanded. The federal government has stopped issuing renewable identification numbers (RIN) credits, which, if reinstated, could provide additional resources.

There are two policy changes that TriMet believes would help facilitate the full conversion of its diesel fleet to non-diesel.

- **Utility partnerships:** In February 2018, the PUC issued Order No. 18-054, adopting a multi-party stipulation that authorized PGE to undertake a number of initiatives to advance the electrification of transportation. One element of that order allowed PGE to partner with TriMet in the design, installation and maintenance of charging infrastructure for five BEBs using on-route opportunity charging. This approach allowed TriMet to focus its time and resources on its area of expertise, the purchase of the BEBS, rather than on the charging infrastructure, an area outside TriMet's expertise. This approach resulted in the purchase of one additional bus and much more efficient and effective implementation of the new technology. TriMet would encourage the PUC and other policy makers to expand the pilot program contained in Order No.

18-054 to allow TriMet, PGE and other utilities to partner in similar ways on full-scale BEB infrastructure.

- **Bonding STIF resources:** Oregon Department of Transportation's (ODOT) current position is that STIF funds cannot be bonded because, although they are allocated based on a formula, the use of the funds depends on periodic plan approval by both the local STIF advisory committee and the OTC. The inability to bond STIF resources reduces TriMet's ability to effectively use these funds to support the BEB strategy. Given the fact that capital costs for BEB conversion occur up front, but benefits in reduced maintenance and fuel costs occur in later years, bonding for BEBs would appear to be an ideal opportunity to more closely align the costs and benefits of the conversion strategy. TriMet would encourage ODOT and the OTC to reconsider their interpretation and allow the bonding of STIF resources, just as they allow the bonding of their own gas tax revenues.

Conclusion

Global climate change is one of the most important environmental and economic challenges of our times. The impacts of unchecked carbon emissions are almost incalculably large. It is imperative that public entities like TriMet take steps not only to reduce their own carbon emissions but to provide leadership in this effort to help advance technological innovation and broader adoption of carbon emissions reduction strategies. Given imperative advances in technology and funding from HB 2017, TriMet can project conversion of its diesel fleet to alternative fuel by the year 2040 or before.

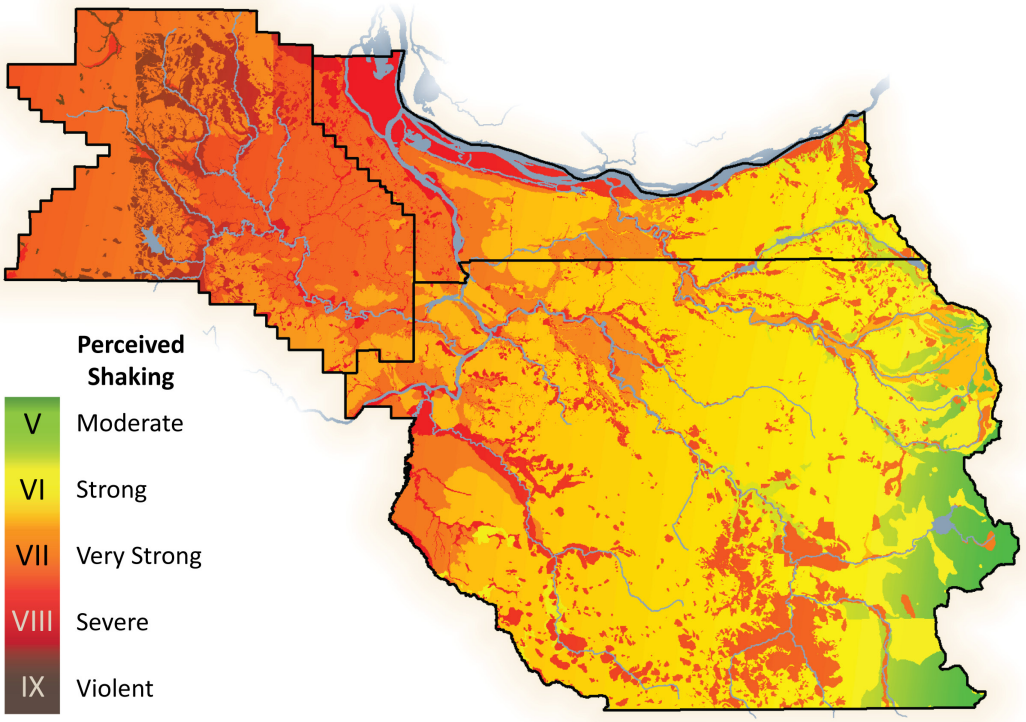
Successful passage of HB 2017, the Keep Oregon Moving Act, provides the region with the opportunity to pursue the combined strategy of substantially expanding transit service while beginning the conversion to a non-diesel bus fleet. Funding from HB 2017 is projected to be sufficient to both expand service hours and support the purchase of a test fleet of BEBs and associated charging infrastructure, plus one year of conversion over the next five years.

This analysis highlights that converting to BEBs has significant benefits in reduced air and noise pollution and, over the very long run, potential net savings due to lower costs of maintenance, operations and fuel. In the short term, however, BEBs and charging infrastructure cost significantly more than traditional diesel buses. These costs are incurred up front, but the savings are realized over many years of operation, with a "breakeven point" occurring years in the future.

TriMet cannot fully convert to a non-diesel fleet with current revenues. With an allocation of HB 2017 funds, TriMet can begin the conversion process, but completing it will require either significant additional resources starting in 2022 or a reduction in costs from innovation or new technologies beyond that currently projected by industry experts.

The analyses regarding technology and trends in the industry lead us to conclude that BEB conversion is the least-cost/least-risk approach to moving TriMet to a non-diesel fleet at this time. However, other technologies and options may also hold promise, and TriMet, in recommending a BEB strategy, is not foreclosing other options. Hydrogen fuel cell technology appears to be advancing to the stage where hydrogen powered buses would be feasible. Renewable natural gas also appears to be worth examining as an option.

TriMet is proposing to take its conversion strategy one step further, through the adoption of a strategy to convert its so-called “non-revenue vehicle” fleet to renewable energy sources. TriMet has approximately 300 vehicles, in addition to its trains and buses, including pool cars, supervisory vehicles, utility trucks and specialized vehicles. Not all of these vehicles are suitable for conversion to either battery electric or CNG. However, of the approximately 250 that are, TriMet plans to move forward with a strategy that would convert those vehicles by FY 2040 or before.



Equity is an important consideration in pursuing any conversion strategy. Low-income and minority neighborhoods often experience greater levels of air pollution from a variety of sources, both transportation and non-transportation related, than other areas. Strategic deployment of a BEB fleet to routes serving vulnerable communities can help reduce emissions in those neighborhoods.

EXECUTIVE SUMMARY

This report was prepared for the Regional Disaster Preparedness Organization (RDPO), with funding provided by the Urban Areas Security Initiative Program. The report provides damage and casualty estimates to buildings, people, and key infrastructure sectors resulting from a major earthquake in the Portland metropolitan region by using updated local geologic information and recent advances in loss estimation methods. Damage and casualty estimates are tabulated at county, jurisdiction, and neighborhood levels, providing actionable information for further use in emergency planning, earthquake mitigation, public awareness, and post-earthquake response and recovery.

The RDPO is a bi-state partnership of local and regional government agencies, non-governmental organizations, and private-sector stakeholders representing the Portland metropolitan region that collaborate to increase the region's resiliency to disasters. The region spans Clackamas, Columbia, Multnomah, and Washington Counties in Oregon and Clark County in Washington. In 2016 the RDPO Steering Committee identified a need for updated, region-wide, detailed loss estimates from a major earthquake and engaged the Oregon Department of Geology and Mineral Industries (DOGAMI) to conduct this study. Previously, earthquake damage estimates in large portions of the Portland metropolitan region were limited to studies conducted in the 1990s, when understanding of the Cascadia Subduction Zone (CSZ) risk was nascent. Since then, advances have occurred in several areas, including loss estimation tool capabilities, subduction zone science, and local geologic mapping in the Portland metropolitan region. The RDPO commissioned this study to harness such advances, thereby enabling local, regional, state, and federal planners and policy makers to apply the results in their efforts to mitigate risk and building seismic resilience and to prepare for response and recovery. DOGAMI and RDPO divided the project into two phases, with the first phase focused on methodology refinement and application of those methods to evaluate impact of a major earthquake in Clackamas, Multnomah, and Washington Counties (Oregon). Phase 2 will apply the same methods in Columbia County, Oregon, and Clark County, Washington.

The Portland metropolitan region is vulnerable to regional and local earthquakes. We modeled damage for two earthquake scenarios: a magnitude 9.0 CSZ earthquake, and a magnitude 6.8 Portland Hills fault earthquake, a local crustal fault situated at the foot of the Tualatin Mountains. In order to better understand the range of possible losses, our analysis quantified impacts during saturated and dry soil conditions—the former are more likely to have earthquake-induced landslides and liquefaction; the latter may have some earthquake-induced landslides, but little occurrence of liquefaction. We derived our damage estimates primarily from Hazus®, a geographic information system (GIS)-based tool and set of methods for loss estimation from natural hazards. Hazus is developed and supported by the Federal Emergency Management Agency (FEMA).

Our project consisted of several major efforts:

- **Building and infrastructure databases**: completion of a region-wide building footprint database, a building database containing detailed descriptions of each building, and an electric power transmission structure database
- **Geotechnical mapping updates:** earthquake-induced landslide susceptibility, liquefaction susceptibility, and soil classification, using recently published high-resolution geologic mapping
- **Ground motion and ground deformation updates:** local ground motion and ground failure data for two earthquake scenarios using the geotechnical mapping updates
- **Earthquake damage estimates:** quantifying impacts to buildings and the people that occupy them, to the region's designated emergency transportation routes, and to the electrical grid

LUBA No. 2020-009
Page 4961

A GIS database containing building footprints, population density grids, detailed casualty, debris, and building loss estimates by jurisdiction and neighborhood, key infrastructure sectors with loss estimates, and updated ground motion and ground deformation data accompanies this report. A separately published report describes the geologic mapping updates for the three-county area, consisting of National Earthquake Hazards Reduction Program (NEHRP) soil types, and earthquake-induced landslide and liquefaction susceptibility.

A Cascadia Subduction Zone (CSZ) magnitude 9.0 earthquake will have a severe impact on the three-county area, with building repair costs amounting to between 23.5 and 36.7 billion dollars (9% and 14% of the total building replacement cost, **Table ES-1**). Although damage estimates vary widely throughout the study area, no community will be unharmed. Depending on the time of day an earthquake occurs, casualties may be in the thousands or low tens of thousands. The earthquake will generate several millions of tons of debris from damaged buildings. Damage and casualty estimates resulting from a magnitude 6.8 Portland Hills fault earthquake are more than twice compared to a CSZ earthquake, primarily because of the Portland Hills fault location below densely populated and heavily developed areas (**Table ES-1**). However, the likelihood of a Portland Hills fault earthquake is considerably less than a Cascadia Subduction Zone earthquake.

Table ES-1. Loss estimate summary for two earthquake scenarios in the Portland metropolitan area. Lower value: dry soil conditions. Upper value: saturated soil conditions.

County	U.S. Census Population Estimate (2010)	Number of Buildings	Building Value ($ Billion)	Building Repair Cost ($ Billion)	Building Loss Ratio	Debris (Millions of Tons)	Long-Term Displaced Population (Thousands)	Total Casualties*	
								Daytime Scenario (Thousands)	Nighttime Scenario (Thousands)
Cascadia Subduction Zone magnitude 9.0 earthquake									
Clackamas	375,992	179,164	62.4	3.2–4.6	5%–7%	1.7–2.1	1.9–10.1	2.0–2.8	0.5–1.1
Multnomah	735,334	255,577	114.0	13.3–20.5	12%–18%	7.7–10.4	9.7–37.5	11.4–16.7	2.8–5.6
Washington	529,710	181,111	82.7	7.0–11.6	8%–14%	3.4–4.8	5.2–37.7	4.9–7.7	1.1–3.7
Total	1,641,036	615,852	259.1	23.5–36.7	9%–14%	12.8–17.3	16.8–85.3	18.3–27.2	4.4–10.4
Portland Hills fault magnitude 6.8 earthquake									
Clackamas	375,992	179,164	62.4	12.9–16.4	21%–26%	4.9–6.0	25.2–50.8	8.9–10.9	3.3–5.2

Washington	529,710	181,111	82.7	15.4–24.3	19%–29%	6.0–8.6	19.6–86.0	10.0–15.8	3.2–8.5
Total	1,641,036	615,852	259.1	60.6–83.4	23%–32%	26.6–33.9	95.6–257	47.8–63.0	15.8–29.0

* Casualty estimates include minor injuries, injuries requiring hospitalization, and fatalities.

The damage estimates are significantly higher than those given in previously published studies for the area, primarily due to usage of an updated building inventory that more accurately reflects the region's building code history with respect to seismic resiliency, and usage of updated soils and liquefaction susceptibility data.

This study addressed a major need for consistent, updated earthquake damage estimates in the Portland metropolitan region. The data are intended not as an end in themselves, but as a platform for counties, jurisdictions, and communities to better understand their needs to prepare for, respond to, and recover from a major earthquake. We conclude our report with recommendations supported by findings in this study that can reduce the region's vulnerability, shorten recovery time, and improve emergency operations.

1.0 INTRODUCTION

1.1 Overview

Casualty and loss estimates for a modeled earthquake provide planners with actionable data for pre-earthquake preparations and mitigation and for post-earthquake recovery efforts. The Regional Disaster Preparedness Organization (RDPO), a bi-state partnership of local and regional government agencies, non-governmental organizations, and private-sector stakeholders representing the Portland Metropolitan Region, collaborate to increase the region's resiliency to disasters, including earthquakes. The Portland Metropolitan Region spans Clackamas, Columbia, Multnomah, and Washington Counties in Oregon, and Clark County in Washington (**Figure 1-1**).

Figure 1-1. Regional Disaster Preparedness Organization counties, spanning Oregon and Washington. Phase 1 study area in tan, proposed Phase 2 study area in lavender. County seats shown as dots.

One of RDPO's guiding principles is ensuring equity and fairness in adopting regional policies, and from an earthquake planning perspective, that principle requires loss estimates that are developed using consistent methods and data across the region. Prior to this study, loss estimates from earthquakes in the Portland Metropolitan Region were derived from several studies, each done at different times, using different datasets (Wang, 1998; Hofmeister and others, 2003; FEMA, 2004; Tetra Tech, 2016a). Technologies and data available for earthquake impact analysis have improved since these studies. RDPO requested that Oregon Department of Geology and Mineral Industries (DOGAMI) develop—using the best tools and methods, updated local geological data, and detailed building and infrastructure data—updated loss estimates from a major earthquake for the five-county RDPO area.

We divided the project into two phases. **Phase 1** focused on methodology refinement and application of those methods to evaluate impact of a major earthquake in **Clackamas**, **Multnomah**, and **Washington Counties** (Oregon)—the "study area." Phase 2 will apply the same methods in Columbia County, Oregon, and Clark County, Washington. This report documents our Phase 1 work.

The three-county study area is home to 44% of Oregon's total population. It continues to experience significant growth, with population increasing from 1.45 million people in 2000, to 1.64 million people in 2010, to 1.78 million people in 2016 (Portland State University Population Research Center, 2016, https://www.pdx.edu/prc/population-reports-estimates). By 2030, the study area's total population is projected at 2.10 million people (Oregon Office of Economic Analysis, 2013, http://www.oregon.gov/das/OEA/Pages/forecastdemographic.aspx). The area hosts 894,000 jobs, or 50% of all jobs in Oregon, with total annual wages estimated at $50.5 billion (Oregon Employment Department, 2016). The area includes an infrastructure hub that houses all of Oregon's major liquid fuel port terminals, and Port of Portland facilities that include the state's largest airport. Most of the population in the study area is concentrated in cities (76%), but all three counties contain large tracts of unincorporated suburban development. All three counties have broad areas of dispersed rural development.

Geology in the 3,076-square-mile study area varies widely, influenced by local and regional processes (Evarts and others, 2009). It includes Columbia River basalts, alluvial deposits, volcanic outcrops, loess deposits, dredge and fill material placed on top of former riverine wetlands, and large areas of fine-grained to coarse-grained Missoula flood deposits (Ma and others, 2012). The geological diversity creates significant local variations in earthquake ground motion and in ground failure from earthquake-induced landslides and liquefaction.

1.2 Earthquake Scenarios and Earthquake Loss Estimation

An earthquake scenario tells the story of a defined earthquake and its potential impacts to a community, presenting narratives and data that can help planners and community members better understand the earthquake and plan for the future (Earthquake Engineering Research Institute [EERI], 2006). Scenarios use the best scientific information available on fault placement, rupture frequency, and earthquake magnitude. Because the loss estimate data are used for planning purposes, scenarios incorporate the upper end of predicted magnitude when modeling a specific earthquake. Full earthquake scenario exercises incorporate experts from multiple backgrounds and responsibilities, such as transportation and utilities. Past examples include the Seattle Fault (EERI, 2005) and the Wasatch Fault (EERI, 2015) scenarios.

Our study is more limited in scope compared to the two example scenarios; we focus on damage to buildings and the people that occupy them, and to two key infrastructure sectors. In this report, our use of the term *scenario* refers to a specific combination of a particular earthquake and one or more additional variables. In order to provide planners a more complete picture of the range of potential impacts from a large earthquake, we modeled two distinct earthquakes: a Cascadia Subduction Zone and a Portland Hills fault. Each earthquake was modeled with a *wet* (saturated) and a *dry* soil condition, and each earthquake was modeled at two different times of the day, at "2 AM" and at "2 PM."

In western Oregon and Washington, soil moisture conditions vary widely throughout the calendar year. Soil moisture conditions influence the likelihood of an earthquake-triggered landslide or liquefaction. An earthquake occurring during wet (saturated) soil conditions is much more likely to induce landslides and liquefaction. Some earthquake-induced landslides may occur in dry soil conditions, but liquefaction is much less likely.

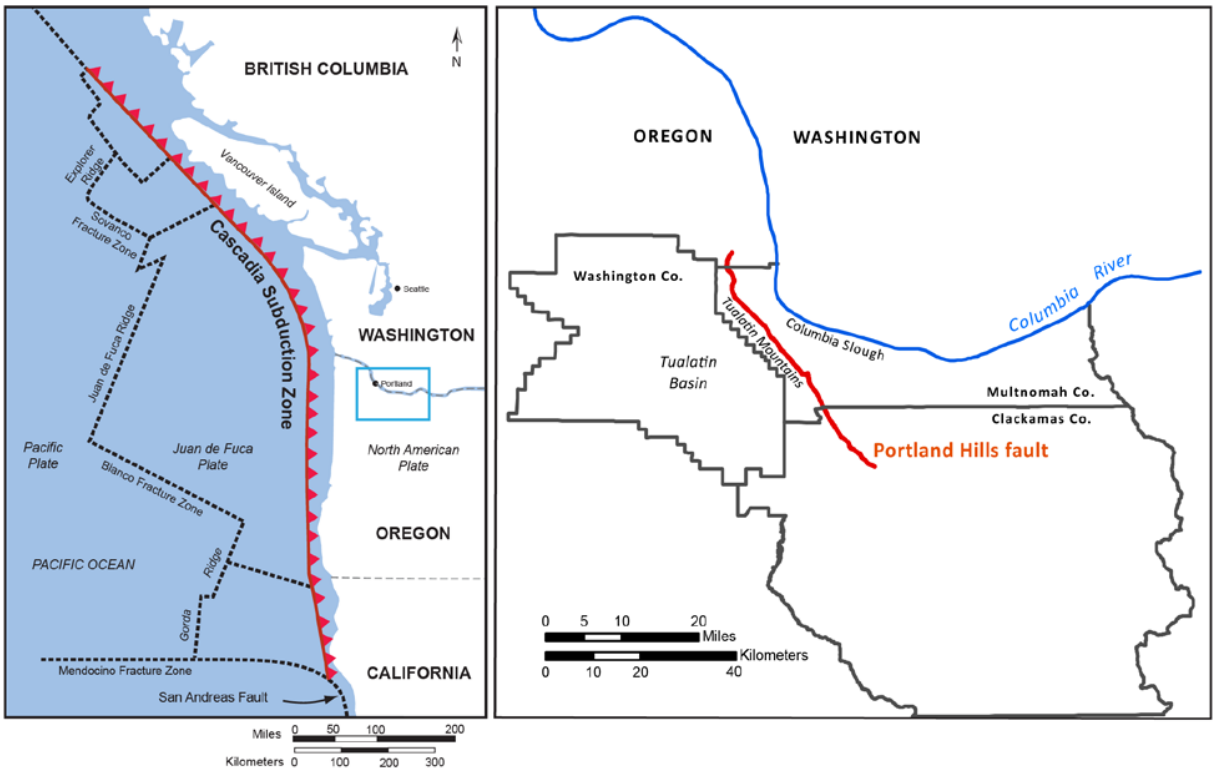
LUBA No. 2020-009
Page 4964

Throughout a typical day, people move between various buildings such as residences, schools, work facilities, and commercial facilities. Some buildings, due to their basic structural system, are more likely to sustain significant damage from an earthquake and, thus, depending on how many people are occupying the building at the time of the earthquake, cause more casualties.

Past earthquakes along the 600-mile Cascadia Subduction Zone fault (**Figure 1-1**) have occurred at highly variable intervals, from decades to centuries, and have ranged widely in magnitude (Oregon Seismic Safety Policy Advisory Commission [OSSPAC], 2013). At least 40 large-magnitude earthquakes have occurred along the fault in the past 10,000 years. The most recent earthquake, estimated at magnitude 9.0, occurred on January 26, 1700 A.D. Studies of the geologic record suggest that a Cascadia Subduction Zone earthquake of magnitude 9.0 has a 10% to 14% chance of occurring within the next 50 years (Petersen and others, 2002; Goldfinger and others, 2012). For the central and northern Oregon coast, recent research suggests the chance of occurrence within the next 50 years may be 15% to 20% (Goldfinger and others, 2017).

Although the Cascadia Subduction Zone fault has garnered significant attention, active local crustal faults should also be evaluated in an earthquake impact analysis. Wong and others (2001) concluded that the Portland Hills fault (**Figure 1-2**) might be seismogenic, with evidence suggesting two ruptures in the past 15,000 years (Liberty and others, 2003). Other active crustal faults exist in the Portland Metropolitan Region, but a rupture on the Portland Hills fault would be the most impactful, given its position directly underneath downtown Portland and the population centers of Clackamas County.

Hazus is a nationally applicable standardized methodology that contains models for estimating potential losses from earthquakes, floods, and hurricanes. Hazus uses geographic information system (GIS) technology to estimate physical, economic, and social impacts of disasters (FEMA, 2011). FEMA developed the earthquake model in cooperation with the National Institute of Building Sciences (Schneider and Schauer, 2006). Hazus damage and loss functions for generic model building types are considered to be reliable predictors of earthquake effects for large groups of buildings (FEMA, 2010). However, good estimates require accurate, updated data inputs.



The first Hazus-based study conducted in Oregon used a magnitude 8.5 model of a Cascadia Subduction Zone earthquake as it was understood at the time (Wang, 1998). The study was intended to provide an overall initial understanding of potential earthquake impacts across Oregon. Further, the Hazus tool at that time did not incorporate liquefaction or landslide information. Subsequent Hazus-based studies were limited to portions of the study area. The City of Portland had two Hazus-based studies (FEMA, 2004; Tetra Tech, 2016a), and Clackamas County had one Hazus-based study (Hofmeister and others, 2003). However, no studies have been conducted for Multnomah County (excluding the City of Portland) and Washington County since Wang (1998).

All previous Hazus-based earthquake studies in the study area were conducted at the census tract level—a spatial unit designated by the U.S. Census Bureau (https://www.census.gov/geo/reference/gtc/gtc_ct.html) that was chosen in the formative days of Hazus tool development out of computational necessity, but one that oversimplifies the building, seismic, and geologic heterogeneity within the census tract (Price and others, 2010). In the past five years, advances in Hazus tools and methods have enabled modeling earthquake damage using detailed data that incorporate local geologic variations and individual building seismic design characteristics. The advancements in the tools and methods provide more accurate loss estimates and permit analysis at a finer, neighborhood-scale level, rather than at the coarser census tract level. The updated methods require that considerable effort be expended on dataset development, including building and infrastructure inventory and local geological data. In Section 2, we provide background on the asset development, which includes all buildings and key infrastructure

LUBA No. 2020-009
Page 4965

sectors in the study area. Further background on the key infrastructure sectors is in the following subsections.

Figure 1-2. Cascadia Subduction Zone fault (left) and Portland Hills fault (right) locations. Blue rectangle in left figure is shown in right figure.

1.2.1 Critical Infrastructure Sectors

The Cities of Eugene and Springfield Multi-Jurisdictional Natural Hazards Mitigation Plan (2014) identified three critical infrastructure sectors fundamental to the operation, maintenance, and restoration of all other infrastructure sectors—namely, electricity, transportation, and fossil fuels. Given the challenges of enumerating the numerous interdependencies among various sectors and of quantifying potential earthquake damage to the components of those sectors, we determined that by limiting our analysis to the key sectors identified in that plan, we could establish a basis upon which to build future infrastructure studies and interdependencies.

In the Portland Metropolitan Region, fossil fuel supply seismic resiliency has been analyzed by Wang and others (2013), with a focus on the Critical Energy Infrastructure (CEI) Hub in northwest Portland. Tetra Tech (2016b) quantified damage estimates to the CEI Hub's fuel storage structures for a Cascadia Subduction Zone and for a Portland Hills fault earthquake scenario, and DOGAMI provided a substantive review of the report. We did not see a need to revisit damage estimates to the nonbuilding structures contained in the CEI Hub. Nonbuilding structures include water towers, storage tanks, piers, dams, and carports, and where human occupancy is incidental (FEMA, 2012b).

A Hazus-based study of the City of Portland (FEMA, 2004) included an analysis of an earthquake impact to electric substations and the transportation network. Although it used best available liquefaction and landslide data, the study was limited to the City of Portland, and its spatial data were not made available for further analysis.

1.2.1.1 Electric Power Transmission

Electric power infrastructure consists of power generation and distribution, including dams, substations, transmission network, and local transformers. Within the network, substation components are typically the most likely to fail given strong ground motion (Fujisaki and others, 2014). Transmission structures (towers and poles) generally perform well under strong ground motion but can fail due to lateral movement from liquefaction or earthquake-induced landslides (Good and others, 2009). Hazus provides a simplified damage model from ground motion and ground failure for substations as a whole unit, but the model may be overly conservative (Kongar and others, 2014), and a more accurate model should consider individual substation components.

From our literature review we determined that our project should 1) provide updated ground motion and ground failure data for local utilities to better quantify their substation seismic resiliency, and 2) address the risk to the transmission network between substations by quantifying potential ground failure at the transmission structures. An example of earthquake-induced ground failure impact on a transmission structure is shown in **Figure 1-3**. Our approach builds on the previous exposure analysis of electric transmission structures to mapped landslides established by Burns and others (2011, 2013).

Figure 1-3. Example of ground failure underneath a transmission tower, 1999 İzmit earthquake (Turkey). Photographic credit: University of California, Irvine Consortium of University for Research in Earthquake Engineering Archives.

1.2.1.2 Emergency Transportation Routes

Functioning transportation networks are essential for emergency response and post-earthquake recovery. Regional planners have identified a subset of arterials in the study area as routes essential for providing emergency services. Understanding which routes may be impacted from an earthquake can permit planners to consider alternative routes or how to distribute services in a more dispersed manner. An example of earthquake-induced ground failure impact on a surface road is shown in **Figure 1-4**. A complete analysis would include a seismic analysis of the bridges and overpasses used by the emergency transportation routes, but such an analysis requires detailed field-gathered information (e.g., Wang, 2017) and was beyond the scope of this project.

Figure 1-4. Damaged road due to liquefaction-induced lateral spreading, 2001 Nisqually, Washington earthquake. Photographic credit: DOGAMI Archives.

1.3 Study Limitations

Hazus-based risk analyses often include damage estimates to various assets such as buildings, buried utilities, above ground utilities, and essential facilities. Such analyses typically use the inventory data that accompany Hazus. Out of necessity, the Hazus inventory data are constructed from readily available nationwide datasets, and often capture a portion of the non-building assets in an area. Users can supplant the inventory with more detailed information, but at significant development cost. Given the constraints on time and budget for this project, and the challenges of obtaining more detailed and accurate local data, we limited our analysis to buildings and the people that occupy them, and the two key infrastructure sectors previously discussed. Specifically, we did not analyze earthquake impacts to communication networks or towers, storage tanks, dams, levees, hazardous material facilities, and buried utilities conveying natural gas, potable water, oil, stormwater, and wastewater.

LUBA No. 2020-009
Page 4968

We did not identify or individually analyze specific buildings that may be considered essential or critical facilities. As discussed in the Recommendations section (Section 7), we maintain that the identification of such facilities should be community driven, and that an earthquake impact analysis of such facilities should be done by using the Rapid Visual Screening method (FEMA, 2015a) rather than a Hazus-based method using generic building models.

The Critical Energy Infrastructure (CEI) Hub along the Willamette River in northwest Portland was not analyzed in this report. A recent analysis conducted by Tetra Tech (2016b) provided a detailed damage assessment of the infrastructure from the same earthquake scenarios we used for this study. We did not include the hub's nonbuilding structures, such as oil tanks, in our building database.

Our economic loss estimates were limited to the direct cost of repairing a damaged building or replacing a severely damaged building with an equivalent structure. Our model assumes standard labor and material costs and availability of capital and credit. It does not factor in any demand surge. We did not model income losses such as wage and rental income, as we maintain that the impacts of a regional earthquake will fundamentally alter the local economy, rendering the basic assumptions used in the current Hazus model moot.

Our study focused on loss to buildings, which includes damage from earthquake-induced landslides and liquefaction. We did not quantify permanent loss of use, and thus value, of the land due to the ground failure. Such loss of use can add to the overall indirect economic loss.

LUBA No. 2020-009
Page 4969

2.0 ASSET DATABASE DEVELOPMENT

In this study we limited our analysis, and thus our asset database, to three components: buildings and the people occupying them, the electric power transmission infrastructure, and emergency transportation routes. A building is defined as a structure containing a roof and walls and occupied by people. Nonbuilding structures include water towers, storage tanks, piers, dams, and carports, and where human occupancy is incidental (FEMA, 2012b). We excluded nonbuilding structures from our building database. The electrical transmission network is limited to the towers and poles that supply power to the distribution substations (Appendix E, **Plate 1**). The surface transportation network is limited to a subset of highways, arterials, and roads identified as Emergency Transportation Routes (Appendix E, **Plate 10**).

2.1 Building Database

A Hazus-compatible building database contains a record for each distinct building, with each record containing required information for estimating damage to the structure and potential harm to the building's occupants (**Table 2-1**). Information associated with the building record, commonly referred to as attributes in a GIS context, is populated primarily from county assessor records or, where better data are available, from other ancillary datasets. Examples of such datasets are provided in **Table 10-1**.

Table 2-1. Building information required by Hazus earthquake model.

Hazus Attribute	Example	Purpose
Location of building	latitude, longitude	Extract ground motion and ground deformation data
Building usage	Single-family Residential; Retail Commercial	Repair/replacement cost; Number of people per building
Building material	wood; steel	Response to ground motion; debris
Year built	1968	Seismic design level: response to ground motion
Number of stories	2	Response to ground motion
Square footage	2250	Repair/replacement cost; debris
Daytime occupancy[+]	2.1	Casualty estimate
Nighttime occupancy[+]	3.4	Casualty estimate

[+]Daytime and nighttime occupancy amounts at the individual building level are based on proration of aggregated population data using the building's square footage, thus are typically fractional.

2.1.1 Building Footprint Development

A building footprint is a GIS polygon representation outlining the shape of the building. It defines a record in the building database. The building footprint establishes the location of the building, thereby placing the building relative to a natural hazard.

Because building footprints define the building record, our first task was to complete a building footprint database for the study area. Building footprints were obtained from Metro Regional Land Information System (http://rlisdiscovery.oregonmetro.gov/, downloaded February 2016) and from two DOGAMI publications (Burns and others, 2011, 2013). Large portions of western Washington County and southwestern Clackamas County had no building footprint data. In these areas we digitized building footprints following the methods described by Mickelson and Burns (2012, Section 3.2.3). Where lidar

LUBA No. 2020-009
Page 4970

data were not present, we used 2016 orthoimagery from the National Agricultural Imagery Program (https://www.fsa.usda.gov/programs-and-services/aerial-photography/imagery-programs/naip-imagery/index). Our digitization effort included removing obsolete building footprints (teardowns) and modifying existing building footprints where additions had been made or other digitization errors were noted.

We did not digitize structures less than 400 square feet in area, as such features are assumed to be non-building structures, such as kiosks, or are not reasonable to model within Hazus, such as portable storage sheds. Structures obtained from previous digitization efforts that were less than 400 square feet were retained in the building footprint database but were attributed as not modeled.

Nonbuilding structures include developments such as water towers, billboards, docks, dams, piers, and hoop houses. Outlines of such structures are often included in a building footprint database. Our study focuses on estimating damage from an earthquake to buildings and the people that reside in them. Many of the nonbuilding structures have no damage model or an overly simplified damage model within the Hazus framework. We identified such structures using orthoimagery and tax lot database queries, and we attributed them as not modeled.

Floating structures such as houseboats do not directly experience seismic shaking. We identified such structures using orthoimagery, attributed them as floating structures, and excluded them from our analysis. As with nonbuilding structures, we retained the building footprint of floating structures in the database. We note that floating structures may be damaged from seismic seiches (Jones and others, 2008).

In the building footprint database obtained from Metro RLIS, building complexes that contain two or more distinct, contiguous buildings were commonly digitized as a single building. Such buildings typically occur in downtown areas and can be identified by several methods, including their spanning multiple tax lots with unique owners, and distinct building heights derived from lidar elevation models. Seismic design level, building usage, and construction material can vary between such contiguous buildings, each of which can influence the damage estimate. We determined that dividing such polygons into individual buildings would result in a more accurate representation of the built infrastructure. Orthoimagery and street-level imagery further clarified whether a building footprint needed further partition. Building footprints digitized as part of this project factored in the guidelines for contiguous buildings.

Although parking garages are by definition nonbuilding structures, Hazus considers them as buildings in its occupancy class library (FEMA, 2011, Table 3.2). We retained that modest inconsistency in our building database by including parking garages in our damage assessment.

2.1.2 Assessor Database Processing

County assessor databases form the basis for assigning Hazus-required information for individual buildings, as the databases have information for most to all of the tax lots in the study area. We obtained detailed tabular data from the three county assessor offices. We used the tax lot spatial data from the Metro RLIS database to associate assessor tabular data with specific buildings, and we extracted information from the assessor tabular data to assign values to the appropriate attributes (**Table 2-1**). For example, Oregon Administrative Rules (OAR 150-308.215) require that county assessors assign a 3-digit property code for all tax lots in Oregon. We constructed a reference table to translate the tax lot property code into one of 36 Hazus occupancy classes, and we assigned that value to the particular buildings occupying that particular tax lot.

LUBA No. 2020-009
Page 4971

Assessor tabular data provided direct or easily-derived information for the following attributes: year built, square footage, number of stories, and building usage. None of the three county assessor databases had consistent information on building type (e.g., wood, steel).

2.1.3 Usage of Ancillary Data

We used a supersedence paradigm, overriding the assessor-derived data with more accurate data where available (Appendix A, Section **10.1**). For example, Lewis (2007) provided detailed information on square footage and building type for public buildings, such as schools, in Oregon. Other examples include the Metro RLIS spatial data on single-family and multi-family residential buildings, and the locations of educational, fire, and police buildings. Appendix A, Section **10.1** provides a complete list of other datasets used to populate the building database.

2.1.4 Building Type

The Hazus building type attribute specifies the basic structural system of a building. For example, a steel-framed building can be categorized as a steel light frame or a steel moment frame. The Hazus Advanced Engineering Building Module (AEBM) tool provides building damage functions for 36 generic building types (FEMA, 2010), and the FEMA Rapid Visual Screening handbook (FEMA, 2015a) provides qualitative descriptions of each building type. We classified all buildings in the study area into one of the 36 generic building types. Although Hazus AEBM permits one to create a unique performance model for individual buildings, such an effort was well outside of this project's scope, given its three-county scale.

We could not find any information in any of the three county assessor databases that provided consistent information on the building's primary construction material. Building types for a portion of the buildings were available from several sources, and we incorporated these into our building database. Lewis (2007) provided building types for public schools, fire, and police buildings. The most valuable dataset was the Metro Area Disaster GIS (MADGIS) database (Metro, 1998), with 40,000 buildings spread across all counties in the study area, categorized into Hazus-compatible building types.

For buildings that had no information on their primary construction material, we assigned a value based on the building's occupancy class, year built, and number of stories. We used an in-house tool that implements the statistical distributions listed in Tables 3.A1–3.A10 of the Hazus Earthquake Technical Manual (FEMA, 2011).

2.1.5 Building Replacement Value

We used the RSMeans valuation method for estimating a building's replacement cost (Charest, 2017), multiplying the building square footage by a standard cost per square foot. We used values from Hazus SQL database tables ([dbo].[hzReplacementCost] and [dbo].[hzRes1ReplCost]) that incorporated the RSMeans valuation to compute the replacement cost. We made no inflation or regional adjustments to the tabular data, for the following reasons. The Hazus tables were based on 2014 RSMeans national values. Because the Consumer Price Index difference between 2014 and 2017 was minimal, we made no further adjustment. The RSMeans location factor adjusts for regional differences in labor and material costs. Portland area's location factor of 0.98 for residential construction (Charest, 2017) was, for simplicity, rounded to 1.0, and thus we did not adjust cost; the commercial construction location factor at 1.0 also resulted in no adjustment.

Building replacement cost is not the same as a property's assessed value. For analysis purposes, we assume repair or replacement costs to damaged structures will be charged at standard construction rates and are independent of a building's age or the land on which the building is placed. Assessed value

takes into account the land's value, which may fluctuate greatly depending on real estate markets, and for improvements, assessors typically factor in the building's depreciation into the assessed value.

An abnormal shortage of skilled labor or materials can occur after a large-scale disaster. Demand surge is a process resulting in a higher cost to repair building damage after large disasters than to repair the same damage after a small disaster (Olsen and Porter, 2011). Adjusting repair/replacement costs due to a likely demand surge was beyond the scope of this project.

2.1.6 Design Level Assignment

The design level assignment in the Hazus-MH earthquake model allows a user to specify, for the given building type, its seismic performance level. Oregon initially adopted seismic building codes in the mid-1970s (Judson, 2012). The established benchmark years of code enforcement are used in determining a "design level" for individual buildings. The design level attributes (pre-code, low-code, moderate-code, and high-code) are then used in the Hazus earthquake model to determine what damage functions are applied to a given building. The year built and the year of the most recent seismic retrofit are the main considerations for an individual design level attribute. We used the benchmark years listed in **Table 10-2** to assign a design level to each building. We are not aware of any building codes adopted at the local or county level that supersede, from a seismic design perspective, building codes established by the Oregon Building Codes Division.

In the past 20 years, many property owners, including private, public, and institutional, have implemented building seismic retrofits—modifications that improve building's seismic resilience. Ideally, we would obtain and incorporate such information into our database, instead of assigning a seismic design level based on the structure's original year of construction. However, such information was not available in any centralized, usable form from any of the county's permitting or assessor offices. The City Club of Portland's analysis (2017) identified a lack of reliable data, in part because permits are not often filed with seismic upgrades, or the seismic upgrades to a building may be part of a larger renovation. We found only one source of data for such information—the Unreinforced Masonry Building database maintained by the City of Portland (2017). Buildings identified as upgraded, 290 total, were assigned Reinforced Masonry (RM1), moderate code building type and design level values, respectively. The dataset was limited to the City of Portland. City Club of Portland's report (2017) found no other source of data for identifying locations of unreinforced masonry buildings in the region.

2.1.7 Daytime and Nighttime Population

In order to calculate casualties and displaced persons, we estimated the number of people occupying each building under two commonly implemented temporal scenarios: daytime and nighttime, commonly referred in a Hazus context as a "2 PM" and a "2 AM" scenario. The nighttime population assignment assumes that at least 95% of the people are in their primary residences and that nonresidential buildings have some level of occupancy, depending on their function. Fire stations, for example, are occupied by a nighttime shift. The daytime scenario assumes a typical weekday in a school year, with population distributed across schools, work facilities, and homes. The population assignments are primary driven by U.S. Census population data, the building's specific usage (i.e., its Hazus-designated occupancy class), and the building's square footage. We did not implement a "5 PM" scenario, as that requires assumptions on road occupancy and bridge failure models, and an evaluation of bridge and overpass seismic design performance was beyond the scope of this project.

For assigning permanent resident population quantities to residential buildings, we pro-rated the U.S. Census Bureau 2010 permanent population value for a given U.S. Census Bureau-defined census block group across the residential buildings, excepting the RES4 (hotel/motel) type, on a square footage

LUBA No. 2020-009
Page 4973

basis. We determined that the census block geometries are often imprecise relative to building footprints, creating frequent scenarios where a census block has one or more residential buildings and zero permanent residents, or zero residential buildings and one or more permanent residents. The census block group's geometries are generally along arterials or physiographic features. Although pro-rating at the census tract was a possible alternative, we decided the finer resolution of the census block group provided the best estimate of residential building occupancy, one that reflected varying demographics within a larger census tract. We retained a *permanent resident* population field, and we populated the *nighttime population* for residential buildings by multiplying the permanent resident population by 0.95—slightly less than the 99% suggested by FEMA (2011, Table 13.2), and one that accounts for night shift employment and recreational and business travel.

For daytime population in nonresidential buildings, we considered the suggested peak population density numbers published in the Hazus Tsunami Model Technical Guidance (FEMA, 2017c, Table 3.14), but we observed that the daytime population was at least 3 times the permanent population of the study area. We determined that such a ratio was unreasonably high, as we assume that at least 75% of the working population in the study area reside within the study area. Instead, we computed people-per-square-footage (ppsf) values by using the estimated commercial, industrial, and educational population estimates by Census Tract in the Hazus SQL database table [dbo].[hzDemographicsT], and our own building stock square footage summaries, and then used the ppsf values and the individual building's square footage to assign people per building.

We assigned daytime populations for residential buildings and nighttime populations for nonresidential buildings by using the Day to Night ratios provided by FEMA (2017c, Table 3.14).

Permanent resident figures per residential building were based on the April 1, 2010 U.S. Census numbers and the 2010 U.S. Census Block Group boundaries. The study area has seen significant growth since then, with the most recent estimate (July 1, 2016 Certified Population Estimates, Portland State University Population Research Center, https://www.pdx.edu/prc/population-reports-estimates) showing an 8.4% increase from 2010. Several jurisdictions have had boundary adjustments via annexations since 2010. Planners may wish to adjust the displaced population and nighttime casualty estimates using the percentages shown in **Table 2-2**. Given the larger uncertainty with the daytime population assignments compared to nighttime population assignments, we do not recommend adjusting daytime casualty numbers.

Table 2-2. Population changes in the study area, 2010 to 2016. Limited to cities with 2010 population of 20,000 or more people and with no to minimal annexations between 2010 and 2016. Certified Population Estimate: Portland State University Population Research Center.

County or Jurisdiction	2010 U.S. Census Population	Certified Population Estimate July 1, 2016	Percentage Increase
Study Area	1,641,036	1,779,245	8.4%
Clackamas County	375,992	404,980	7.7%
Multnomah County	735,334	790,670	7.5%
Washington County	529,710	583,595	10.2%
Portland	583,776	627,395	7.5%
Gresham	105,594	108,150	2.4%
Lake Oswego	36,619	37,425	2.2%
Oregon City	31,859	34,240	7.5%
Tualatin	26,054	26,840	3.0%
West Linn	25,109	25,615	2.0%

2.2 Electric Power Transmission

We constructed a transmission pole and tower point file database from several data sources, including Burns and others (2011, 2013), spatial data obtained from Portland General Electric Company (PGE, written communication, 2016), and where large gaps occurred, from our own digitization. Gaps in the transmission network were highlighted using the transmission line corridors and substations dataset downloaded from the Homeland Infrastructure Foundation-Level Data (HIFLD; U.S. Department of Homeland Security, 2017). The linear corridor data were used as a backdrop to digitize additional poles and towers, following the method established by Burns and others (2011). We did not distinguish between the type of structure (e.g., lattice tower or wood) or the voltage carried on the wires. To keep the problem tractable, we limited our analysis to the high-voltage network from power generation facilities up to the neighborhood distribution substations.

We identified a total of 18,098 poles and tower locations. The transmission network is incomplete, however, as we did not complete digitization of poles and towers in portions of North Portland, and data were not made available from the local utility. Electric power transmission distribution in North Portland is typically conveyed on single poles, which are difficult to distinguish using lidar-derived imagery or orthoimagery.

2.3 Emergency Transportation Routes

We obtained a GIS shapefile representing the Metro Emergency Transportation Routes (ETR) from Portland Bureau of Emergency Management (L. Bruno, written communication, 2017). Though the Metro Data Resource Center has not maintained the dataset for at least 10 years (S. Erickson, written communication, 2017), it is still considered operative at the regional level. The ETR extends into all five counties within the RPDO (**Figure 1-1**), but our analysis was limited to our three-county study area (Appendix E, **Plate 10**). Multiple transportation agencies have responsibility for various components of the ETR, and as outlined in a 2005 Memorandum of Understanding (Emergency Transportation Route Post-Earthquake Damage Assessment and Coordination Portland, Oregon/Vancouver, Washington Regional Area; State of Oregon Misc. Contracts & Agreements No. 21,273):

> (Terms of Agreement #1): ODOT, WSDOT and Agencies have identified the ETR. […] The ETR have been identified as "critical infrastructure" by the parties to the Memorandum of Understanding. ODOT, WSDOT and Agencies would give their jurisdictional ETR the highest priority for assessment of road and bridge conditions during an earthquake emergency […]
> (Exhibit A, I. Purpose [p. 8]): An Emergency Transportation Route or ETR is defined as a route needed during a major regional emergency or disaster to move response resources such as personnel, supplies, and equipment to heavily damaged areas.

The road network consists of GIS polylines placed at the road centerline and includes highway ramp and detailed highway intersection information. For our analysis purposes, polylines are not as useful as polygons, as we need to quantify the amount of ground deformation to a road that has some width. In order to prepare the road network for analysis, we first buffered the road centerlines by 50 foot, and then we dissolved the geometries. This typically generalizes highway areas, such as the I-5 corridor, into a single polygon. The dissolved polygon file was then manually edited to create a segment/node model,

LUBA No. 2020-009
Page 4975

with segments beginning and ending at intersections. However, major intersections, such as the I-5—I-205 intersection, were treated as a single segment instead of a node. We identified 238 road segments and gave each a unique key for analysis purposes.

3.0 NATURAL HAZARD DATA DEVELOPMENT

3.1 Bedrock Ground Motion

The Hazus model requires four descriptors of ground motion at a building's location: peak ground acceleration (pga), peak ground velocity (pgv), spectral acceleration at 1.0 second (sa10), and spectral acceleration at 0.3 second (sa03). Peak ground acceleration and peak ground velocity are the largest acceleration and velocity that can be expected at a particular site due to an earthquake. Peak ground acceleration is a widely used measure of ground shaking for a range of geotechnical and structural engineering applications. Spectral acceleration definitions and usage are given by the U.S. Geological Survey (USGS) at https://earthquake.usgs.gov/hazards/learn/technical.php.

For the Cascadia Subduction Zone magnitude 9.0 earthquake, Madin and Burns (2013) obtained synthetic bedrock ground motions from Arthur Frankel (USGS, written communication, 2012); we used the same bedrock ground motion data for this project. Bedrock ground motions for a synthetic Portland Hills fault magnitude 6.8 earthquake (firm rock conditions, V_{s30} = 760 m/s) were provided by Arthur Frankel (written communication, 2016) of the USGS at 0.01 degree intervals and are included in the accompanying geodatabase.

3.2 Site Ground Motion

The intensity of ground shaking during an earthquake depends on the geotechnical properties of the soil or bedrock at a particular site. The National Earthquake Hazard Reduction Program (NEHRP) provisions (FEMA, 2015b) specify, for each ground motion descriptor, level of bedrock ground motion, and NEHRP soil classification, a multiplication factor for calculating the ground motion at the surface (also known as the site) where buildings and infrastructure are placed. The NEHRP soil classification for a site is based on the average shear wave velocity within 30 meters of the ground surface. NEHRP classifications and general descriptions of the bedrock and soil material are as follows:

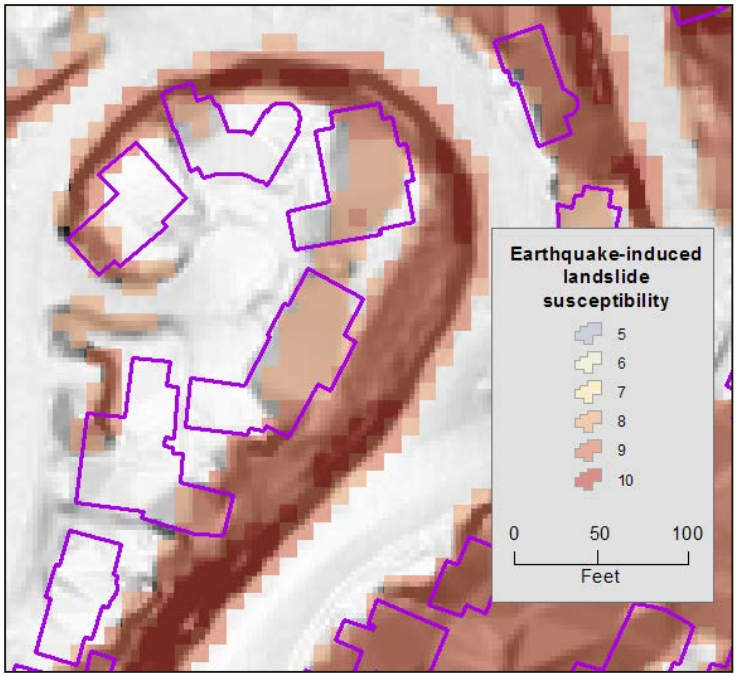
- site class A—hard rock
- site class B—rock
- site class C—very dense soil and soft rock
- site class D—stiff soil
- site class E— soft soil
- site class F—soils susceptible to potential failure

For our site ground motion data, we used updated NEHRP soil classification mapping that we completed as part of this project (Appleby and others, in preparation). Sites classified as "F" were, for amplification purposes, reclassified as "E". This is a conservative but commonly implemented assumption for loss estimation purposes. We overlaid the bedrock ground motion data with the NEHRP soil classification polygons, and we applied the appropriate amplification to derive the site ground motion. Further details on the site ground motion dataset development are provided in Appendix B.

The site ground motion from the synthetic earthquakes in our two scenarios differ dramatically across the study area, with the Portland Hills fault exhibiting significantly higher ground motion proximal to the fault (Appendix E, **Plate 5**). The technical descriptions of earthquake ground motion, such as depicted on Plates 4 and 5 (Appendix E), can be challenging to interpret, so we developed damage potential maps using the Modified Mercalli Intensity (MMI) scale (Appendix E, Plates 6 and 7). The MMI scale is an empirical scale that describes the building damage and felt effects experienced from ground shaking in an earthquake. For the MMI categories, we used our site peak ground velocity ground motion data and the relationships used by USGS ShakeMap products (Wald and others, 2006, Figure 2.5).

What is not depicted in such maps is the duration of the earthquake. A local crustal fault will likely result in strong ground motion for up to 60 seconds, whereas a megathrust earthquake typically results in strong ground motion for 3 to 5 minutes. The Hazus building damage model uses the magnitude of the earthquake as a surrogate for duration, categorizing the earthquake as short, medium, or long duration (FEMA, 2011, Section 5.4), with a longer duration producing more building damage for a given ground motion. The Cascadia Subduction Zone magnitude 9.0 earthquake was modeled in Hazus as long duration, and the Portland Hills fault magnitude 6.8 earthquake was modeled in Hazus as medium duration.

3.3 Liquefaction and Landslide Susceptibility



For our Hazus building damage model, we provided a liquefaction and landslide susceptibility value for each building record, thereby allowing the Hazus model to calculate the amount of ground deformation and probability of ground deformation. The Hazus building loss model incorporates that calculated information into its overall building damage estimate.

A Hazus-based liquefaction susceptibility rating for each building record was obtained by using a simple overlay of the liquefaction susceptibility polygons developed for this project (Appleby and others, in preparation). Because the liquefaction susceptibility polygons are at a coarser scale relative to the building footprints, we determined that assigning the liquefaction susceptibility value at the building centroid was sufficient.

We developed a high-resolution, 10-foot Hazus-based landslide susceptibility grid for this project (Appleby and others, in preparation), following the methods specified in the Hazus®-MH 2.1 Technical manual, Earthquake model (FEMA, 2011, Chapter 4), for both a wet (saturated) and a dry scenario. We calculated landslide susceptibility zonal statistics for each building footprint by using the Esri® Spatial Analyst Zonal Statistics as Table tool. The arithmetic mean of the landslide susceptibility, rounded to the nearest integer, was then assigned to the building record. Such an assignment more accurately captures the earthquake-induced landslide hazard across the entire building footprint area, compared to a simple building centroid sampling approach (**Figure 3-1**).

LUBA No. 2020-009
Page 4977

Figure 3-1. Example: Capturing the variability of landslide susceptibility within building footprints (magenta polygons). Landslide susceptibility values use the Hazus landslide susceptibility 0 through 10 scale. Areas of no shading: minimal to no landslide susceptibility. Earthquake-induced landslide susceptibility data from Appleby and others (in preparation).

Liquefaction requires saturated soil conditions. Hazus permits a user to specify, on a per-building basis, the depth of the water table, and adjusts the ground failure estimates accordingly. However, there currently exists no region-wide groundwater mapping information. Water tables vary significantly throughout the year, and even if such information were available, the use of an average water table level could significantly underestimate liquefaction occurrence during peak moisture conditions. We were aware of a regional groundwater study (Snyder, 2008) but noted that it covered only a portion of the study area. We chose to mimic the "wet" (saturated soil) and "dry" landslide scenarios by setting water depth to two distinct values: 0 feet and 1,000 feet, respectively. Thus, each of the two synthetic earthquakes was run with "wet" and "dry" soil moisture conditions, for a total of four unique scenarios.

3.4 Permanent Ground Deformation

Permanent ground deformation (PGD) data include an estimate of the amount of lateral spreading due to liquefaction and ground failure due to earthquake-induced landslide, along with a probability of their occurrences. We provided the liquefaction and landslide susceptibility data from Appleby and others (in preparation) and the site ground motion data for both earthquakes developed in Section **3.2** as input to the tool developed by Sharifi-Mood and others (M. Sharifi-Mood, M. J. Olsen, D. T. Gillens, and I. P. Madin, Complementary ground motion, ground deformation, and damage potential maps for deterministic scenarios of Cascadia Subduction Zone earthquake events, manuscript in preparation). The tool implements the methods for ground deformation estimation described by Madin and Burns (2013, Section 4), and provides raster grids describing the PGD amount and probability of occurrence, using the Hazus ground deformation models described in the Hazus-MH 2.1 Technical manual (FEMA, 2011).

Because the tool is currently constrained to calculating liquefaction lateral spreading at a fixed water depth, we generated liquefaction ground deformation (lateral spreading) data for only the "wet" (saturated soil) scenario. We calculated earthquake-induced landslide ground failure data for both wet and dry soil condition. The PGD and probability of occurrence data are in the accompanying geodatabase. Further details on the dataset development are documented in Appendix B, Section **11.2**.

To quantify impacts to infrastructure, we combined the grids from the two ground failure mechanisms, obtaining the maximum PGD and maximum probability of occurrence across the area for a given earthquake and soil moisture scenario. Although liquefaction and landslide are two distinct physical mechanisms, the specific cause of the ground failure is not important for our key infrastructure sector analysis purposes.

Page 4979

4.0 LOSS ESTIMATION METHODS

4.1 Impacts to Buildings and People

4.1.1 Building Repair Cost and Casualties

We used the Hazus Advanced Engineering Building Module (AEBM) (FEMA, 2010) included in Hazus-MH v4.0 to calculate individual building repair costs and casualties and to obtain parameters needed to calculate debris and displaced population. Although the AEBM permits a user to specify unique building profiles, including adjusted individual capacity curve or fragility curve parameters, we instead used the generic building profiles provided in the Hazus SQL database table [dbo].[eqAebmProfile]. The particular AEBM profile for an individual building in the building database is constructed from its occupancy class, building type, and seismic design level. The building's square footage, replacement cost, daytime occupants, and nighttime occupants were also supplied to the Hazus AEBM model.

The Hazus AEBM model was run for a given user-supplied seismic scenario, with site ground motions supplied in polygon form. The model returns a building repair cost and casualty estimate for each building, along with five probability of damage state (PDS) values, each, for the structural, nonstructural drift, and nonstructural acceleration components. We used the PDS values to calculate debris and displaced population and to estimate the total number of red-tagged and yellow-tagged buildings.

The Hazus AEBM model first calculates a building's structural and nonstructural probability of damage state values from the ground motion and liquefaction/landslide data provided to the model. It then uses the PDS values to calculate casualties, based on the number of user-specified people occupying the building and the building type. The methodology is based on the assumption of a strong correlation between building damage and number and severity of casualties (FEMA, 2011). Casualties are classified into four levels (**Table 4-1**). Levels 2 and 3 are generally interpreted as "injuries requiring hospitalization."

Table 4-1. Hazus casualty level descriptions (taken from FEMA, 2011). The broad description of each category is shown in boldface.

Injury Severity Level	Injury Level Description
Level 1: **Minor Injuries**	Injuries requiring basic medical aid that could be administered by paraprofessionals. These types of injuries would require bandages or observation. Some examples are: a sprain, a severe cut requiring stitches, a minor burn (first degree or second degree on a small part of the body), or a bump on the head without loss of consciousness. Injuries of lesser severity that could be self-treated are not estimated by Hazus.
Level 2: **Injuries Requiring Hospitalization**	Injuries requiring a greater degree of medical care and use of medical technology such as x-rays or surgery, but not expected to progress to a life threatening status. Some examples are third degree burns or second degree burns over large parts of the body, a bump on the head that causes loss of consciousness, fractured bone, dehydration, or exposure.
Level 3: **Life-Threatening Injuries**	Injuries that pose an immediate life-threatening condition if not treated adequately and expeditiously. Some examples are: uncontrolled bleeding, punctured organ, other internal injuries, spinal column injuries, or crush syndrome.
Level 4: **Deaths**	Instantaneously killed or mortally injured.

LUBA No. 2020-009
Page 4980

4.1.2 Building Debris Estimation

The Hazus AEBM does not provide a debris estimate for a damaged building. We manually calculated debris by first calculating the total weight of each building, in tons, using the total square footage of the building, the type of building (e.g., steel frame or wood frame), and the per-square-footage weight estimates listed in the Hazus SQL database table [dbo].[eqDebrisAnalParms]. Debris was then calculated based on the methods outlined in the Hazus Earthquake Technical Manual (FEMA, 2011, Equation 12-3), by using the structural and nonstructural drift probability of damage states obtained for the individual building from the Hazus AEBM.

The debris estimate is limited to buildings. We did not estimate debris tonnage from landslides, damaged bridges, buckled roads, sand and silt ejecta caused by liquefaction (Villemure and others, 2012), or damaged nonbuilding structures.

4.1.3 Displaced Population and Shelter Needs

Unlike the Hazus General Building Stock tool, Hazus AEBM does not calculate displaced households or displaced population. We adapted the methods outlined in the Hazus Earthquake Technical Manual (FEMA, 2011, Chapter 14), but instead of calculating displaced households we calculated displaced population. Displaced population is more direct to calculate given the methods discussed previously for assigning people, and not households, to distinct multi-family and single-family residential buildings (Section **2.1.7**). We followed the guidance provided by FEMA (2011, Table 14.1) that was based on the work of Perkins and Chuaqui (1998), but we altered the weight factor for multi-family residential building type, W_{MFE}, by setting it to zero. The displaced population then becomes a simple computation: the number of permanent residents in the building times the building's probability of *complete* structural damage state, with the latter factor directly obtained from the Hazus AEBM output.

We equated the red tag term used in a post-earthquake building safety evaluation context (ATC, 1989) with the Hazus "complete" structural damage state, following the guidance of FEMA (2010, Table 6.1). Similarly, yellow tag was associated with "extensive" damage state, and green tag with buildings in a none, slight, or moderate damage state. We recognize that alternate mappings of Hazus damage states or repair costs to ATC-20 tag levels exist (e.g., MMI Engineering [2012] presents two such definitions).

The Hazus displaced population computation assumes the building has been categorized into one of the three ATC-20 tags. In practice, the post-earthquake building inspection process is estimated to take weeks, if not months (EERI, 2015; p. 25). Thus, what is being computed is an estimation of *post*-inspection, longer-term displaced population. Our summary tables use the term *Long-term Displaced Population* to emphasize the point.

The topic of displaced population and shelter needs is involved, and estimates can vary throughout the response and recovery phases based on numerous factors, including psychological, sociological, and economic considerations. For example, some portion of the population may occupy a damaged building until it is officially inspected and red tagged, at which point they must vacate. An owner of a moderately damaged (green-tagged) apartment building may decide to replace the structure rather than repair it. For this project, we provide detailed information on permanent residents per building damage state, thereby allowing a basis from which to estimate Day 1, Day 7, and Day 30 displaced population and shelter needs (Appendix C, **Table 12-4** through **Table 12-7**). A portion of the displaced population may need long-term publicly provided shelter while residences are repaired or replaced (FEMA, 2011, Section 14.3). We determined that the ethnic, racial, and income level factors listed in Hazus Earthquake Technical Manual (FEMA, 2011, Equation 14.2) were too assumption-laden, and thus we did not calculate shelter requirements with such factors. For reference purposes, past Hazus runs for a Cascadia

LUBA No. 2020-009
Page 4981

Subduction Zone earthquake that used these assumptions calculated the portion of displaced population needing temporary shelter/housing solutions between 20% and 30% (Wang, 1998; Hofmeister and others, 2003; EERI, 2015, p. 34).

4.1.4 Aggregation Unit

Although the inputs into the Hazus model are individual buildings with occupants, loss estimates from the model are statistically meaningful only at an aggregated level. As Pinter and others (2016) emphasized, Hazus-calculated damages are estimates appropriate for comparison and planning purposes, particularly when pooled among a group of structures. Hazus-calculated damages are not appropriate for individual building analysis. We considered various aggregation units, including city neighborhoods and fire districts. Several jurisdictions in the study area have well-defined neighborhoods, but most do not. Further, unincorporated areas have no formal or usable neighborhood definitions. For example, we considered fire districts in unincorporated areas, but we determined they were too coarse to be useful for community level planning.

We chose the census block group (CBG), a U.S. Census Bureau-designated geographical unit that is between the census tract and the census block, as the basic mapping aggregation unit for damage estimates. Census block groups typically have between 600 and 3,000 people, but the number of buildings can vary widely, depending on the type of buildings and the number of multi-family residential structures within a CBG. Where warranted, we combined contiguous CBGs to create a larger unit encompassing at least 300 buildings. The process resulted in reducing the study area's 1,041 CBGs into 876 *neighborhood units.*

To provide a larger-scale perspective across the study area, we also aggregated loss at the jurisdictional level, with all buildings associated with a particular city, designated community, or unincorporated county. The jurisdiction layer combined city jurisdictional boundaries published by Metro RLIS (Metro, 2016), along with hamlet and village designations by Clackamas County (2017). Given the City of Portland's size relative to surrounding cities, we used the Portland Bureau of Emergency Management's (PBEM) Risk Reporting Areas (Tetra Tech, 2016a, Section 4.4, Table 4.4) as subdivisions for aggregation. All buildings not associated with a jurisdiction were designated as unincorporated.

4.1.5 Seismic Design Level Improvement Modeling Exercise

Most of the buildings in the study area were constructed with minimal consideration given to seismic resilience (**Table 10-3**). Seismic retrofits to more vulnerable buildings can reduce damage to the building and casualties to the building occupants when an earthquake occurs. Our Hazus model can be used to generate an overall benefit estimate for seismic retrofitting. Levi and others (2015) performed such an analysis for Israeli building inventory, where at least 25% of the building inventory was designed with minimal resistance to earthquakes.

We ran two alternative loss scenarios, wherein we upwardly adjusted seismic design levels within our building database. For the moderate scenario, all buildings with a seismic design level of pre code or low code were updated to moderate code, and all unreinforced masonry buildings were altered to RM1 (reinforced masonry) building type. Buildings with high code were left unchanged. For the high scenario, the seismic design level was set to high code for all buildings, with all unreinforced masonry buildings altered to RM1 (reinforced masonry) building type. We then ran Hazus AEBM, using the same ground motion, liquefaction/landslide susceptibility, and building population occupancy, and tabulated loss estimates (see Section 5.3.1). Our analysis was limited to the Cascadia Subduction Zone earthquake scenario, and run for both wet (saturated) and dry soil conditions.

4.2 Electric Power Transmission

Using the ground deformation estimates, we calculated the mean lateral spread within a 10-meter buffer of each transmission structure for the Cascadia Subduction Zone earthquake and Portland Hills fault earthquake, for wet (saturated) and dry soil moisture conditions. The mean permanent ground deformation at each point was then classified into three categories: less than 1 meter, 1 to 2 meters, and greater than 2 meters. For all points with greater than 1-meter permanent ground deformation, the probability of occurrence is between 20% and 30% (Appendix E, **Plate 13**).

4.3 Emergency Transportation Routes

The Hazus tool provides an analysis of linear features such as roads, but we determined it inadequately captures the range of variability of permanent ground deformation throughout the length of the segment. Currently, the tool samples only at the linear feature segment's endpoints and at its midpoint. We take a conservative approach in our evaluation of earthquake impact on surface transportation by considering the possibility of permanent ground deformation across the entire length of the road segment. A road segment is considered failed if any portion of that road segment exceeds an amount of ground deformation and a probability of occurrence.

Ground deformation and probability estimates were available in a 10-foot raster grid format (Section **3.4**). We combined the landslide and liquefaction PGD grids using Esri Spatial Analyst Cell Statistics function to obtain the maximum value per pixel. For our analysis purposes, the mechanism of the ground failure is not relevant; the amount and probability of lateral spread is of primary concern. Following the methods outlined by Mahalingam and others (2015), we then generated a new grid based on focal statistics of the ground deformation within a 100-foot window (10 pixel × 10 pixel; a pixel is 10 ft). Inclusion of surrounding areas adjacent to the road segment is a more conservative approach, because we wanted to include potential landslides slightly distant from the road. We then classified the maximum value of the ground deformation within each road segment into four bins, using Esri Spatial Analyst Zonal Statistics as Table tool: less than 0.5 meters, 0.5 to 1.0 meters, 1.0 to 2.0 meters, and greater than 2.0 meters. The process was repeated for the CSZ dry soil conditions scenario and the PHF wet (saturated) and dry soil conditions scenarios, with the results stored in the accompanying geodatabase. Appendix E, Plates 10 and 11 represent the impacts of ground failure per segment under a Cascadia Subduction Zone earthquake, given the two soil moisture scenarios. For another perspective, Appendix E, **Plate 12** highlights the maximum potential permanent ground deformation at specific locations throughout the segment.

4.4 Model Limitations

Our damage estimates were primarily derived from the Hazus AEBM. Limitations and uncertainties are inherent in any loss estimation methodology. They arise in part from incomplete scientific knowledge concerning earthquakes and their effects on buildings and facilities.

4.4.1 Geological Models

An actual earthquake may vary significantly in ground motion and site amplification compared to the synthetic data we provided the model in this study. Our analysis used the best available information for a subduction zone fault and a local crustal fault. We used the upper bound for the earthquake magnitude, recognizing that an actual earthquake may rupture on only a portion of its fault. Further, the

LUBA No. 2020-009
Page 4983

NEHRP site classification is a simplification of complex surficial geology, and local site amplification effects within a given NEHRP site class may be at significant variance with the standard ground motion amplification model.

We did not model damage from aftershocks. Wein and others (2017) presented scenario examples and the consequences of such earthquakes. The impact of aftershocks on slightly damaged buildings has be modeled in a Hazus context (Seligson and others, 2015), but we did not have aftershock scenarios available, nor was such modeling within the scope of our project.

Although our loss model includes the impact of earthquake-induced landslides on buildings, we do not model the impact of large landslide flows on structures downhill from the source. Such flow can wreak significant damage to buildings and people (Daniell and others, 2017), but such modeling capability is not available with existing tools.

4.4.2 Building Damage Models

Limitations and uncertainties also result from the approximations and simplifications that are necessary for comprehensive analyses. Although we gave extensive effort to correctly attributing each of the 615,852 individual buildings in this study, we recognize that misclassifications are present, and we made statistical distribution assumptions on building type when attribution information was not otherwise available.

We used the generic building damage models provided by the Hazus tool. These models simplify the vast variability present in existing building construction, such as vertical irregularities, plan irregularities, usage of cripple walls, hybrid construction techniques, and pounding from adjacent buildings (FEMA, 2015b). The Hazus AEBM allows a user to specify individual building-specific parameters, but it is not possible to conduct a study at this regional scale that incorporates such detail. The Hazus generic building damage model captures the *average* building response to an earthquake—the primary reason we present loss estimates not at the individual building level but at a minimum aggregation unit (Section **4.1.4**).

The duration of a subduction zone earthquake is significantly longer than for other types of earthquakes, including those generated from local crustal faults. Although the Hazus tool provides a method to distinguish short, medium, and long shaking duration (FEMA, 2011, Equation 5-10), the damage functions are expert- and model-driven. The most recent long-duration earthquake to impact the United States was Alaska's Good Friday earthquake in 1964, which was approximately 4.5 minutes long. Post-earthquake damage assessment protocols were not in place at the time. Hazus modelers do not have USA-construction-based empirical data for long-duration earthquakes from which to calibrate the model. The current Hazus model may be underestimating the damage to tall buildings and other large structures in response to great subduction zone earthquakes. Gomberg and others (2017) have identified this as an important research need.

In **Tables 12.8** through **Table 12.11**, we present Hazus damages and casualty estimates as single value. Such representations can be misleading, as they suggest a high level of precision that is not warranted, in part by the uncertainties of the data that were provided to the Hazus model (Remo and Pinter, 2012). One reason we chose to model both wet (saturated) and dry soil condition scenarios for a given earthquake is to better communicate our damage estimates as a range of values (**Table ES-1**).

4.4.3 Casualty Estimates

Casualty estimates are dependent on several assumptions and may underestimate the true impact from an earthquake. Daytime occupancy values use people-per-square-footage assumptions, which may be reasonable in the aggregate, but building occupancy density can vary significantly across businesses that

LUBA No. 2020-009
Page 4984

are grouped for our modeling purposes into a fixed classification, such as "Commercial-Retail." Running Hazus with a large number of alternate point-in-time population models may assist in better understanding the uncertainty in daytime casualties (FEMA, 2012a, Section 3.4).

In the Hazus AEBM, the casualty calculations do not include injuries to people outside of and proximal to a building. During strong ground motion, fascias can fall off buildings, masonry walls can collapse, and windows can shatter, sending shards of glass down to the pavement. Other casualties, such as from heart attacks, loss of power to medical devices such as respirators, electrocutions, collapsing bridges, exposure to released hazardous materials, and car accidents are not quantified in the Hazus model. Further, we did not model fire following earthquake, which can result in additional casualties.

4.4.4 Other Model Limitations

Fires typically follow a major earthquake and are exacerbated by compromised transportation networks and broken buried utilities. Fire following earthquake can be a major contributor to building loss and displaced population (Scawthorn and others, 2005). Early versions of the Hazus tool modeled "fire following earthquake" as an induced damage; however, due to significant bugs producing erroneous damage estimates, the option had been disabled in recent versions of the tool. The Hazus v4.2 release (FEMA, 2018) restored the Fire Following functionality, but the tool release was not available in time for this project, which used Hazus v4.0.

Several other sources may contribute to road damage, none of which we modeled in this project, and thus may lead to an underestimate of road damage. Our road damage model does not include debris generated by taller buildings that may block road access, or a road cordoned off due to a proximal building that is in danger of collapse (City Club of Portland, 2017). Our Hazus-based landslide ground deformation model does not incorporate deposits from distant earthquake-induced landslides that may block road access.

Past Hazus-based studies typically attached standardized reports generated by the Hazus tool that summarize casualties and losses in a convenient format. Such reports are currently available only with Hazus analyses using General Building Stock data, which are modeled at the census tract level. Users analyzing loss on a per-building basis, such as what we have done in this study, cannot obtain such summary reports from Hazus; thus, none are attached to this report. Instead, we present such information as tables in Appendices A and C, in graphical form in Appendix E, and in electronic form in the accompanying GIS database (Appendix D).

LUBA No. 2020-009
Page 4985

5.0 RESULTS

5.1 Population and Building Density

We developed a 20-acre hexagonal grid, then overlaid the grid on our building database, totaling the number of individual buildings, the number of residential buildings, and the number of permanent residents associated with the buildings within each hexagonal cell. Cells with no buildings were removed from the dataset. Cells with at least one building yet no permanent residents frequently occur in commercial/industrial corridors or predominantly agricultural areas (Appendix E, Plates 1–3). The hexagon layer provides a convenient overlay to explore population and building exposure relative to a particular natural hazard. The layer can also be useful in focusing the areas of building loss or casualties in neighborhood units with large tracts of undeveloped areas.

5.2 Building Statistics

Single-family residential buildings dominate the building inventory in all three counties (**Figure 5-1**). Wood frame construction dominates the residential buildings (**Table 5-1**). The number of masonry buildings in **Table 5-1** is due primarily to the Hazus building type statistical distribution described in Section **2.1.4**. **Table 10-8** in Appendix A contains a complete breakdown of building type for all generalized building use categories.

Figure 5-1. Building primary usage statistics by county. Tabular summary is in Table 10-7. Single-family residential combines Hazus occupancy classes RES1 and RES2 (manufactured housing). Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines Hazus occupancy classes RES3, RES5, and RES6.

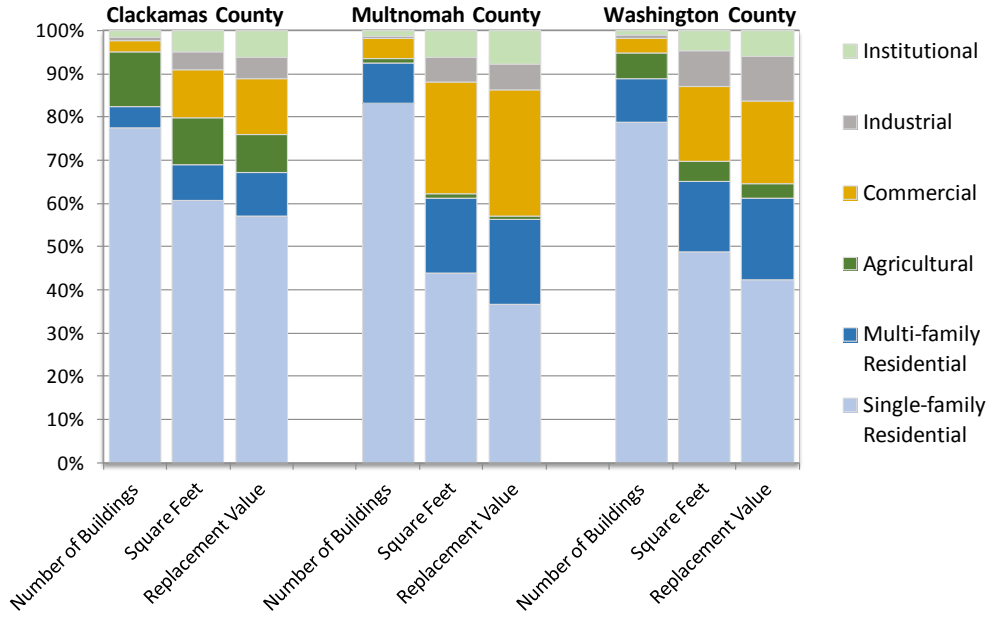

Table 5-1. Residential buildings by building type.

Occupancy Type	Building Type	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Permanent Residents	Permanent Residents Percent
Single-Family Residential	Wood	471,926	95.5%	914,096	96.7%	1,182,770	96.3%
	Manufactured Housing	16,852	3.4%	20,966	2.2%	32,969	2.7%
	Reinforced Masonry	3,549	0.7%	7,349	0.8%	9,321	0.8%
	Unreinforced Masonry	1,455	0.3%	2,298	0.2%	3,277	0.3%
	Other	138	0.0%	377	0.0%	581	0.0%
Multi-Family Residential	Wood	47,055	91.1%	204,253	73.0%	316,575	76.8%
	Reinforced Masonry	1,331	2.6%	16,026	5.7%	24,203	5.9%
	Unreinforced Masonry	403	0.8%	5,380	1.9%	8,139	2.0%
	Steel	1,636	3.2%	22,913	8.2%	24,051	5.8%
	Concrete*	1,206	2.3%	31,277	11.2%	39,150	9.5%

*Concrete includes the precast concrete building type.

Building occupancy within the different building types varies significantly between the daytime and nighttime scenario (**Table 5-2**). In the 2 AM scenario, most (87%) of the population is within wood frame construction. The daytime and nighttime occupancy models assume people from outlying counties commute into the study area; thus, daytime occupancy totals are generally higher than permanent resident population totals.

Table 5-2. Occupancy by building type.

Building Type	Number of Buildings	"2 PM" Daytime Occupancy	Daytime Percent	"2 AM" Nighttime Occupancy	Night Time Percent	Permanent Residents	Percent
Concrete	8,599	314,378	19%	60,383	4%	35,679	2%
Manufactured Housing	17,295	11,221	1%	31,387	2%	32,969	2%
Precast Concrete	6,603	195,438	12%	12,539	1%	3,811	0%
Reinforced Masonry	16,125	205,964	12%	43,218	3%	33,525	2%
Steel	16,487	213,478	13%	49,246	3%	24,291	1%
Unreinforced Masonry	5,092	52,271	3%	13,766	1%	11,416	1%
Wood	545,651	697,336	41%	1,442,287	87%	1,499,345	91%
All building types	615,852	1,690,086		1,652,825		1,641,036	

5.3 Building Damage, Casualties, and Displaced Population

We tabulated the impacts to buildings and people at the county and jurisdictional level (Appendix C, **Table 12-8** through **Table 12-11**) and at the neighborhood unit level for all earthquake scenarios. Jurisdictional and neighborhood unit level summaries are available in tabular form in the accompanying GIS database. Building damage results were also expressed as a *loss ratio*—the total repair cost estimate for all buildings in a given spatial unit divided by the total replacement cost for all buildings. Building debris tonnage was summarized at the given spatial unit. Casualties were summarized for the given spatial unit at the individual casualty level, and a total casualty level for daytime and nighttime was calculated. The tables in the GIS database enable one to express graphically the damage estimates in any

LUBA No. 2020-009
Page 4987

number of ways, such as displaying Level 2 casualties per 10,000 people. For demonstration purposes, we present the total injuries requiring hospitalization per neighborhood unit, daytime scenario, CSZ earthquake with saturated soil conditions, in Appendix E, Plates 14–16.

Damage estimates vary widely across the study area, depending on local geology, soil moisture conditions, type of building stock, and distance from the fault. In the Cascadia Subduction Zone scenario, damage is generally greater in the western portion of the study area than in the eastern portion. Yet local geology variations can result in significant damage even well east of the Willamette River, such as the neighborhood of North Troutdale (Appendix E, **Plate 15**).

The 9% ("dry" soil conditions) to 14% ("wet") overall estimated loss from a CSZ magnitude 9.0 earthquake includes all buildings in the study area (**Table 12-8** and **Table 12-9**). The damage is not equally distributed across all building uses or building types, as seen in the referenced tables. Many high-value commercial and industrial buildings exist on areas of high to very high liquefaction hazard. The average loss ratio for wood-framed single-family residential buildings ranges from 2% to 7% (for "dry" and "wet" soil conditions, respectively; **Table 5-3**).

Although the timing of an earthquake has no impact on building damage or displaced population, more people will experience casualties during a workday earthquake scenario than if the earthquake occurred at night (Appendix C, **Table 12-8** through **Table 12-11**). During the daytime scenario, most people are occupying non-wood structures (**Table 5-2**), which typically fare worse in an earthquake than wood-frame construction.

Even though a Portland Hills fault earthquake is of shorter duration than a CSZ earthquake, its placement relative to significant assets in the region would result in much higher damage overall (Appendix C, **Table 12-10** and **Table 12-11**). At distances beyond 15 miles from the Portland Hills fault zone, damages from a Cascadia Subduction Zone scenario generally exceed a Portland Hills fault scenario, which can be visualized by comparing the ground motion data in Appendix E, Plates 4 and 5.

Soil moisture conditions significantly influence loss estimates, with overall building loss ratios of 9% versus 14% for the Cascadia earthquake between the "dry" soil conditions and "wet" (saturated) soil conditions (Appendix C, **Table 12-8** and **Table 12-9**). The large percentage of buildings in moderately liquefiable zones, such as the Tualatin Basin in Washington County, combined with the high-value buildings in very high liquefiable zones in the Columbia Slough, downtown Portland near the Willamette River, and the northwest industrial area of Portland account for much of the increase in the wet scenario loss.

Several smaller jurisdictions exhibit higher or lower loss ratios compared to other jurisdictions, due to unique situations. Johnson City in Clackamas County is almost exclusively composed of manufactured housing—a building type that experiences significantly more damage for a given ground motion than does a wood frame house (Kircher and others, 1997). The city of Barlow in Clackamas County is situated entirely on soft soils (Section **3.2**) that amplify the ground motion, on potentially liquefiable soils, and much of its building value is contained in four storage facilities constructed of a more fragile building type compared to wood-frame construction. Although the City of Sandy's boundaries span multiple soil types and liquefaction susceptibility categories, nearly all of its assets are on firm, non-liquefiable soils, and thus its loss ratio is comparatively low (1%, **Table 12-8**).

Building damage is higher in non–single-family residential structures (**Table 5-3**). Single-family residential is dominated by light-frame wood construction (**Table 5-1**), the most resilient of the 36 generic building types available in the Hazus AEBM. Multi-family residential is a mixture of wood frame construction and less resilient building types. "Single-family residential: manufactured housing" was broken out to highlight its relative seismic vulnerability.

Table 5-3. Damage to buildings by building category and by earthquake scenario.

		Cascadia Subduction Zone Magnitude 9.0 Earthquake				Portland Hills Fault Magnitude 6.8 Earthquake			
		"Dry" Conditions		"Wet" (Saturated) Conditions		"Dry" Conditions		"Wet" (Saturated) Conditions	
Building Category	Building Value ($ Million)	Building Repair Cost ($ Million)	Loss Ratio	Building Repair Cost ($ Million)	Loss Ratio	Building Repair Cost ($ Million)	Loss Ratio	Building Repair Cost ($ Million)	Loss Ratio
Agricultural	9,263	947	10%	1,347	15%	1,271	14%	1,796	19%
Commercial	57,134	10,381	18%	14,133	25%	22,240	39%	27,326	48%
Industrial	18,485	3,651	20%	4,888	26%	6,578	36%	8,216	44%
Institutional	17,609	2,438	14%	3,114	18%	5,871	33%	7,089	40%
Multi-family residential	44,391	3,288	7%	5,621	13%	10,118	23%	14,423	32%
Single-family residential	111,408	2,695	2%	7,421	7%	14,234	13%	24,254	22%
Single-family residential: manufactured housing	879	158	18%	186	21%	257	29%	307	35%
Total	259,169	23,558	9%	36,710	14%	60,569	23%	83,411	32%

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines Hazus occupancy classes RES3, RES5, and RES6.

The Hazus AEBM model estimates each building's probability of being in one of five damage states: *None*, *Slight*, *Moderate*, *Extensive*, and *Complete*. The five individual probabilities sum to 1.0. General descriptions for the structural damage states of 16 common building types are provided by FEMA (2011, Section 5.3); **Figure 5-2** shows an example. We obtained the total number of buildings in a particular spatial unit by summarizing all buildings' individual structural probability of damage state values, per the guidance provided by FEMA (2017a). The data in Appendix C, **Table 12-3** can be used to estimate the number of red-tagged and yellow-tagged buildings, and the number of buildings needing structural inspection after an earthquake. In addition, we summarized all permanent residents per building damage state, by generalized building types: single family residential (excluding manufactured housing); single family residential in manufactured housing, and multi-family residential.

LUBA No. 2020-009
Page 4989

Figure 5-2. Example damage state descriptions for a light-frame wood building (FEMA, 2010). The "None" damage state is not provided.

Damage State		Description
	**Slight**	Small plaster cracks at corners of door and window openings and wall-ceiling intersections; small cracks in masonry chimneys and masonry veneers. Small cracks are assumed to be visible with a maximum width of less than 1/8 inch (cracks wider than 1/8 inch are referred to as "large" cracks).
	**Moderate**	Large plaster or gypsum-board cracks at corners of door and window openings; small diagonal cracks across shear wall panels exhibited by small cracks in stucco and gypsum wall panels; large cracks in brick chimneys; toppling of tall masonry chimneys.
	**Extensive**	Large diagonal cracks across shear wall panels or large cracks at plywood joints; permanent lateral movement of floors and roof; toppling of most brick chimneys; cracks in foundations; splitting of wood sill plates and/or slippage of structure over foundations.
	**Complete**	Structure may have large permanent lateral displacement or be in imminent danger of collapse due to cripple wall failure or failure of the lateral load resisting system; some structures may slip and fall off the foundation; large foundation cracks. Three percent of the total area of buildings with Complete damage is expected to be collapsed, on average.

5.3.1 Seismic Design Level Improvement Exercise

Modeling adjustments to the building inventory seismic design level results in much lower amounts across all categories of loss (**Table 5-4**), although the effect is muted in the "wet" (saturated) soil condition scenario. The Hazus building damage model assumes damage due to ground shaking is independent of damage due to ground failure (FEMA, 2011, Section 5.6.3). In the Hazus model, improved seismic design levels will reduce damage estimates from ground shaking but not from ground failure. In our study area, more than half of the building inventory is situated on sites with a moderate or higher liquefaction susceptibility rating (**Table 10-5**). Thus, the reduction in loss in the "wet" (saturated) soil conditions is muted, due primarily to liquefaction probability being incorporated into the damage estimate. The reduction in loss estimates is more dramatic in the "dry" soil conditions scenario, where liquefaction and earthquake-induced landslide impacts are minimal.

Table 5-4. Seismic design level improvement exercise, Cascadia Subduction Zone magnitude 9.0 earthquake. See Section 4.1.5 for scenario definitions.

	"Dry" Soil Conditions			"Wet" (Saturated) Soil Conditions		
Seismic Design Level Scenario	**Unchanged**	**Moderate**	**High**	**Unchanged**	**Moderate**	**High**
Building Repair Cost ($ million)	23,558	6,466	4,230	36,710	20,988	18,979
Building Loss Ratio	9%	2%	2%	14%	8%	7%
Debris (thousands of tons)	12,794	2,512	1,304	17,292	8,148	7,121
Long-term Displaced Population	16,852	2,438	1,664	85,211	72,329	71,617
Casualties — Daytime Scenario						
Total Casualties	18,286	2,032	987	27,175	12,606	11,711
Level 1 Casualties	13,342	1,681	839	19,489	9,005	8,281
Level 2 Casualties	3,518	278	118	5,454	2,567	2,431
Level 3 Casualties	484	25	10	758	352	340
Level 4 Casualties	942	48	20	1,473	682	659
Casualties — Nighttime Scenario						
Total Casualties	4,334	902	596	10,400	7,259	6,989
Level 1 Casualties	3,338	775	525	7,838	5,484	5,262
Level 2 Casualties	739	106	60	1,979	1,404	1,364
Level 3 Casualties	87	7	4	203	131	129
Level 4 Casualties	169	14	7	380	240	235

Loss estimates for unchanged scenario are taken from **Table 12-8** and **Table 12-9**, and provided for reference. Casualty Level definitions are provided in **Table 4-1**. Total building replacement costs used for building loss ratio taken from **Table 5-3**.

5.4 Electric Power Transmission

Of the 18,098 poles and towers in our database, 921 (5%) have a 20% to 30% chance of experiencing between 1 and 2 meters of ground deformation, and 2,203 (12%) have a 20% to 30% chance of experiencing more than 1 meter during a Cascadia magnitude 9.0 earthquake with "wet" (saturated) soil conditions (Appendix E, **Plate 13**). In the "dry" soil conditions, only 6 poles and towers have a 20% to 30% chance of experiencing between 1 and 2 meters of ground deformation, with none experiencing more than 2 meters of deformation. In the "dry" soil conditions scenario, permanent ground deformation is due exclusively to earthquake-induced landslides. In the "wet" (saturated) soil conditions scenario, liquefaction is a significant contributor to permanent ground deformation proximal to the power pole or tower.

Similar potential impact is observed for the Portland Hills fault magnitude 6.8 earthquake scenario. Of the 18,098 poles and towers in our database, 2,367 (13%) have a 20% to 30% chance of experiencing between 1 and 2 meters of ground deformation, and 3,687 (20%) have a 20% to 30% chance of experiencing more than 1 meter during "wet" (saturated) soil conditions. In the "dry" soil conditions scenario, 100 (0.5%) poles and towers have a 20% to 30% chance of experiencing between 1 and 2 meters of ground deformation, and 8 poles and towers have a 20% to 30% chance of experiencing more than 2 meters.

5.5 Emergency Transportation Routes

In the Cascadia magnitude 9.0 earthquake, "wet" (saturated) scenario, most (177 out of 238, or 74%) route segments will have a 20% to 30% chance of experiencing significant ground deformation along some portion of the segment (Appendix E, **Plate 10**). Although the regional post-earthquake road conditions significantly improve under the "dry" soil conditions scenario, (Appendix E, **Plate 11**), several road segments (6 out of 238, or 3%) may still be impacted. In the "dry" soil conditions scenario, the road segments that have a chance of failure are due to their placement on 1) existing landslides, 2) areas of elevated landslide susceptibility based on slope and geology, or 3) fill material that includes a significant slope proximal to the road segment. The 20% to 30% probability of failure on a per segment basis may sound modest when taken in isolation, but when individual location probabilities of failure are combined in a binomial distribution statistical method (probability of failure = $(1 - p)^n$), the overall failure estimate for the segment can increase significantly.

For mapping and planning purposes, we categorized road segments into distinct bins, even though only a fraction of a given road segment may experience significant ground deformation. An example of this effect can be observed in Washington County, where emergency transportation routes commonly cross alluvial deposits that may fail due to liquefaction (inset map in Appendix E, **Plate 12**). Although only a portion of the road may be impacted by ground failure, the road segment is considered impassable in its entirety until repairs are made. **Plate 12** (Appendix E) shows the portions of the segments that may experience significant ground failure in a Cascadia magnitude 9.0 earthquake.

For a Portland Hills fault magnitude 6.8 earthquake, 66 out of 238 (28%), and 205 of 238 (95%) of segments have a 20% to 30% chance of experiencing significant ground deformation along some portion of the segment, in the "dry" and "wet" soil condition scenarios, respectively. The increase in percentage compared to the CSZ can be explained by the significant difference in ground motion between the two earthquake scenarios (Plates 4 and 5).

LUBA No. 2020-009
Page 4992

6.0 DISCUSSION

This study is the first conducted in the three-county area that provides damage estimates at levels useful for both regional and local planning. It presents loss estimates as a range for two building occupancy scenarios and two soil moisture scenarios. By doing so, planners can get a better sense of the range of damages and casualties that may occur with a major earthquake: Which areas may have experienced more damage, given the potential for liquefaction and local site amplification? Where were people when the earthquake occurred? How many casualties might that produce?

A magnitude 9.0 Cascadia Subduction Zone earthquake will result in significant damage to buildings, with concomitant casualties, throughout the three-county area. Transportation networks may be severely impaired, compromising emergency response. Millions of tons of debris will need removal to staging areas for sorting and eventual permanent disposal. Hundreds of thousands of buildings will need timely safety inspections, and thousands to tens of thousands of people will need to find other permanent housing arrangements. In comparison, a magnitude 6.8 Portland Hills fault earthquake will be devastating, primarily due to its position relative to the study area's major assets and population centers, with losses more than double those from a magnitude 9.0 Cascadia Subduction Zone earthquake.

6.1 Earthquake Impacts

6.1.1 Geographic Variations

Damage and casualty estimates vary widely throughout the three-county area. Primary reasons for the variation include the seismology, local geology, and building development history. In a Cascadia Subduction Zone earthquake, ground motion will be less in eastern part of the study area compared to the western part. Local geological characteristics can produce significant variations in ground motion (Appendix E, Plates 4 and 5). Such variation should not be interpreted to suggest that some areas within the three counties are unaffected. The City of Sandy, for example, has a relatively low building loss ratio, at 1% (Appendix C, **Table 12-9**), yet the Cascadia earthquake is estimated to generate $12 million in damage within the city boundaries.

6.1.2 Casualties

For both the Cascadia Subduction Zone earthquake and the Portland Hills fault earthquake, and in both "dry" and "wet" (saturated) soil condition scenarios, casualty estimates for a daytime earthquake are at least double in quantity compared to a nighttime earthquake. During nighttime most, but not all, of the population are in more resilient wood-frame construction (**Table 5-1**, **Table 5-2**), while during the daytime, much of the population is dispersed among non-wood frame construction buildings, such as offices, schools, and factories. This temporal pattern has been observed in past earthquakes, most recently in Christchurch, New Zealand, where two earthquakes struck, one at 4:35 AM on September 4, 2010, and one at 12:51 PM on February 22, 2011 (EERI, 2011). No deaths occurred from the early morning earthquake, whereas the afternoon earthquake resulted in the deaths of 185 people.

We emphasize that our daytime building occupancy model used as a basis for generating daytime casualty numbers is a simplification of the dynamic and complex human environment, but it is still useful for planning purposes. Post-earthquake emergency operations can be enhanced by having an awareness of the types of population shifts between buildings throughout the day and week, and the seismic resiliency of those buildings.

LUBA No. 2020-009
Page 4993

6.1.3 Building Damage Inspection and Displaced Population

After a major earthquake, at least 200,000 buildings in the Portland Metropolitan Region will need timely ATC-20-based safety inspection by qualified personnel (ATC, 1989). Our estimate includes all buildings with slight to complete damage (Appendix C, **Table 12-3**), following the quantification method outlined by EERI (2015), which assumed a rate of four to five buildings per day per inspector. Assuming a goal of completing the task in 30 days, our results identify a need for 1,600 to 2,000 certified inspectors for a Cascadia Subduction Zone magnitude 9.0 earthquake. A Portland Hills fault earthquake would require twice the number of inspectors. Many out-of-area inspectors can be brought into an affected area after an earthquake, as discussed in the Oregon Resilience Plan (OSSPAC, 2013, Section 2). Inspection may displace some portion of building occupants who assumed buildings were structurally sound. In other cases, inspection may restore confidence in the building's structural integrity. We can only speculate on such dynamics, but we can provide permanent resident occupancy counts per building damage state (Appendix C, **Table 12-4** through **Table 12-7**).

6.1.4 Debris

Debris removal will require local staging areas for storing, sorting, and eventual transfer to a permanent disposal location. Assuming 25 tons per truckload, 400,000 to 680,000 truckloads of building debris would be generated by a Cascadia Subduction Zone earthquake ("wet" [saturated] soil scenario). We did not estimate other types of debris, such as buckled roads, collapsed overpasses, and landslide flows. Identifying staging areas is partly a GIS exercise that uses the debris-per-neighborhood estimates supplied with this report, along with information on potential long-term compromises to the local transportation network such as bridge collapse. In addition, debris staging site selection should be informed by other emergency or recovery planning efforts that may identify the same areas for other operational needs.

6.1.5 Infrastructure

Our emergency transportation route analysis graphically shows the likelihood of a fragmented emergency transportation route network, one where distribution of goods and services may be significantly affected. It is intended to inform the planning process, emphasizing the need for adaptability and consideration of alternative routes. Our analysis did not consider other potential route blockages, such as collapsed buildings and failed bridges and overpasses. Engineering judgment from transportation sectors can be applied to determine which segments may be quickly restored and which segments may be out for longer periods. Together, such information and perspectives can be used as a basis for establishing, prior to an earthquake, local points of distribution, including food, water, and fuel for emergency operations.

Portions of the electric distribution network may be significantly impacted due to ground failure compromising the integrity of transmission structures. As with the emergency transportation route analysis, our work is intended to inform the planning process. Engineering judgment from electrical utilities sectors can be applied to determine if some areas will be impacted for longer durations, and if additional capacity or redundancy is warranted. During the Christchurch, New Zealand, earthquake sequences of 2010-2011, electric poles and towers generally fared well in the presence of liquefaction (Kwasinksi and others, 2014).

6.1.6 Alternative Earthquake Scenarios

For planning purposes, we chose to model an earthquake at the upper end of its estimated potential energy release. The Cascadia Subduction Zone magnitude 9.0 earthquake scenario assumes a full margin rupture. Partial ruptures along the CSZ have been inferred from the geologic record, with the most frequent occurrences along the southern portion of the CSZ (summarized by Priest and others, 2014). The Oregon State University Hazard Explorer for Lifelines Program maintains a web-GIS tool that displays a full CSZ rupture and three partial rupture CSZ scenarios (http://ohelp.oregonstate.edu/). We obtained the same synthetic bedrock ground motion data used in the OHELP tool from A. Frankel (written communication, 2016) of the USGS. In the Portland Metropolitan Region, the synthetic CSZ magnitude 8.7 bedrock ground motion data averages about 85% of CSZ 9.0 bedrock ground motion data, and the synthetic CSZ magnitude 8.4 bedrock ground motion, with its northern rupture extent west of Waldport, Oregon, is about 40% of the full rupture CSZ magnitude 9.0 earthquake.

Damage estimates do not scale linearly with bedrock ground motion, and one should not assume damage from a CSZ magnitude 8.4 earthquake would be 40% of the CSZ magnitude 9.0 earthquake damage estimate. Yet significant damage could still occur in the study area, primarily due to the seismic site effect where the bedrock ground motion is strongly amplified by soft soils (Section **3.2**). The most dramatic consequence of the seismic site effect observed to date is from the 1985 Mexico City earthquake, where a relatively distant rupture produced devastating building damage within the historic lakebed (Singh and others, 1988). Future studies could quantify the influence of the site effect on damage estimates across lower magnitude CSZ earthquake scenarios.

The Portland Hills fault was modeled at the upper end of its estimated magnitude range (M 6.8); it could rupture at lower magnitude. Buildings above the rupture zone will likely experience the same damage as estimated in this report. Buildings more distant from the rupture zone but situated on softer soils would experience more damage than nearby buildings situated on stiffer soils. The Portland Hills fault is part of a fault zone that includes the Oatfield fault and the East Bank fault (Wong and others, 2001). Other seismogenic faults exist in the study area (Personius and others, 2003; USGS Quaternary Fault and Fold Database: https://earthquake.usgs.gov/hazards/qfaults/). Again, buildings above the fault will experience the most damage, but buildings distant from the fault situated on soft soils may be significantly damaged.

6.2 Seismic Design Level Improvements

Our seismic design level improvement modeling exercise (Section 5.3.1) provides strong support to the suggestion that seismic upgrades to buildings, or replacement of older buildings, can significantly reduce loss and casualties. Levi and others (2015) provided a case for a wide-scale retrofitting program to poor quality buildings throughout Israel, by using Hazus-generated loss estimates based on existing building inventory and a hypothetically retrofitted building inventory. The study assumed an average estimate of US$100/per square meter (US$9.30 per square foot) to upgrade older buildings to limit extensive or complete damage. Yet any proposed improvement should take site-specific conditions into account. In the “wet” (saturated) soil scenario, ground failure due to liquefaction reduces the benefits of retrofitting, as seismic upgrades do little to prevent foundation rupture, but mitigation techniques such as compaction grouting can minimize the ground failure impact, albeit at additional cost.

We urge caution in interpreting the results of **Table 5-4**. Although it offers a hypothetical upper bound of what could be achieved from seismic retrofitting, it should not be used to support the proposed retrofitting or replacement of a particular building. A building-specific analysis incorporates individual

LUBA No. 2020-009
Page 4995

characteristics of the structure, specifying parameters such as its yield point (FEMA, 2010). We used generic building type models in our Hazus AEBM (Section **2.1.4**), which in the particular case, may over- or underestimate the loss (Lu and others, 2017). Further, the exercise did not incorporate building foundation depth or other local site conditions that may mitigate the effects of ground failure from liquefaction. In the Moderate scenario, our modeling exercise assumed a retrofit brings buildings up to moderate or high seismic design standards. In practice, the decision to retrofit or replace an older structure is complex (Williams and others, 2009; City Club of Portland, 2017; Paxton and others, 2017), and one that we cannot address directly in this report.

6.3 Comparison with Previous Studies

Wang (1998), using an early version of Hazus, quantified the impact of a magnitude 8.5 Cascadia Subduction Zone earthquake scenario across the state of Oregon, reporting losses by individual county. Liquefaction and landslide information were not regionally available, nor was it possible to incorporate such information in the Hazus model at that time. Hofmeister and others (2003) used Hazus to estimate impact of a magnitude 6.8 Portland Hills fault and a magnitude 9.0 Cascadia Subduction Zone earthquake scenario to buildings and bridges in Clackamas County, Oregon. The study incorporated building data from the Metro (1998) inventory, and updated soil classification and liquefaction and landslide susceptibility. Local building data were aggregated into the Hazus-MH model's General Building Stock (GBS) inventory, a census track-based unit, with loss estimates derived at the GBS level. Excluding building content, the building repair cost, expressed as a percentage of the building replacement cost, was 13.3% for the Portland Hills fault and 3.4% for the Cascadia Subduction zone earthquake. More recently, Tetra Tech (2016a) updated General Building Stock inventory data for the City of Portland, using ground motion and ground failure data from Madin and Burns (2013), and estimated loss ratios of 4.3% for a Cascadia Subduction Zone scenario and 14.3% for a Portland Hills fault magnitude 6.5 scenario, using USGS ShakeMap data.

Our building loss ratio estimates of 9% to 14% for a Cascadia Subduction Zone magnitude 9.0 earthquake, and 23% to 32% for a Portland Hills fault magnitude 6.8 earthquake are higher than the loss ratios published in the aforementioned studies. We account for this increase due to several factors. The largest contributor to the difference is the method by which the two Hazus tools (General Building Stock [GBS] and Advanced Engineering Building Module [AEBM]) factor the probability of ground failure from liquefaction or from earthquake-induced landslide into the building damage model. In the GBS model, the Hazus tool distributes the ground failure probability across the Moderate, Extensive, and Complete damage states (FEMA, 2011, Equation 5-16), with most of the ground failure probability assigned to the Moderate and Extensive states and a small (<10%) portion assigned to the Complete state. In the AEBM model, the Hazus tool assigns the ground failure probability in its entirety to the Complete damage state. The effect is that AEBM-derived building loss, casualty, and debris estimates will be larger than GBS-derived estimates when all other model inputs are equal, local geological conditions are set to moderate or higher liquefaction and/or landslide susceptibility levels, and sufficient ground motion is present to induce landslides or liquefaction.

Other contributors to the difference are as follows. In our AEBM building database, our seismic design levels (Section **10.1**) were more conservative than the seismic design level distributions embedded within the GBS database, sometimes referred to as the default Hazus mapping scheme. Our review of that scheme suggested it was primarily based on California benchmark years and thus overly optimistic, as California building codes through the twentieth century were more stringent than Oregon

LUBA No. 2020-009
Page 4996

building codes (Olson, 2003; Judson, 2012, FEMA, 2017c, Table 3.5). Although it is possible to alter the Hazus mapping scheme in the General Building Stock (e.g., Seligson, 2008), to our knowledge, such manipulations were not done in the aforementioned GBS-based studies. A higher level of seismic design assignment to building inventory will result in reduced loss estimates (**Table 5-4**).

Within large portions of the developed areas in the study area, our updated liquefaction susceptibility ratings were higher than the liquefaction susceptibility ratings used in the aforementioned studies (primarily Mabey and others, 1997). Appleby and others (in preparation), using the guidelines provided by FEMA (2011, Table 4.10), classified large areas containing high-value building assets with a Very High and High rating compared to the rating of High and Moderate assigned by Mabey and others (1997), particularly in the Columbia Slough, northwest industrial Portland, and eastern downtown Portland. A large portion of the developed area in Washington County was assigned a Moderate liquefaction rating by Appleby and others, which also contributed to the increased loss estimates observed in our study.

We could not directly compare our loss estimates to the losses published by FEMA (2017b), due to their usage of a probabilistic model that did not include a 500-year earthquake, which most closely resembles the Cascadia Subduction Zone scenario modeled in our study. Their debris estimate for the state of Oregon (2.1 to 21.6 million tons) is smaller than our estimate of 12 to 17 million tons, after adjusting for our study's area. (We assume our study includes about 44% of the building assets in the state, based on the area's population ratio compared to the state of Oregon.) The FEMA report used the GBS model and a simplified NEHRP "D" assignment. To our knowledge, the study did not incorporate any liquefaction susceptibility data. Further, default Hazus building inventories, such as were used in the FEMA study, commonly underestimate the square footage for nonresidential buildings, which are generally more sensitive to ground motion. Although that study provided a good nationwide comparative perspective on earthquake hazards, it is too generalized to use for county loss estimation purposes.

We examined the geological updates and the updated ground motions within the Critical Energy Infrastructure (CEI) Hub, and we compared them to the datasets used by Tetra Tech (2016b). Although some increases were observed in the updated ground motion data, we determined that the changes were not large enough to significantly alter the overall damage estimates and recommendations made in the Tetra Tech study. We note that the Hazus GBS tool was not used to generate the damage estimates in that study; damage estimates to the infrastructure were obtained from a Hazus tool that incorporates the ground failure in a manner equivalent to the Hazus AEBM.

Our Portland Hills fault results are similar to what was estimated for a magnitude 7.0 Wasatch fault earthquake in the Salt Lake City area (EERI, 2015, p. 26). The Salt Lake City area has approximately 775,000 buildings, compared to 616,000 buildings in our study area. The two faults have significant assets constructed on top of, and near to, the fault. Both areas have major assets on moderate to high liquefaction potential soils. The key difference between the two faults is the frequency of occurrence—at least 22 large earthquakes have ruptured along the central segments of the Wasatch Fault in the past 6,000 years, whereas evidence suggests the Portland Hills fault has had two ruptures in the past 15,000 years (Liberty and others, 2003).

7.0 RECOMMENDATIONS

This study provides detailed, actionable earthquake loss estimation data for the Portland metropolitan region at a range of scales. Communities, counties, businesses, non-governmental organizations, and regional agencies can use the accompanying data to better plan for, respond to, and recover from a major earthquake. Many of these recommendations build upon those listed in the Oregon Resilience Plan (OSSPAC, 2013). Planning for, responding to, and recovering from a major earthquake is a multi-faceted, multi-disciplinary effort. The scope of this project was limited to estimating damage to buildings and the people that occupy them, and to two key infrastructure sectors. Our recommendations below are directly supported by the findings in this study, and they should not be considered comprehensive.

Our recommendations build on the efforts done to date by agencies, institutions, businesses, and private homeowners to improve the region's seismic resilience. The Oregon Seismic Rehabilitation Grant Program, in place since 2007, has funded upgrades to more than 50 schools and emergency service buildings (http://www.oregongeology.org/sub/projects/rvs/). Bonneville Power Administration has identified seismic vulnerability of its transmission system and has taken several actions to improve its resiliency (Scruggs, 2014). Modifications to the Oregon statewide building code have, through time, increased the seismic resiliency of newer construction (Judson, 2012). The City of Portland's current building code requires owners of unreinforced masonry buildings to seismically retrofit their buildings on the basis of certain triggers (PBEM, 2017). The Great Oregon Shakeout program, managed by Oregon Office of Emergency Management, has more than 580,000 participants, elevating public awareness of the earthquake hazard; the program suggests actions individuals can take to minimize casualties and preparation for post-earthquake disruption of services.

Planning

We encourage regional and local planners, each who have their own questions and needs, to explore the accompanying GIS data. Static maps, such as in Appendix E, Plates 14–16, are just one representation of the loss estimates. We suggest that a primary value of the database is the spatial component: in addition to asking how many or how much, we can ask *where*—where might we expect casualties to be higher, given the time of day of the earthquake? Where can we plan staging areas for debris? At the same time, we caution against over-interpreting the loss estimates, as the data and methods used in this project contain large uncertainties.

Casualty estimates supplied in this report can be used to compare with the region's existing medical facility capacity, including trained, available personnel. The spatial nature of the data supplied with this report can be used to better understand the potential demands on specific facilities, and to quantify emergency care coordination needs at a regional level.

Counties and jurisdictions updating their natural hazard mitigation plans (NHMPs) can use the earthquake damage estimates provided in this report.

Recovery

Hundreds of thousands of buildings in the study area will need safety inspections after a major earthquake. The state can sponsor annual Applied Technology Council (ATC)-20 training to qualified engineers, and negotiate mutual aid agreements with other neighboring states. Timely inspection of damaged buildings will reduce pressure on temporary shelters.

LUBA No. 2020-009
Page 4998

Resiliency: Buildings

The majority of buildings in the study area do not meet current seismic building code standards, although the buildings did meet code standards in place at time of construction. The state and counties can consider incentives and other options that encourage building owners to seismically upgrade their buildings. Such upgrades will reduce casualties and building repair costs and will minimize potential loss of businesses and workforce housing. Jurisdictions can consider triggers that require seismic upgrades, such as a major building renovation.

Resiliency: Infrastructure Improvements

We cannot overstate the need for a secure, regional liquid fuel supply that supports emergency response and recovery. The emergency transportation route analysis provided in this study suggests the need to identify strategically placed local fuel points of distribution. We encourage counties to work with the Oregon Department of Energy in implementing the Oregon Fuel Action Plan (ODOE, 2017), specifically, identifying priority lifeline routes and fuel points of distribution.

Electric utilities can use this study's updated ground motions and ground failure to evaluate the potential threat to their infrastructure, such as substations. Electric system resiliency analysis can incorporate the transmission structure information provided in our geodatabase to determine if additional capacity or redundancy is needed.

Resiliency: Essential and Critical Facilities

Our project did not explicitly identify or evaluate essential facilities, such as fire stations, in the study area. We encourage all communities and planners to clearly define such facilities and evaluate their seismic resilience by using the updated ground motion and ground failure data accompanying this report along with updated Rapid Visual Screening surveys (FEMA, 2015a; Lewis, 2007). Such facilities include emergency shelters and community points of distribution.

Enhanced Emergency Management Tools

Building footprints developed for this project can be incorporated into regional and statewide databases. Location and number of buildings, especially on larger rural lots, are essential information during emergency operations such as wildfire fighting.

A rapid earthquake loss assessment tool could be developed for Oregon by building on methods established in this study and other research such as that of Erdik and others (2011). Each earthquake presents scientists with new information. The synthetic earthquake ground motion data used for this project is the best estimate available from a full rupture subduction zone and a local crustal fault earthquake. In practice, the magnitude and location of an earthquake and the ground motions and ground deformation will likely vary from what was anticipated. In addition to the Portland Hills fault, several other active local crustal faults, such as the Gales Creek fault zone, exist in the study area (Personius and others, 2003). The USGS ShakeMap program (https://earthquake.usgs.gov/data/shakemap/) provides near-real-time maps of ground motion data following significant earthquakes. Having a building database and tools in place to estimate response to a particular earthquake with its own unique ground motions can provide emergency planners with a rapid post-earthquake assessment of the situation.

LUBA No. 2020-009
Page 4999

Database Improvements

County and city databases could be improved with information on seismic retrofits and upgrades to individual buildings. Currently, such information is not readily available for analysis or to potential buyers of a property. At present, only one jurisdiction in the study area maintains the basics of such a database (City of Portland [2017], Unreinforced Masonry buildings).

Public Awareness

The technical information contained in this report can be used to develop practical tools and materials aimed at increasing public awareness of regional earthquake risks and encouraging preparedness actions. Examples of such tools include the Seattle and King County Ready disaster preparedness website, https://hazardready.org/seattle/ (which incorporates other natural hazards), and the report developed by the Utah Chapter of the Earthquake Engineering Research Institute describing the Wasatch Fault in Salt Lake City (EERI, 2015). Public awareness efforts should strive to reach underserved communities and communities whose primary language is other than English, as well as community members with disabilities and access or functional needs.

Future Studies

Our study was primarily focused on direct physical impacts from a major earthquake, including building repair or replacement costs. It did not consider other direct and indirect economic losses, such as lost wages. We recommend incorporating the detailed loss information from this report into a more sophisticated economic analysis, one that factors in other items such as availability of investment capital and a trained labor force, and willingness of businesses to return to the area after a damaging earthquake.

We aggregated loss data at census block groups, which is often the same aggregation unit used when social vulnerability indices are constructed (e.g., Toké and others, 2015). Schmidtlein and others (2011) compared census tract Hazus-based earthquake loss estimates with their social vulnerability indices. A similar type of an analysis could be conducted in our study area at the census block group level.

The methods developed for this project could facilitate similar earthquake impact analyses for other urbanized areas of Oregon that have known earthquake hazards, such as Klamath Falls/Altamont, Salem/Keizer, Albany/Corvallis, and Eugene/Springfield.

Although our analysis focused on impacts from an earthquake, the underlying building database can be used to quantify potential loss due to other natural hazards, such as floods, landslides, or wildfires.

8.0 ACKNOWLEDGMENTS

The Regional Disaster Preparedness Organization (RDPO), Portland, Oregon, provided funding for this project through an Urban Areas Security Initiative grant (UASI) 15-170 from U.S. Department of Homeland Security (Funding Opportunity [NOFO] #DHS-15-GPD-067-000-01; Federal Award Identification Number [FAIN] EMW-2015-SS-0004-S01). Oregon Office of Emergency Management administered the grant on behalf of RDPO. Many people contributed to this report at various levels, ranging from data creation, literature research, methods, information technology, tool development, and technical review. From the Oregon Department of Geology and Mineral Industries: Ken Aaro, Christina Appleby, Lowell Anthony, Quinn Butler, Robert Hairston-Porter, Robert Houston, Lina Ma, Gustavo Monteverde, Jesse Schaefer, Deb Schueller, Yumei Wang, Rudie Watzig, and Matthew Williams. From the

10.0 APPENDIX A: BUILDING DATABASE DEVELOPMENT

10.1 Building Database Data Sources

Table 10.1 lists the several data sources used for constructing the building asset database. The table is organized as follows: the most general data source for a particular attribute is listed first, then, where available, the source of more specific and accurate data. For example, the Regional Land Information System tax lot database had an Oregon Department of Revenue-based Property Class designation assigned to each tax lot. A lookup table provided a Hazus-based occupancy class mapping for most Property Class values. All buildings on the tax lot are given that occupancy class assignment. If better information on occupancy class was available, such as the Metro Fire/Police/School/Hospital spatial dataset, we updated the attribute with that information. More detailed datasets are typically restricted to a small subset of the buildings.

The Year Built attribute is not directly consumed by Hazus AEBM, but this attribute is used to establish the seismic design level (Section **10.2**).

LUBA No. 2020-009
Page 5008

Table 10-1. Data sources used in construction of the building database. Table uses Hazus occupancy class names (FEMA, 2011, Table 3.2).

Dataset Owner/Distributor	Dataset	Date of Publication or Acquisition	Occupancy Class	Year Built	Square Footage	Number of Stories	Building Type	Summarization Unit	Notes
Metro, Portland, Oregon	Regional Land Information System: Tax Lots	February 2016	✓						Spatial association of building footprint with assessor tabular information.
Clackamas County Assessor, Oregon City, Oregon	Clackamas County Assessor Database (tabular)	June 2016	✓	✓	✓	✓	(RES2)+		Detailed information on individual structures. Square footage available only for residential properties.
Multnomah County Assessor, Portland, Oregon	Multnomah County Assessor Database (tabular)	March 2016	✓	✓	✓	✓	(RES2)+		Detailed information on individual structures.
Washington County Assessor, Hillsboro, Oregon	Washington County Assessor Database (tabular)	March 2016	✓	✓	✓	✓	(RES2)+		Detailed information on individual structures. Square footage not available for governmental or institutional buildings. Year Built information variable.
Oregon Dept. of Geology and Mineral Industries	Building footprint digitization	December 2016	✓						Assigned occupancy class during heads-up digitization with NAIP and oblique imagery. Limited to building footprint digitized for this project.
Metro, Portland, Oregon	Metro Area Disaster GIS (MADGIS) Database	1999					✓		Building construction type based on field visits and identification for ~40,000 non-single family residential buildings.
Metro, Portland, Oregon	Multi-family housing inventory	February 2017	✓				✓		Refined the distinction between single-family and multi-family residential buildings.
City of Portland	Unreinforced Masonry Building Database	January 2017		✓			✓		Includes information on seismic retrofits to URMs. Limited to City of Portland. https://www.portlandoregon.gov/bds/70767
Oregon Employment Department	North American Industry Classification System (NAICS)	September 2016	✓						Refinement of occupancy class designation for commercial and industrial buildings, building on methods described by Wein and others (2013). Data obtained under terms of a confidentiality agreement; information from dataset can be shared only in aggregate, non-individually identifiable, form.
Metro, Portland, Oregon	Regional Land Information System: Fire, Police, School, Hospital Buildings	February 2016	✓						Refinement of occupancy class designation for educational and certain governmental buildings.
Oregon Dept. of Geology and Mineral Industries	Oregon Statewide Seismic Needs Assessment (Lewis, 2007)	2007	✓	✓	✓	✓	✓		Most detailed information; limited to 777 public schools and government agency buildings.
Metro, Portland, Oregon	Regional Land Information System: Building footprints	February 2016			✓				Combined with other building footprint databases; see Section 2.1.1.
Oregon Dept. of Geology and Mineral Industries	Building footprints (Burns and others, 2011, 2013)	2011, 2013			✓				Previously digitized building footprints for portions of Multnomah and Clackamas counties.
City of Portland	Development Capacity Analysis GIS Model (City of Portland, 2012)	October 2012				✓			Established number of stories attribute for buildings in City of Portland. Used to establish building height to number of stories relationship for buildings where number of stories data were not available.
Oregon Dept. of Geology and Mineral Industries	Lidar compilation: bare earth and highest hit models	2009–2014			✓	✓			Used for building footprint (BF) development in areas where no BFs existed, and to refine existing BF database. Building height derived from lidar elevation models (highest_hit minus the bare_earth) and converted to Number of Stories using relationships established by analysis of data from City of Portland Development Capacity Analysis GIS Model. Lidar acquisition dates vary, depending on area. https://gis.dogami.oregon.gov/lidarviewer/
Metro, Portland, Oregon	Regional Land Information System: County and City Boundaries	February 2016						✓	Building spatial associations with particular jurisdictions and counties, including county unincorporated areas.
Tetra Tech, Portland, Oregon	City of Portland Risk Reporting Areas (Tetra Tech, 2016a)	September 2016						✓	Building spatial associations with one of nine Risk Reporting Areas within the City of Portland.
U.S. Census Bureau	2010 Census Block Groups	April 2010						✓	U.S. Census Block Group (CBG) 2010 boundaries, with contiguous CBGs combined by DOGAMI where needed, to establish neighborhood units. Buildings spatially associated with neighborhood units. Population numbers used to assign residential building population. https://www.census.gov/geo/reference/gtc/gtc_bg.html

+RES2 (Single-Family Manufactured Housing) available from Assessor records and, by definition, a Manufactured House building type.

10.2 Seismic Design Level Assignments

We assigned a Hazus seismic design level based on the building's construction year and type. Seismic design codes have evolved with time, with more stringent requirements developing as the natural hazard threat is better understood. We interpreted the relevant state building code histories as described by Judson (2012), Oregon Building Code Division (2002, 2010), and Business Oregon (2015) and developed a seismic design level categorization table (**Table 10-2**). The design level assignment is one of the parameters used by the Hazus tool to derive a damage estimate. Once the seismic design level was assigned to each building, we summarized the number of buildings, square footage, and replacement cost per seismic design level (**Table 10-3**). We did not have sufficient information to further classify buildings into the Hazus-supported Low-Special, Moderate-Special, and High-Special seismic design levels.

Table 10-2. Oregon seismic design level benchmark years.

Building Type	Year Built	Design Level	Basis
Single Family Dwelling (includes Duplexes)	prior to 1976	Pre Code	Interpretation of Judson (2012)
	1976 – 1991	Low Code	
	1992 – 2003	Moderate Code	
	2004 – present	High Code	
Manufactured Housing	prior to 2003	Pre Code	Interpretation of Oregon Manufactured Dwelling Special Codes (Oregon Building Codes Division, 2002)
	2003 – 2010	Low Code	
	2011 – present	Moderate Code	Interpretation of Oregon Manufactured Dwelling Special Codes Update (Oregon Building Codes Division, 2010)
All other buildings	prior to 1976	Pre Code	Interpretation of Oregon Benefit-Cost Analysis Tool (Business Oregon, 2015, p. 24)
	1976 – 1990	Low Code	
	1991 – present	Moderate Code	

LUBA No. 2020-009
Page 5010

Table 10-3. Building statistics by seismic design level, per county.

County	Seismic Design Level	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Cost Percent
Clackamas	Pre Code	89,647	50%	202,323	42%	24,922	40%
	Low Code	43,530	24%	146,754	30%	19,523	31%
	Moderate Code	30,638	17%	88,682	18%	11,550	19%
	High Code	15,349	9%	48,363	10%	6,394	10%
Multnomah	Pre Code	184,704	72%	489,280	60%	67,497	59%
	Low Code	28,280	11%	111,783	14%	15,884	14%
	Moderate Code	26,383	10%	101,405	13%	14,248	12%
	High Code	16,210	6%	107,620	13%	16,418	14%
Washington	Pre Code	55,806	31%	145,812	24%	19,341	23%
	Low Code	46,556	26%	215,049	36%	31,128	38%
	Moderate Code	55,092	30%	147,174	24%	18,728	23%
	High Code	23,657	13%	94,936	16%	13,534	16%
Total Study Area	Pre Code	330,157	54%	837,415	44%	111,760	43%

10.3 Buildings by Geological Classification

To better understand the potential influence of local geology on the damage estimates, we summarized building information by National Earthquake Hazards Reduction Program (NEHRP) site classification and landslide and liquefaction susceptibility.

The NEHRP site classification bins a soil column's average shear wave velocity (V_{s30}), measured between 0 (surface) and 30 meters depth, into one of six categories. The site classification can be used to estimate the amplification of bedrock ground motion that may be experienced at the surface during an earthquake. Lower ratings, such as "B" and "C," minimally amplify the bedrock ground motion. Softer soil columns with lower V_{s30} values experience more surface ground motion due to the soil column's amplifying the bedrock ground motion. NEHRP site class "F" is assigned to soil columns primarily composed of fill material or certain types of clays or peat. For building seismic design purposes, such soils generally require site-specific investigations. For Hazus modeling purposes, we take a conservative approach by reclassifying NEHRP site class "F" into NEHRP site class "E"—the classification with the highest site amplification (Section **11.1**). Summary statistics in **Table 10-4** show that while a relatively small percentage of buildings are placed on NEHRP Site Classification "E" and "F" soils, their proportional building value in Multnomah County is large.

Table 10-4. Building statistics by NEHRP site classification, per county.

County	NEHRP Site Classification	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Value Percent
Clackamas	B	367	0%	746	0%	84	0%
	C	109,012	61%	278,528	57%	35,172	56%
	D	58,301	33%	178,653	37%	23,616	38%
	E, F	11,484	6%	28,195	6%	3,518	6%

	C	118,487	46%	251,404	31%	32,828	29%
	D	126,550	50%	403,956	50%	58,160	51%
	E, F	10,508	4%	154,665	19%	23,050	20%
Washington	C	21,724	12%	63,586	11%	8,484	10%
	D	154,153	85%	525,041	87%	72,507	88%
	E, F	5,234	3%	14,343	2%	1,741	2%
Total Study Area	B	399	0%	808	0%	92	0%
	C	249,223	40%	593,519	31%	76,483	30%
	D	339,004	55%	1,107,651	58%	154,284	60%
	E, F	27,226	4%	197,202	10%	28,310	11%

The liquefaction and earthquake-induced landslide susceptibility rating is a description of a site's characteristics; it is *not* descriptive of an earthquake-induced landslide or liquefaction occurrence for a particular earthquake scenario. The susceptibility ratings are a generalization of the Hazus-based classifications, obtained from Appleby and others (in preparation), with the groupings listed at the bottom of each table (**Table 10-5** and **Table 10-6**). In all three counties, relatively few buildings are in high landslide susceptibility areas. In Washington County, at least 80% of the building value is on moderate liquefaction susceptibility soils.

10.4 Buildings by Primary Usage

We summarized the number of buildings on a generalized Hazus occupancy class basis, which is a classification of a building's dominant use (**Table 10-7**). In the case of mixed-use buildings, such as retail stores on the first floor and residential quarters on the upper floors, we assigned the occupancy class based on the largest square foot usage.

Table 10-7. Buildings statistics by primary usage, per county.

County	Building Use	Number of Buildings	Building Percent	Square Footage (Thousand)	Square Footage Percent	Building Value ($ Million)	Building Value Percent
Clackamas	Agricultural	22,768	13%	52,063	11%	5,541	9%
	Commercial	4,593	3%	54,616	11%	7,929	13%
	Industrial	1,573	1%	20,621	4%	3,063	5%
	Institutional	2,558	1%	23,264	5%	3,940	6%
	Multi-family Residential	8,959	5%	40,880	8%	6,293	10%
	Single-family Residential	138,713	77%	294,677	61%	35,624	57%
Multnomah	Agricultural	2,540	1%	8,146	1%	867	1%
	Commercial	11,544	5%	210,231	26%	33,390	29%
	Industrial	1,685	1%	45,292	6%	6,874	6%
	Institutional	3,094	1%	50,145	6%	8,812	8%
	Multi-family Residential	24,197	9%	140,585	17%	22,428	20%
	Single-family Residential	212,517	83%	355,689	44%	41,675	37%
Washington	Agricultural	10,753	6%	26,823	4%	2,855	3%
	Commercial	5,863	3%	104,377	17%	15,815	19%
	Industrial	1,399	1%	50,567	8%	8,548	10%
	Institutional	1,931	1%	28,098	5%	4,856	6%
	Multi-family Residential	18,475	10%	98,385	16%	15,671	19%
	Single-family Residential	142,690	79%	294,721	49%	34,987	42%

Commercial includes the Hazus RES4 class. Institutional combines the Hazus GOV1, GOV2, EDU1, EDU2, and REL1 classes. Single-family residential combine the Hazus RES1 and RES2 classes.

LUBA No. 2020-009
Page 5014

10.5 Building Type by Primary Usage

We summarized the number of buildings by their generalized basic structural system (in Hazus, referred to as the building type), by generalized occupancy class (**Table 10-8**). Although several ancillary datasets informed our assignments (Section **2.1.4**), most (563,583 out of 615,852, or 92%) were based on the statistical distributions listed in the Hazus Earthquake Technical Manual (FEMA, 2011, Tables 3.A1–3.A.10).

	Unreinforced Masonry	1,455	0%	2,298	0%	268	0%
	Wood	471,926	99%	914,096	99%	110,199	99%
Single-Family Res. – Manuf. Housing		16,852	100%	20,966	100%	882	100%

Commercial combines all Hazus COM occupancy classes and RES4. Institutional combines Hazus occupancy classes REL1, GOV1, EDU1, and EDU2. Multi-family residential is limited to RES3, RES5, and RES6 types. Single-Family Residential – Manuf. Housing is the Hazus occupancy class RES2, and is broken out separately, given the building type's heightened sensitivity to ground shaking.

11.0 APPENDIX B: SITE GROUND MOTION AND GROUND DEFORMATION MAP DEVELOPMENT

11.1 Site Ground Motion Maps

We converted the bedrock ground motion data referenced in Section 3.1 to a 30-foot grid limited in extent to the three-county study area. For the Portland Hills fault magnitude 6.8 earthquake, we used the Nearest Neighbor tool in the Esri Spatial Analyst. For the Cascadia Subduction Zone magnitude 9.0 earthquake, we used the bedrock data published by Madin and Burns (2013). The NEHRP site classification polygons from Appleby and others (in preparation) were converted to a 30-foot grid. Sites classified as NEHRP "F" were re-assigned to NEHRP "E," a conservative and commonly implemented assumption for loss estimation purposes.

We used the revised F_a, F_v, and F_{PGA} site coefficients as published by FEMA (2015b, Tables 11.4-1, 11.4-2, 11.8-1) to derive site ground motion. For completeness, we include the NEHRP "A" class (V_{s30} > 1,500 m/s), even though such stiff material is not present in the study area. We note the coefficients are identical to what is used by the Hazus 4.0 model for probabilistic and arbitrary earthquake events available in the Hazus SQL database tables as:

[dbo].[eqPGASoilAmpFact],
[dbo].[eqPGVSoilAmpFact] ,
[dbo].[eqSa03SoilAmpFact] , and
[dbo].[eqSa10SoilAmpFact].

The coefficients applied directly will result in a non-monotonic site amplification function. To overcome the problem, we implemented the straight-line interpolation guidance given by FEMA (2015b) for intermediate values, and we added a *y*-intercept to the amplification function and adjusted the slope factor, so that the end point of the interval matches the specified amplification. We note the Hazus tool implements a similar piecewise linear function for probabilistic and arbitrary earthquakes. The functions listed in **Table 11-1** through **Table 11-4** were then implemented using the Esri Spatial Analyst raster calculator as a series of conditional statements.

For Hazus purposes, the raster data were converted to the requisite polygon data format by first discretizing the continuous site ground motion data into integer *percent g* bins, then converting the integer raster data to polygon format. The pgv was rounded to the nearest integer inches/second category, and then converted to polygon format.

11.2 Ground Deformation Maps

We provided the liquefaction and landslide susceptibility data from Appleby and others (in preparation) and the site peak ground acceleration data for both earthquake scenarios developed in Section 3.2 as input to the tool developed by Sharifi-Mood and others (in preparation). The tool implements the methods for permanent ground deformation (PGD) estimation described by Madin and Burns (2013, Section 4), which implemented the Hazus ground failure models described in the Hazus Earthquake Technical Manual (FEMA, 2011). The tool generates raster grids describing the amount and probability of PGD resulting from liquefaction lateral spreading and earthquake-induced landslides. The tool is currently limited to modeling lateral spread from liquefaction in "wet" (saturated) soil conditions. For earthquake-induced landslide modeling, it implements the WET portion of Table 4.15 in the Hazus Earthquake Technical Manual (FEMA, 2011). For liquefaction, it assumes a water depth of 5.0 feet. The tool provides PGD and probability of occurrence estimates for liquefaction lateral spreading and for earthquake-induced landslides. The data are provided in the accompanying geodatabase for the CSZ and the Portland Hills fault simulated earthquakes.

To aid in interpretation, Appendix E, Plates 8 and 9 combine the PGD and probability occurrence from the two mechanisms (earthquake-induced landslides and lateral spread resulting from liquefaction). For a given raster cell, the plates represent the maximum PGD and maximum probability from the two mechanisms.

Our "dry" soil conditions scenario assumes non-saturated soils, thus ground failure due to liquefaction does not occur. However, earthquake-induced landslides may still occur, depending on the ground shaking intensity and local geologic conditions (FEMA, 2011, Table 4.15(A)). To overcome the current limitation of the tool, we developed a "dry" soil conditions scenario ground failure model due to earthquake-induced landslides as follows. As part of a statewide multi-hazard risk assessment effort for Oregon, we developed a lookup table method for rapid loss estimation from a Cascadia Subduction Zone earthquake (Bauer, 2016). All combinations of ground motion, at discrete intervals, and all combinations of liquefaction and landslide susceptibility values, were run through the Hazus model. Building loss ratios, along with ground failure probabilities and lateral spread amount, were captured in a lookup table. Of the four site ground motion parameters (Section **11.1**), the Hazus ground failure model uses only the site peak ground acceleration. A Hazus-based ground failure layer can then be created by associating the local landslide susceptibility rating and the site peak ground acceleration with the lookup table. We repeated the lookup table process for the Portland Hills fault "dry" soil conditions scenario.

The "dry" soil conditions scenario ground failure and probability values are included in the accompanying geodatabase. The lookup table method used the discretized peak ground acceleration (pga) intervals described in Section **11.1** and while it is not as continuous as what is available via the tool developed by Sharifi-Mood and others (in preparation), we determined it is a reasonable representation of the Hazus ground failure model for earthquake-induced landslides in the "dry" soil conditions scenario.

12.0 APPENDIX C: BUILDING DAMAGE ASSESSMENT AND IMPACTS TO OCCUPANTS

12.1 Number of Buildings by Damage State

We summarized the number of buildings in each damage state, by county (**Table 12-1**), using the structural damage states (StrPDS) obtained from the Hazus AEBM output. The quantification of buildings in each damage state follows the methods discussed by FEMA (2017a). The information can inform the planning process for post-earthquake building inspection needs.

Table 12-1. Number of buildings per damage state, by county and by earthquake and soil moisture scenario. Numbers for buildings in the None damage state are not included.

12.2 Number of Collapsed Buildings

We used the collapse percentage rates listed in the Hazus Earthquake Technical Manual (FEMA, 2011, Table 13.8), together with probability of Complete structural damage state from the Hazus AEBM output, to estimate the number of collapsed buildings by county and earthquake scenario (**Table 12-2**). The casualty calculations built into Hazus AEBM factor in an assumption that a percentage of completely damaged buildings will collapse, which varies based on building type. For example, the Hazus methods estimate 15% of completely damaged unreinforced masonry buildings will collapse, whereas completely damaged manufactured housing and single family wood frame construction buildings have only a 3% chance of collapse.

Table 12-2. Collapsed buildings by county and by earthquake and soil moisture conditions

		Cascadia Subduction Zone Magnitude 9.0 Earthquake		Portland Hills Fault Magnitude 6.8 Earthquake	
County	Total Number of Buildings	"Dry" Soils	"Wet" (Saturated) Soils	"Dry" Soil	"Wet" (Saturated) Soils

Multnomah	255,577	302	677	1,001	1,876
Washington	181,111	209	619	387	1,155
Total	615,852	668	1,609	2,054	4,097

12.3 Permanent Residents by Building Damage State

We assigned permanent residents to individual residential buildings based on the building's square footage, the total square footage of residential buildings for a census block group, and the U.S. Census 2010 population amount for that census block group (Section **2.1.7**). Using the Hazus AEBM output, we multiplied the individual building's permanent residential population by each structural probability of damage state. Summary statistics by county and earthquake scenario are provided in **Table 12-3**. Note the figures in the Complete state are the same as the long-term displaced population figures in **Table 12-4** through **Table 12-7**. The Hazus Complete damage state equates to the ATC-20 red-tag designation (ATC, 1989), and the Extensive damage state equates to the ATC-20 yellow-tag designation. All other building damage states are considered green-tagged (FEMA, 2010, Table 6.1). Qualitative descriptions of the building damage states as relates to the characteristics of the building, per building type (such as Steel Moment Frame), are provided by FEMA (2011, Section 5.3).

Table 12-3. Permanent residents per building damage state, by county and by earthquake and soil moisture conditions scenario.Numbers for permanent residents occupying buildings in the None damage state are not included.

We recognize that planning for short-term and long-term shelter needs throughout the response and recovery phases is a complex task requiring many assumptions, but at its base the planning requires underlying data on demographics as relates to predicted building damage. **Table 12-4** through **Table 12-7** quantify the number of buildings and permanent residents by generalized occupancy, per county and per building damage state, for the four earthquake scenarios.

Table 12-4. Buildings and permanent residents per building damage state for Cascadia Subduction Zone magnitude 9.0 earthquake, "dry" soil conditions. Dash (—): not applicable

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

Table 12-6. Buildings and permanent residents per building damage state for Portland Hills fault magnitude 6.8 earthquake, "dry" soil conditions. Dash (—): not applicable

Number of buildings estimates are derived using the Hazus Advanced Engineering Building Module (AEBM) structural probability of damage states (FEMA, 2010).

Institutional combines Hazus occupancy classes REL1, GOV1, GOV2, EDU1, and EDU2. Commercial combines all Hazus COM occupancy classes and RES4. Multi-family residential combines the Hazus occupancy classes RES3, RES5, and RES6 categories.

Permanent resident values are based on U.S. Census 2010 population data. Permanent residents are assigned only to buildings designated as Hazus occupancy class RES1, RES2, RES3, RES5, and RES6.

Manufactured housing building category is limited to Hazus occupancy class RES2, and does not include modular construction that may be present in other Hazus occupancy classes.

12.4 Loss Estimates by Jurisdiction

Table 12-8 through **Table 12-11** provide county-level and jurisdictional level building inventory and building loss estimates, along with casualty estimate for the daytime and nighttime earthquake scenarios. The jurisdictional data are available electronically in the accompanying geodatabase. Casualty and displaced population estimates are based on 2010 U.S. Census data and Hazus population distribution models across business types (Section **2.1.7**). The estimates for jurisdictions include all buildings within their 2016 jurisdictional boundaries, as defined by the Metro (2016) Regional Land Information System city boundary layer, dated February 2016.

LUBA No. 2020-009

[+] The jurisdiction is associated with the county it occupies most by area. Figures are for the entire jurisdiction and may include building data from neighboring counties. Summaries by all jurisdictions and unincorporated area for a given county will vary slightly with the county total.

[*] Gaston census numbers are for entire jurisdiction. Gaston loss figures limited to buildings and residences in Washington County and do not include buildings, casualties, debris, and displaced population in Yamhill County.

Casualty level definitions are provided in **Table 4-1** and are based on U.S. Census 2010 population figures.

[+] The jurisdiction is associated with the county it occupies most by area. Figures are for the entire jurisdiction and may include building data from neighboring counties. Summaries by all jurisdictions and unincorporated area for a given county will vary slightly with the county total.

[*] Gaston census numbers are for entire jurisdiction. Gaston loss figures limited to buildings and residences in Washington County and do not include buildings, casualties, debris, and displaced population in Yamhill County.

Casualty level definitions are provided in **Table 4-1** and are based on U.S. Census 2010 population figures.

13.0 APPENDIX D: GEOGRAPHIC INFORMATION SYSTEM (GIS) DATABASE

The GIS data included with this publication are partitioned into two ArcGIS version 10.1 file geodatabases. Earthquake loss estimates and impact assessment data are contained in RDPO_ Earthquake_Impact_Analysis_Phase1.gdb. Loss estimates for a particular earthquake scenario are contained in independent tables and can be joined to the appropriate polygon dataset to graphically represent impacts. Ground motion and ground deformation data are contained in RDPO_GroundMotion_GroundFailure_Phase1.gdb.

RDPO_Earthquake_Impact_Analysis_Phase1.gdb:

Feature Dataset Phase1:

Building_Footprints	Outlines of buildings and other non-building structures.
Electrical_Transmission_Structures	Pointfile containing locations of electrical transmission poles and towers, and an estimate of permanent ground deformation at the location for all four earthquake scenarios.
Emergency_Transportation_Routes	Buffered and segmented version of the Metro area Emergency Transportation Routes, and a categorization, per segment, of the impact of permanent ground deformation on the segment, for all four earthquake scenarios.
Jurisdictions	Cities, villages, hamlets, and unincorporated areas, and summary statistics for number of buildings, square footage, replacement cost, and population estimates. Contains **Jurisdiction** attribute for joining to loss estimate tables.
Neighborhood_Units	Neighborhood units (876 total), and summary statistics for number of buildings, square footage, replacement cost, and population estimates. Contains **NUID** attribute for joining to loss estimate tables.
Population_and_Building_Density	20-acre hexagonal grid with summary statistics for number of buildings, number of residential buildings, and permanent residents per hexagonal cell. All cells contain at least one building.

Tables with building loss, casualty, and displaced population estimates for a given scenario

Loss estimates by jurisdiction

Tables can be joined to the Jurisdictions *feature class using* **Jurisdiction** *attribute*

Loss_Jurisdiction_CSZ_M9p0_dry	Scenario: Cascadia Subduction Zone M 9.0, “dry” soil conditions
Loss_Jurisdiction_CSZ_M9p0_wet	Scenario: Cascadia Subduction Zone M 9.0, “wet” (saturated) soil conditions
Loss_Jurisdiction_PHF_M6p8_dry	Scenario: Portland Hills fault M 6.8, “dry” soil conditions
Loss_Jurisdiction_PHF_M6p8_wet	Scenario: Portland Hills fault M 6.8, “wet” (saturated) soil conditions

Loss estimates by neighborhood unit

Tables can be joined to the Neighborhood_Units *feature class using the* **NUID** *attribute*

Loss_Neighborhood_Unit_CSZ_M9p0_dry	Scenario: Cascadia Subduction Zone M 9.0, “dry” soil conditions
Loss_Neighborhood_Unit_CSZ_M9p0_wet	Scenario: Cascadia Subduction Zone M 9.0, “wet” (saturated) soil conditions
Loss_Neighborhood_Unit_PHF_M6p8_dry	Scenario: Portland Hills fault M 6.8, “dry” soil conditions
Loss_Neighborhood_Unit_PHF_M6p8_wet	Scenario: Portland Hills fault M 6.8, “wet” (saturated) soil conditions

RDPO_GroundMotion_GroundFailure_Phase1.gdb:

Synthetic Cascadia Subduction Zone magnitude 9.0 earthquake

Site ground motion (rasters)

CSZ_M9p0_pga_site	Site peak ground acceleration, in g (standard gravity).
CSZ_M9p0_pgv_site	Site peak ground velocity, in centimeters per second.
CSZ_M9p0_sa03_site	Site spectral acceleration at 0.3 sec, in g (standard gravity).
CSZ_M9p0_sa10_site	Site spectral acceleration at 1.0 sec, in g (standard gravity).

Permanent Ground Deformation (PGD) (rasters)

Each PGD raster is accompanied with a probability (Prob) raster

CSZ_M9p0_PGD_landslide_dry	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_landslide_dry	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
CSZ_M9p0_PGD_landslide_wet	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_landslide_wet	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
CSZ_M9p0_PGD_liquefaction_wet	Permanent ground deformation due to liquefaction lateral spreading. Liquefaction assumes wet (or saturated) soil conditions, in centimeters.
CSZ_M9p0_Prob_liquefaction_wet	Probability of liquefaction under wet (or saturated) soil conditions. In percent.

Synthetic Portland Hills fault magnitude 6.8 earthquake

Bedrock ground motion

PHF_M6p8_bedrock_groundmotion	Pointfile with descriptors of bedrock ground motion (pga, pgv, sa03, sa10)

Site ground motion (rasters)

PHF_M6p8_pga_site	Site peak ground acceleration, in g (standard gravity).
PHF_M6p8_pgv_site	Site peak ground velocity, in centimeters per second.
PHF_M6p8_sa03_site	Site spectral acceleration at 0.3 sec, in g (standard gravity).
PHF_M6p8_sa10_site	Site spectral acceleration at 1.0 sec, in g (standard gravity).

Permanent Ground Deformation (PGD) (rasters)

Each PGD raster is accompanied with a probability (Prob) raster

PHF_M6p8_PGD_landslide_dry	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_landslide_dry	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
PHF_M6p8_PGD_landslide_wet	Permanent ground deformation due to earthquake-induced landslide under wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_landslide_wet	Probability of earthquake-induced landslide under wet (or saturated) soil conditions. In percent.
PHF_M6p8_PGD_liquefaction_wet	Permanent ground deformation due to liquefaction lateral spreading. Liquefaction assumes wet (or saturated) soil conditions, in centimeters.
PHF_M6p8_Prob_liquefaction_wet	Probability of liquefaction under wet (or saturated) soil conditions. In percent.

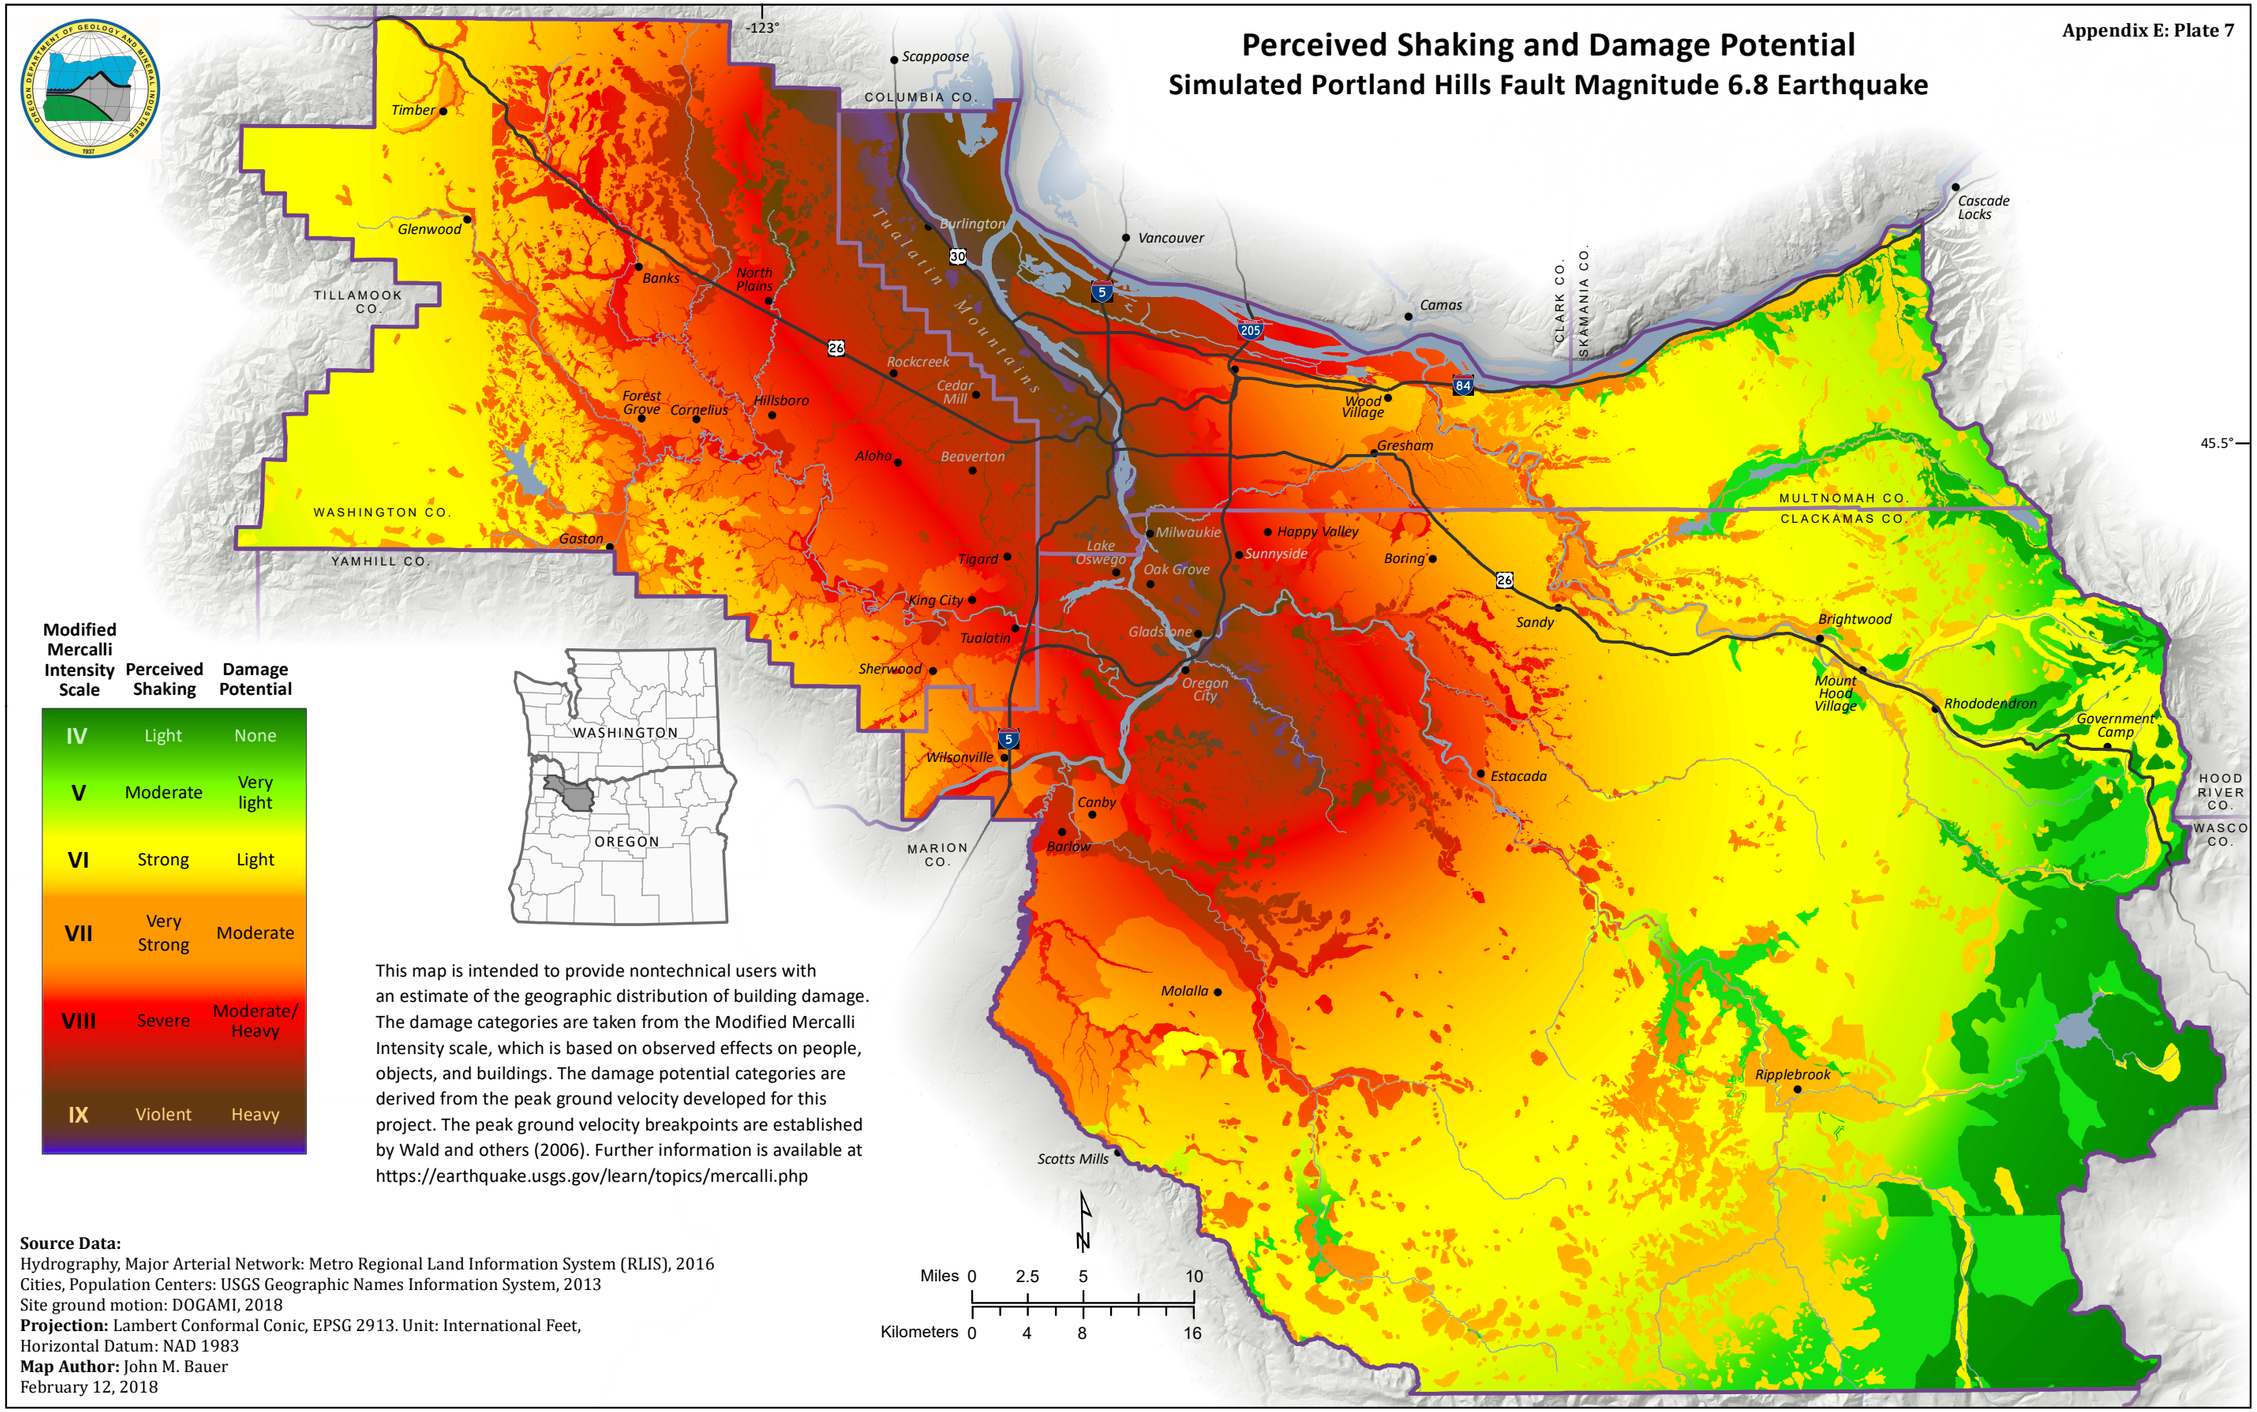
Appendix E: Plate 6

Perceived Shaking and Damage Potential

Simulated Cascadia Subduction Zone Magnitude 9.0 Earthquake



This map is intended to provide nontechnical users with an estimate of the geographic distribution of building damage. The damage categories are taken from the Modified Mercalli Intensity scale, which is based on observed effects on people, objects, and buildings. The damage potential categories are derived from the peak ground velocity developed for this project. The peak ground velocity breakpoints are established by Wald and others (2006). Further information is available at https://earthquake.usgs.gov/learn/topics/mercalli.php

Potential Impact of Permanent Ground Deformation to Metro Emergency Transportation Routes

Cascadia Subduction Zone Magnitude 9.0 Earthquake

Wet (Saturated) Soil Scenario

Closeup, Oregon Highway 8, showing potential permanent ground deformation (same color scale as main map)

Miles 0 2.5 5 10

Kilometers 0 4 8 16

Potential Permanent Ground Deformation

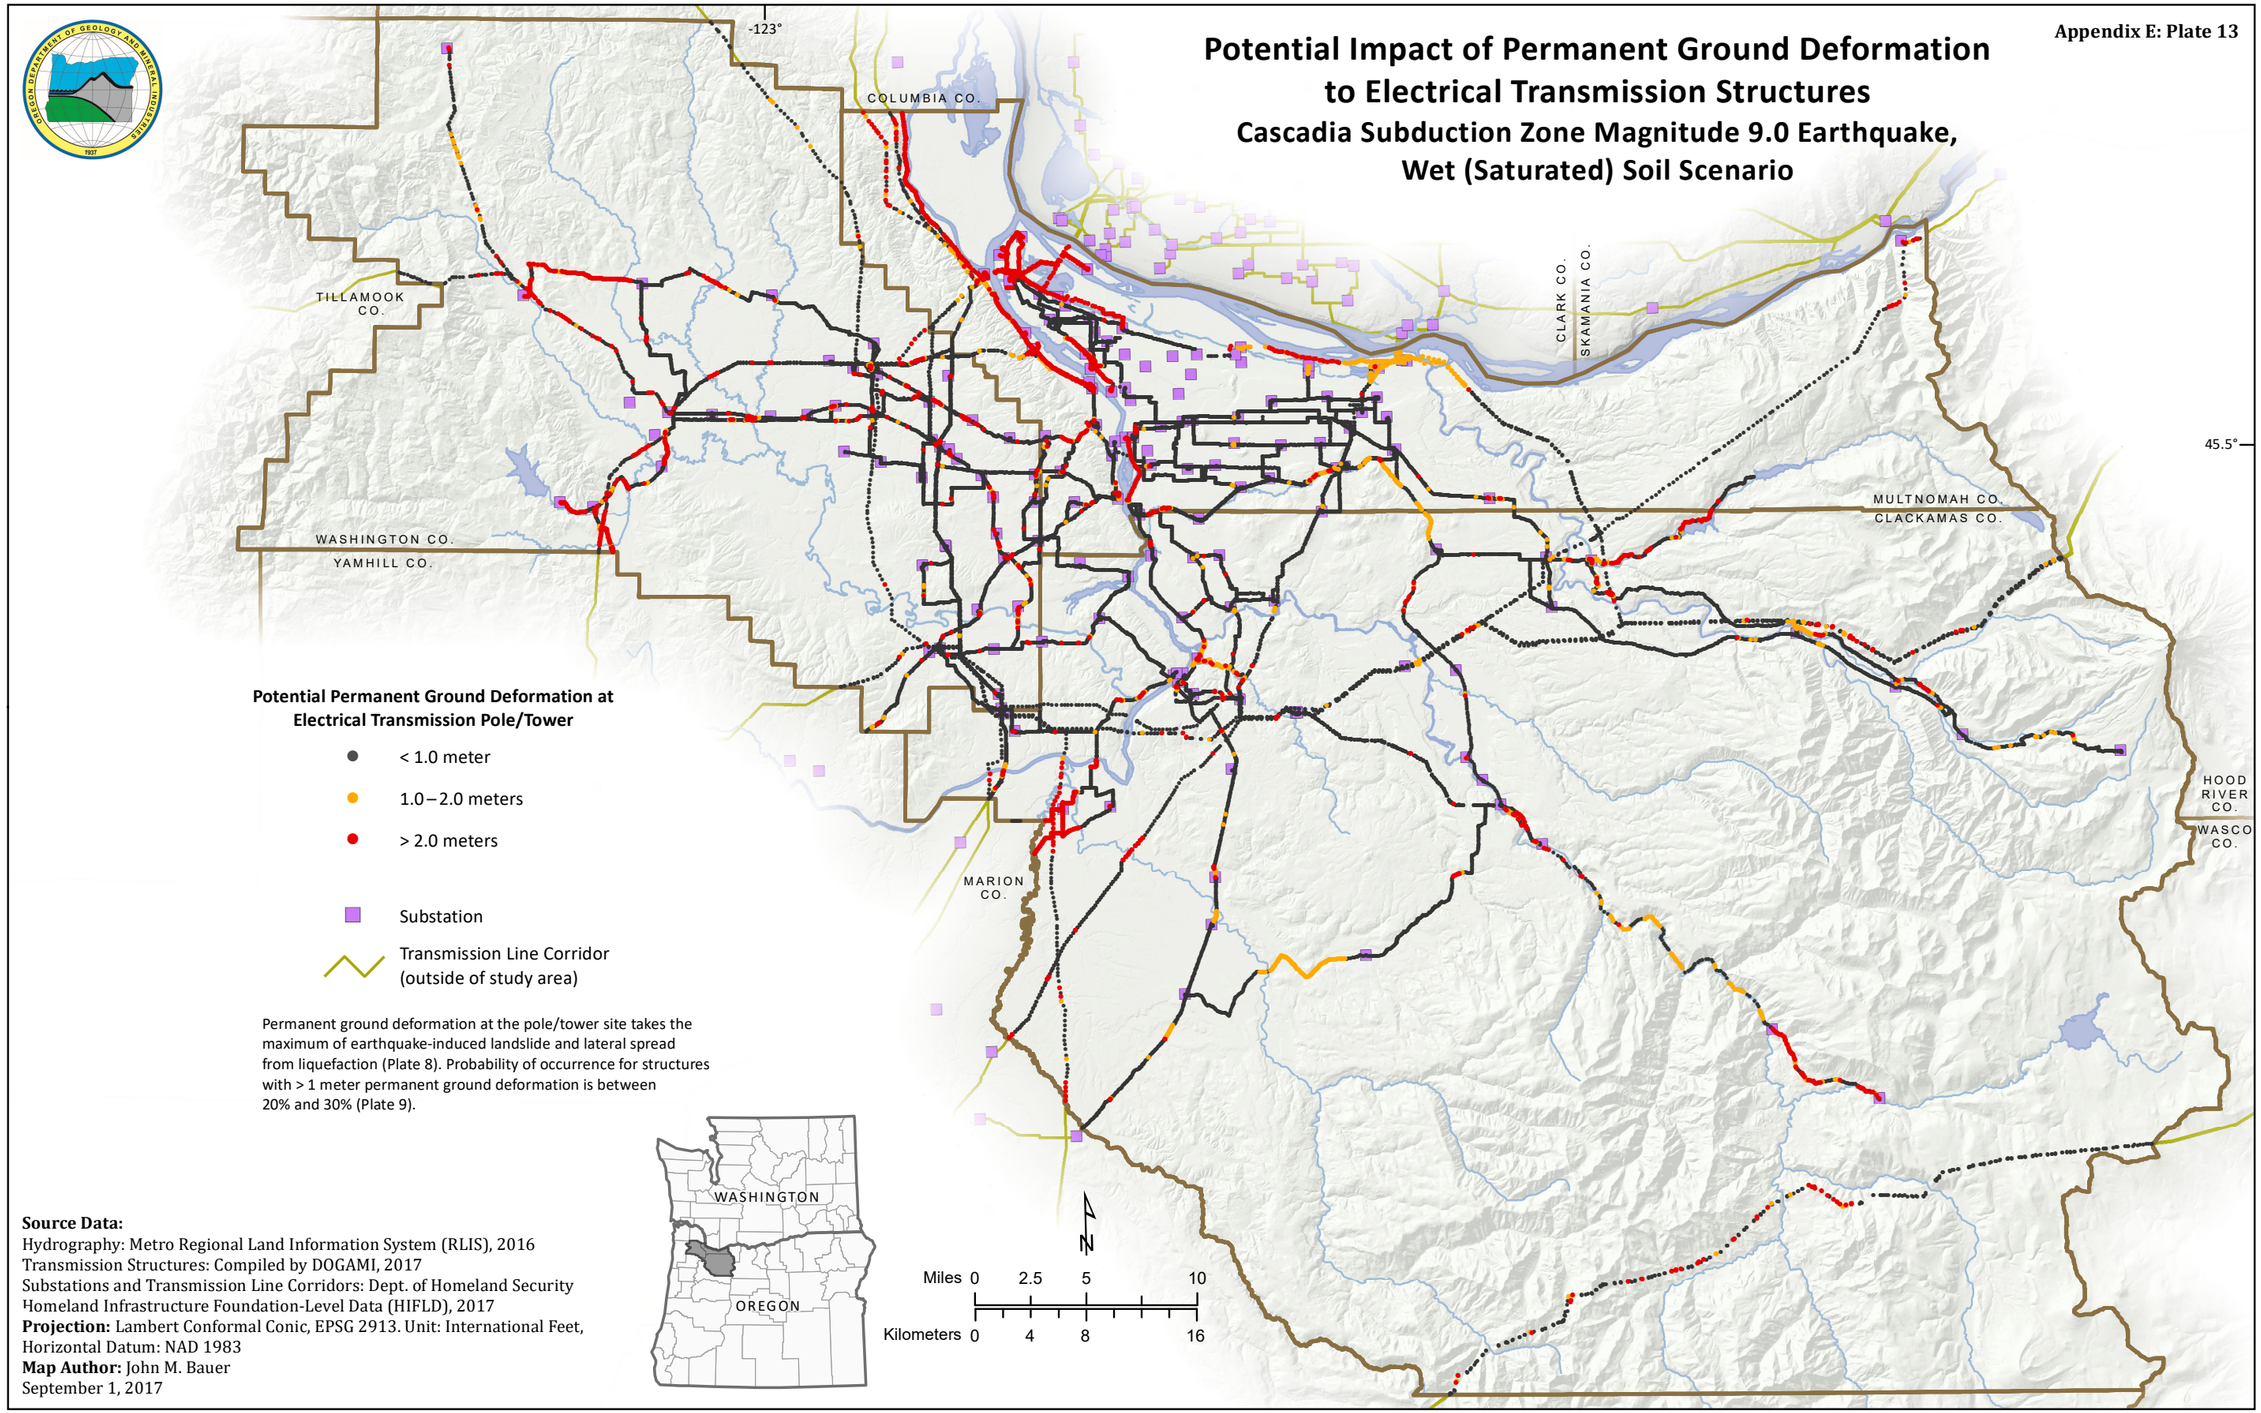
- < 0.5 meters
- 0.5 – 1.0 meters
- 1.0 – 2.0 meters
- > 2.0 meters

Permanent ground deformation takes the maximum of earthquake-induced landslide and lateral spread from liquefaction (Plate 8).

Probability of occurrence for road areas with > 0.5 m permanent ground deformation is between 20% and 30% (Plate 9).

Emergency Transportation Routes in Columbia County (OR) and Clark County (WA) not analyzed nor fully represented in this map.

Highway labels are placed on areas with minimal to no ground deformation (< 0.5 m).



Not all cities are labeled.

NW Natural

2018 Integrated Resource Plan

LC-71

UG-170911

Compression at Miller Station Study

Mist was originally built with 80,000 Dth/day of maximum deliverability in 1989, which grew to 190,000 Dth/day by 2000. The core portion of Mist has now grown to 305,000 Dth/day, and future Mist recalls of course will increase that amount until it equals all of the existing Mist deliverability. Two reciprocating compressors (the "recips") were part of the original facility design in the 1980s, and two large turbine compressors (the "turbines") were added in the late 1990s and early 2000s, respectively. The recips are inefficiently sized now for the flow conditions and operations at Mist. The result is overuse of the turbines, which causes additional maintenance cost due to excessive use and deformations. NW Natural will conduct a study to determine the best solutions for compressor operations at Miller Station. The study is to be completed in 2019, and if necessary, the first phase of compressor replacement could start as early as 2020. It is estimated the study would have a total cost of $600,000.

6.2. PORTLAND LNG PLANT PROJECTS

The Portland LNG plant (also referred to as "Gasco") was constructed by Chicago Bridge and Iron and commissioned in 1969. As a resource specifically used for peak shaving, NW Natural requires high availability and reliability from Gasco. The facility and its major process components were designed for a nominal 25- to 30-year life, and it is now almost 50 years old.

Several mechanical and operational issues have been identified within the facility, and an in-depth engineering, economic, and alternatives analysis is underway. Contingent on the results of this analysis, NW Natural will identify and move forward with the best combination of solutions to address the issues. Two potentially significant issues — the facility's liquefaction system and cold box heat exchangers — are described below.

NW Natural retained an engineering consultant to study the existing liquefaction and pretreatment systems. This study is still in progress, and along with internal analysis by NW Natural, will identify which refurbishment and/or replacement options are best for the plant. The consultant's liquefaction study is expected to run through 2018 at a total cost of $850,000. Contingent on the results of this study and internal analysis, NW Natural will proceed with refurbishment or replacement of the liquefaction and associated system.

The other significant issue identified at Portland LNG is that the facility's cold box heat exchangers — original to the plant — no longer function reliably. The cold box was not designed to process current pipeline deliveries with their higher concentration of NGLs (as mentioned in Section 4.4), which condense in unintended parts of the heat exchanger. This causes the production rate to decrease, fouls the liquid separation system, and periodically requires a complete shutdown and blow down to clear the system, leading to downtime in the liquefaction process. Contingent on the results of the internal evaluation of the facility, NW Natural may have to replace the pretreatment system with a modern system designed to process current gas streams, and replace the cold box, associated appurtenances and instrumentation, boil off compressors, and glycol system heat exchangers. It is estimated that these replacements could have a total cost of roughly $40 million.

compressors which causes additional maintenance cost due to excessive use and deformations.
- Study to be completed in 2019. First phase of compressor replacement will take place in 2020 and 2021.
- $600,000 in 2019.

Instrument and Controls Upgrade (Phase 2)
- Upgrade flow computers at Miller Station and the I/W wells. This involves replacing 37 total systems.
- Current systems are at end-of-life.
- Planning and execution phases will both be in 2019.
- Estimated cost $200,000 (out of a total estimated cost of $1.1 million).

2.2 PORTLAND LNG PLANT PROJECTS[2]

This section discusses NW Natural's plan for capital projects at the Portland LNG plant (this facility also is referred to as "Gasco"). The Portland LNG projects are typically performed within the facility boundaries. They encompass the replacement of mechanical process equipment used for the liquefaction, vaporization, or storage of LNG.

Fire and Gas System
Additional gas and fire sensors were added throughout the facility in 2017. This was based on the result of a third-party study.
- Installed a high resolution articulated camera on top of the tank to monitor the relief stacks.
- Installed new relief stacks, which direct venting upward instead of horizontal.
- $360,000

Replace Piping Insulation
Removed and replaced deteriorated insulation on part of the liquefaction piping system in 2017.
- $326,000

Replace H-6 Vaporizer
Replaced H-6 vaporizer and associated control system in 2017.
- $2.8 million

Replace Mole Sieve
Replaced pretreatment system mole sieve in 2017.
- $105,000

[2] Estimated or actual costs related to Portland LNG projects do not include construction overhead (COH).

Process Instrumentation
Installed two gas chromatographs and combination CO_2 moisture analyzer in 2017.

- $220,000

Cold Box Cleaning
Dust has settled in sections of the cold box causing periodic plugging which requires system shutdowns.

- Purge and clean cold box internal aluminum heat exchangers in 2018.
- The cold box will be purged with gas to push particulate out of the system.
- Estimated cost $150,000

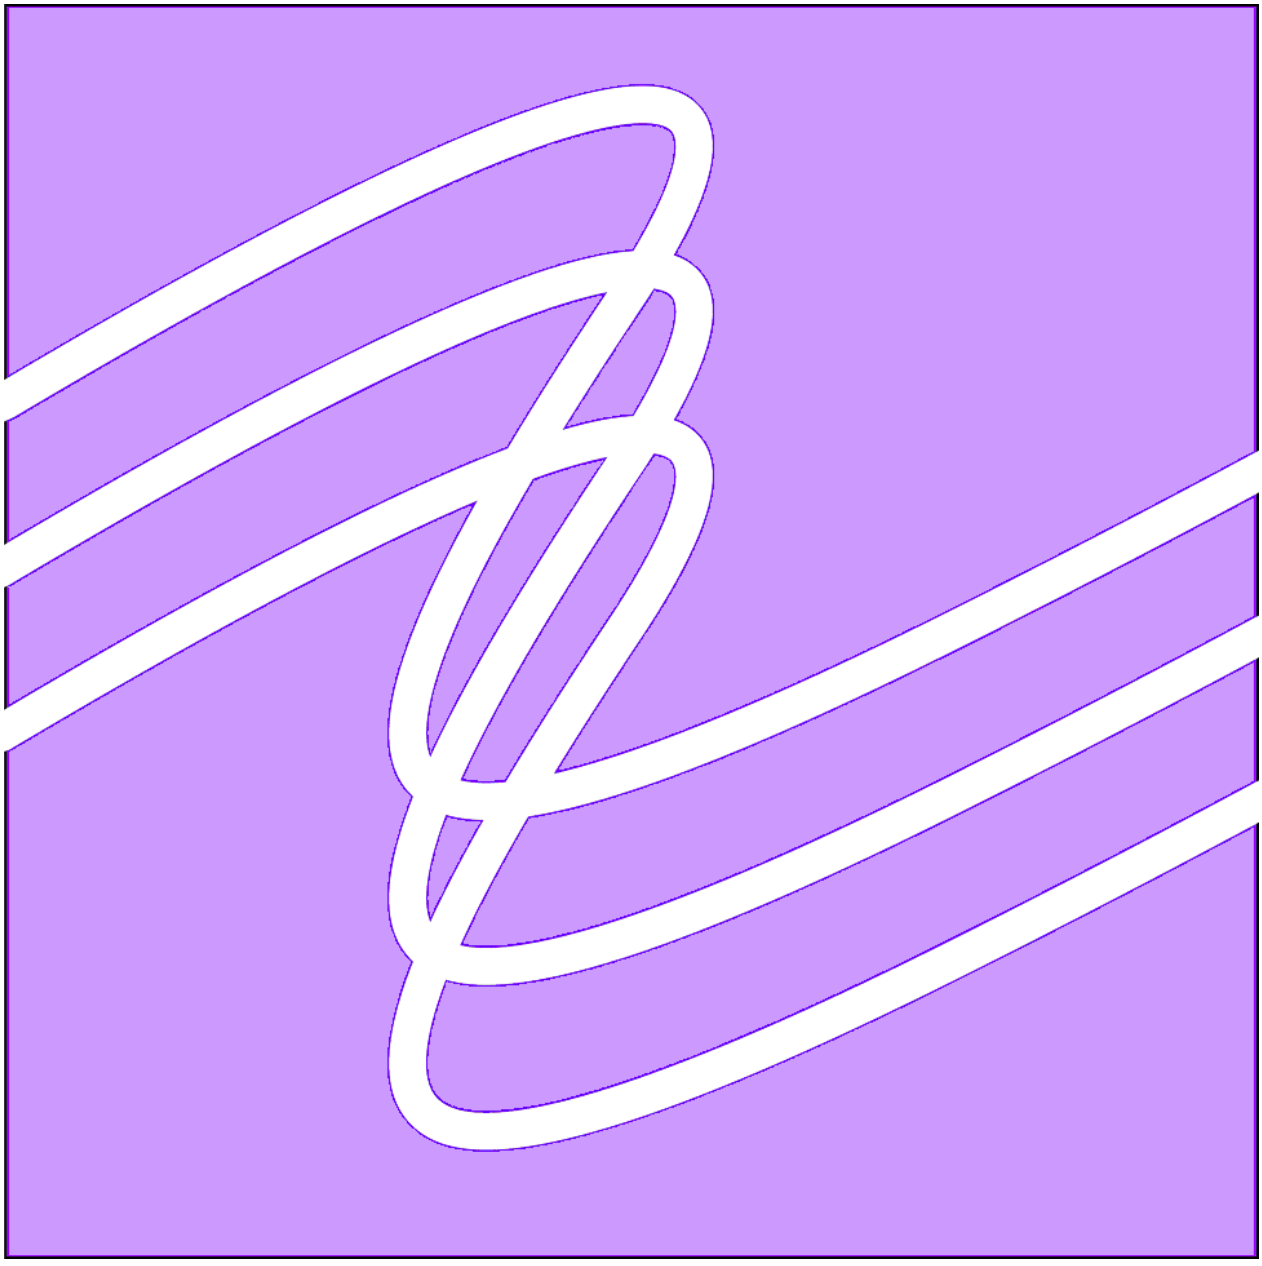
Note that the cold box is the core of the liquefaction process at Portland LNG and critical to the entire plant.

Tank Impoundment
Design and construct a liner to be installed in T-1 impoundment area in 2018. This liner will separate contaminated ground water from comingling with rain water. This will reduce total contaminated ground water in the impoundment, enabling the discharge of clean water into the Willamette River.

- Estimated cost $5.5 million

Liquefaction System Study
Retained a consulting engineering company to study the existing LNG plant's liquefaction and pretreatment systems. The study will clarify what replacement and refurbishment options are suitable for the facility.

- Estimated cost $850,000
- Results of this study may lead to other capital projects in ensuing years such as:
    - Replace H-7 vaporizer controls (estimated cost $2 million).
    - Replace liquefaction and associated system (very roughly estimated cost $40 million).
    - Tank seismic study (estimated cost $300,000).
    - Cyber security and control building (estimated cost $5 million).



2.3 NEWPORT LNG PLANT PROJECTS[3]

This section discusses NW Natural's plan for capital projects at the Newport LNG facility. The Newport LNG projects are typically performed within the facility boundaries. They encompass the replacement of mechanical process equipment used for the liquefaction, vaporization, or storage of LNG.

[3] Estimated or actual costs related to Newport LNG projects do not include construction overhead (COH).

Executive Summary

Executive Summary

INTRODUCTION

Preserving and enhancing the efficiency of Oregon's freight system is essential to supporting economic development and the quality of life in Oregon. Whether it is carrying goods from Oregon manufacturers, farmers and other producers to markets, or delivering goods to homes and workplaces, the movement of freight supports the daily functioning of the state's businesses and residents. In 2008, manufacturing, agriculture, construction and retail trade (freight-dependent industries) provided 700,000 jobs and generated $29 billion of personal income.[1] Transportation and warehousing accounted for another 70,000 jobs and $3.2 billion of personal income.

This plan provides a roadmap for the Oregon Department of Transportation (ODOT), other state and local agencies, tribal governments and the private sector to work together to preserve and enhance the state's freight system. Implementation of the OFP will ensure a future freight system that supports diverse industrial sectors, including both traditional resource-based industries (like agriculture and forestry) and the modern high-tech sectors. It will be a system that ensures the safety of its users, connects businesses with their supply chains and global markets and provides steady employment while incorporating stewardship of natural resources.

[1] U.S. Bureau of Economic Analysis, Regional Economic Accounts, State Economic Profiles.

Oregon Transportation Plan Vision

> *By 2030, Oregon's transportation system supports people, places and the economy. We travel easily, safely and securely, and so do goods, services and information. Efficient vehicles powered by renewable fuels move all transportation modes. Community design supports walking, bicycling, travel by car and transit wherever appropriate. Our air and water are dramatically cleaner, and community sensitive and sustainable transportation solutions characterize everything we do.*
>
> *Oregonians and visitors have real transportation choices and transfer easily between air, rail, motor vehicles, bicycles and public transportation while goods flow just in time through interconnected highway, rail, marine, pipeline and air networks. Our communities and economies – large and small, urban and rural, coastal and mountain, industrial and agricultural – are connected to the rest of Oregon, the Pacific Northwest and the world. Land use, economic activities and transportation support each other in environmentally responsible ways.*
>
> *We excel in using new technologies to improve safety and mobility. We maximize the use of existing facilities across traditional jurisdictions and add capacity strategically. Public/private partnerships respond to Oregonians' needs across all transportation modes. Transportation system benefits and burdens are distributed fairly, and Oregonians are confident transportation dollars are being spent wisely. By 2030, Oregonians fully appreciate the role transportation plays in their daily lives and in the region's economy. Because of this public confidence, Oregonians support innovative, adequate and reliable funding for transportation.*

The OFP is a multimodal topic plan as required by the 2006 *Oregon Transportation Plan* (OTP). The OTP Vision defines the kind of transportation future we want to build and the outcomes we want to achieve. As an element of the OTP, the OFP will implement the OTP Vision.

The OTP includes a general discussion of freight in its identification of goals, policies and strategies for the state's multimodal transportation system and calls for the development of strategies and actions to implement the freight goals and policies of the OTP.[2] The OFP focuses more specifically on the economic benefits that a strong freight transportation system will support.

[2] The *Oregon Transportation Plan* is available online at: https://www.oregon.gov/ODOT/Planning/Pages/Plans.aspx

Oregon Freight Plan Vision

By 2035, Oregon benefits from a reliable, multimodal freight transportation system that supports its quality of life. This multimodal freight transportation system supports a healthy economy by safely and efficiently moving goods within Oregon, regionally, nationally and internationally. The quality, dependability and efficiency of Oregon's multimodal freight transportation system encourage businesses to remain in and move to Oregon, providing jobs in a diverse set of industries.

PURPOSE STATEMENT

A Freight Plan Steering Committee of freight industry and public sector stakeholders guided the development of the *Oregon Freight Plan (OFP)*. The committee developed the following purpose statement that helps focus the OFP vision:

The purpose of the Oregon Freight Plan is to improve freight connections to local, Native American, state, regional, national and global markets in order to increase trade-related jobs and income for workers and businesses.

To achieve the purpose statement, the *Oregon Freight Plan*:

- Supports identifying, prioritizing and facilitating investments in Oregon's highway, rail, marine, air and pipeline transport infrastructure to advance a safe, seamless multimodal and interconnected freight system;
- Identifies institutional and organizational barriers to an efficient and effective freight transportation system in Oregon, and develops strategies for addressing issues associated with overcoming these barriers; and
- Adopts strategies for implementation of OTP goals and policies related to the maintenance and improvement of the freight transportation system.

PLAN DEVELOPMENT

The OFP was developed with the involvement of a diverse group of organizations and stakeholders, including the Oregon Transportation Commission (OTC); the OFP Steering Committee; the Oregon Freight Advisory Committee (OFAC); other freight transportation, industry, land use and environmental experts; tribal governments; regional and local governments; and

other stakeholders. The process by which the OFP was developed is described in more detail in Chapter 1.

The OFP is informed by a series of topical technical papers developed in coordination with the Working Groups and Steering Committee during 2009 and 2010.

Using this technical input and with the guidance of the Steering Committee and Working Groups, the OFP was developed to:

- Describe the economic structure of the state's freight industries and the freight infrastructure that supports these industries and movements;
- Analyze impacts of potential changes in commodity flows, the economy and other factors on the freight system;
- Discuss possible implications of climate change on freight movements;
- Present options for financing the state freight system and for evaluating the relative importance of undertaking specific improvements that would enhance freight movement; and
- Present strategies for ensuring a safe, efficient and sustainable freight transportation system.

THE OREGON ECONOMY

Understanding the structure of the Oregon economy and how it will grow and change in the future is critical for understanding the needs of the state's freight transportation system because:

- The industries that comprise the economy and their supply chain and logistics systems determine the type of freight services that will be required.
- The growth of the overall economy and specific industry sectors will determine future freight demand and the growth rate for modal services.
- The relative economic growth by region will determine where freight modes will experience demand and where new connections to the freight system will be required.

Two key indicators of the future health of the Oregon economy, Gross State Product (GSP) and employment are projected to grow over the next 25 years. Oregon's GSP, a measure of the value added to products and services by all Oregon businesses and industries, is projected to top $310 billion,[3] by 2035

[3] Real GSP in year 2000 dollars.

growing by 121 percent.[4] Total non-farm employment in Oregon is projected to grow to 2.19 million jobs by 2035, an increase of 34 percent from 2009. Slower growth in employment as compared to GSP is an indication of a shift in the Oregon economy to higher value products and increasing labor productivity. This means that demand for freight transportation may grow faster than employment and come from different industrial sectors than it has in the past.

The Oregon Office of Economic Analysis (OEA) estimates that Oregon is the ninth most trade-dependent state in the nation.[5] The ranking illustrates the importance of export-oriented sectors, such as computer and electronics manufacturing, logistics and distribution, and processed foods to the Oregon economy.

Freight transportation demand is not only driven by the needs of Oregon's businesses. Growth and changes in the age and incomes of the state's population also determine consumer demands that must be supported by the freight system. Oregon's population is projected to grow approximately 34 percent between 2009 and 2035.[6]

4 Data from the Oregon Office of Economic Analysis (OEA), IHS Global Insight November 2009 data.

6 The U.S. Census Bureau's projection to 2030 and Oregon's Office of Economic Analysis projection to 2030 differ by only 1.5 percent or about 57,000 people.

FREIGHT TRANSPORTATION DEMAND AND NEEDS OF OREGON INDUSTRIES

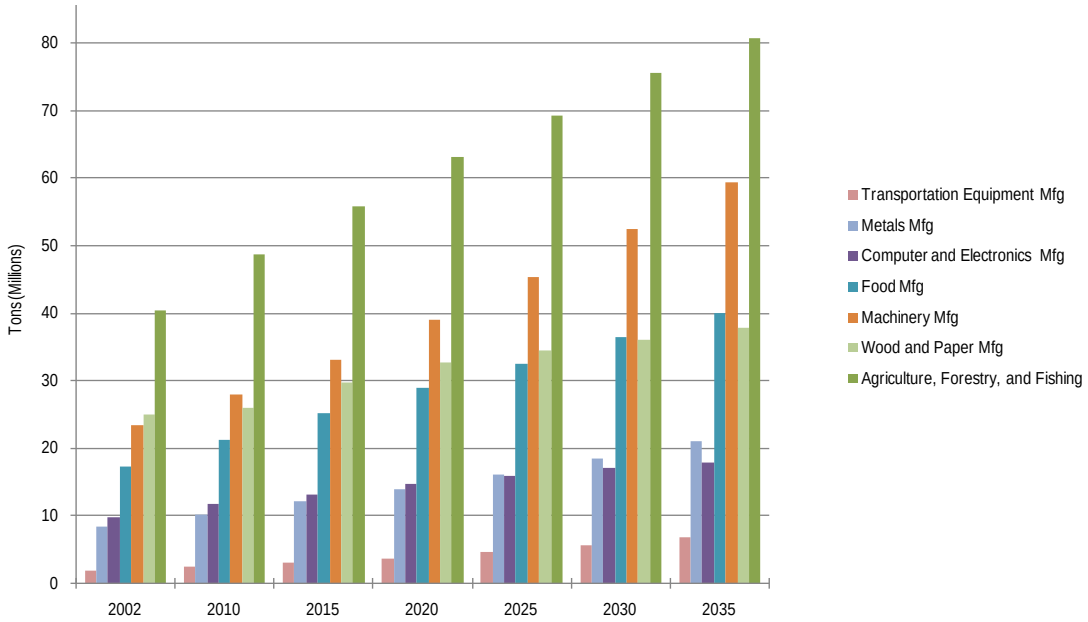
Analysis identified eight industries that represent freight-dependent industries that contribute significantly to Oregon's economy:

- High value product industries:
  - 1) Computer and electronics manufacturing; and
  - 2) Wholesale trade, footwear, apparel and recreation products.
- General manufacturing industries:
  - 3) Metals manufacturing;
  - 4) Machinery manufacturing;
  - 5) Food manufacturing; and
  - 6) Transportation equipment manufacturing.
- Natural resource-dependent industries:
  - 7) Agriculture, forestry, and fishing; and
  - 8) Wood and paper manufacturing.

In addition to these industries, the OFP analysis also identified the transportation, logistics and distribution industry as a critical freight-dependent industry cluster.

The growth of these industries, their products and the supplies they require explains the mix of commodities that will be shipped in the Oregon freight system, the modes that will experience growth in demand and the freight corridors that will see the most growth in freight traffic. A larger population will also increase demand for consumer goods.

Observations about anticipated future modal freight demand in Oregon include the following:



- The value of freight movements shows a steeper increase in value than tonnage as the economy continues its shift to higher value products.
- Trucking will continue to be the dominant mode for freight transport reflecting the shift towards higher value products, greater time sensitivity in product movements, and the ability of trucks to reach all parts of the state. This will create increasing demand on the state's highways and local roads, and metropolitan congestion will become an increasing concern for key industries.

- High level of rail demand from growth in consumer goods that are shipped by long haul intermodal and bulk commodity shipments through the state's seaports may create capacity issues. This could affect important industries in the state, such as the wood product and transportation equipment manufacturing industries, and may cause highway maintenance issues if these products are diverted to trucking.
- Substantial increase in airfreight is expected and will require improved access to major cargo airports.

Figure ES.1 highlights the anticipated growth in tonnage shipments of key industries. The industries currently responsible for the highest tonnage of shipments (agriculture, forestry and fishing; machinery manufacturing; and, food manufacturing) are expected to experience the highest growth.

Figure ES.0.1 Key Oregon Industries – Projected Growth of Related Commodity Tonnage with Oregon Origin*

2002 to 2035

Source: Oregon Commodity Flow Forecast data, October 2009.

*Retail trade and wholesale trade were not included in the tonnage overview.

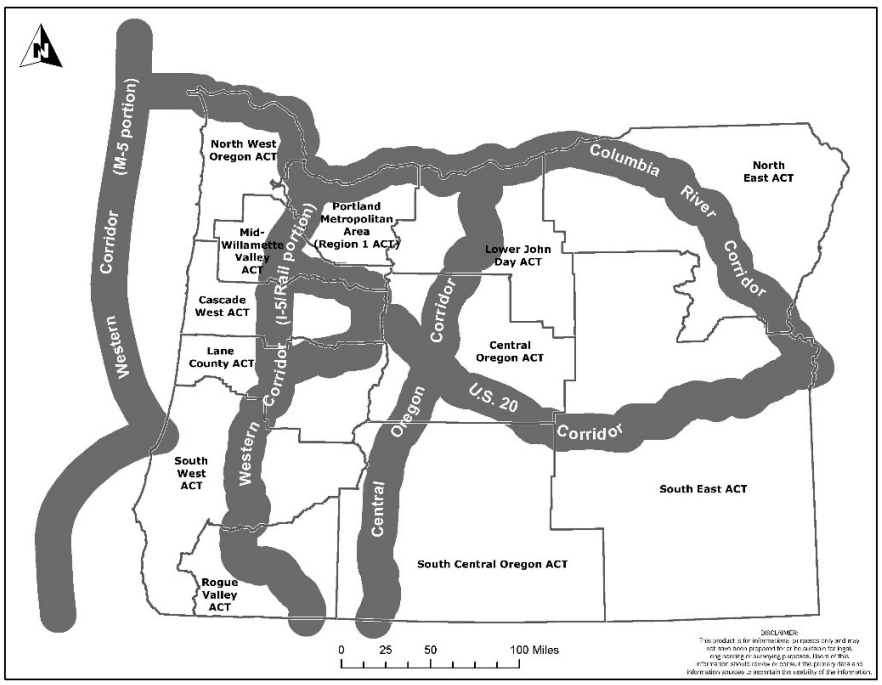
While tonnage is a better indicator of the impact that product shipments have on the state's freight system, the value of shipments is an important indicator of the impact that an industry's shipments have on the economy. Viewed from this perspective, computer and electronics manufacturing contributes most to the value of shipments and is expected to continue to experience high growth. The major categories of freight-dependent industry sectors have their own unique

transportation and logistics requirements, and a well-functioning freight system will need to meet all of these needs.

A survey for the OFP of shippers and carriers identified a number of critical issues:

- Highway congestion on major freight corridors, particularly within the Portland area and on major connector routes to airports, seaports, and freight terminals, affect many Oregon industries adding costs and uncertainty to shipments.
- Growing rail congestion on mainlines and at terminals and declining shortline services could limit the ability of the state to fully realize the potential of its rail system.
- Necessary road and bridge size and weight restrictions makes it critical to ensure that there is connectivity and redundancy in corridors that experience relatively high volumes of permitted truck loads. Lack of highway system redundancy, in certain major freight corridors, makes the state's freight system vulnerable to disruptions caused by weather, the need to move nondivisible loads in key corridors and congestion/safety related delays.
- Lack of rural highway infrastructure or motor carrier services to support rural shippers remains a critical issue in certain parts of the state where natural resource-based shipments occur.
- Lack of designated truck routes and maintenance of truck routes, particularly off the state highway system, can create gaps in the freight system and limit access via "last mile" connections to major freight terminals.
- Increased demand for urban and waterfront industrial land supply to support freight-dependent industries, such as wood and paper manufacturing, may conflict with residential and commercial developments in the same real estate markets. A focused effort to protect industrial land throughout the state is important to maintain Oregon industry competitiveness and viability.

THE FREIGHT SYSTEMS



Freight mobility in Oregon is provided by a multimodal network that includes highways, local roads, rail, air, marine and pipeline operations. The transportation system includes the following infrastructure:

- 7,441 miles of state highways,
- 4,664 miles of other state roads,
- 26,861 miles of county roads,
- 10,011 miles of city roads,

- 38,666 miles of other government-owned roads,
- 2,086 miles of privately-owned route miles of rail track,
- 314 miles of publicly-owned rail track,
- 1,126 miles of Class I carrier operated rail track,
- 1,274 miles of Class III shortline-operated railroad track,
- 18 Class I railyards,
- Five deep-draft marine ports,
- Four shallow-draft marine ports,
- Numerous private marine terminals,
- 31 Category I, II, and III airports, and
- Nine pipelines to move petroleum and natural gas.

To ensure a long-term competitive advantage for Oregon freight-dependent industries, the OFP identifies a strategic network of multimodal freight corridors. This system has been developed with a focus on the strategic routes and modes used by the important freight-dependent industries to support their supply and distribution chains. The OFP defines multimodal corridors that include these strategic routes based on the value and tonnage of freight carried and connections to centers of economic activity. Figure ES.2 illustrates these corridors described in Chapter 4.

Figure ES.0.2 Freight Strategic Corridors in Oregon

FREIGHT AND CLIMATE CHANGE

According to the EPA, transportation sources account for one-third of carbon dioxide emissions which contribute to global climate change.[7] Research and policy have historically focused on reducing GHG emissions from passenger vehicles. However, freight sources are increasingly being considered due to their contribution to carbon dioxide, nitrogen oxides, sulfur dioxide and particulate matter emissions. The Transportation Research Board found that the conveyance of freight—via rail, commercial trucks, ships, boats and pipelines—accounts for 38 percent of all transportation-related carbon dioxide emissions[8] or 12 percent of all man-made sources. Thus, addressing freight emissions and efficiency has the potential for long-term effects on GHG emissions and public health parameters.

7 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2006, Table 2-14

8 "Potential Impacts of Climate Change on U.S. Transportation" (TRB 290), Table B-2

FUNDING

Federal, state and local governments provide much of the funding for freight transportation system improvements including highways, airports and certain marine port facilities. The private sector provides funding for those elements of the transportation system that are privately owned and operated, including marine terminals, pipelines and rail lines. Governments and the private sector sometimes work together in public-private partnerships to fund freight transportation improvements.

The state has shown foresight in the development of an array of multimodal funding sources, many of which involve partnerships with federal, local and private sources and across a number of different state agencies to leverage all available funding. For example, the Multimodal Transportation Fund (also known as *Connect*Oregon) is a model program that has supported numerous non-highway freight investments and that other states have sought to emulate.

The OFP presents a number of potential funding opportunities that should be explored. These include:

- Existing federal funding and financing programs that Oregon could take greater advantage of, such as:
  - CFR Title 23, Section 129 loans,
  - Transportation Infrastructure Finance and Innovation Act (TIFIA) credit assistance, and
  - Grant Anticipation Revenue Vehicles (GARVEE) bonds.
- State funding sources such as:
  - *Connect*Oregon,
  - Oregon Jobs and Transportation Act (JTA),
  - Oregon Transportation Improvement Acts (OTIAs), and
  - Public-private partnerships.

Chapter 6 discusses these funding sources in detail along with a number of other potential alternatives that would need to be authorized at the federal level and looks towards potential changes and opportunities for funding freight projects through programs that may be incorporated in reauthorized federal surface transportation funding legislation. Chapter 9 discusses the funding sources that were included in the Fixing America's Surface Transportation (FAST) Act.

ISSUES AND STRATEGIES

Analysis and outreach efforts supporting the development of the *Oregon Freight Plan* have identified a number of issues that need to be addressed in order to ensure that Oregon has an efficient and sustainable freight transportation system that continues to support economic growth. These issues are summarized below.

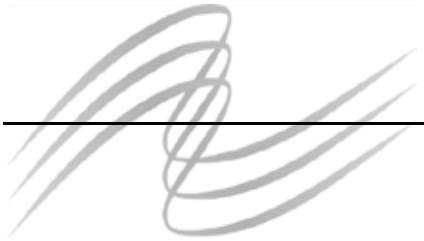
- Issue 1. A clearly defined, multimodal "Strategic Freight System," is essential in order to focus freight system improvements, maintenance and protection on the freight corridors that play the most critical role in supporting the state's economy. Currently, this does not exist.
- Issue 2. Capacity constraints, congestion, unreliability, and geometric deficiencies in key highway, rail, air and marine freight corridors cause inefficiencies in statewide freight movement.
- Issue 3. Congestion and unreliable travel time on roads to access major intermodal facilities can cause disruptions to freight movement and industry supply chains.
- Issue 4. Improvements to the efficiency, reliability and safety of long-haul freight corridors require collaboration between Oregon and neighboring states in the region.
- Issue 5. Changes to the physical dimensions of a highway may either accommodate or restrict permitted loads throughout the entire state and can cause connectivity issues to key businesses and freight generating activities.
- Issue 6. Freight needs to be able to move throughout the state in a manner that is as safe as possible. Its movement may impact safety in Oregon communities and to the environment.
- Issue 7. Industrial land supply for freight-dependent land uses may be insufficient to meet future demand. Lack of necessary land use protections may threaten the viability of freight transportation systems.
- Issue 8. Freight emissions include pollutants such as GHGs and particulate matter that contribute to climate change and health risk concerns.
- Issue 9. National Environmental Policy Act (NEPA) review procedures and permitting requirements for freight projects involve complexities that, if overlooked, can result in negative impacts to project development and implementation cycles.
- Issue 10. New and emerging safety, security and environmental regulations, though beneficial, can be confusing to shippers and carriers and be expensive to implement.

- Issue 11. The freight system in Oregon lacks system redundancy in several key locations. This leaves it vulnerable to disruptions that threaten freight system continuity, especially during emergencies.
- Issue 12. Lack of a sustained source of statewide freight funding decreases the ability of the public sector to plan for long- and medium-term freight needs in a comprehensive manner.
- Issue 13. Limited availability of state transportation funds means that use of existing sources of funding must be effectively optimized.
- Issue 14. The lack of a continuous federal freight funding source makes it very challenging for Oregon to implement the ongoing planning and programming of freight projects. Those projects that are of regional or national significance should be eligible for federal participation and funding.
- Issue 15. The economic importance of freight is not always understood or appreciated by the public.

For each freight issue, Chapter 8 details strategies and actions that Oregon can use to implement the plan.

Plan Implementation

Implementation of the OFP strategies and actions will build on the planning framework established in the OTP and other modal and topic plans. This will include working with a variety of public agencies and private sector stakeholders through existing and new partnerships. Implementation of some of the strategies and actions can be accomplished in the short-term while others will require commitments over the longer term. Some may require legislative action or action by other governmental entities. Implementation will occur in phases and will require coordination with efforts to update other plans such as the modal and topic plans as well as regional and local transportation system plans. Funding availability will be critical to implementing many of the strategies and associated actions.



Some implementation actions can start soon after the plan is adopted. These include the following:

- Develop an Implementation Plan using the OTP key initiatives and *Oregon Freight Plan* purpose statement to provide a framework.
- Continue discussions to update Oregon's transportation finance structure with stakeholders and the public.
- Develop performance measures and analytical tools for plan implementation.

- Seek freight stakeholder input on bottlenecks or choke points on the Strategic Freight System.
- Communicate the bottlenecks or choke point locations to infrastructure owners.

Introduction

1.0 Introduction

1.1 OVERVIEW OF THE PLAN

Preserving and enhancing the efficiency of Oregon's freight system is essential to supporting economic development, prosperity and the quality of life in Oregon. Whether it is carrying goods from Oregon manufacturers, farmers and other producers to markets, or delivering goods to homes and stores for consumption, the movement of freight supports the daily functioning of the state's businesses and residents. In 2008 freight-dependent industries like manufacturing, agriculture, construction and retail provided 700,000 jobs and generated $29 billion of personal income.[9] Transportation and warehousing accounted for another 70,000 jobs and $3.2 billion of personal income.

Anticipated growth in Oregon's population, freight volumes and resulting congestion highlight the need to plan for transportation system improvements to meet requirements of shippers, carriers and other freight system stakeholders. Oregon's population is forecast to increase from 3.4 million people in 2000 to 5.2 million by 2035.[10] In 2008, roughly 389 million tons of freight worth about $242 billion moved on Oregon's transportation system.[11] These values are projected to grow to 651 million tons of freight worth $554 billion by 2035, even after taking the impacts of the recent recession into account.[12,13] This growth will increase infrastructure and capacity needs and impact industries, communities and the natural environment.

10 Oregon Office of Economic Analysis Forecasts of Oregon's County Populations and Components of Change, 2000-2040. Release: April 2004. Website: https://www.oregon.gov/das/OEA/Pages/forecastdemographic.aspx

11 These values do not include freight movements that do not have an Oregon origin or destination.

12 Oregon Commodity Flow Forecast data. Prepared by Parsons Brinckerhoff using FAF2 commodity flow data, October 2009.

13 At the time of the OFP adoption by the OTC in 2011, Oregon was still recovering from the 2009 recession. The plan and data presented within the plan take into account the expected impacts of the 2009 recession on future freight growth. However, growth values are best estimates. Chapter 7 discusses general impacts on freight under several scenarios, including higher and lower than expected growth.

The *Oregon Freight Plan* (OFP) expresses a 25-year vision of a freight system that supports diverse industrial sectors, including both traditional resource-based industries (like agriculture and forestry) as well as the modern high-tech sectors. The freight system connects Oregon to the rest of the global supply chain while at the same time ensuring that all regions of the state have access to quality transportation services. It is a system that ensures the safety of its users while maintaining a sustainable future – socially sustainable, providing for the physical needs of the residents of the state; economically sustainable, providing steady employment and financing the transportation system; and, environmentally sustainable, incorporating stewardship of natural resources.

The OFP brings together issues affecting all freight-related modes of transportation and proposes strategies to maximize the effectiveness of the multimodal freight system. The OFP:

- Describes the economic effect of the state's freight-dependent industries, and the freight infrastructure that supports these industries and movements;
- Analyzes impacts of potential changes in commodity flows, the economy and other factors of the freight system;
- Discusses possible implications of climate change on freight movements;
- Presents options for financing the state freight system and for evaluating the relative importance of undertaking specific improvements that would enhance freight movement; and
- Presents strategies for creating and improving a safe, efficient and sustainable freight transportation system.

As a statewide plan adopted by the Oregon Transportation Commission (OTC), it will guide the Oregon Department of Transportation's (ODOT) freight-related actions and investments and guide freight planning in state, regional and local plans.

Oregon Transportation Plan Vision

> *By 2030, Oregon's transportation system supports people, places and the economy. We travel easily, safely and securely, and so do goods, services and information. Efficient vehicles powered by renewable fuels move all transportation modes. Community design supports walking, bicycling, travel by car and transit wherever appropriate. Our air and water are dramatically cleaner, and community sensitive and sustainable transportation solutions characterize everything we do.*
>
> *Oregonians and visitors have real transportation choices and transfer easily between air, rail, motor vehicles, bicycles and public transportation while goods flow just in time through interconnected highway, rail, marine, pipeline and air networks. Our communities and economies – large and small, urban and rural, coastal and mountain, industrial and agricultural – are connected to the rest of Oregon, the Pacific Northwest and the world. Land use, economic activities and transportation support each other in environmentally responsible ways.*
>
> *We excel in using new technologies to improve safety and mobility. We maximize the use of existing facilities across traditional jurisdictions and add capacity strategically. Public/private partnerships respond to Oregonians' needs across all transportation modes. Transportation system benefits and burdens are distributed fairly, and Oregonians are confident transportation dollars are being spent wisely. By 2030, Oregonians fully appreciate the role transportation plays in their daily lives and in the region's economy. Because of this public confidence, Oregonians support innovative, adequate and reliable funding for transportation.*

The OFP is a multimodal topic plan as required by the 2006 *Oregon Transportation Plan* (OTP). The OTP Vision defines the kind of transportation future we want to build and the outcomes we want to achieve. As an element of the OTP, the OFP will implement the OTP Vision.

The OTP includes a general discussion of freight and calls for the development of the OFP to further its freight goals and policies.[14] The OFP focuses on the economic benefits that a strong freight transportation system will support.

[14] The *Oregon Transportation Plan* is available online at: https://www.oregon.gov/ODOT/Planning/Pages/Plans.aspx

Oregon Freight Plan Vision

By 2035, Oregon benefits from a reliable, multimodal freight transportation system that supports its quality of life. This multimodal freight transportation system supports a healthy economy by safely and efficiently moving goods within Oregon, regionally, nationally and internationally. The quality, dependability and efficiency of Oregon's multimodal freight transportation system encourage businesses to remain in and move to Oregon, providing jobs in a diverse set of industries.

Oregon Freight Plan Initiation and Development

Over the last 20 years, ODOT and other state agencies have addressed freight in statewide multimodal, modal and topical transportation plans, including the 2006 *Oregon Transportation Plan* (OTP). The OTP includes a general discussion of freight in its identification of goals, policies and strategies for the state's multimodal transportation system. The OTP recommends that other multimodal, modal/topic and system plans further define the OTP's broad goals, policies, strategies and investment scenarios.[15] The OFP responds to this recommendation by taking freight planning in the state to the next level. It is the first plan at the state level focused entirely on the improvement of the freight system. The OFP builds on efforts of the OTC, the Oregon Freight Advisory Committee (OFAC), the state's ports, shippers, railroads and other public and private stakeholders.

Oregon's Freight Plan Purpose and Implementation Statements

A Freight Plan Steering Committee (See Appendix A) of executive-level industry and public sector stakeholders guided the development of the OFP. The committee developed the following purpose statement for the Plan that focuses the OFP vision:

The purpose of the Oregon Freight Plan is to improve freight connections to local, Native American, state, regional, national and global markets in order to increase trade-related jobs and income for Oregon workers and businesses.

[15] Volume 1 of the OTP contains detailed information on OTP goals, policies, strategies and investment scenarios.

To achieve the state's freight planning goals, the *Oregon Freight Plan*:

- Supports identifying, prioritizing and facilitating investments in Oregon's highway, rail, marine, air and pipeline transport infrastructure to further a safe, seamless multimodal and interconnected freight system;
- Identifies institutional and organizational barriers to an efficient and effective freight transportation system in Oregon, and develops strategies for addressing issues associated with overcoming these barriers; and
- Adopts strategies for implementation of OTP goals and policies related to the maintenance and improvement of the freight transportation system.

As the guiding statement for the *Oregon Freight Plan* process, the purpose statement recognizes that freight system efficiency supports the competitiveness of the state's industries by providing more efficient access to domestic and international markets. Market competitive industries contribute to economic growth across the state. Finally, the OFP furthers the goals of the OTP, including the development of strategies to make freight movements more efficient and to lessen the impact on Oregon's communities and natural environment.

Freight Impacts

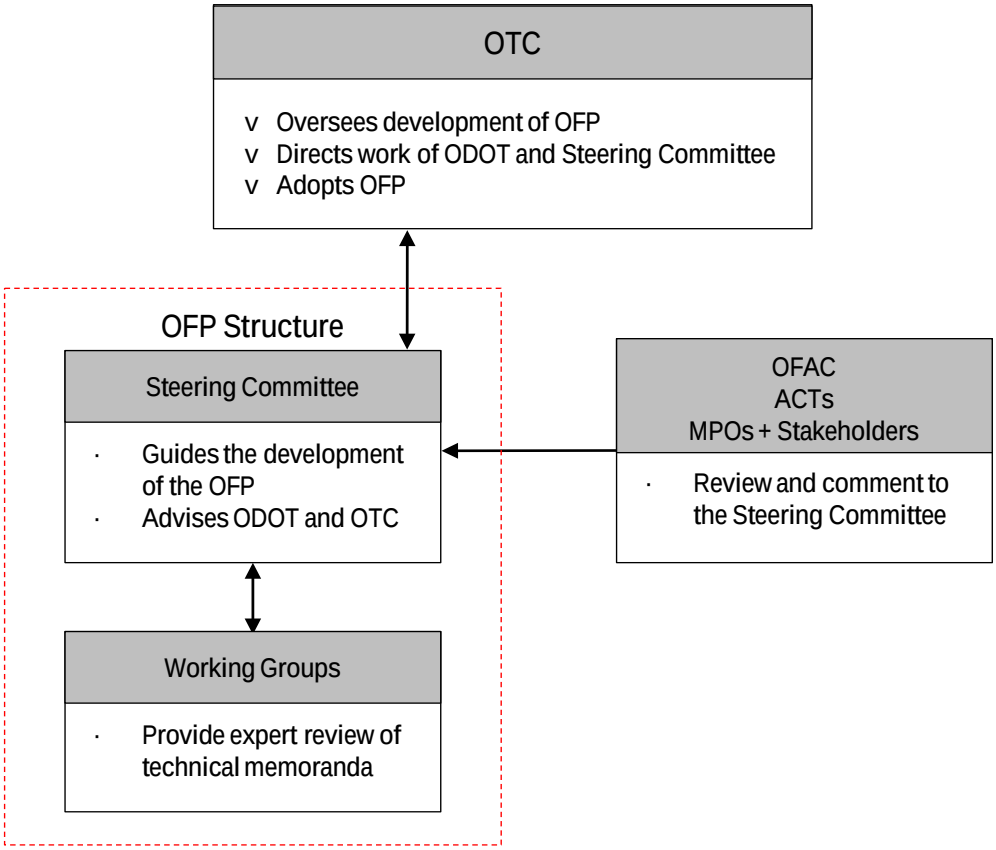
Development of the OFP required input by private and public stakeholders as a result of the vast impact of freight on communities, regions and the state. Public sector stakeholders rely on freight to support local, regional and state industries; provide jobs to constituents; and maintain a high standard of living. Private sector stakeholders rely on freight movements to and from various markets in an efficient and affordable manner. In turn, public and private stakeholders decisions affect the freight system and surrounding communities. The relationships between public and private sector actions and the freight system are briefly summarized in Figure 1.1.

Figure 1.1 Stakeholder Roles and Relationships

	How Stakeholders Impact Freight
Local Government	· Design and maintain local roads · Route of truck traffic through local communities · Make land use decisions that impact where freight-dependent industries are located and that impact how freight will interact with the community · Develop a local vision for portions of highways that also serve significant local needs · Work with railroads, trucking firms, shipping lines and others on the mitigation of impacts to the environment and communities
Regional Agencies and Groups (includes MPOs and ACTs)	· Support statewide decision-making by prioritizing and supporting selection of necessary regional transportation and freight projects · Consider local/regional transportation and freight issues if they impact the state system · Recommend (ACTs) or direct (MPOs) projects in their area or jurisdiction to receive federal funds
Port Authorities (Marine and Airports)	· Improve freight efficiency by managing and maintaining key intermodal freight facilities such as ports and airports, which improves economic opportunity and quality of life in the region and state. Ports and airports rely on the surface transportation infrastructure provided by railroads and road authorities to move goods.

State Agencies	· Plan for statewide improvements in the transportation and freight system · Design, construct, operate and maintain multimodal state facilities
Tribal Governments	· Consult with Tribal governments throughout the statewide and metropolitan planning and programming processes (23 USC 134 and 23 USC 135)
Private Sector	· Creates economic demand that generates freight traffic · Select modes and distribution patterns which will impact freight system efficiency, local/regional/state economies, environment and other critical factors

Source: Prepared by Cambridge Systematics, Inc. for the Oregon Freight Plan



As a result of different levels of government jurisdiction over freight infrastructure, conflicts can arise. For example, a local community's decision to develop a pedestrian oriented streetscape that does not adequately support truck traffic impacts the efficiency and the quality of the regional and state freight system. This makes communication and cooperation among stakeholder groups essential.

Plan Development[16]

The Oregon Transportation Commission, OFP Steering Committee, other freight transportation, industry, land use and environmental experts, regional and local governments and other stakeholders were involved in the development of the *Oregon Freight Plan* (Figure 1.2). Groups included the following:

[16] Information on the consultation process associated with the 2017 amendment can be found in Appendix A.

Figure 1.2 Stakeholder Groups Involved in the Development of the OFP[17,18]

- The Oregon Transportation Commission. The OTC, a five-member commission appointed by the Governor, establishes state transportation policy and is responsible for guiding the planning and management of Oregon's transportation system. This includes adoption of the OFP as a component of the OTP. The OTC played a leadership role in the development of the freight plan by convening the OFP Steering Committee, monitoring plan progress and providing input on plan content, strategies and decisions. A commissioner chaired the Steering Committee.
- The Freight Plan Steering Committee. The Steering Committee, which included executive-level freight, industry, community and transportation professionals from around the state, provided overall direction to ODOT for development of the OFP, its contents and its strategies. Appendix A provides a list of Steering Committee members.

[17] See text below and Appendix E – Glossary for an explanation of acronyms.

[18] Information on the consultation process associated with the 2017 amendment can be found in Appendix A.

- Freight Plan Working Groups. Three Working Groups provided expert review of the technical memoranda prepared by consultants. Lists of Working Group members are provided in Appendix A.
- The Oregon Freight Advisory Committee. The OFAC is a multimodal advisory committee made up of shippers, carriers, intermodal operators and public agency representatives created by the state legislature to advise the OTC and ODOT about freight issues and high priority freight projects. OFAC work was instrumental to the development of this OFP. Several of the OFAC members were members of the OFP Steering Committee and Working groups. In addition, the OFAC discussed updates to the status of the freight plan at its quarterly meetings.
- Oregon Area Commissions on Transportation. The ACTs are advisory bodies of local and regional officials and other stakeholders chartered by the OTC; the 11 ACTs cover all parts of Oregon except the Portland Metro area and Hood River County. They provide comment on transportation plans and play an important advisory role in the State Transportation Improvement Program (STIP) in establishing area project priorities. Information and studies completed by the ACTs were consulted during the creation of this plan. Appendix B provides a list of ACTs.
- Oregon Metropolitan Planning Organizations. MPOs are responsible for planning, programming and coordinating federal transportation investments in Oregon's largest urbanized areas. Appendix B provides a map of MPOs in Oregon.
- Topical Technical Papers. The OFP has been informed by a series of topical technical papers developed in coordination with the Working Groups and Steering Committee during 2009 and 2010.

1.2 POLICY AND LEGAL CONTEXT OF THE PLAN

Consistency with Oregon Statewide Transportation Plans

Oregon Transportation Plan and Statewide Modal and Topic Plans

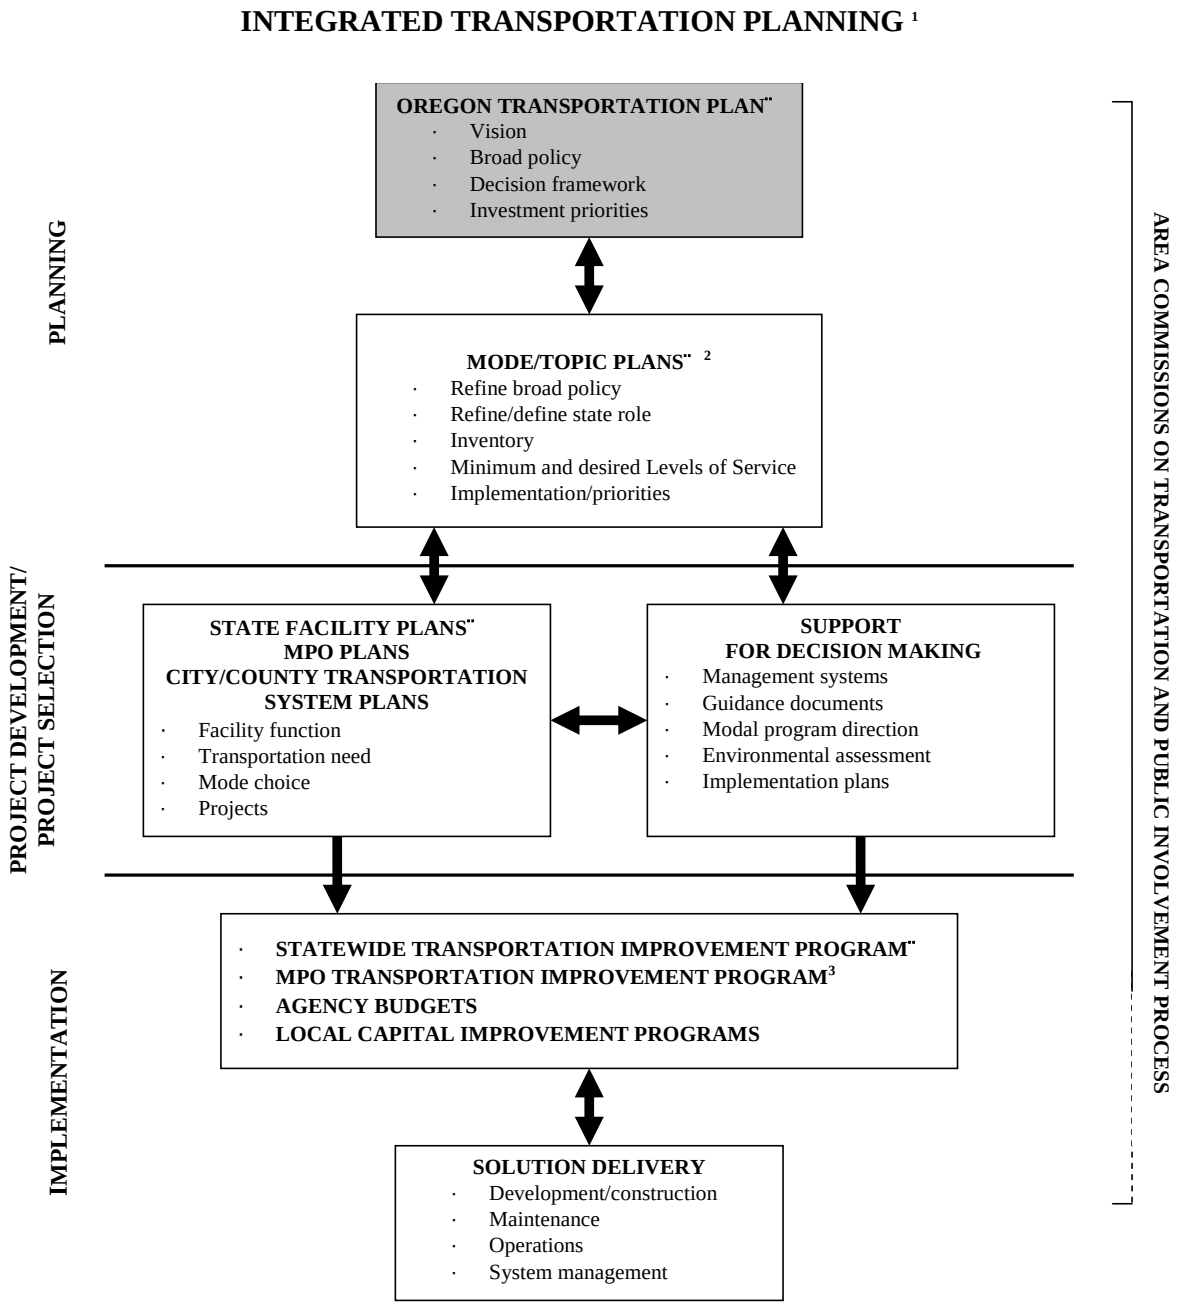
The OFP is one of several statewide transportation plans that further define and implement the OTP's goals, policies, strategies and investment scenarios. The freight plan helps the OTC fulfill its responsibilities under Oregon Revised Statute (ORS) 184.619(1). Appendix C details how the Oregon Freight Plan meets consistency and other requirements for multimodal, modal and topic plans, as specified in the OTP.

In addition to helping define and implement the OTP, the freight plan complements and helps to implement various statewide modal/topic plans,

including the Aviation Plan, Highway Plan, Ports Strategic Plan, Rail Plan and Transportation Safety Action Plan. See Figure 1.3.

Federal Requirements

Federal Regulations



Like the OTP, the *Oregon Freight Plan* is required to comply with federal requirements. This includes:

- The planning regulations stipulated in the federal Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU);
- The Passenger Rail Investment and Improvement Act (PRIIA) of 2008; and
- The Federal Aviation Administration (FAA) policy and guidance for aviation system planning.

Appendix C provides a detailed discussion of relevant federal legislation and requirements that apply to the *Oregon Freight Plan* and describes how the OFP maintains consistency with these requirements.[19]

[19] Chapter 9 details how the plan is consistent with MAP-21and the FAST Act.

Figure 1.3 Relationship of Integrated Transportation Planning to the OTP and Statewide, Regional and Local Transportation Plans

¨ Oregon Transportation Commission action.
1. Influenced by the Transportation Planning Rule.
2. Aviation, Bicycle/Pedestrian, Freight, Highway, Public Transportation, Rail, Transportation Safety Action.
3. MPO TIPs must be included in ODOT's STIP without modification. To ensure state priorities are considered, ODOT must be involved in the MPO planning project selection process.

Source: Prepared by ODOT

Oregon State Requirements

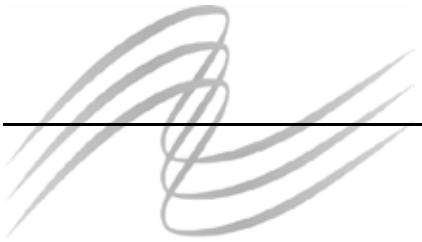
The Land Conservation and Development Commission (LCDC) has adopted 19 statewide land use planning goals that express Oregon's goals on land use, transportation, economic development and related topics. To implement Goal 12, Transportation, the LCDC adopted the Transportation Planning Rule (TPR), which requires ODOT to prepare a state transportation system plan (TSP) that identifies a system of transportation facilities and services adequate to meet identified state transportation needs. The *Oregon Freight Plan* is part of the state TSP. Regional and local transportation plans, in turn, must be consistent with the state TSP. This requirement extends the *Oregon Freight Plan's* influence to local and regional freight planning.

To facilitate coordination of land use planning activities among various governmental entities, Oregon statutes require that state agencies prepare coordination programs. ODOT's coordination program establishes procedures that ODOT uses to ensure compliance with statewide planning goals in a manner compatible with acknowledged city, county and regional comprehensive plans. Appendix C provides *Oregon Freight Plan* findings of compliance with the State Agency Coordination Program and statewide planning goals.

Oregon Transportation Commission Public Involvement Policy

To assist in meeting state and federal public participation requirements for statewide planning processes and the STIP development, the OTC has adopted a public involvement policy for the commission and ODOT activities.

The public involvement process for the *Oregon Freight Pl*an was consistent with the OTC's public involvement policy and included periodic briefings and discussions at OTC meetings, *Oregon Freight Plan* Steering Committee and Working Group meetings, quarterly updates at OFAC meetings, newsletters on the freight plan website, meetings with stakeholder groups and interested parties to solicit comments and coordination internally within ODOT and with other governmental agencies. Further information on the public involvement process for the plan can be found in Appendix D.



1.3 SUMMARY OF OREGON FREIGHT PLAN CONTENTS

Plan Chapters

This OFP is organized into an executive summary and nine chapters:

- **Executive Summary.** Major findings and recommendations of the plan;
- **Chapter 1 – Introduction.** Background and overview of the OFP, including its development, the plan structure, planning compliance and public involvement;
- **Chapter 2 – Economy and Freight Demand.** Oregon's current economic structure, including major industry sectors and key goods-dependent industries and anticipated economic trends and forecasts; this is followed by an overview of commodity flows in Oregon, including weight, value, mode splits and specific freight corridors;
- **Chapter 3 – Oregon Industries and Freight Movement.** Key industries in Oregon, their contribution to statewide economic output and jobs, and their needs, issues and opportunities as they relate to the freight plan;
- **Chapter 4 – Freight Systems.** Oregon's multimodal freight network, methodology of strategic system selection and corridor connectivity;
- **Chapter 5 – Freight and Climate Change.** Discussion about the impact of climate change on freight, Oregon's actions to mitigate greenhouse gases from freight and potential additional methods to reduce freight impact on greenhouse gases;
- **Chapter 6 – Funding.** Comparison of funding resources to funding needs, and identification of opportunities for closing the funding gap;
- **Chapter 7 – Alternative Scenarios.** Overview of the impact on freight and goods movement when taking alternative economic and policy scenarios into consideration; and
- **Chapter 8 – Freight Issues and Strategies.** Recommended policy, investment, operational and institutional strategies to maintain and improve freight mobility in Oregon and further the goals of the plan.
- **Chapter 9 – Federal Compliance.** Brings the Oregon Freight Plan into compliance with the federal FAST Act.

Economy and Freight Demand

2.0 Economy and Freight Demand

2.1 INTRODUCTION

Economic growth and the composition of Oregon's economy is an important driver of freight transportation demand. This chapter describes the state's economy and factors that may affect future growth patterns, followed by a discussion of current and expected freight demand on the state's transportation network.

This chapter is divided into the following sections:

- Summary of major Oregon economic and demographic trends and the relationship between these trends and freight demand;
- Freight demand on Oregon's freight network; and
- Freight demand by Area Commissions on Transportation (ACTs).

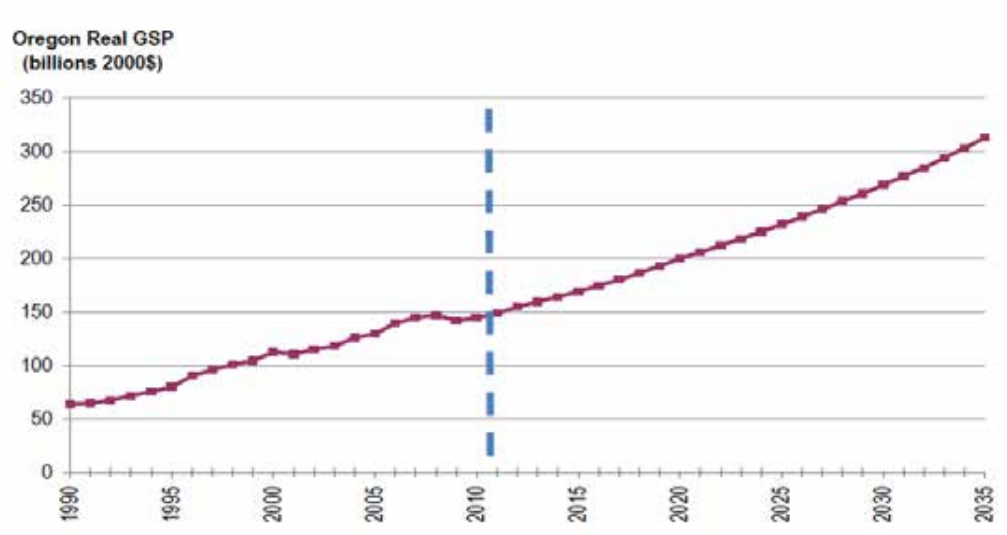
2.2 OREGON'S ECONOMY

A review of the Oregon economy – in terms of Gross State Product (GSP), employment, population growth and industry trends – is critical to understanding future demand and use of the state's freight system.

Oregon's GSP and Employment

In the long term, Oregon's GSP and employment are projected to grow. The focus of this plan is on long term trends while acknowledging near term fluctuations in growth rates. GSP, as a measure of the value added to products and services by all Oregon businesses and industries, is a broad indicator of the level and strength of economic activity in a state. Oregon's GSP was $162 billion[20] in 2008, making it the 26th largest economy among U.S. states.

Figure 2.1 shows the trend in Oregon GSP from 1990 to 2035. By 2035, Oregon's GSP is projected to top $310 billion,[21] growing by 121 percent at an



[20] Figure 2.1 shows inflation-adjusted numbers; hence the $162 billion GSP in 2008 becomes $147 billion in the comparison graphic.

[21] Real GSP in year 2000 dollars.

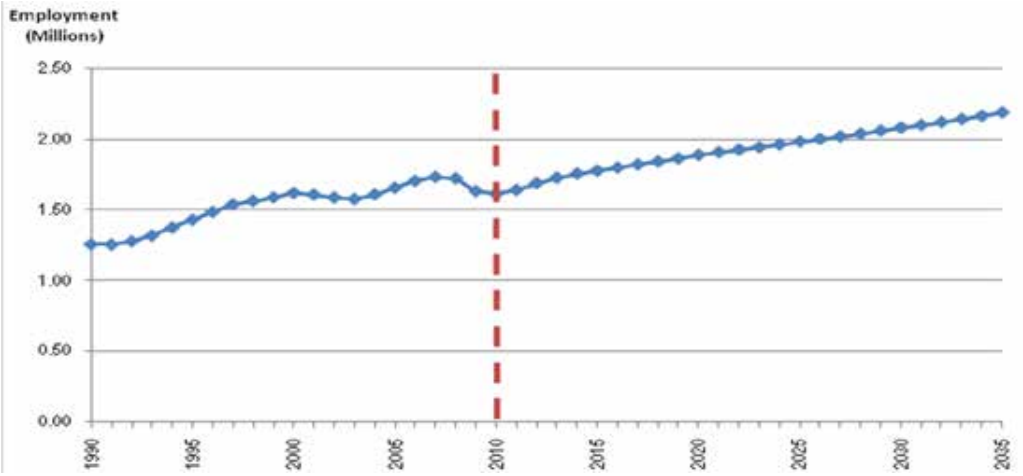
average rate of 3.1 percent between these years.[22] In comparison, the output of the U.S. economy (US GDP) is expected to grow by about 90 percent by 2035 (around 2.6 percent annually).

Figure 2.1 Oregon Real Gross State Product, 1990 to 2035

In Billions of Constant 2000 Dollars

Source: Oregon Office of Economic Analysis, IHS Global Insight November 2009.

* Blue line indicates the present.



Employment is another key indicator of economic health. Oregon's total nonfarm employment was about 1.69 million in 2009, which is a slight decline from the previous year as a result of the 2008 recession (See Figure 2.2). Total nonfarm employment is projected to grow to 2.19 million in 2035, an increase of 33 percent from 2009. The Oregon Office of Economic Analysis (OEA) forecasts that employment growth between 2009 and 2015 (forecasted to increase 9.3 percent during this time period)[23] will be slower than in the mid 1990s, but greater than the growth rate for the nation as a whole.

[22] Data from the Oregon Office of Economic Analysis, IHS Global Insight November 2009 data.

[23] Oregon Office of Economic Analysis, Oregon Economic and Revenue Forecast, September 2010.

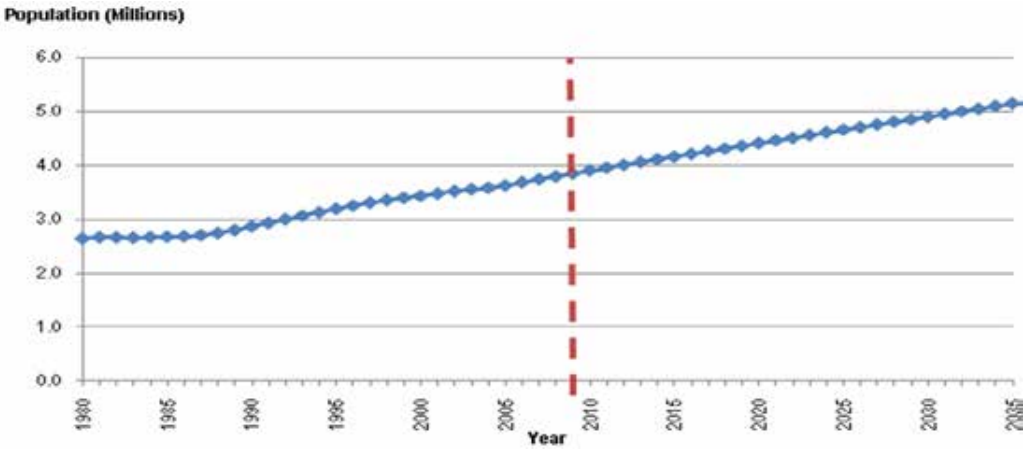
Oregon's Pronounced Economic Cycles

Oregon's economic growth rates fluctuate substantially because of the concentration of value in a few industries and the State's dependence on trade as indicated in Figure 2.3. In six of the ten years depicted, Oregon grew more rapidly than the United States as a whole, and in two of the last ten years, it grew at about the national average. In the other two years, Oregon's rate was lower than the national rate.

Figure 2.3 U.S. and Oregon Annual Real GSP Growth Rates, 1998 to 2007

Source: U.S. Bureau of Economic Analysis, U.S. Department of Commerce



Oregon's Growing and Aging Population

Population growth is another key indicator that can help predict long-term economic growth. Figure 2.4 shows that the population of Oregon is projected to grow to approximately five million by 2035.[24] Except for the Oregon coastal communities, all Oregon regions are projected to grow by 33 percent or more by 2035. The Greater Portland Metropolitan Statistical Area is projected to increase 47 percent.[25] Oregon population growth will be driven by in-migration of working age adults attracted by job opportunities in the state, and relatively lower-cost housing compared to California and the Southwest. The 2035 Oregon population is expected to include fewer children under 19, more adults aged 20 to 65, and a sharp increase in the number of residents over age 65. A growing population suggests increased consumption of goods, fueling economic growth.

[24] The U.S. Census Bureau's projection to 2030 and the Oregon's Office of Economic Analysis, 2009 projection to 2030 differ by only 1.5 percent or about 57,000 people.

[25] Oregon Office of Economic Analysis, "Oregon Economic and Revenue Forecast," May 2009.

Figure 2.4 Oregon Population, 1980 to 2035

Source: Oregon Office of Economic Analysis, IHS Global Insight November 2009.

Oregon's Productivity

The productivity of Oregon businesses and industries is forecast to remain relatively high, which creates a competitive advantage for Oregon in both domestic and international markets. Factors that impact productivity include workforce education, workers compensation rates and energy prices.

- 87 percent of Oregon residents have completed a high school or equivalent degree, ranking the state 19th in the nation; 26 percent have a Bachelor's degree or higher, ranking the state 24th; and 10 percent have completed an advanced degree, ranking the state 16th.[26]
- Oregon ranked 39th in workers compensation rates.[27]
- Oregon ranks 20th in the nation for total energy prices. Oregon spends 18.23 nominal dollars per million British Thermal Units (BTU).[28] In terms of diesel prices to power the majority of trucks and trains, Oregon also has relatively high costs. Oregon's cost per gallon of diesel was $4.29 per gallon in April of 2011, which was the seventh highest average price for diesel in the nation.[29]

Transformation of Oregon's Economy

Oregon's economy will continue to change from a resource-based economy to a high-value-added manufacturing and service economy. As shown in Figure 2.5, Oregon's top private sector industries in 2009 in terms of real GSP include durables manufacturing, real estate and rental/leasing, health care and social assistance, retail trade and wholesale trade. The manufacturing sector alone accounted for 34 percent of the state's GSP in 2009.

The OEA anticipates strong GSP growth in manufacturing. This comes as a result of increased production of high-value products such as those manufactured by the computer and electronics industry. Offshore sales and productivity gains should also contribute to the expected growth in manufacturing. Figure 2.5 compares the estimated real GSP by industry sector in 2009 with the projected real GSP by industry in 2035. The data show continued strength in professional, scientific and technical services, retail trade, wholesale trade, transportation and warehousing and other sectors.

Figure 2.5 Real GSP by Oregon Industry Sector, 2009 and 2035

In Billions of 2000 Dollars

Source: Oregon Office of Economic Analysis, IHS Global Insight November 2009.

Oregon's resource-based industries – comprised primarily of the agricultural, forestry and fishing sector – contributed approximately 3 percent to GSP. Wood products manufacturing is the second largest manufacturing subsector but accounts for only a small portion of total manufacturing value and GSP.

Oregon's Dependency on Trade and Freight Transportation

The OEA estimates that Oregon is the ninth most trade-dependent state in the nation.[30] The ranking illustrates the importance of export-oriented sectors, such as computer and electronics manufacturing, logistics and distribution and processed foods to the Oregon economy. As shown in Table 2.1 below, manufactured products, such as computers and electronics, have medium to high dependency on highway, railroad, and water/marine transportation, and for some types of products, on air transportation. While professional and technical services are generally low freight dependent, they are predominately dependent on air freight when utilizing freight options.

Table 2.1 Oregon Transportation Dependency Rating of Oregon's Top Industries

Industry Sector	Highway	Railroad	Water/ Marine	Air	Pipeline
Agriculture, Forestry and Fishing;	High	High (except fishing)	Medium	Low (except Fishing)	Low
Computer and Electronics Manufacturing;	High	Medium	Medium	High	Low
Food Manufacturing;	High	Medium	Medium	Low	Low
Machinery Manufacturing and Metals Manufacturing;	High	High	High	Medium	Low
Wood and Paper Manufacturing;	High	High	High	Low	Low
Retail Trade;	High	Medium (Except long distance)	Medium	Low	Low
Services and Other.	Low	Low	Low	Low	Low

Source: Cambridge Systematics with data from Parsons Brinckerhoff, "Relationship of Freight Transportation to Economic Development."

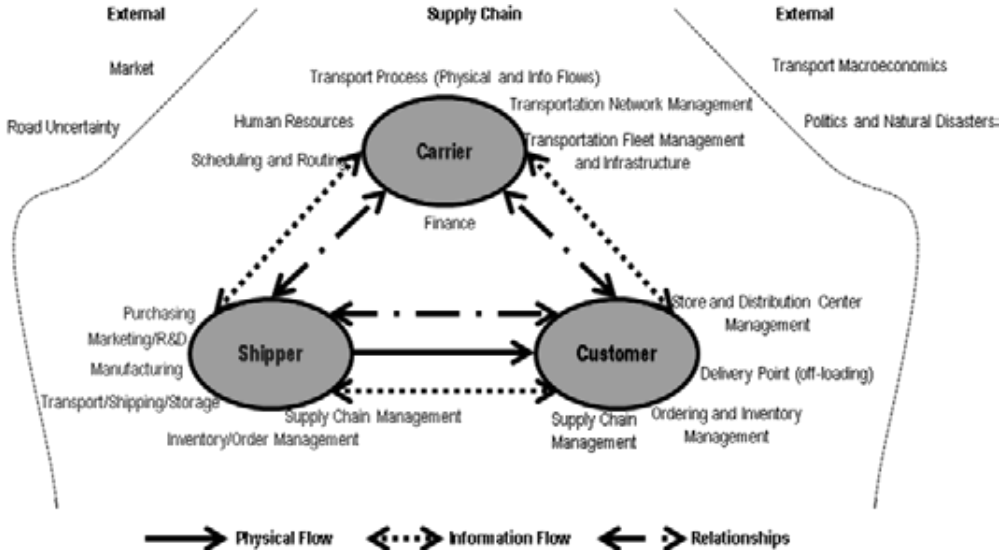
For Oregon businesses to grow, they must be able to ship goods quickly and effectively to U.S. and international markets. To retain or gain market share, Oregon businesses must be cost-competitive in both producing and shipping their goods to market. The same is true for raw materials, components and other inputs

[30] Oregon Business: https://www.oregonbusiness.com

transported to Oregon manufacturing and processing facilities. Many manufacturing businesses and other industries have adopted the just-in-time inventory strategy to reduce inventory and associated carrying costs, which requires a high degree of flexibility by suppliers. Just-in-time inventory strategies also make shipments more time-sensitive as a result of decreased inventories at production locations. In turn, reduced congestion and low travel time variability is important to facilitate businesses using the just-in-time model.

Another trend that impacts the retail trade industry is the sustained increase in online retailing, or business-to-consumer shopping. In the U.S., online retailing is forecasted to grow by 10 percent annually through 2014, with its share of total U.S. retail sales increasing from 6 percent in 2009 to 8 percent in 2014.[31] This will result in an increase in the volume of small package deliveries to homes by carriers, such as UPS, FedEx and the U.S. Postal Service. As a result of these and other trends, the future of Oregon's economy will be highly dependent on dependable, flexible and affordable freight transportation services.

2.3 FREIGHT DEMAND OVERVIEW - OREGON



Freight demand and the transportation modes chosen to accommodate this demand are driven by the characteristics of the economy that were discussed in Section 2.2. Industry growth or decline, shifting population patterns and factors such as shifting international trade and logistics patterns all influence freight demand patterns.

Where, when, how often and why businesses make freight movements is largely dependent on industry supply chains. Every shipper, carrier and customer makes decisions frequently that will affect how goods move in Oregon and thus how the surrounding environment will be impacted by freight. Figure 2.6 below highlights the complexity of variables that each player in supply chains needs to consider, in addition to outside uncertainties such as the market, transport macroeconomics, disasters and others. In this figure, the shippers, carriers and customers are shown to be the three main actors in the supply chain process. The variables directly surrounding each actor in the supply chain process (as shown in the same color font as the actor) are considerations that may impact the supply chain process, specific to that actor. External variables that may impact the supply chain process are shown in the periphery of Figure 2.6 including variables such as the market, politics and macroeconomics. Both actor-specific and external variables have an impact on the supply chain and how freight moves in Oregon.

[31] Forrester Research, Inc. Reported in Tech Crunch, March 8, 2010, at https://techcrunch.com/2010/03/08/forrester-forecast-online-retail-sales-will-grow-to-250-billion-by-2014/.

A state's commodity flow profile is, therefore, a reflection of a state's socioeconomic and population profile as well as the industries and businesses that make up the state's economy. This section will present data and observations concerning the impact of future freight demand on policy and the statewide multimodal transportation system.

Figure 2.6 Supply Chain Nodes and Internal/External Factors that Create Uncertainty of Freight Movements

Source: Diagram concept and much of the content taken from "Establishing a Transport Operation Focused Uncertainty Model for the Supply Chain" Rodrigues et al, 14th International Annual EuROMA Conference, Ankara, June 2007. Diagram content was adjusted to focus on key contributors in the supply chain for the purposes of this freight plan.

Oregon GSP and employment growth signal an increase in demand for the freight system in general. In addition, a larger population will consume more food, clothing, housing, and other household goods, increasing freight demand. As a result of these economic and demographic forecasts, the Oregon Commodity Flow Forecast estimates significant increases in total freight traffic in Oregon, as shown in Table 2.2.[32]

[32] Oregon Commodity Flow Forecast data, October 2009: http://library.state.or.us/repository/2010/201010251112531/index.pdf

2002, 2010 and 2035

	2002	2010	2035	2002 to 2035 % Growth
Weight (millions of tons)	347	403	651	88%
Value (billions of $)	213	253	554	161%

Source: Oregon Commodity Flow Forecast data, October 2009.

Freight Demand by Mode

A number of factors influence mode selection by industry and commodity. Cost of service and accessibility are key criteria when selecting mode for transport of goods. Figure 2.7 below shows the type of cargo that certain modes tend to transport. For instance, water and non-intermodal rail modes tend to ship high weight, lower value products that are not time sensitive. Heavy commodities such as gravel and lumber tend to use rail and barge. Therefore, businesses that require lower cost transportation service and are able to deal with slower shipments turn to barge and rail carload or unit trains. On the other hand, trucks generally ship lighter goods that are of higher value and more time-sensitive. Truck and intermodal rail are faster and more reliable than options with lower service costs. Finally, air cargo is used to ship the most time-sensitive and highest value cargo. The air mode represents a small but increasingly important share of total freight movements.

Figure 2.7 Freight Transportation Service Spectrum

Source: Freight Rail Bottom Line Report AASHTO.

[33] The values in this table do not include freight movements that do not have an Oregon origin or destination.

As shown in Table 2.3, all major transportation modes – air, pipeline, rail, truck and water – will see growing volumes of freight, with truck volumes growing the most in terms of total weight and value. The projected 88 percent increase in freight tonnage moving into, out of and within Oregon will place additional demands on the Oregon freight system. This number does not take into account the impact of "through" tonnage, which is also growing. As a comparison, the United States freight system is expecting a 93 percent increase in total tonnage between 2002 and 2035, with a compound annual growth rate (CAGR) of 2.0 percent.[34] Oregon's expected CAGR for tonnage moving into, out of and within Oregon is 1.9 percent, average for the nation.

Table 2.3 Oregon Freight Demand by Weight/Value (All Modes)[35]

2002, 2010 and 2035

Mode	Weight (Millions of Tons)				Value (Billions of Dollars)			
	2002	2010	2035	2002-2035 % Growth	2002	2010	2035	2002-2035 % Growth
Air	0.22	0.27	0.75	236%	12	17	56	349%
Pipeline	14	13	17	28%	3	3	4	37%
Rail	39	47	64	65%	16	17	27	76%
Truck	259	294	508	96%	159	185	406	155%
Water	35	48	60	73%	22	32	61	171%
Total	347	403	651	88%	213	253	554	161%

Source: Oregon Commodity Flow Forecast data, October 2009.

Other important observations can be made from Table 2.3:

- The value of freight movements shows a steeper increase than tonnage. The value of freight moved into, out of and within Oregon is expected to increase 161 percent between 2002 and 2035, substantially higher than the 88 percent increase in tonnage. The 2002 to 2035 CAGR of total tonnage is at 1.9 percent, while the CAGR of value of all commodities shipped is 2.9 percent. Machinery manufacturing is one of the fastest increasing commodities by value during this time period and is a high-value product, which is a likely contributor to the high increases in value moved on Oregon's freight system. This increase in higher-value commodities on the

[34] FHWA, "Freight Facts and Figures 2009," based on FAF2 data, https://ops.fhwa.dot.gov/freight/freight_analysis/nat_freight_stats/docs/09factsfigures/table2_1.htm.

[35] Table does not include commodities traveling through Oregon, without an Oregon origin or destination.

freight system implies a greater reliance on truck and air cargo and the growing importance of reliability, urban mobility and access to airports and international cargo handling facilities.

- Trucking will continue to be a dominant mode for freight transport. Although Table 2.3 shows that tonnage/value movements by rail, air and water are expected to increase substantially on a percentage basis between 2002 and 2035, truck tonnages will continue to increase the most in absolute terms (total tonnage and value). Table 2.3 also shows that truck tonnage will increase at a more rapid rate than all other modes, except air travel, which represents a small but important share of overall freight demand. Increasing truck traffic places further demands on the system and requires substantial investment in maintenance of the existing highway and road network. The growth of truck share reflects the shift towards higher value products and greater time sensitivity in product movements. With truck traffic anticipated to rise substantially in the future, roadway congestion issues, transport reliability and road access issues will be exacerbated. Roadway issues are therefore anticipated to become an even greater focus of future freight planning in Oregon.
- High rail demand may create capacity issues. The 64 percent increase in rail tonnage moving into, out of and within Oregon will create capacity issues on major corridors, especially around Portland and along the Columbia River Gorge.[36] Capacity issues will impact all industries that utilize freight rail, including the lumber and transportation equipment industries. Failure to address capacity issues may result in increased diversion of commodities to other modes[37].
- A substantial increase in airfreight by tonnage is expected. Airfreight demand in Oregon is expected to increase sharply as a result of projected increases in the high-value-manufacturing (i.e., computer and electronics products) and professional service industries. The expected 240 percent increase in airfreight between 2002 and 2035 will require improved access to airports as freight demand grows. Improving access will make it easier and more efficient for trucks to get to airports to pick up and unload cargo. Capacity for the cargo airports (primarily Portland International) is not expected to be an issue during the planning period.

[36] It should be noted that the data on rail tonnages does not include data on through movements that have neither an origin nor a destination within the state. Through tonnage and value were not available in the commodity flow data. However, through movements are discussed further in Section 4.5 of this plan

[37] Failure to address rail capacity issues will also impact efforts to increase passenger rail options.

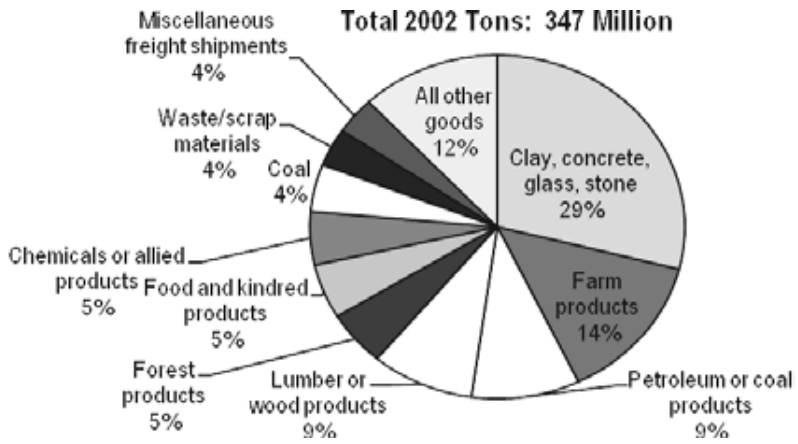
Commodity Movements and Freight Demand

Different modes are responsible for moving key commodities into, out of and within Oregon. For example, marine vessels are often used to carry heavy, low-value items, within states or between regions. Airfreight often carries low-weight, high-value goods to markets all across the world. Table 2.4 highlights the major commodities carried into, out of and within Oregon by mode in 2002 and the expected yearly growth rate of tonnage and value between 2002 and 2035.

Table 2.4 Top Commodities by Mode (Into, Out of and Within Oregon)

Compound Annual Growth Rate (CAGR) 2002 to 2035

	Top Commodities (Tonnage)	CAGR % 02-35	Top Commodities (Value)	CAGR % 02-35
Truck Freight	Clay, concrete, glass, stone	1.6%	Miscellaneous freight shipments	3.6%
	Farm products	1.9%	Non-electrical machinery	4.0%
	Lumber or wood products	0.7%	Food and kindred products	2.5%
	Petroleum, natural gas and other petroleum-based products[38]	2.3%	Electrical machinery	3.4%
	Forest products	-0.1%	Apparel/finished textile products	-0.8%
Rail Freight	Lumber or wood products	1.1%	Lumber or wood products	1.1%
	Chemicals or allied products	1.2%	Transportation equipment	2.5%
	Farm products	0.1%	Pulp, paper or allied products	1.4%
	Pulp, paper or allied products	1.4%	Miscellaneous mixed shipments	1.4%
	Miscellaneous mixed shipments	1.4%	Chemicals or allied products	1.2%
Water/ Marine Freight	Clay, concrete, glass, stone	1.2%	Non-electrical machinery	5.1%
	Farm products	2.1%	Chemicals or allied products	2.3%
	Chemicals or allied products	2.3%	Transportation equipment	0.0%
	Petroleum, natural gas and other petroleum-based products	0.4%	Farm products	2.1%
	Forest products	-1.6%	Petroleum, natural gas and other petroleum-based products	0.4%
Air Freight	Electrical machinery	4.8%	Electrical machinery	4.8%
	Food and kindred products	3.6%	Chemicals or allied products	3.6%
	Fabricated metal products	-0.7%	Misc. manufactured products	3.9%
	Chemicals or allied products	3.6%	Transportation equipment	5.7%
	Fresh fish	2.3%	Precision instruments	6.1%



[38] This commodity group includes some coal products as well.

Source: Oregon Commodity Flow Forecast data, October 2009.

While commodity group classifications used in the OFP provide sufficient detail about the types of goods moving on Oregon's freight system, the classifications used are summaries of many specific commodities. An example of commodity classification group summarization is "concrete/glass/clay/stone." The amount of tons moving on Oregon's system, for the group as a whole is known, but the percentage of tons moving for each commodity of concrete, glass, clay or stone is not known.[39] The analysis of commodity movements represents estimates based on best available data. It is important to make a note of this before attempting to understand the commodity flow data in Chapter 2 and 3. Appendix F presents detailed information on which commodities make up each commodity group.

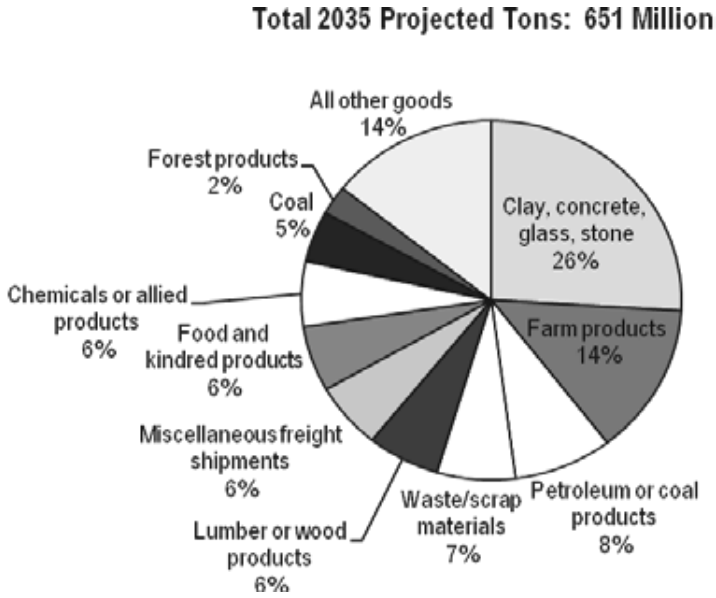
Figures 2.6 to 2.11 present an overview of the top commodities that used the freight system in 2002, by tonnage and value, compared to those that will be using the freight system in 2035.

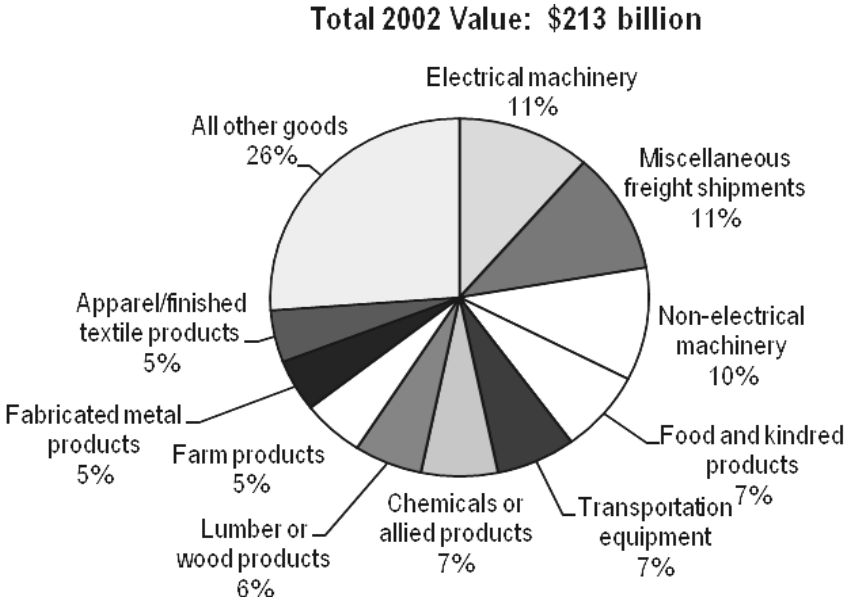
Figure 2.8 Breakdown of Commodity Shipments – Weight, All Modes, In/Out/Intra – 2002

Source Oregon Commodity Flow Forecast data, October 2009.

[39] The commodity of glass is rarely or never shipped by marine freight modes, although the analysis indicates that a certain percentage of the commodity group of "clay / concrete / glass / stone "is moved by ship.

Figure 2.9 Breakdown of Commodity Shipments – Weight, All Modes, In/Out/Intra – 2035





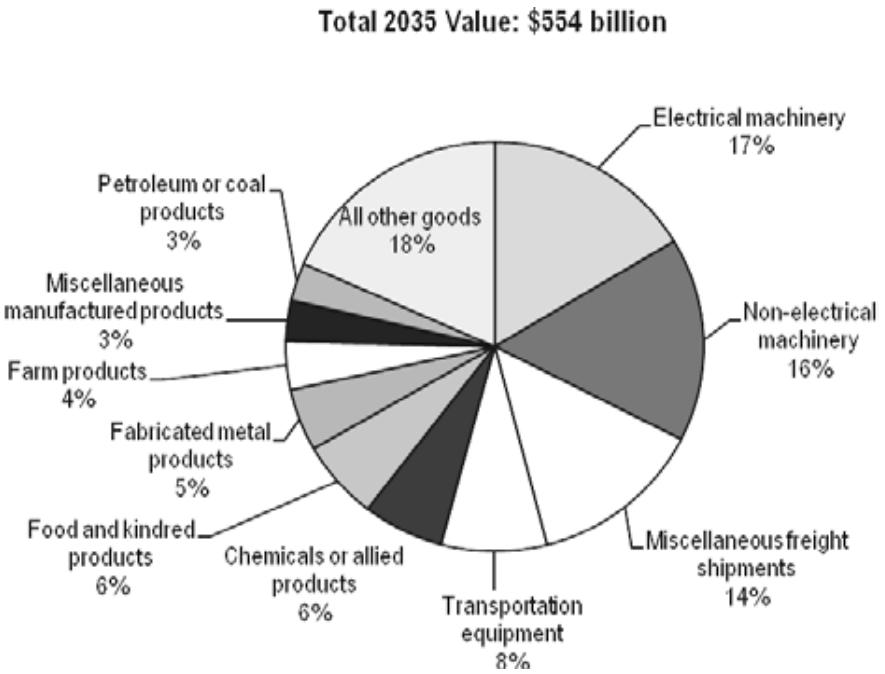


Figure 2.10 Breakdown of Commodity Shipments – Value, All Modes, In/Out/Intra – 2002

Source Oregon Commodity Flow Forecast data, October 2009.

Figure 2.11 Breakdown of Commodity Shipments - Value, All Modes, In/Out/Intra – 2035

Source: Oregon Commodity Flow Forecast data, October 2009. Values derived from tons on a $/ton basis per commodity, as defined in Oregon Commodity Flow Forecast, October 2009: http://library.state.or.us/repository/2010/201010251112531/index.pdf .

The information in Table 2.4 and Figures 2.6 – 2.11 has the following implications for freight transportation in Oregon:

- Oregon will see continued growth in heavy goods movement.[40] Shipments of heavy commodities such as clay, concrete, glass and stone commodities and lumber products will continue to increase. Since a number of these heavy commodities depend on rail, for example lumber, a steady demand for rail traffic should persist. This will require the public sector to work with private

[40] Oregon's permitting system for truck loads that exceed standard limits can be broken into three general components: 1) trucks moving divisible loads may carry up to 105,000 pounds but axle weights must be standard, comply with Oregon's bridge formula, and be of standard widths and heights; 2) trucks moving nondivisible loads up to 98,000 pounds may have slightly higher than standard axle weights, must not exceed 12 feet in width and 13 feet, 6 inches in height and must meet the bridge formula; and 3) trucks moving nondivisible loads exceeding 98,000 pounds, with widths greater than 12 feet and height greater than 13 feet, 6 inches (very small percentage of trucks that require a permit). These latter trucks may exceed axle weights but usually do not exceed the bridge formula.

sector railroad companies to ensure adequate supply of rail infrastructure. Keeping a share of heavy goods, such as farm products, on rail can reduce the maintenance costs of Oregon roads and, therefore, should be considered in planning for future investments. Trucks are critical to moving heavy goods throughout Oregon. The location of industries that require permitted loads may change over time; the monitoring of where clusters of industries that require permitted loads are locating will reduce disruptions in the flow of goods.

- The lumber or wood products industry is by far the biggest user of the rail system in Oregon excluding through rail shipments. Rail infrastructure in the regions where lumber or wood products are picked up will need to be able to handle the increased demand for rail freight to move these goods.
- Several commodities will continue to rely on timely delivery through airfreight. Some of the commodities produced in Oregon, including electrical machinery (includes computer products and computer-related goods), fresh fish and precision instruments, are expected to continue to increase their demand for airfreight in order to deliver their high-value (electronics) and perishable (fish) goods to market. It will be critical to ensure the industries that produce these commodities have adequate access to airports and that bottlenecks between production facilities and the airport are minimized.
- Machinery will continue to be moved by truck, air and marine modes. As the machinery manufacturing industry is one of the largest contributors to manufacturing GSP in Oregon, it is critical that this industry have adequate airport access. For machinery exported or imported by water, it is critical that trucks are able to make timely and reliable deliveries to or from port facilities.
- Transportation equipment movements will continue to increase. This commodity will continue to increase for both truck and rail. It will be the top commodity by value moved on rail in 2035. On truck, it will increase in terms of value, after machinery and miscellaneous freight shipments.
- Farm products, chemicals and clay, concrete, glass and stone will continue to dominate goods moved by water. It is important to have adequate connections from point of production to ports for these commodities in order to meet the expected demand for water movements. Adequate access and routing to and from ports for trucks, including those requiring permits, as well as the consideration of additional rail service may be necessary to facilitate movement of these heavier goods to and from ports.

Freight Demand – By Direction

Inbound, internal and outbound movements are all expected to grow at a moderate rate through 2035. Table 2.5 below shows expected tonnages for 2010 and 2035, as well as baseline tonnages for 2002 by direction of movement.

Through traffic exists on Oregon highways, railways, waterways and pipelines. Through traffic for each mode is discussed in further detail in Chapter 4.

Table 2.5 Oregon Commodity Flow Tonnage by Direction, 2002 to 2035

In Thousand Tons

Direction	Year			Growth Rate 2002-2035
	2002	2010	2035	
Inbound	86,365	101,157	131,957	1.30%
Internal	197,993	223,356	364,482	1.90%
Outbound	62,533	78,909	154,644	2.80%

Source: Oregon Commodity Flow Forecast data, October 2009.

* Compound Annual Growth Rate (CAGR) % 02-35 in the figure represents the compound annual growth rate projections per commodity between 2002 and 2035.

** CAGR is based on analysis of historic trends. Closure or changing the type of fuel used in Portland General Electric's Boardman coal plant that is currently being negotiated will result in a significant reduction in coal shipments.

Information in Tables 2.5 and 2.6 has the following implications:

- Outbound tonnage, compared to inbound and internal, will grow fastest. Table 2.5 shows the amount of freight originating in Oregon is expected to exceed the amount of freight coming into Oregon by 2035. This is a change from 2002, where inbound tonnage exceeded outbound tonnage by nearly 24 million tons. Directional imbalances in freight flows could impact service levels for certain modes and need to be monitored as an issue for the freight community. Outbound tonnage for all modes is expected to grow at a CAGR of 2.8 percent between 2002 and 2035, while inbound and internal movements are expected to increase annually at 1.3 percent and 1.9 percent, respectively. This reflects relative growth in Oregon's export-oriented commodities that are critical to overall economic growth, including chemicals or allied products, lumber or wood products, machinery and transportation equipment. As a result, it will be critical to continue to maintain and improve connections between Oregon and the rest of the world for all modes in order to be able to support this expected increase in exports.
- Internal freight movements will remain substantial. The movement of goods within Oregon (more than 364 million tons in 2035) will remain higher than both inbound and outbound shipments combined, indicating that transportation connections within and between cities and industries need to be maintained and potentially enhanced to meet this growth. Internal freight movements in Oregon are dominated by the truck mode to an even greater degree than trucking dominates overall freight movement.[41] As noted in the Oregon Rail Study, changes in Class I business models over the last decade and the general economics of rail and truck transportation have tended to limit the use of rail as a mode alternative for internal freight movements in Oregon. Given the high level of anticipated growth in internal freight movements, strategies should be examined to encourage shorter haul freight rail movements where there is measurable public benefit (such as reduction of highway investment and maintenance needs) and where the economics of freight rail can be made competitive with trucking.
- Many important inputs for Oregon industries will continue to be imported. Strong continued growth of inbound machinery shipments by value will most likely be production inputs for the computer and electronics sector, a major export area for the state. It will be critical to Oregon industries to make sure that the transportation system supports reliable and timely service to get these goods into the state.

[41] According to the Oregon Commodity Flow Forecast, 2002, 98.3 percent of all intra-Oregon tons moved and 99.1 percent of intra-Oregon value moved by truck. For all in, out and intra movements in 2002, trucks moved 74.7 percent of total tonnage and 74.8 percent of total value.

- A major driver in the growth in commodities supporting personal consumption is population growth. The expected growth rate of Oregon's population is similar to the expected growth rate of inbound and internal shipments of staple commodities, including food, fuels and construction-related commodities (clay/concrete/glass/stone).

2.4 FREIGHT DEMAND OVERVIEW – OREGON AREA COMMISSIONS ON TRANSPORTATION (ACTS)

So far, this chapter has highlighted key statewide trends in freight demand. Another perspective from which to analyze freight demand is that of Area Commissions on Transportation, advisory bodies chartered by the Oregon Transportation Commission. ACTs address all aspects of transportation (road, marine, air and transportation safety) with a primary focus on the state transportation system. ACTs consider regional and local transportation issues if they affect the state system, and they work with other local organizations dealing with transportation-related issues.[42,43] Oregon ACTs are shown in Figure 2.12.

Figure 2.12 Oregon Area Commissions on Transportation (ACTs)[44]

42 https://www.oregon.gov/ODOT/Get-Involved/Pages/Area_Commissions.aspx.

43 ACTs play an important advisory role in the development of the Statewide Transportation Improvement Program, which schedules funded transportation projects. ACTs establish a public process for area project selection priorities for the STIP. Through that process and following adopted project eligibility criteria, they prioritize transportation problems and solutions, and recommend projects in their area to be included in the STIP.

44 Since the OFP was originally adopted in 2011, the Region 1 ACT was created to cover area noted as the Portland Metropolitan Area.

Northwest ACT

Table 2.7 Northwest ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rate

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	54%	1.7%	52%	54%	6%	0.6%	17%	4%
Food or Kindred Products	12%	1.3%	37%	10%	10%	0.8%	23%	8%
Petroleum, Coal, Chemicals	8%	2.1%	68%	9%	15%	2.4%	81%	18%
Pulp or Paper Products	4%	2.2%	72%	5%	2%	1.5%	43%	2%
Other/Miscellaneous	12%	1.9%	60%	12%	1%	2.1%	69%	2%
Forest or Wood Products	9%	1.9%	61%	9%	41%	2.1%	67%	45%
Clay, Minerals, Stone	1%	0.4%	10%	1%	25%	1.1%	33%	21%

The Northwest ACT includes Clatsop, Columbia, Tillamook and approximately two-thirds of Washington County. About 165,000 people currently reside in this area, representing 4 percent of Oregon's total population. Population centers include Astoria, St. Helens and Tillamook. Table 2.7 lists Northwest ACT commodity flow shares and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group represents the largest share (54 percent) of the Northwest ACT but only a six percent share in terms of tonnage in 2010. This pattern is expected to continue into the future, with value forecast to increase about 52 percent over 25 years at a Compound Annual Growth Rate (CAGR) of 1.7 percent. The next largest commodity group produced by value is Food or Kindred Products, with a CAGR of 1.3 percent over the next 25 years.

Forest or Wood Products represents the largest share of the Northwest ACT production in terms of tonnage, but a fairly small share in terms of value. Commodity production for this group is expected to increase from 61 to 67 percent in terms of tonnage and value, increasing at a CAGR of 1.9 percent by value and 2.1 percent by tonnage.

Growth by tonnage in the Petroleum, Coal and Chemical group is expected to be larger than the other commodity groups, although this group represents a fairly small share of regional production and is subject to variation in production levels

due to economic conditions.[45] The Paper and Pulp Products group's regional share of production is similarly affected by economic conditions, meaning production levels and growth depend on the overall strength of the economy. When the economy expands or contracts, commodity production varies more for these two groups than the other five groups in the Northwest ACT. The Northwest ACT's top exported commodities are in the Machinery, Instruments, Transportation Equipment and Metals, Forest or Wood Products, and Food or Kindred Products groups. [46]

Portland Metro Area[47]

Table 2.8 Portland Metro Area Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2035	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2035
Machinery, Instruments, Transportation Equipment, Metals	60%	1.40%	42%	57%	10%	1%	28%	8%
Food or Kindred Products	10%	1%	27%	8%	15%	1%	29%	13%
Petroleum, Coal, Chemicals	8%	2.40%	80%	10%	22%	2.80%	99%	29%
Pulp or Paper Products	6%	2.40%	80%	7%	4%	2.10%	68%	4%
Other/Miscellaneous	13%	2.20%	72%	15%	3%	1.90%	60%	3%
Forest or Wood Products	2%	2%	63%	2%	23%	2.10%	67%	25%
Clay, Minerals, stone	1%	0.60%	17%	1%	23%	0.80%	22%	18%

The Portland Metro Area contains the majority of Oregon's population, representing about 40 percent of statewide population. This area includes about one-third of Washington County, Multnomah, Hood River and Clackamas Counties. A large amount of commodity production for the state comes from the Portland Metro area. Table 2.8 lists the Portland Metro Area commodity production shares and forecast growth rates. In 2010, Machinery, Instruments,

45 More information on economic uncertainty can be found in Chapter 7

46 More detail on ACT export patterns can be found in Chapter 7

47 Since the original adoption of the OFP in 2011, jurisdictions in the Portland Metro Area and Hood River County formed the Region 1 ACT.

Transportation Equipment and Metals production represents the largest share of the area commodity production in terms of value (60 percent), and a relatively small share in terms of tonnage (10 percent). This share of total area production is expected to continue into the future, with the value expected to increase over 40 percent over the next 25 years, increasing at a CAGR of 1.4 percent by value and 1 percent by tonnage.

In 2010, the Petroleum, Coal, and Chemicals group, Pulp or Paper Products, and Other Miscellaneous Goods groups represented over 25 percent of the total value of commodity production in the area in terms of value (29 percent by tonnage.) These three commodity groups are expected to grow at rates higher than other commodity groups. However, production levels within these three categories vary significantly depending on economic conditions. The Petroleum, Coal and Chemical group tonnage is expected to nearly double over the next 25 years.

Many of the commodities produced are consumed within the area. Exported commodities include the Machinery, Instruments, and Transportation Equipment and Metals, Pulp or Paper Products, and the Petroleum, Coal and Chemicals groups.

North East ACT

Table 2.9 North East ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2035	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2035
Machinery, Instruments, Transportation Equipment, Metals	26%	1.40%	42%	25%	2%	1.30%	37%	2%
Food or Kindred Products	43%	1.60%	49%	43%	26%	1.80%	55%	22%
Petroleum, Coal, Chemicals	9%	2.80%	102%	12%	17%	3.90%	159%	24%
Pulp or Paper Products	1%	3.30%	124%	1%	0%	1.70%	54%	0%
Other/Miscellaneous	13%	-0.50%	-11%	7%	1%	1.10%	33%	1%
Forest or Wood Products	7%	3.20%	119%	11%	33%	2.70%	95%	35%
Clay, Minerals, Stone	1%	1.60%	48%	1%	21%	1.60%	49%	17%

The North East ACT is predominantly rural. This ACT includes Morrow, Umatilla, Union, Wallowa and Baker Counties. Population centers for the ACT

include Hermiston, Pendleton, LaGrande and Baker City. Table 2.9 lists the North East ACT commodity production shares and forecast growth rates. In 2010, Food or Kindred Products was the principal commodity, making up over 40 percent of the regional production in terms of value and over 25 percent by tonnage. The amount of production is expected to increase by 49 percent by value and 55 percent by tonnage over the next 25 years. Machinery, Instruments, Transportation Equipment and Metals is the next largest commodity group in terms of value but is quite low in tonnage. In 2010, the Other Miscellaneous Goods group represented 13 percent of ACT commodity production by value, only 1 percent by tons. Tonnage for this commodity group is expected to increase about 30 percent over the next 25 years, but decrease more than 10 percent in terms of value, dropping to about half the current share of regional production.

The fastest growing commodity groups for the North East ACT are the Petroleum, Coal and Chemicals group, Pulp or Paper Products, and Forest or Wood Products. All three groups are expected to at least double their share of regional production by value over the next 25 years. Growth for the Petroleum, Coal and Chemical group by tons is quite high – 159 percent higher in 2035 and growing to nearly one quarter of the region's commodity production in terms of tonnage. However, production levels within this category vary significantly depending on economic conditions.

The North East ACT's top exported commodities include Food or Kindred Products, Petroleum, Coal and Chemicals, Machinery, Instruments, Transportation Equipment and Metals, and Forest or Wood Products.

South Central ACT

Table 2.10 South Central ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rate

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	35%	-0.80%	-18%	27%	2%	-2.30%	-44%	1%
Food or Kindred Products	17%	0.10%	3%	16%	11%	-0.70%	-16%	8%
Petroleum, Coal, Chemicals	11%	3.10%	113%	21%	24%	2.30%	76%	33%
Pulp or Paper Products	3%	0.30%	8%	3%	1%	1.40%	42%	1%
Other/Miscellaneous	16%	0.20%	5%	16%	1%	2.60%	88%	2%
Forest or Wood Products	16%	0.50%	12%	17%	47%	0.70%	19%	45%
Clay, Minerals, Stone	1%	-0.10%	-2%	1%	14%	-0.40%	-9%	10%

The South Central ACT is predominantly rural and includes Klamath and Lake Counties. Population centers include Klamath Falls and Lakeview. Table 2.10 lists the South Central ACT commodity production shares and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group is the largest commodity group produced in the South Central ACT. This group represents over one-third of the commodity production by value. Production is expected to decline in this group over the next 25 years but will remain a major commodity group for the region.

The Petroleum, Coal and Chemicals group makes up about 10 percent of commodity production by value and nearly one-fourth of production by tons. This commodity group is expected to grow at a fairly high rate, resulting in an expected increasing share of regional production. Production levels within this category and Forest or Wood Products vary significantly depending on economic conditions. Most of the other commodity groups' production shares are expected to remain the same over time. Other Miscellaneous Goods are expected to grow in terms of tonnage, but the share remains quite small for the area.

The South Central ACT's exported commodities include Forest or Wood Products, Petroleum, Coal and Chemicals, and Food or Kindred Products.

Rogue Valley ACT

Table 2.11 Rogue Valley ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	40%	0.60%	15%	35%	3%	0.10%	1%	3%
Food or Kindred Products	11%	0.90%	25%	11%	8%	1.10%	31%	8%
Petroleum, Coal, Chemicals	8%	2.60%	92%	11%	16%	2.80%	98%	22%
Pulp or Paper Products	6%	1.10%	32%	6%	1%	1.20%	34%	1%
Other/Miscellaneous	23%	1.50%	44%	25%	2%	0.80%	21%	2%
Forest or Wood Products	12%	0.80%	22%	11%	53%	0.70%	19%	46%
Clay, Minerals, Stone	1%	0.50%	12%	1%	16%	1.60%	48%	18%

The Rogue Valley ACT includes Josephine and Jackson Counties located on the California-Oregon border and includes the population centers of the Rogue Valley MPO (Medford vicinity) and Grants Pass. Table 2.11 lists the Rogue Valley ACT commodity production shares and forecast growth rates. The largest commodity group is Machinery, Instruments, Transportation Equipment and Metals in terms of value, and Forest or Wood Products in terms of tons. Neither group is expected to grow particularly fast over the next 25 years, which results in a decline in their share of total ACT commodity production. The Petroleum, Coal and Chemicals group is expected to nearly double over the next 25 years both in terms of value and tons. Production levels within this category and Machinery, Instruments, Transportation Equipment and Metal vary significantly depending on economic conditions.

The Other Miscellaneous Goods group is expected to grow in terms of value over the next 25 years, increasing its share of ACT commodity production to about one-fourth of the total. The Food and Kindred Products share of ACT production will remain stable over time, but increase more than 25 percent over the next 25 years. The Clay, Minerals and Stone group is not expected to increase production share much in terms of value. However, in terms of tons production the group is expected to increase nearly 50 percent over the next 25 years.

The Rogue Valley ACT's exported commodities include Machinery, Instruments, Transportation Equipment and Metals, Forest or Wood Products, Food or Kindred Products, and Pulp or Paper Products.

Lower John Day ACT

Table 2.12 Lower John Day ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	29%	4.10%	172%	48%	4%	1.10%	32%	4%
Food or Kindred Products	27%	0.50%	12%	18%	15%	0.40%	10%	14%
Petroleum, Coal, Chemicals	14%	2.60%	89%	16%	29%	1.30%	37%	33%
Pulp or Paper Products	3%	2%	66%	3%	1%	3.10%	114%	2%
Other/Miscellaneous	17%	-0.70%	-16%	9%	2%	-2.30%	-43%	1%
Forest or Wood Products	9%	-0.20%	-5%	5%	31%	0.70%	18%	30%
Clay, Minerals, Stone	2%	-1.20%	-27%	1%	17%	0.60%	15%	16%

The Lower John Day ACT includes Wasco, Sherman, Gilliam and Wheeler Counties. Less than 1 percent of the state's population resides within this ACT. Table 2.12 lists the Lower John Day ACT commodity production shares and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group and Food and Kindred Products group represent the major commodities produced within this ACT. Together they make up over half the commodity production for the area. The Food and Kindred Products group is expected to grow modestly in the future. Growth is expected for Machinery, Instruments and Transportation Equipment, with production more than doubling over the next 25 years. This commodity group is subject to varying levels of production depending on economic conditions.

Other Miscellaneous Goods, Forest or Wood Products, and Clay, Minerals, and Stone commodity production are expected to decline over the next 25 years in terms of value. A decline in terms of tons is expected only for Other

Miscellaneous Goods; tonnage increases modestly for the other two commodity groups.

Lower John Day ACT's exported commodities include Petroleum, Coal and Chemicals, Food or Kindred Products, and Machinery, Instruments, Transportation Equipment and Metals.

Central Oregon ACT

Table 2.13 Central Oregon ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	45%	1%	28%	40%	3%	0.40%	9%	2%
Food or Kindred Products	12%	1.40%	40%	12%	8%	1.70%	53%	7%
Petroleum, Coal, Chemicals	7%	3.40%	130%	12%	16%	3%	109%	21%
Pulp or Paper Products	2%	1.60%	48%	2%	1%	1.10%	30%	1%
Other/Miscellaneous	16%	1.20%	34%	15%	2%	1.70%	53%	2%
Forest or Wood Products	16%	2%	66%	18%	53%	1.90%	58%	52%
Clay, Minerals, Stone	1%	0.40%	10%	1%	17%	1.30%	40%	15%

The Central Oregon ACT includes the counties of Jefferson, Deschutes and Crook. About 6 percent of Oregon's population resides within this ACT, and it includes the Bend MPO. Table 2.13 lists the ACT's commodity production shares and forecast growth rates. Machinery, Instruments, Transportation Equipment and Metals is the largest commodity production group for this ACT, making up nearly half the commodities produced in terms of value. Forest or Wood Products is the largest commodity group in terms of tons. The Machinery, Instruments, Transportation Equipment and Metals group is expected to grow modestly over the next 25 years, resulting in a small reduction in the share of regional commodity production. The Forest or Wood Products group is expected to increase over 50 percent over the next 25 years both in terms of value and tons.

The Petroleum, Coal and Chemicals group represents less than 10 percent of the total commodity production in the ACT, but the forecast growth rate is relatively high. The share of total commodity production in terms of value and tons is expected to more than double over the next 25 years. This commodity group and the Machinery, Instruments, Transportation Equipment and Metals group vary in the level of production depending on economic conditions.

Central Oregon ACT exports include Machinery, Instruments, Transportation Equipment and Metals, Forest or Wood Products, Food or Kindred Products, and Petroleum, Coal and Chemicals.

Mid Willamette Valley ACT

Table 2.14 Mid Willamette Valley ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	42%	1.50%	45%	41%	3%	0.90%	24%	2%
Food or Kindred Products	22%	1%	29%	19%	15%	1%	30%	12%
Petroleum, Coal, Chemicals	10%	2.40%	83%	12%	15%	2.60%	91%	17%
Pulp or Paper Products	5%	1.60%	50%	5%	2%	1.50%	44%	2%
Other/Miscellaneous	11%	2.40%	82%	14%	4%	1.90%	61%	3%
Forest or Wood Products	8%	2%	66%	8%	39%	2.10%	69%	40%
Clay, Minerals, Stone	1%	1.70%	51%	1%	22%	2.40%	81%	24%

The Mid Willamette Valley ACT includes Marion, Yamhill and Polk Counties. About 12 percent of the state's population resides in this ACT, and it includes the state capital of Salem. Table 2.14 lists the ACT's commodity production share and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group makes up the largest share of commodity production by value for this ACT. Growth is forecast to be modest, but the share of production is expected to be stable. The level of production varies, depending on economic condition.

The Food and Kindred Products group represents the next largest commodity production share with modest growth and a stable share expected. The Petroleum, Coal, and Chemicals group and Other Miscellaneous Goods group are expected to grow significantly, over 80 percent over the next 25 years. This results in their commodity share increasing a little in the future. The Forest or Wood Products, Petroleum, Coal and Chemicals, and Clay, Minerals and Stone commodity groups are expected to grow at a CAGR rate greater than 2 percent over the next 25 years in terms of tonnage.

The Mid Willamette Valley ACT's exports include Machinery, Instruments, Transportation Equipment and Metals, Food or Kindred Products, Petroleum, Coal and Chemicals, and Pulp or Paper Products.

Cascades West ACT

Table 2.15 Cascades West ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	66%	0.80%	23%	66%	5%	0.50%	13%	4%
Food or Kindred Products	10%	0.10%	2%	8%	10%	0.10%	3%	7%
Petroleum, Coal, Chemicals	5%	1.80%	56%	7%	13%	1.90%	58%	15%
Pulp or Paper Products	4%	0.30%	7%	3%	3%	0%	0%	2%
Other/Miscellaneous	8%	1.20%	34%	9%	1%	-0.40%	-9%	1%
Forest or Wood Products	6%	1.20%	36%	7%	45%	1.40%	40%	46%
Clay, Minerals, Stone	1%	0.90%	25%	1%	23%	1.50%	45%	25%

The Cascades West ACT includes Lincoln, Benton and Linn Counties. About 6 percent of the state's population resides within this ACT, and it includes the Corvallis MPO. Table 2.15 lists the ACT's commodity shares and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group is the major commodity production group by value, over 60 percent of the area total production. Growth is forecast to be modest for this group within the Cascades West ACT. Production is expected to increase slightly more than 20

percent over the next 25 years with regional production share remaining the same over time. Production levels vary significantly depending on economic conditions.

Food and Kindred Products is the next largest commodity production group, making up about 10 percent of ACT production with growth expected to be flat into the future. The Petroleum, Coal and Chemicals group is expected to grow over the next 25 years at CAGR rates close to 2 percent. However, this commodity group has a fairly small share of ACT production and will increase in share modestly in the future. The Forest or Wood Products group represents a large share of commodity production in terms of tons, with an expected increase of 40 percent over the next 25 years.

The Cascades West ACT's exports include Machinery, Instruments, Transportation Equipment and Metals, Petroleum, Coal and Chemicals, Food or Kindred Products, and Pulp or Paper Products.

South West ACT

Table 2.16 South West ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	28%	1%	30%	29%	1%	0.30%	9%	1%
Food or Kindred Products	17%	0.30%	7%	15%	6%	0.80%	21%	6%
Petroleum, Coal, Chemicals	6%	2.90%	104%	11%	10%	2.40%	81%	13%
Pulp or Paper Products	8%	-1.10%	-25%	5%	2%	-1.10%	-25%	1%
Other/Miscellaneous	15%	0.50%	13%	13%	1%	1.80%	56%	1%
Forest or Wood Products	25%	1.20%	34%	26%	66%	0.90%	26%	64%
Clay, Minerals, Stone	1%	-0.10%	-3%	1%	14%	1.10%	31%	14%

The South West ACT includes Douglas, Coos and Curry Counties. Just over 4 percent of the state's population resides in this ACT. Table 2.16 lists the ACT's commodity shares and forecast growth rates. The Machinery, Instruments,

Transportation Equipment and Metals, and Forest or Wood Products groups make up just over half of the ACT commodity production in terms of value. The Machinery, Instruments, Transportation Equipment and Metals group represents a very low share by tons, while the Forest or Wood Products group makes up a very large share of commodity production by tons. Both commodity groups are expected to grow modestly over the next 25 years in the South West ACT, and their share will remain stable.

The Petroleum, Coal, and Chemicals group is expected to more than double in terms of value over the next 25 years, increasing the production share from 6 percent to more than 10 percent. Tonnage for this commodity group is expected to increase as well, but not quite to the same extent. The ACT's production of Pulp or Paper Products is expected to decline in the future. The forecast CAGR is negative, resulting in an expected 25 percent decrease in commodity production for this group in terms of value and tons.

This ACT's commodity production occurs in areas subject to variation due to economic conditions, including the Machinery, Instruments, Transportation Equipment and Metals, Petroleum, Coal and Chemicals, and Forest or Wood Products groups. The South West ACT's exports include these three commodity groups and also Food or Kindred Products.

South East ACT

Table 2.17 South East ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	9%	2.70%	93%	12%	1%	0.50%	14%	0%
Food or Kindred Products	45%	1%	27%	38%	25%	1%	29%	20%
Petroleum, Coal, Chemicals	12%	2.60%	88%	15%	27%	2.60%	90%	31%
Pulp or Paper Products	4%	-0.90%	-21%	2%	1%	-0.90%	-20%	0%
Other/Miscellaneous	22%	2.10%	67%	25%	1%	2.50%	84%	1%
Forest or Wood Products	8%	1.60%	49%	8%	28%	1.90%	61%	28%
Clay, Minerals, Stone	0%	1.90%	60%	0%	18%	2.40%	79%	20%

The South East ACT area is predominantly rural, including Grant, Harney and Malheur Counties. Population centers for the ACT include Ontario and Burns. Table 2.17 lists the South East ACT's commodity production shares and forecast growth rates. Food and Kindred Products are the principal commodity produced, making up over 40 percent of the regional production in terms of value and 25 percent by tons. The amount of production is expected to grow at a moderate pace, resulting in a reduced share of the ACT's commodity production.

Growth is expected for the Machinery, Instruments, Transportation Equipment and Metals group, Petroleum, Coal and Chemicals group, and Other Miscellaneous Goods group. All three groups are expected to grow at CAGRs greater than 2 percent. The commodity production shares by value for these three groups together increase from 43 percent to 52 percent over 25 years. The Clay, Minerals and Stone group represents a very small share of commodity production by value, but nearly 20 percent in terms of tons. This share by tons is expected to increase nearly 80 percent over the next 25 years. Pulp or Paper Products are expected to decline in the future. This commodity group represents a small share of production, which is forecast to decline about 20 percent over the next 25 years.

The South East ACT's exports include Food or Kindred Products, Petroleum, Coal or Chemicals, and Forest or Wood Products. Commodities produced within these categories are subject to less variation due to economic conditions than commodities in other ACTs within Oregon.

Lane County ACT

Table 2.18 Lane County ACT Shares by Commodity Group 2010 – 2035, by Tons, Value and Growth Rates

	Value				Tons			
	Region Share - 2010	CAGR	25 Year Percent Change	Region Share - 2030	Region Share - 2010	CAGR	25 Year Percent Change	Region Share – 2030
Machinery, Instruments, Transportation Equipment, Metals	54%	1.70%	52%	54%	6%	0.60%	17%	4%
Food or Kindred Products	12%	1.30%	37%	10%	10%	0.80%	23%	8%
Petroleum, Coal, Chemicals	8%	2.10%	68%	9%	15%	2.40%	81%	18%
Pulp or Paper Products	4%	2.20%	72%	5%	2%	1.50%	43%	2%
Other/Miscellaneous	12%	1.90%	60%	12%	1%	2.10%	69%	2%
Forest or Wood Products	9%	1.90%	61%	9%	41%	2.10%	67%	45%
Clay, Minerals, Stone	1%	0.40%	10%	1%	25%	1.10%	33%	21%

The Lane County ACT is a mix of rural and urban activity. Over 8 percent of the state's population resides in this county, and it includes the Eugene/Springfield MPO. Table 2.18 lists the Lane County ACT commodity production shares and forecast growth rates. The Machinery, Instruments, Transportation Equipment and Metals group makes up over 50 percent of the share of commodity production by value, only 6 percent by tons. Production within this group is expected to increase over 50 percent over the next 25 years. The Food or Kindred Products group and Other Miscellaneous Goods make up nearly one-fourth of commodity production for the Lane County ACT by value. The Food or Kindred Products group is expected to increase somewhat modestly over the next 25 years with the regional share of production declining a small amount.

The Forest or Wood Products group is expected to grow at a CAGR of nearly 2 percent over the next 25 years, increasing more than 60 percent in terms of value. Commodities in this group are heavy, making up over 40 percent of the region's commodity production by tons. The Petroleum, Coal and Chemicals group

makes up about 8 percent of the area commodity production by value, 15 percent by tons, and is expected to increase more than 80 percent over the next 25 years.

Lane County ACT exports include Machinery, Instruments, Transportation Equipment and Metals and Petroleum, Coal and Chemicals, which vary significantly depending on economic conditions. Pulp or Paper Products, Forest or Wood Products, and Food or Kindred Products are also exported from this area.

2.5 CONCLUSION

Generally, Oregon's economy is expected to grow and increase the demand for freight, despite the recent setbacks witnessed during the recession. This is assumed to be the most likely direction that the economy will take in the future. However, it is possible that significant changes, such as faster or slower than expected economic growth, may occur in coming years, which would have significant impacts on freight demand. Chapter 7 discusses potential impacts on Oregon freight demand if alternate scenarios were to occur.

Oregon Industries and Freight Movement

3.0 Oregon Industries and Freight Movement

3.1 INTRODUCTION

A state's economy and industry structure – its major businesses, their suppliers, the markets they serve and their growth prospects – have a direct impact on the condition and performance of its freight transportation system. Understanding how Oregon industries rely on transportation is critical to developing a system which meets user needs. Such a system supports industry competitiveness and ensures a healthy Oregon economy in the future.

In order to better understand the relationship between industry needs and the freight transportation system, data analyses, in-depth interviews with Oregon businesses, industry stakeholders and American companies that use Oregon's multimodal transportation network were completed. Results of this process include:

- Identification of key Oregon industries;
- Analysis of the impact of key industry supply chain operations on Oregon's freight transportation system; and
- Understanding of the critical issues that companies in these key industries encounter when moving their products on the Oregon freight system.

Several major Oregon industry groups were analyzed, as listed in Table 3.1. These industries were selected for a number of reasons:

- They are the largest sectors in Oregon based on a number of economic measures (contribution to state gross domestic product, contribution to state employment, overall payroll ranking); and/or
- They have substantial transportation system requirements and are highly freight dependent; and/or
- A sizable portion of their production costs consist of transportation costs.

Table 3.1 Key Oregon Industries Profiled in this Chapter

Industry Title (NAICS code[48])	2009 Employment*	2009 Share of Total Employment
Agriculture, Forestry, Fishing, (111)	48,700**	3.0%
Computer and Electronics Manufacturing (334)	35,500	2.5%
Food Manufacturing (311)	23,700	1.0%
Machinery Manufacturing (333),	9,700	0.6%
Metals Manufacturing (331 & 332),	22,000	1.0%
Transportation Equipment Manufacturing (336)	10,000	0.6%
Wood and Paper Manufacturing (321)	20,900	1.0%
Wholesale Trade (42)	75,500	5.0%
Retail Trade (44)	183,600	11.0%
Services and All Others (5)***	1,224,100	74.0%
Total Non-Farm Employment	1,653,700	100.0%

*Oregon Employment Department "Current Employment Statistics 2009" https://www.qualityinfo.org/ed-ceest/

** Oregon Employment Department "Covered Employment and Wages 2009" This number also represents employment for Hunting, Mining and Logging.

***The 'Services and All Others' category includes a wide range of industries, but primarily includes service-sector industries, such as financial activities, government, real estate and educational and health services, which generate limited freight transportation demand and are thus less dependent on freight services.

3.2 INDUSTRY CONTRIBUTION TO OREGON'S ECONOMY

The contribution of the key industries to Oregon's economy will be discussed in terms of 1) output and Oregon GSP share, 2) contribution to employment and 3) anticipated industry growth.

Output and Oregon Gross State Product (GSP) Share

Table 3.2 below describes industry contribution to total Oregon GSP and total Oregon manufacturing GSP of each of the key industries. As is true of much of the U.S. economy, the majority of Oregon GSP is concentrated in service sector industries that are not generally dependent on freight transportation services.

[48] North American Industry Classification System (NAICS): See Appendix F.

However, the key freight-dependent industries highlighted in Table 3.2 provide many of the products that Oregon trades with other parts of the U.S. and the world and therefore represent a particularly important component of the state's economy.

Table 3.2 Industry Contribution to GSP

Industry Sector*	2008 GSP (in Millions)	Percentage of Total Manufacturing GSP	Percentage of Total GSP
Agriculture, Forestry & Fishing	$3,984	N/A	2.50%
Computer & Electronics Manufacturing	$15,211	50.40%	9.40%
Food Manufacturing	$2,669	8.80%	1.70%
Machinery Manufacturing	$1,288	4.30%	0.80%
Metals Manufacturing	$2,569	8.50%	1.60%
Transportation Equipment Manufacturing	$941	3.10%	0.60%
Wood and Paper Manufacturing	$3,302	10.90%	2.00%
Wholesale Trade	$10,514	N/A	6.50%
Retail Trade	$8,691	N/A	5.40%
Service and All Others*	$112,404	14.00%	69.50%
2008 Oregon Total GSP (in Millions: 2008)	$161,573	100%	100%

Source: State of Oregon Office of Economic Analysis (OEA) Data and 2006 Annual Survey of Manufactures.

* The 'Services and All Others' category, which includes the remaining 69.5 percent of GSP, includes a wide range of industries, but primarily includes service-sector industries, such as financial activities, government, real estate and educational and health services, which generate limited freight transportation demand and are thus less dependent on freight services. The 14 percent of total manufacturing GSP in the "Service and Others" Industry Sector includes apparel, chemical, plastics/furniture manufacturing and others.

Several observations can be drawn from the data in Tables 3.1 and 3.2:

- Oregon is a state that relies heavily on the manufacturing sector. Table 3.2 shows that a significant percentage of total state GSP comes from the manufacturing sector. According to the Bureau of Economic Analysis (BEA), 18.7 percent of Oregon's total GSP comes from the manufacturing sector; comparatively, only 11.6 percent of the U.S. total GDP and 9.9 percent of the State of Washington's GSP come from the manufacturing sector.[49] Oregon's

[49] Bureau of Economic Analysis: Regional Economic Accounts at: https://www.bea.gov/regional/index.htm.

heavy dependence on the manufacturing sector leaves the state vulnerable as a result of cheaper labor in overseas manufacturing. However, current forecasts predict increases in Oregon manufacturing GSP (both in terms of actual value and as a percentage of total GSP), especially in durables manufacturing.[50] Due to the state's heavy reliance on this industry, it is important that businesses in the manufacturing industry are well served by the transportation system to keep costs low and remain competitive in the global economy.

- Computer and electronics manufacturing is a major contributor to total state GSP and state manufacturing GSP (in 2008, more than 50 percent of state manufacturing GSP came from computer and electronics manufacturing). In the past several decades, Oregon has seen a strong increase in high-technology companies and their contribution to GSP. As the state succeeds in attracting more computer and electronics manufacturing firms, which have high-value-added product content and require higher than average skilled workers, Oregon's manufacturing GSP (actual value and share of total GSP) is expected to increase in the future. High-tech companies have high or medium dependence on all modes of transport except pipeline, as well as complex international supply chains. It will be important as volumes increase for the state to enhance freight mobility on these modes, particularly truck and air, and facilitate better connections between modes to satisfy the needs of this critical industry group.[51]
- Industries in decentralized locations are important contributors to the Oregon economy. Agriculture, forestry and fishing, and wood and paper manufacturing are critical components of Oregon's economy, particularly where employment and rural economic vitality are concerned. These industries rely on having multimodal transportation access and tend to be distributed in remote and rural areas. Bulk commodities, such as wood products, are often trucked to reload facilities and transferred into rail containers, railcars or ocean containers for movement to destinations across the U.S. and the world. Rural production areas are not always served by multiple modes of transportation (i.e., barge and rail), thereby restricting modal choice. Transportation costs for these sectors usually make up a large percentage of the cost of goods, so constrained access or mobility can drive up operating costs. To ensure the support of these basic industries, multimodal access and mobility must be preserved and improved, when viable.

50 State of Oregon Office of Economic Analysis (OEA) data 2008

51 See Table 2.1 in Chapter 2 for more detail.

Anticipated Industry Growth in Freight Shipments

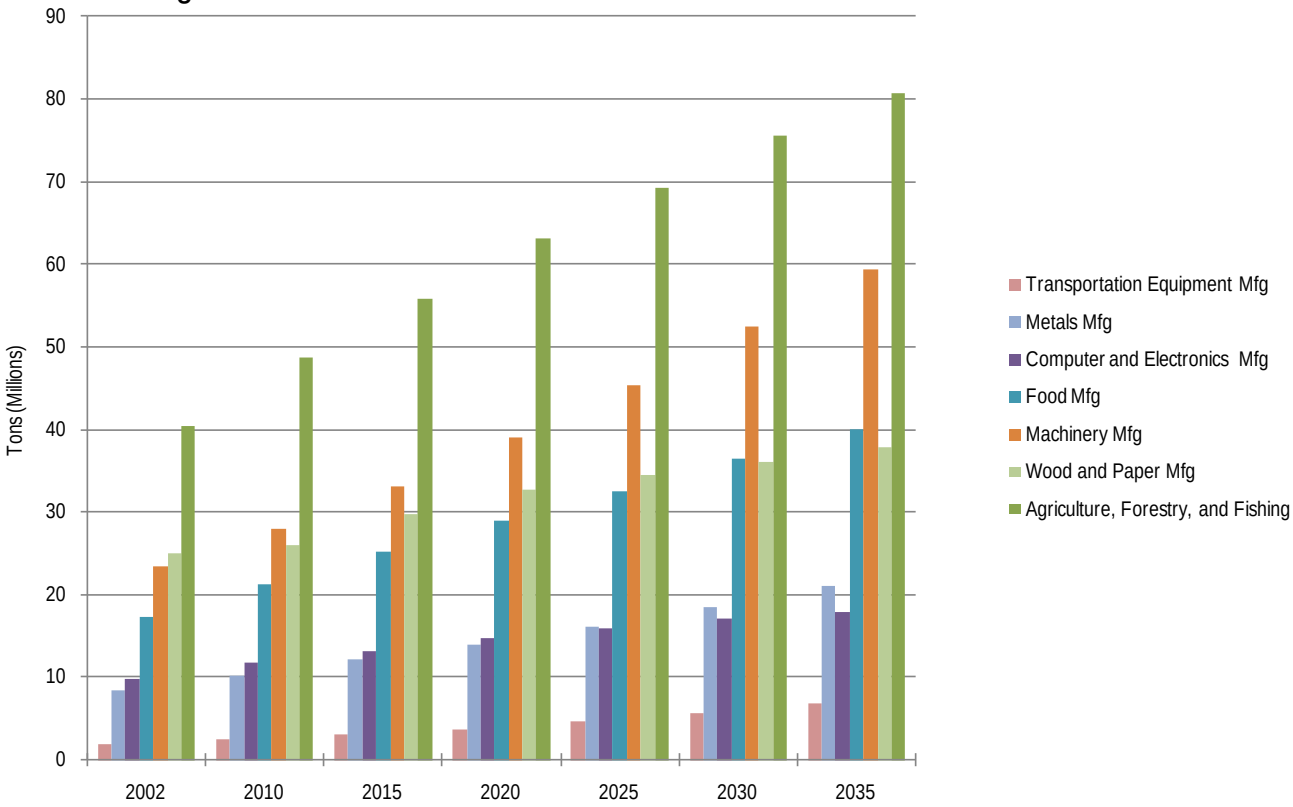

Figure 3.1 highlights the anticipated growth in tonnage shipments of key industries. The commodities that make up these industries can be found in Appendix F. The data shows that there are moderate to high-growth industries and slower-growth industries in terms of tonnage movements. High-growth industries include the following:

- Agriculture, Forestry and Fishing. Shipments related to this sector are expected to grow at a high rate of around 2.1 percent annually through 2035.
- Computer and Electronics Manufacturing. The volumes of commodity movements associated with the computer and electronics manufacturing industry are expected to grow at a steady pace, about 1.9 percent annually through 2035.[52]
- Food Manufacturing. Movements related to food manufacturing are expected to increase at a high annual rate of around 2.6 percent by 2035.
- Machinery Manufacturing. Shipments of machinery manufacturing outputs are expected to continue to increase substantially through 2035, with an expected annual growth rate of around 2.9 percent.
- Metals Manufacturing. Movements related to metals manufacturing are expected to grow at a fast pace of around 2.9 percent through 2035.
- Transportation Equipment Manufacturing. The volume of movements of transportation equipment manufacturing-related commodities is expected to grow at a very high rate – around 4 percent annually through 2035.
- Wood and Paper Manufacturing. Movements are expected to increase modestly at 1.3 percent annually through 2035.

[52] Oregon Commodity Flow Forecast, October 2009.

Figure 3.1 Key Oregon Freight Dependent Industries – Projected Growth of Related Commodity Tonnage with Oregon Origin[53,54] 2002 to 2035

Source: Oregon Commodity Flow Forecast data, October 2009.

53 Retail trade and wholesale trade were not included in the tonnage overview because tonnage conversion data are not available for these industries.

54 Tonnage does not translate into the value of goods or economic output. Thus, the growth rate of Agriculture, Forestry and Fishing does not indicate that jobs in this sector are going to increase at the same rate. The only growth that this graph shows is the growth in tonnage.

Implications of Industry Growth for the Freight System

Implications for Oregon freight transportation can be drawn from the data in Figure 3.1:

- High growth in volume of goods will occur in the computers and electronics manufacturing industry. The growth in economic importance (and increased freight tonnage in support of this growth) of computer and electronics manufacturing and the industry's reliance on air and trucking and complex global supply chains will result in an increasing need to strengthen the intermodal connections between these modes and focus efforts on improving overall system reliability.
- Many of Oregon's resource-based industries will still play an important role in the state's economy and a critical role in the economies of many rural and coastal areas. However, the Class I railroad business model currently focuses on long haul freight movements. This consolidation of service and the unprofitable nature of some carload movements have resulted in reduced rail service to some of Oregon's resource-based industries that move their railcar cargo in small lots. Oregon grain shippers struggle to obtain competitive pricing, for example, from Class I railroads because of their low volumes and relatively short hauls. Grain growers usually move goods from rural Oregon, east of the Cascades, to grain export facilities on the Columbia River and the Puget Sound. The change in Class I railroad operations makes rail a less viable option to move goods from the field to these export facilities. Shifting these commodities to trucks has both a cost and competitiveness impact for these sectors and has potential implications for road maintenance and congestion. As a result, ensuring transportation access and routes that can handle heavier loads is particularly important to these industries.

3.3 INDUSTRY LOCATION AND CLUSTERING

While many of Oregon's industries are located near Portland and around the I-5 corridor, many others, especially Oregon's traditional resource-based industries, are located in rural areas throughout the state. Industry site location can be influenced strongly by the nature of the products that are grown, processed or manufactured, domestic or international trade orientation, and the type of transportation modes required.

High-Value Industries

The computer and electronics manufacturing industry is clustered almost entirely within the Portland metropolitan area and Willamette region. In general, this urban clustering provides the following benefits to these industries, which help them be successful:

- Access to transportation infrastructure that facilitates exports (including airports, highways and rail), which is critical to these export-heavy industries;
- Availability and relatively low cost of utilities and land on the urban fringe; and
- Ability for companies to draw on a pool of highly-skilled employees (such as engineers and computer technicians) from the Portland metropolitan region.

Firms within high value-added manufacturing industries, such as machinery manufacturing, are relatively mobile and tend to locate near places with access to ports and relatively congestion-free highway corridors. However, larger manufacturers tend to be stationary due to the investment and infrastructure required to sustain their production sites.

Green technology is a sector that Oregon seeks to promote and develop. Wind turbine farms have clustered along the Columbia River Gorge and central and eastern Oregon, where strong wind currents combine with sparsely-populated land to facilitate installation of wind farms. Oregon is also becoming a hub for solar power manufacturing. Solar energy firms are located in urban areas, including Hillsboro, Gresham, Salem and Eugene, where plentiful higher-skilled labor and large land parcels are available.

Companies in the wholesale trade, footwear, apparel and recreation products sectors are predominantly located in the Portland metro region because of easy access to maritime, air, truck and rail transportation. These industries also have a strong import orientation, which makes access to various modes critical.

General Manufacturing Companies

General manufacturing companies are located across Oregon, with many concentrated in the Portland and Salem urban areas. Metals manufacturers are clustered in the northwest portion of the state, in particular in the Portland metro and upper Willamette Valley areas. Most food manufacturers are located in the western half of the state, with a heavy concentration around Portland and Salem. There are also some clusters in eastern Oregon near the Columbia River. Outside of these urban clusters, this industry is somewhat more dispersed than others

because location decisions tend to be driven by proximity to cheaper, inexpensive land, rail corridors and raw materials (e.g., agricultural inputs).

Natural Resource-Dependent Industries

Natural resource-dependent industries tend to be located in the state's rural areas. Fishing companies are naturally located on the coast near their supply source, though they generally have sales offices in the Portland region.

Wood manufacturers are based in mountainous areas, largely west of the Cascade Range close to where timber is harvested to reduce transportation costs, which make up a high percentage of the products' total market price. Clusters of wood and paper mills and production facilities are located throughout the Portland metro area and upper Willamette Valley and in coastal, southwest and central Oregon.

The agriculture sector tends to be fixed by location but is also relatively dispersed throughout the state, depending on the type of resource. Most farms and agricultural reload and processing facilities are spread throughout the upper Willamette Valley, and western, central, eastern and southern Oregon, where land is rich and abundant. Within this diverse industry cluster, specific industries tend to cluster in certain regions. For example:

- Many of Oregon's vineyards are located in the Willamette Valley, as well the Columbia River, Umpqua, Rogue and Applegate Valleys because of the nature of the soil and climate; and
- Growers of nursery stock and trees used in residential and commercial landscaping are highly concentrated in the Willamette Valley,

Transportation and Logistics Service Companies

Service companies, such as those in the transportation, logistics and distribution sector, serve domestic and international shippers all across Oregon and therefore operate where their customers are located.

3.4 INDUSTRY TRANSPORTATION SYSTEM AND SERVICE REQUIREMENTS, ISSUES AND OPPORTUNITIES

High-Value Industries

High-value industries are characterized by complex, long-distance supply chains that require materials from all over the world. In turn, many of the products produced by these high-value industries are also sold globally. As a result, these

industries are dependent on smooth functioning marine and air transport. Domestic shipments of high-value industries move by truck and, to a lesser extent, on rail, and reliability on these modes is critical. Companies that manufacture high-value products have the following transportation requirements:

- Access to international air cargo service at Portland International Airport (PDX). Since the majority of the finished products in this sector are high value, time sensitive and/or relatively small, they utilize airfreight to international and out-of-state domestic customers. Therefore, having adequate, reliable and direct international air carrier service at Portland International Airport is important; otherwise, products must be trucked to Seattle-Tacoma International Airport or San Francisco International Airport, which may increase costs and transit time. In addition, to satisfy promised delivery dates to their customers, technology firms must be able to access Portland International Airport in a reliable and consistent manner via the road and highway network to meet airfreight deadlines.
- Dependable transit times to and from the Port of Portland. Raw materials and components required by these industries for production often arrive from Europe and Asia by ship. Ensuring these goods can move quickly through the Port of Portland and over the surface transportation system is of utmost importance to the just-in-time manufacturing processes of this industry cluster.
- Supply chain consistency and reliability. Predictable supply chains are essential to manage the complexity of materials arriving from all over the world and to mitigate the risk of business interruption. High-value industries are less price-sensitive than other industries when it comes to transportation costs and are more concerned about transportation service reliability.
- Access to regions of new industry development. Green energy businesses are branching out to rural parts of the state to develop infrastructure such as wind farms. Growth in the wind industry will depend on having sufficient transportation to rural locations and planned wind farm facilities for delivering the heavy and large wind turbine components.

General Manufacturing Industries

Food and metals manufacturers depend on having low-priced transportation options, supply chain consistency and reliability, transportation modal choice, and access to fast, refrigerated transportation modes to ship perishable goods. A supply of industrial land near major markets is also essential to keep transportation costs down for these industries.

Supply chain consistency and reliability are essential to companies in the wholesale trade, footwear, apparel and recreation equipment industries. They are

less transportation price-sensitive than firms in some other industry clusters, such as agriculture and forest products.

Resource-Dependent Industries

Wood and paper manufacturers rely heavily on trucks, Class I rail and shortline rail to get their goods to market and on barges for shipment of raw materials. Though wood and paper manufacturers source many inputs from Oregon and the Pacific Northwest, they also ship to and from many international locations, using marine ports on the Pacific, Gulf and Atlantic coasts, as well as several international land border gateways with Canada.

Overall, resource-dependent industries receive a high percentage of value-added from transportation, which means that the overall direct effect of freight investments on them is high. Some of the critical transportation system needs of these industries include the following:

- Supply chain dependability. These industries rely on a steady flow of raw materials to function. Therefore, fast and reliable transportation is critical, in particular if the commodity being shipped is perishable.
- Modal choice. Resource-dependent shippers need modal flexibility, depending upon the products being transported, so having access to all modes – shortlines, Class I railroads and intermodal facilities, barge, ocean transport, air service (for certain exported perishable agricultural products) and truck – is very important.
- Access to the nation's marine and land border crossing/gateways. These industries make use of ports on all three coasts of the U.S., as well as several land border gateways with Canada like Blaine, Washington, to import raw materials and export finished goods.
- Widespread truck network. These industries rely on trucking for many trips that are less than 500 miles in length, to and from locations all around the Oregon and bordering states.
- Special equipment and designated routes for trucks that require permits. Some agricultural products and fish are highly perishable, so access to refrigerated equipment in all modes (rail, truck, air and barge) is essential. Some products like mining and construction materials are heavy, so having an adequate number of over-dimensional truck routes across the state facilitates safe, timely and cost-effective transportation of heavy loads.

Transportation and Logistics Service

Companies in the transportation, logistics, distribution and warehousing industry require consistent transit times to ensure customer satisfaction and on-time

delivery of manufacturing inputs and finished products, access to all modes of transport and smooth connections between transportation modes.

Critical Industry Issues

A survey for the OFP of shippers and carriers identified a number of critical issues.

High-Value Industries

Several issues can adversely affect the critical transportation functions of high-value industries, including the following:

- Highway congestion issues within the Portland area and around Portland International Airport. Congestion and bottlenecks on highways leading to/from Portland International Airport can result in cost and transit time reliability issues for industries dependent on air freight.
- Limited direct international air freight service at Portland International Airport and ocean carrier service at Port of Portland. The availability of air cargo service and marine cargo service is volatile. The addition or removal of a single flight at Portland International Airport may have far-reaching impacts on supply chains throughout the region. For example, airlines may determine to remove service because of market conditions or add service to a new market which might reduce travel time and cost for Oregon businesses significantly. This type of change in freight carriers and destinations impact distribution patterns and costs for those industries reliant on air freight to get goods to lucrative overseas markets. A similar situation exists at Portland's marine terminals.
- Permitted load truck standards and regulations. Size and weight permitting is necessary to protect transportation infrastructure from excessive wear, especially from those trucks that have significantly higher weights per axle. Highways are designed to specific national or state standards, which are exceeded by trucks that require permits. These trucks are a low percentage of truck movements; however, industries clustered in certain areas can benefit from or need access to trucks that require permits. For example, the wind industry requires transportation of wind turbines, which are heavy and overdimensional. A well-functioning and user-friendly permitting system requires knowing where these movements are concentrated and understanding the logistics patterns and common routes of these industries. It may be possible to offer more permitting opportunities or to selectively upgrade roads, bridges and tunnels to accommodate permitted loads. In some cases, it may also be cost-effective for the state to assist shortline railroads with track upgrades to maintain adequate service for the shipment of heavy loads.

- Weather-related delays. Some major corridors are often affected by weather-related road closures including I-5, I-84, I-205, U.S. 26, U.S. 30 and facilities over the Siskiyou Pass.

General Manufacturing Industries

Companies in these sectors are impacted by the following challenges:

- Growing transportation delays from increasing highway congestion and lack of highway system redundancy. Shippers report negative impacts from increasing congestion on highways in Oregon and on bridges in metro Portland. Also reported was lack of adequate highway system redundancy that would enable the motor carriers to route around traffic bottlenecks.
- Growing rail congestion and general rail issues. Some shippers noted in interviews that local Class I railroad yards are congested, particularly around Portland. Periodic rail equipment shortages make rail a less attractive option for some shippers, which can lead companies to use trucks instead of rail. This, in turn, increases transport costs. Most shippers are limited to one Class I railroad, which can limit options for service and competition for pricing.[55] Other challenges exist, including the Class I railroads' current pricing structure which favors more efficient longer trains traveling long distances. Shippers requiring short-haul moves or those with insufficient cargo volume sometimes are priced out of the rail market. Access to rail is limited in certain rural areas where shippers would like to use rail. Some stretches of shortline track are deteriorating or unable to handle heavier loads.
- Bridge restrictions. These restrictions are critical to keeping bridges safe for a long period of time and for reducing damage to bridge infrastructure, as damage prevention saves money for repairs. These restrictions do, however, impact routing choices for some general manufacturing companies with heavy loads, such as food or beverage products. Oregon has replaced or repaired hundreds of bridges with Oregon Transportation Investment Act III Bridge Program funds.[56] Oregon, unlike most other states, has taken the initiative to ensure that critical bridges necessary for efficient freight movements are capable of handling heavier loads. Still, it is important to get a clear picture of route and logistics patterns for major industries and to consider upgrading any industry-critical bridges that require work.

---

55 "Oregon Freight Rail System." Prepared by Parsons Brinckerhoff for the Oregon Rail Study, April 2010.

56 Background Brief: Legislative Committee Services: Bridges. State of Oregon at https://www.oregonlegislature.gov/lpro/Publications/BB2014Bridges.pdf

- Increased demand for industrial land supply on waterfronts and in urban areas. As a result of increased maritime trade to support marine-dependent industries, such as wood and paper manufacturing, the demand for waterfront terminal facilities and waterfront industrial land supply will increase. However, pressure exists to convert industrial land to other uses, such as residential or commercial land. The Metro Regional Freight Plan 2035, suggests that "industrial sanctuaries should continue to be considered a unique and protected land use" in the Metro region.[57] A focused effort to protect industrial land throughout the state is important to maintain Oregon industry competitiveness and viability.
- Ocean carrier and direct international air freight service schedules at the Port of Portland. At times, limitations in port calls or flight schedules can cause companies to use alternate gateways such as the Puget Sound ports of Seattle-Tacoma, or San Francisco-Oakland, which increase costs and transit times.

Resource-Dependent Industries

Companies in this sector are impacted by the following challenges:

- Congestion on major freight corridors. In interviews, shippers reported that increasing congestion is a major concern, especially in Oregon's urban areas and on the Columbia River Crossing I-5 Bridge.
- Lack of highway system redundancy. There are few roads connecting the Oregon coast and coastal range to major population centers in Oregon including the Willamette Valley and beyond the state, as well as to the Port of Portland and Portland International Airport. Because road and highway system redundancy is lacking, companies in the forestry and fisheries industries that harvest and process products off the Oregon coast and in the coastal range face supply chain disruptions when winter weather-related events like flooding, landslides and downed trees cause road closures, or increased summer traffic slows down driving speeds.
- Lack of motor carriers to support rural shippers. Shippers in some rural areas reported having difficulty procuring sufficient empty trucks during certain times of the year. Access to adequate motor carrier service is often limited when motor carriers are resistant to serve rural areas because there often is no return cargo to create a revenue paying round-trip. Therefore, trucks either return empty or motor carriers charge higher rates than for their urban customers.

[57] The Metro "Regional Freight Plan 2035," which was released in June 2010, also brings this up as a key finding.

- Truck permitting issues and diminished routing choices. Shippers mentioned that restrictions and rules for permitting heavy and over-dimensional vehicles are somewhat cumbersome; this includes restrictions concerning, for example:
  - Location of pilot car for some loads: some are required in front, others in back, others both;
  - Restrictions on transporting during certain times of day;
  - Restrictions on transporting during certain weather conditions; and
  - Restrictions against holiday moves.

  Permitting regulations allow heavy and over-dimensional loads while balancing the needs of public safety and road users. Good connectivity of routes available to permitted loads is important to industries, as reduced transit time lowers costs and increases competitiveness.
- Challenges with rail service. Forestry shippers lack nearby rail access in certain rural areas where timber harvesting and processing occur. Grain growers have not been able to consistently attain dependable and affordable rail service. In addition, inadequate maintenance and insufficient capacity on some shortline railroads can negatively affect shippers.

Service Companies

Companies in this sector are primarily challenged with growing congestion, in particular in and around the Portland metropolitan region. Decreasing direct commercial airline flights as a result of systemwide capacity reductions may have an impact on Portland competitiveness in the service and other industries sector.

Freight Systems

4.0 Freight Systems

4.1 INTRODUCTION

The previous chapters provide background on the economy, freight demand and critical freight dependent industries and their supply chains. This chapter focuses on describing the freight transportation system and its importance to the industries that use the system. The chapter is divided into the following sections:

- Freight System Overview. This section provides an overview of the multimodal freight system in Oregon, with a focus on truck, rail, marine and aviation, and the connectivity between these modes.
- Strategic Freight Network Selection Methodology and Description. This section provides a system description of how the freight dependent industries of Oregon use major multimodal corridors that support the Oregon economy. The information is used to define a list of strategic freight corridors by industries for the entire state.
- Connectivity. This section provides a description of system elements (roads, rail lines, marine facilities, airports and pipelines) that help connect centers of economic activity for freight-dependent industries with strategic freight corridors.

4.2 FREIGHT SYSTEM OVERVIEW

Freight mobility in Oregon is provided by a multimodal network that includes highways, local roads, rail, air, marine and pipeline operations. The freight system is also part of the National Defense System. According to the 2006 OTP and ODOT's Rail Division, Oregon's transportation system is made up of the following infrastructure:

- 7,441 miles of state highways.
- 4,664 miles of other state roads; 26,861 miles of county roads; 10,011 miles of city roads; 38,666 miles of other government-owned roads. These roads help connect Oregon industries, businesses, population centers and other freight-generating facilities to the major freight transportation corridors.
- 2,086 miles of privately-owned route miles of rail track; 314 miles of publicly-owned track; 1,126 miles of Class I carrier-operated track; 1,274 miles of Class III shortline-operated track; and, 4 miles of switching railroad

track (included in the shortline total).[58] This includes two major transcontinental railroads: The Burlington Northern Santa Fe (BNSF) Railway and the Union Pacific (UP).

- 18 Class I railyards and nine facilities that have the capacity to load and unload unit trains.
- Five deep-draft and four shallow-draft marine port locations.
- Two marine highways.
- 97 public-use airports.
- Nine pipelines to move petroleum and natural gas.

Road/Highway System[59]

The north/south Interstate 5 and east/west Interstate 84 corridors carry the majority of freight traffic in Oregon. These facilities provide Oregon with freight system connections with national and international destinations. I-5 forms part of an international freight corridor connecting Oregon with California and Mexico to the south and Washington and Canada to the north, while I-84 provides connection to the east including Idaho, Utah and other states.

Several state highways offer important opportunities for freight movement because of their location and connectivity to a variety of markets. Large sections of the state, where no interstates are nearby, rely on state highways to import and export goods. Within major urban areas, the complex road network of arterials and connectors is critical for freight movement. Local arterial roadways that lead to marine facilities or other modal terminals are designated by the Federal Highway Administration as Intermodal Connectors on the National Highway System.

The 1999 *Oregon Highway Plan* establishes long-range policies and investment strategies for the state highway system. These policies include the designation of a system of freight routes. The OHP freight routes provide for highway freight

[58] Oregon DOT Rail Division.

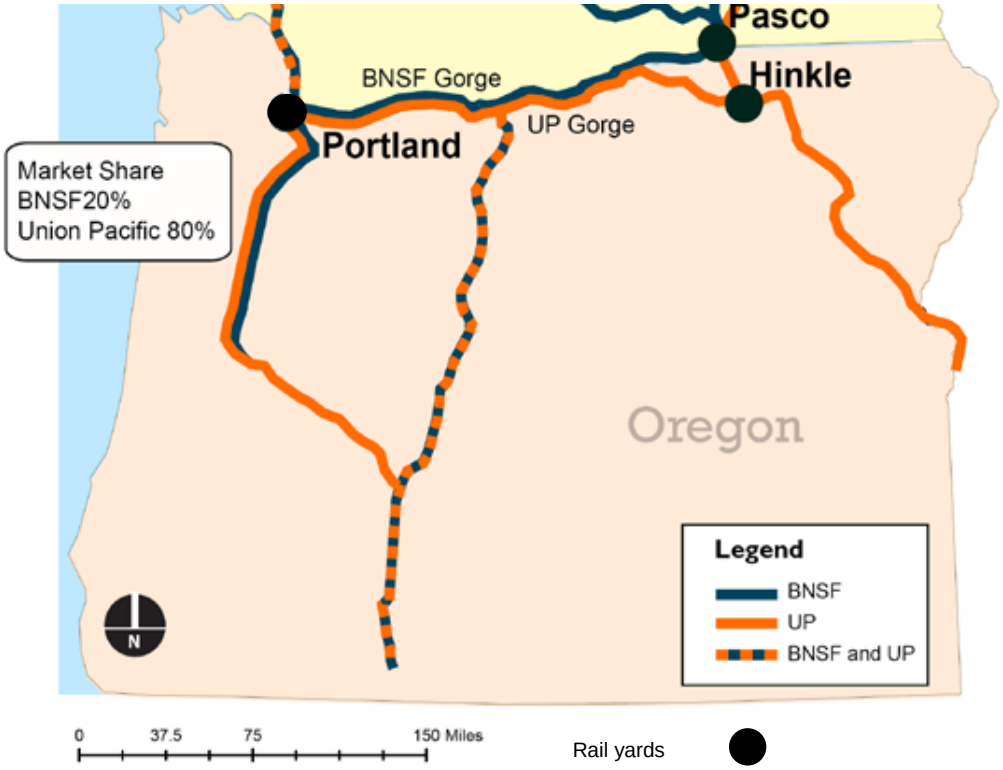
[59] Please see Chapter 9 for discussion of National Highway Freight Network established under Map-21 and the FAST Act.

through movements and connectivity across the state. Many of the OHP freight routes serve as connectors between the coast or specific communities and the interstate system. The strategies and action items identified in Chapter 8 of the OFP should be used with the OHP policies and investment strategies when planning for freight on the state highway system.[60]

Rail System

Oregon's rail network is predominated by two Class I railroads: the UP and the BNSF Railroads. Oregon's rail system consists of a total of 2,400 route miles of track. The two Class I railroads account for 1,126 miles of track, and the remainder is shared by 21 shortline railroads (Class III railroads). Portland & Western Railroad and Central Oregon & Pacific Railroad have the most track mileage for non-Class I railroads in the state, with the former at 286 track miles and the latter at 241 miles.

Oregon's entire rail network is part of the national rail network since all tracks connect to a Class I railroad. The Oregon network is concentrated in the western part of the state, where forest products industry, agricultural producers and population centers rely on the movement of significant freight volumes. The five main lines, or principal routes, that provide mobility throughout Oregon and connect Oregon to the national network are:



- BNSF Railway (shared by Union Pacific Railroad), northward to Seattle and Canada and eastward to the northern tier states via a crossing of the Columbia River between Portland and Vancouver, Washington;
- Union Pacific Railroad, northward to Spokane, Washington, and Canada via the Hinkle Yard (near Umatilla);
- Union Pacific Railroad, eastward toward the intermountain states and central tier states via La Grande;
- BNSF Railway, crossing the Columbia River into Oregon via Vancouver and Wishram, Washington, and going southward to California through Bend and Klamath Falls; and
- Union Pacific Railroad, southward from Portland to California via Eugene and Klamath Falls.

Figure 4.1 provides an overview of where these Class I corridors are located. The Hinkle and Pasco rail yards, along with the yards in Portland, are important hubs

[60] Oregon Highway Plan, https://www.oregon.gov/ODOT/Planning/Documents/OHP.pdf

for rail freight traffic moving through Oregon. For further details, see Oregon Rail Study 2010[61]

Figure 4.1 BNSF and UP Class I Rail Corridors in Oregon

Source: Oregon Rail Study 2010, ODOT.

One factor that could impact freight rail capacity in Oregon is the potential increase in passenger service. As passenger trains increase, tracks could become increasingly congested, which could affect freight rail efficiency. To preserve efficient movement of goods and people in the future, it will be important to make rail improvements so that both freight and passenger capacity needs are met.

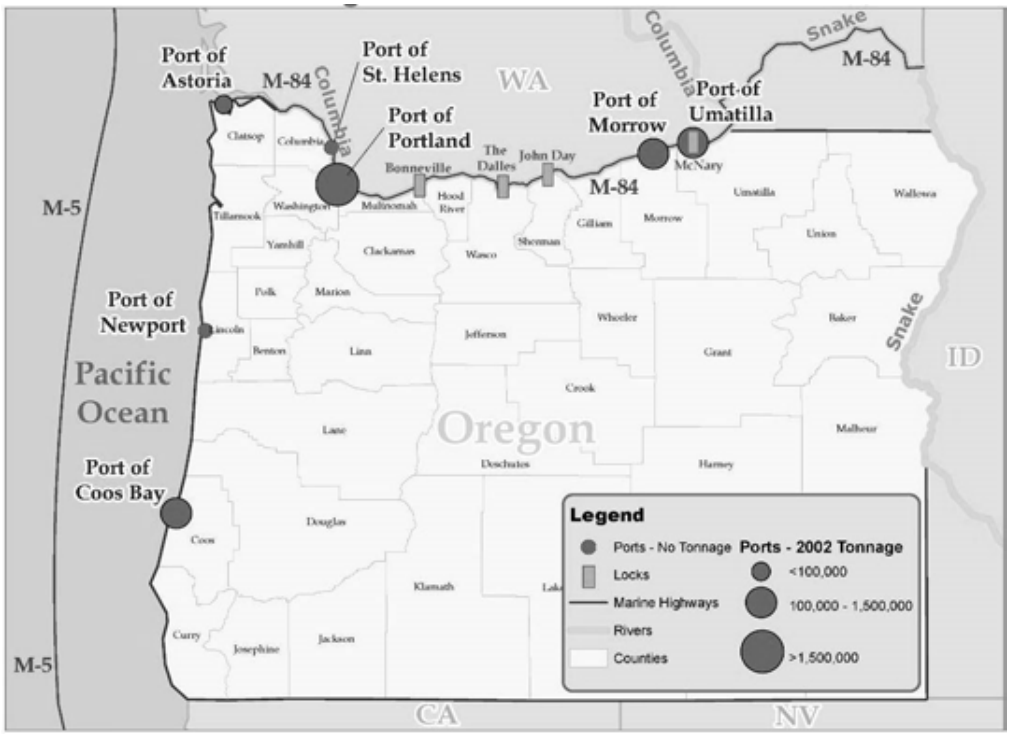
Marine System

Oregon's marine freight network is comprised of several waterways and numerous ports. Oregon's waterways serve a large portion of the state through water access to the Pacific Ocean, the Columbia River and Snake River. In

[61] ODOT's website: https://www.oregon.gov/ODOT/RPTD/RPTD%20Document%20Library/Oregon-Rail-Study-2010.pdf

August 2010, two major Oregon marine corridors (the Columbia/Willamette/Snake River corridor from the Pacific Ocean to Lewiston, Idaho and the north-south corridor on the Pacific Ocean along Oregon's coast) were designated by the U.S. DOT's Marine Administration as marine highways. Marine highways are eligible for federal funding for improvements and are selected because they will be able to relieve congested truck and rail corridors. The Columbia and Willamette Rivers and the Pacific Coast routes were named M-84 and M-5, respectively.

M-84 connects the ocean Port of Astoria and Oregon's major deep draft port (Portland) with Lewiston, Idaho, and all ports on the Columbia River between the two. In addition, the Pacific Coast Ports of Coos Bay and Newport offer marine outlets for goods moving to and from the central and southern coastal regions of the state. In total, 23 Oregon port districts operate along the Pacific Coast and the Columbia River system, five of which are identified as deep-draft freight terminals: Coos Bay-North Bend and Newport along the coast; Astoria and St. Helens along the Columbia River; and Portland along the Columbia and Willamette Rivers. Shallow-draft freight terminals serve shippers on the Columbia River at The Dalles, Arlington, Boardman (Morrow) and Umatilla. In addition to port districts, the marine system serves many terminals that are entirely owned and operated by private sector entities.



The Portland harbor, located at the confluence of the navigable portion of the Columbia and Willamette Rivers, handles the majority of marine freight in Oregon.[62] The Columbia River's 43-foot channel depth gives Portland access to Pacific Rim trade. From ports to the east of Portland, barges bring agricultural, wood and other products to Portland's marine terminal facilities. Portland harbor constitutes a 12-mile stretch of the Willamette River and two miles along the Columbia River located within Portland's northern industrial districts.

Several locks were built in Oregon. The major locks on the Columbia River are located at McNary Dam, The Dalles Dam, Bonneville Dam and John Day Dam. Channel and jetty maintenance, improvements, dredging and operational locks are all necessary to increase freight throughput and decrease delay and costs for marine freight. Repair and maintenance of jetties on the coast and the jetty on the Columbia River are necessary to protect navigational channels and marinas. Investments in navigational aids are necessary to improve safety and efficiency

[62] Parsons Brinckerhoff Ports 2010: A New Strategic Business Plan for Oregon's Statewide Port System December 2009.

on the marine freight network. Figure 4.2 highlights Oregon ports that move a substantial amount of goods, as well as locks and marine highways.

Figure 4.2 Oregon Ports, Locks and Marine Highways

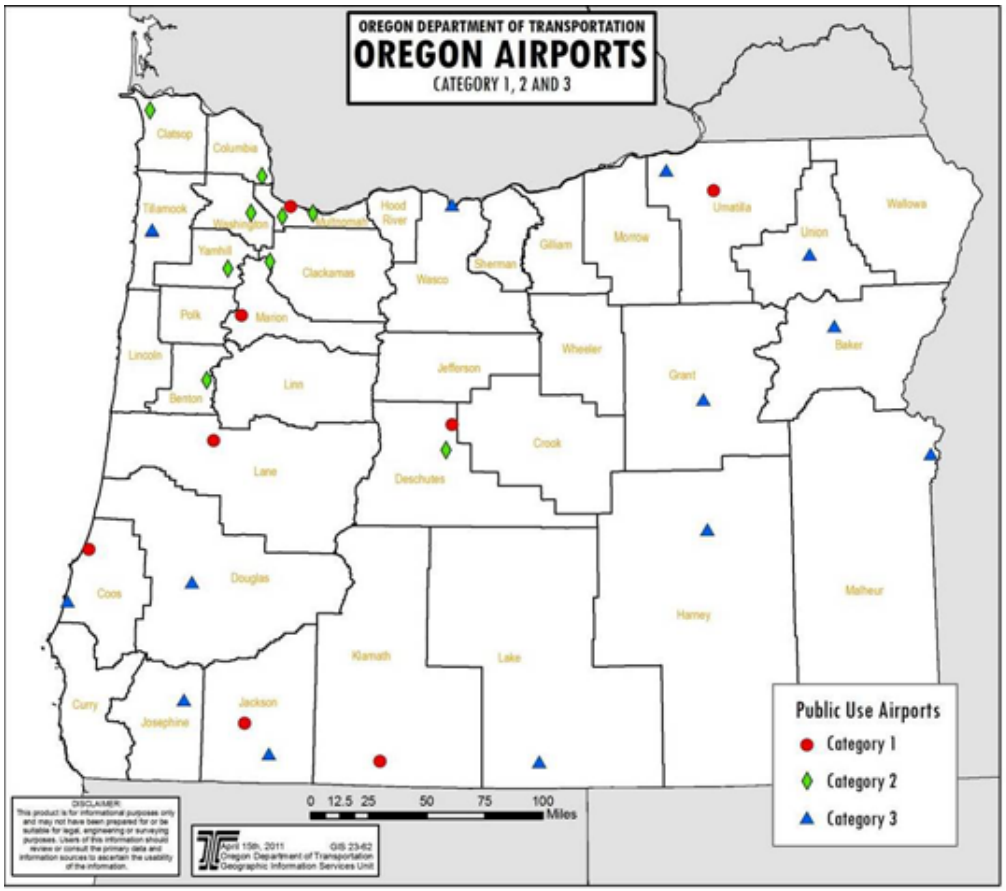
Aviation System

The *Oregon Aviation Plan* (2007) includes 97 public-use airports in the state's airport system. The Portland International Airport (PDX), operated by the Port of Portland, handles the majority of the airfreight movements in the state. Despite the dominance of Portland International Airport, other regional airports in Oregon provide capacity for the movement of airfreight.



The OAP contains a recommended system of airport classification as shown in Table 4.1. The classification system contains five categories:

1. **Category I –** commercial service airports;
2. **Category II –** urban general aviation airports;
3. **Category III –** regional general aviation airports;
4. **Category IV –** local general aviation airports; and
5. **Category V –** remote access/emergency service airports.

Of the five categories, measurable air cargo shipment volumes are only expected at Category I, II and III airports. These airports are identified in Figure 4.3.

See the OAP and the *Technical Memorandum: Inventory of Oregon Freight Infrastructure*.[63,64]

Figure 4.3 Oregon Category I, II and III Airports

*Note: Location is shown when the airport name does not clearly identify the location of the airport.

Pipeline System

Pipelines are an important part of the multimodal freight network and are responsible for delivering petroleum and related products throughout Oregon. The largest pipelines in the state tend to parallel major freight corridors, such as I-5, I-84 and U.S. 97. The pipeline system in Oregon is completely owned by private companies. The private ownership of this system limits the amount of public information available regarding system capacity and planning.

Pipelines in Oregon carry two primary commodities:

1. **Natural Gas.** There are more than 17,000 miles of natural gas pipeline in Oregon. These lines supply five gas utilities that provide power to households, businesses and industrial users.[65] Oregon does not have any proven gas reserves, so all natural gas must be imported to the state.
2. **Refined Petroleum Products.** Over 300 miles of petroleum product pipelines in Oregon supply the state with gasoline, diesel, jet fuel and other refined petroleum products.[66] Oregon has no petroleum refineries so like natural gas, all of its petroleum must be imported. Oregon is especially reliant on the Olympic Pipeline, which connects Puget Sound refineries to distribution terminals in Portland.

Although the pipeline system is privately owned and operated, it does interact with the rest of the state's transportation network. Petroleum product pipelines, for instance, create demand for truck transportation at their termini since fuel products must be shipped from the terminal to their final destination. If Oregon's pipeline systems reach capacity in the future and no new ones are built, these shipments would have to be made by truck, with potential negative impacts such as infrastructure wear and tear and increased roadway congestion.[67]

65 American Gas Association, The Natural Gas Industry in Oregon

66 ODOT, Oregon Transportation Plan: Transportation Needs Analysis Summary Report 2005 -2030, July 14, 2005.

67 According to the *Oregon Transportation Plan: Needs Analysis Summary Report 2005*, current and near-term capacity of petroleum pipeline is adequate. However,

4.3 STRATEGIC FREIGHT NETWORK SELECTION METHODOLOGY AND DESCRIPTION

Chapters 2 and 3 summarize the importance of freight-dependent industries to Oregon. These chapters provide background information on factors that drive freight transportation demand in Oregon: the economy, critical freight-dependent industries and their supply chains. The importance of freight-dependent industries to the Oregon economy is highlighted by their contribution to total Oregon GSP (total GSP was $161.5 billion in 2008),[68] total Oregon manufacturing GSP and employment.[69]

To ensure a long-term competitive advantage for Oregon freight-dependent industries, it is necessary to define the elements of the transportation system used by these industries. This analysis highlights the strategic routes for each freight-dependent industry.

The approach to defining the strategic freight network included the following steps:

1. A set of eight important freight-dependent industries was identified by using information contained in Chapters 2 and 3. The Oregon Statewide Integrated Model (SWIM) was used to identify regional commodity production and consumption for each industry.
2. SWIM was used to identify corridors used to transport commodities for each industry. Each corridor focuses on the major state highways in the corridor and includes all non-highway transportation modes such as rail, marine, aviation and pipelines.
3. For each industry, the corridors that carry the largest value and tonnage of freight are considered to be strategic for those industries. In turn, all of the major truck, rail, marine and airport facilities in these strategic corridors are considered to be part of the strategic freight system.
4. In addition to ensuring that corridors serving freight-dependent industries are part of the strategic system, the system was defined to include corridors that carry the majority of freight for each ACT in the state. This ensures that the economies of each of the state's regions are connected to the strategic freight system.

---

capacity issues are expected, which may require barges and trucks to transport petroleum. The report also states that natural gas pipelines will require additional improvements to meet future demand, which the natural gas industry should be able to handle over the next 20 years.

68 IHS Global Insight – U.S. Regional Service, Oregon Data: November 2009.

69 Reference Chapter 3 Source: Oregon Office of Economic Analysis, November 2009.

5. Once these strategic routes were defined based on industry needs, corridors were identified that provide connections between centers of industry activity and the strategic backbone corridors.

The following sections present more detail on how this industry-level view of freight flows in the state was used to define the strategic freight network. Additional data on Oregon commodity flows can be found in the *Oregon Commodity Flow Forecast, October 2009*.[70]

Freight Industries Strategic Network Methodology

Based on the data summarized in Chapters 2 and 3, the following freight-dependent industries were analyzed to determine which corridors they use to transport goods to markets and receive supplies:

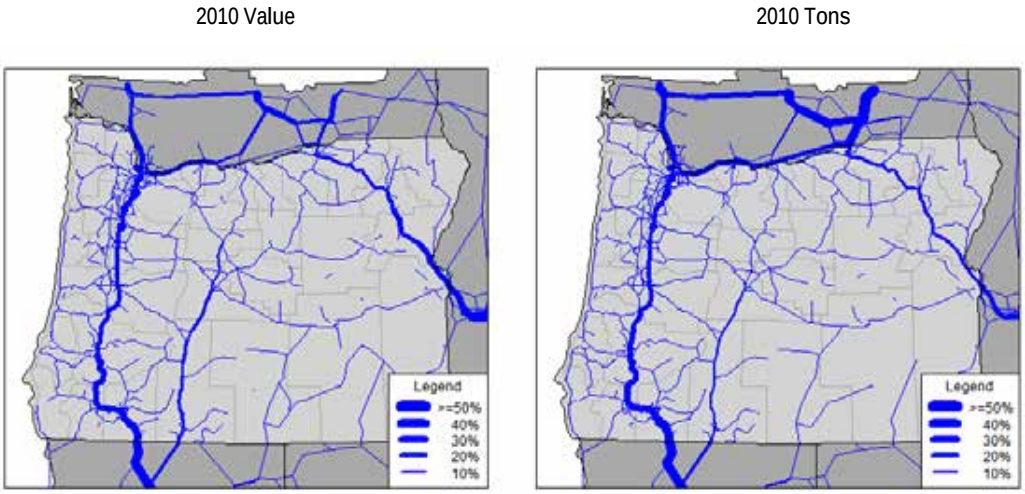
- Agriculture, Forestry and Fishing;
- Computer and Electronics Manufacturing;
- Food Manufacturing;
- Machinery Manufacturing and Metals Manufacturing;
- Wholesale Trade;
- Wood and Paper Manufacturing;
- Retail Trade;
- Services and All Other.

Each industry was analyzed and represented in terms of the value of freight moved and tonnage[71].

Figures 4.4 through 4.11 show average daily statewide corridor flow by value and tonnage for year 2010 for each of the eight freight-dependent industry groups.[72] The maps are intended to illustrate the broad, multimodal corridors over which industry moves its goods. The maps use the state highway system (and the corridors are often referenced in terms of the principal state highway route in the corridor) to represent all modes of flow. The non-highway freight flows actually move along the modal facility closest to the major highway in the corridor.

---

70 http://library.state.or.us/repository/2010/201010251112531/index.pdf



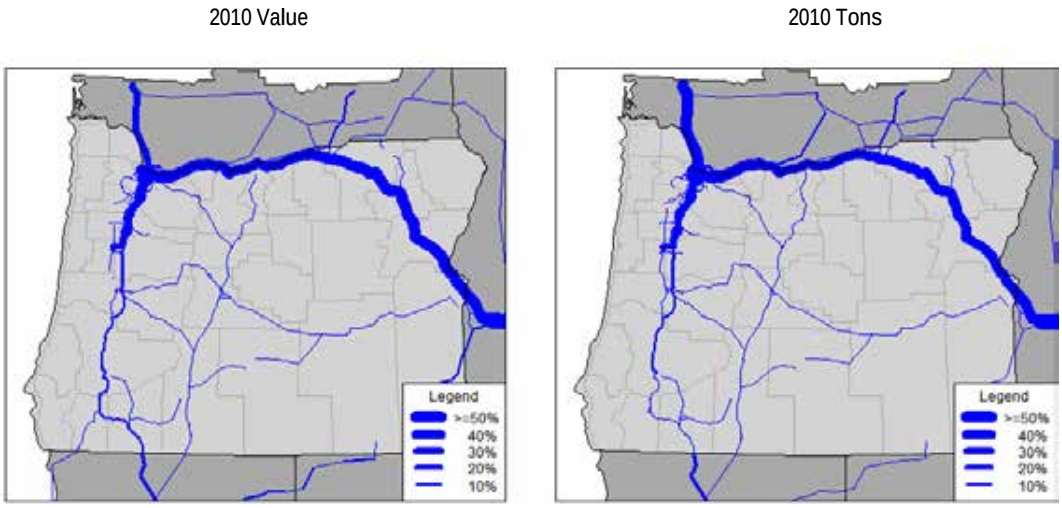
71 Information produced by SWIM for the OFP reference scenario was used to estimate flows by industry.

72 Flow rates outside the state of Oregon represent Oregon activity and do not reflect actual calibrated freight movements.

In Figures 4.4 through 4.12 flows beyond the Oregon borders are illustrative and do not represent all flows on those facilities.

Agriculture, Forestry and Fishing

Figure 4.4 Estimated Agriculture, Forestry and Fishing Industry Output Flows by Value and Tonnage, 2010

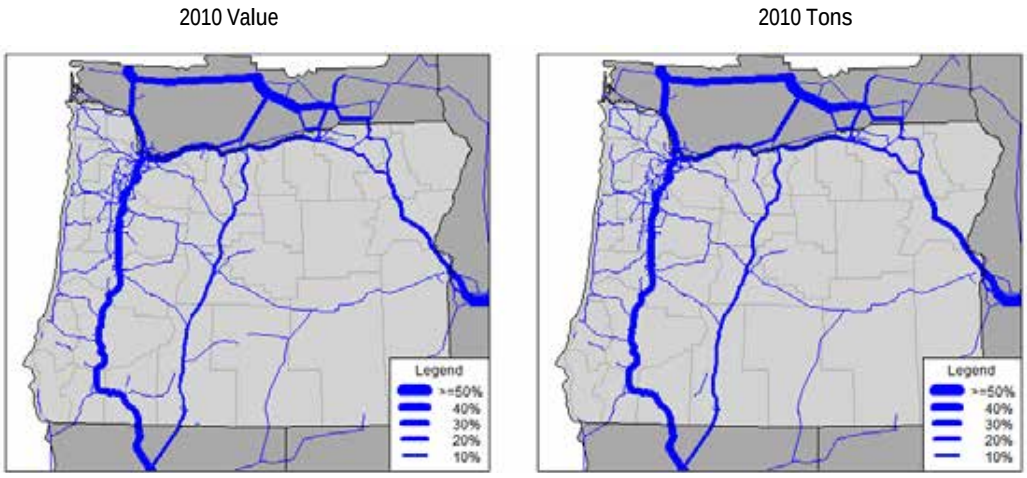


Source: Prepared by ODOT, 2010.

Figure 4.4 presents product flows for the Agriculture, Forestry and Fishing industry group. Goods shipped by industries classified within this group include logs and other wood in the rough and wood products, agricultural products, and fish and wildlife products.

Computer and Electronics Manufacturing

Figure 4.5 Estimated Computer and Electronics Manufacturing Industry Output Flows by Value and Tonnage 2010

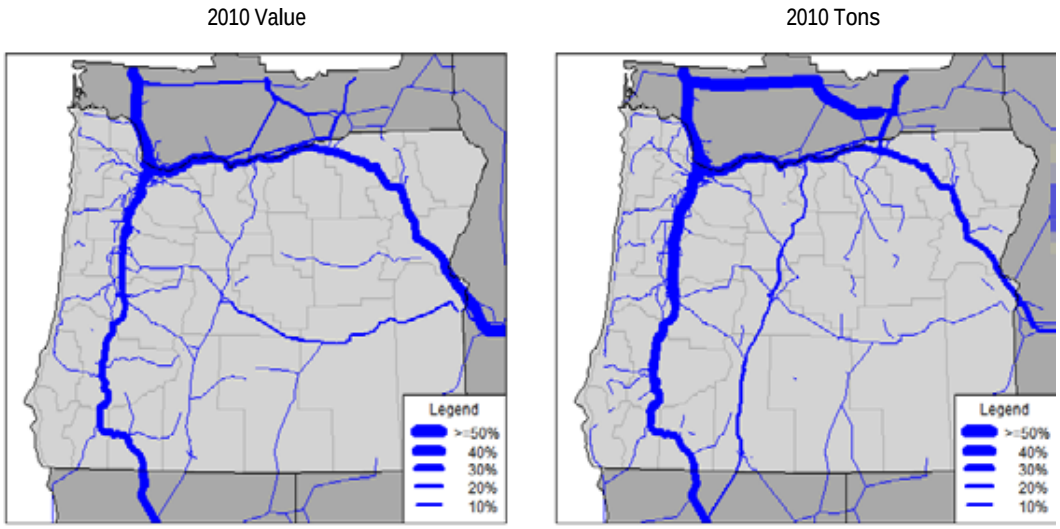


Source: Prepared by ODOT, 2010.

Figure 4.5 shows freight flows for the products of the Computer and Electronics Manufacturing sector. This industry group produces a mix of computer and electronics-related goods and is characterized as a high-value, low weight commodity. Commodity flow is predominantly from outside the state and flows from the north in the I-5 corridor to the Willamette Valley. There are flows east of Portland in the I-84 corridor towards the eastern states. Some of these flows head north into Washington State via the U.S. 97 corridor and the I-82 corridor.

Food Manufacturing

Figure 4.6 Estimated Food Manufacturing Industry Output Flows by Value and Tonnage 2010



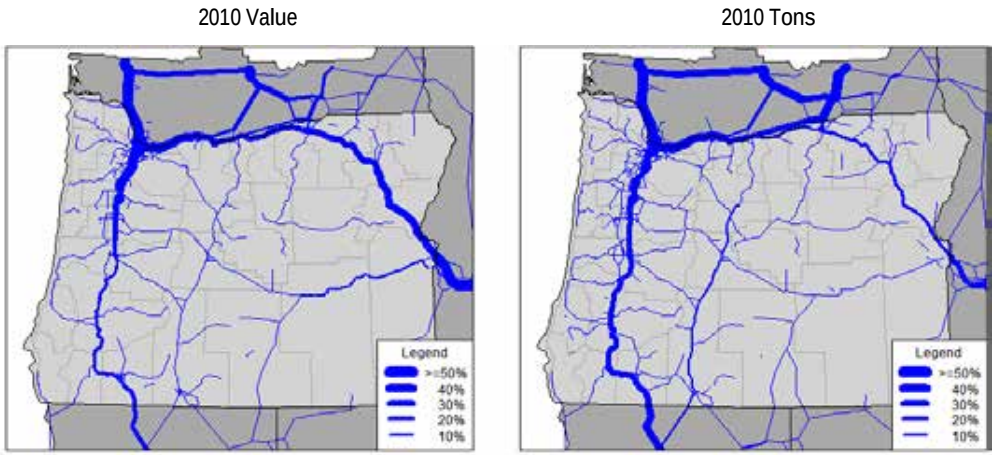
Source: Prepared by ODOT, 2010.

Figure 4.6 presents corridor flows for the products of the Food Manufacturing and Kindred Products industry group. Commodities within this category include live animals and fish, cereal grains, animal feed, meat, seafood, milled grain products, alcoholic beverages and tobacco products. This group represents a wide range of products in terms of value and weight and a mid-range value per unit weight.

Production of these agricultural and food products occurs primarily in the eastern and central areas of the state, as well as in the northwest Willamette Valley to Astoria. The flow maps reveal that the north-south I-5 corridor, particularly in the Willamette Valley area carries many of the food products in Oregon. However, considerable food manufacturing traffic moves in the I-5 corridor and the U.S. 97 corridor to California and Washington and in the I-84 corridor to the Idaho border.

Machinery Manufacturing and Metals Manufacturing

Figure 4.7 Estimated Machinery/Metals Manufacturing Industry Output Flows by Value and Tonnage 2010



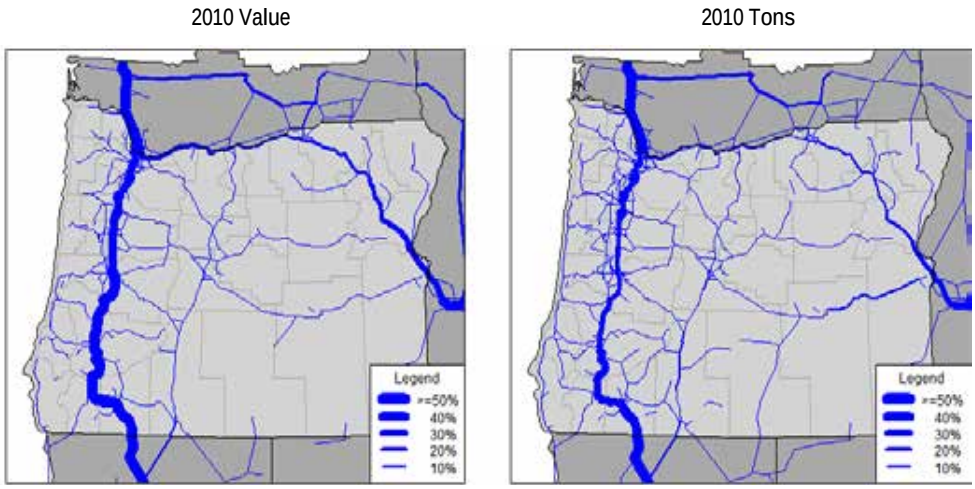
Source: Prepared by ODOT, 2010.

Figure 4.7 shows corridor flows for the products of the Machinery and Metals Manufacturing industry group. Goods within this category include base metal in primary or semi-finished form, articles of base metal, machinery, electronic and other electrical equipment, motorized and other vehicles (including parts), transportation equipment, and precision instruments and apparatus.

The machinery and metals companies producing the flows shown above are predominantly located in the urban areas of the Willamette Valley, with some located in Bend, Astoria and Medford. Their products are primarily trucked to Washington and eastern states. Products of the Machinery and Metals Manufacturing industry group tend to be higher in value and lower in weight. By value goods predominantly move in the I-5 corridor and in the I-84 corridor. The heavier goods movement within this industry group tends to flow in the Willamette Valley I-5 corridor and north of Portland.

Wholesale Trade

Figure 4.8 Estimated Wholesale Trade Industry Output Flows by Value and Tonnage – 2010

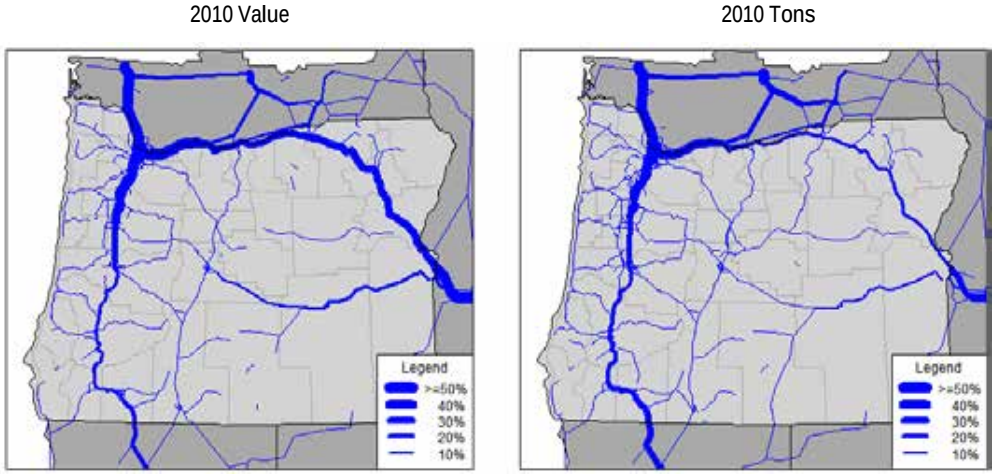


Source: Prepared by ODOT, 2010.

Wholesale Trade products make use of many freight system corridors, as shown in Figure 4.8. However, these goods move primarily on the northern I-5 corridor and on the I-84 corridor. The majority of Wholesale Trade value moves along the I-84 corridor and stays in the northern section of the state. The majority of tonnage moves on I-5.

Wood and Paper Manufacturing

Figure 4.9 Estimated Wood and Paper Manufacturing Industry Output Flows by Value and Tonnage 2010

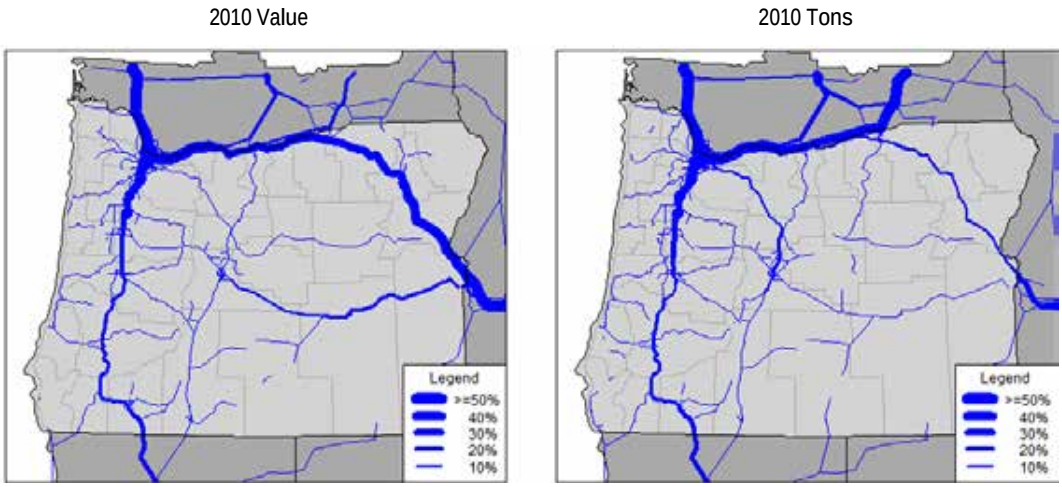


Source: Prepared by ODOT, 2010.

Figure 4.9 presents corridor flows for the Wood and Paper Manufacturing industry group. Industry production in this group includes newsprint, paperboard, paper or paperboard products and printed products. Western Oregon is a heavy production area for these products. Truck flows of this industry group are concentrated along the I-5 corridor and move down to California and up to Washington State.

Retail Trade

Figure 4.10 Estimated Retail Trade Industry Flows by Value and Tonnage 2010



Source: Prepared by ODOT, 2010.

Figure 4.10 shows corridor flows for the Retail Trade industry group. The largest proportion of Retail Trade products by value move in the I-5 and I-84 corridors. A substantial amount of Retail Trade products in value also moves on the U.S. 20 corridor, especially in the eastern one-half of that corridor. In terms of tonnage, the majority of retail goods move in the area around Portland and on I-5 between Portland and Seattle. This highlights the movement of retail goods between major population centers such as Salem, Portland and Seattle.

Services and Other

Figure 4.11 Estimated Services and All Other Industry Flows by Value and Tonnage 2010

Source: Prepared by ODOT, 2010.

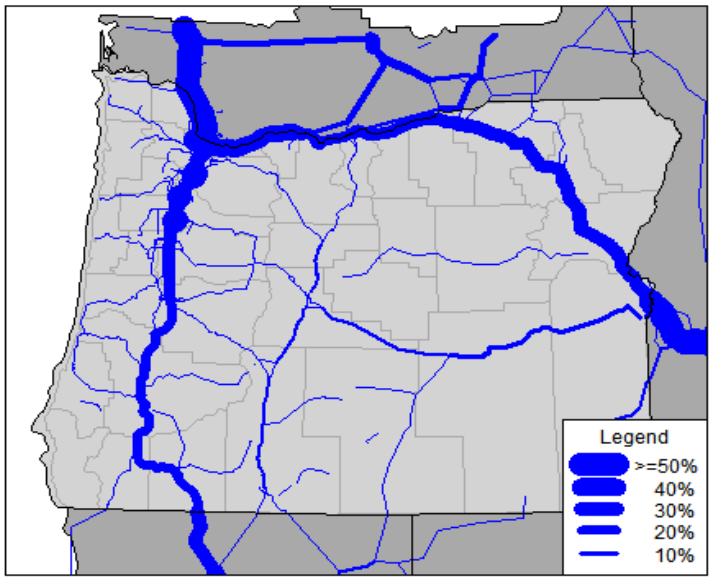


Figure 4.11 presents corridor flows for the Services and All Other industry group. Goods produced within this industry include textiles, leather, articles of textiles or leather, furniture, mattresses and miscellaneous manufactured products.

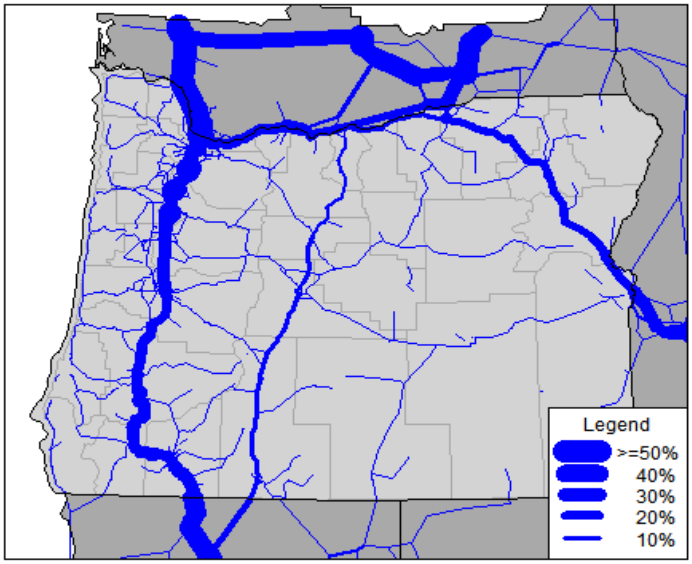
More Service and Other flows are concentrated in the northern section of the I-5 corridor. There is a notable high-value flow of this industry's output on I-84. Lower value flows occur within the southern one-half of the I-5 corridor. Large lower-value flows are forecast for this commodity group on the entire I-5 corridor, especially the southern portion.



Summarizing Freight-Industry Freight Flows and Defining the Strategic System

Figure 4.12 Total Statewide Industry Output Flows by Value and Tonnage 2010, All Modes

2010 Value

2010 Tons

Source: Prepared by ODOT, 2010.

Figure 4.12 depicts the total flows for all industries. Tables 4.2 and 4.3 highlight how each industry utilizes the major corridors. This information is important in defining the strategic freight network, as the corridors that carry high levels of goods for each industry are critical to the state's economic health and to the businesses utilizing these corridors. Table 4.2 shows the percentage of total value of products shipped by each industry in each major corridor, and Table 4.3 shows the percentage of ton-miles of shipments by each industry in each corridor.

Table 4.2 Industry Output Flows by Percent of Value, per Corridor

Corridor	Total	Computer & Electronics	Wholesale Trade	Machinery & Metals	Retail Trade	Wood & Paper	Agriculture Forestry & Fishing	Food Mfg	Services & Other
I-84	49%	67%	46%	44%	44%	22%	29%	34%	46%
I-5	30%	21%	28%	34%	30%	52%	33%	35%	27%
U.S. 20	6%	4%	7%	8%	9%	7%	6%	3%	11%
U.S. 97	4%	1%	5%	4%	4%	5%	11%	13%	4%
U.S. 26	2%	1%	2%	2%	2%	3%	3%	2%	3%
All other corridors[73]	9%	6%	12%	8%	11%	11%	18%	13%	9%

Table 4.3 Industry Output Flows by Percent of Total Ton-Miles, per Corridor

Corridor	Total	Computer & Electronics	Wholesale Trade	Machinery & Metals	Retail Trade	Wood & Paper	Agriculture Forestry & Fishing	Food Mfg	Services & Other
I-5	37%	24%	37%	38%	37%	45%	35%	35%	34%
I-84	32%	63%	33%	37%	34%	18%	30%	34%	35%
U.S. 97	9%	1%	8%	9%	6%	7%	9%	15%	8%
U.S. 20	5%	4%	5%	2%	7%	8%	5%	2%	7%
U.S. 26	3%	2%	3%	3%	3%	5%	3%	2%	5%
All other corridors	23%	6%	14%	11%	11%	17%	18%	12%	11%

Source: Prepared by ODOT, 2010.

[73] Other corridors analyzed included I-82, I-205, I-405, US30, US101, US199, US395, OR6, OR11, OR18, OR22, OR34, OR58, OR99, OR126, OR140, OR204, OR207, and OR217.

From the data in these tables and figures, it becomes apparent that the I-5 and I-84 corridors are the dominant corridors in terms of tonnage and value. This includes all modes that travel along this corridor. In addition, the U.S. 97 and U.S. 20 corridors carry moderate freight volumes but are critical because they provide redundancy in the freight system. U.S. 97 and U.S. 20 act as secondary north-south and east-west cross-state highways, respectively. Tables 4.2 and 4.3 illustrate that the I-5 and I-84 corridors carry the largest share of freight for each of the state's freight-dependent industries. The tables also show that the U.S. 20 corridor is a significant secondary corridor for most industries particularly in terms of tonnage shipped over relatively long distances. The U.S. 97 corridor carries relatively high-value products in the Agriculture, Forestry and Fishing industry group and the Food Manufacturing industry group.

Based on this analysis, the following four corridors are strategic in terms of their significance to major freight-dependent industries:

1. Western corridor (I-5),
2. Columbia River corridor (I-84),
3. U.S. 20 corridor, and[74]
4. Central Oregon corridor (U.S. 97).

The next section of this chapter describes how these and other corridors provide critical connections to centers of freight-dependent economic activity in the state.

4.4 CONNECTIVITY

Connectivity in this section refers to the ability of the freight network to safely and efficiently move goods between important components of the Oregon freight network. This includes connectivity between major highways and intermodal facilities such as airports or marine ports, between all regions of the state, and between key industries and the freight network. Connectivity is critical because it allows businesses and industries to move their goods throughout Oregon and beyond in a cost-effective manner. Four multimodal corridors were selected as major corridors whose connectivity is vital to the state economy.

[74] U.S. 26 is also significant to Oregon industries from Portland to Idaho. However, U.S. 20 carries more freight by industry (see tables on previous page), and it also acts as an important highway for remote areas in southeastern and south central Oregon with little other east-west highway access. Selecting both would not be warranted, as they run parallel to each other for much of eastern and central Oregon.

Strategic Freight Corridors and Connectivity

Western Corridor

The Western Corridor is a split corridor with several components: Marine Highway 5 (M-5), north-south Interstate 5 (I-5) and all parallel truck/rail facilities that connect Oregon with the rest of the nation. M-5 is a designated marine highway in the Pacific Ocean that connects Oregon with other West Coast ports, from Canada to Mexico. I-5 truck and rail facilities connect the three largest population centers of Portland, Eugene and Salem and are the state's primary arteries for truck and rail freight shipments. Together, this Western Corridor connects Oregon with the national freight transportation system via several truck, rail, seaport and airport facilities, including I-84, U.S. 30, U.S. 20 and U.S. 199; Class I and shortline railroads; marine facilities at Astoria, Coos Bay and the Port of Portland; and air facilities at Portland International Airport. These connections are critical for the movement of the majority of goods produced throughout Oregon and on the I-5 corridor.

The Western Corridor contains some of the major intermodal facilities in the state, which move both heavy and valuable goods to markets around the world. Important intermodal infrastructure on the I-5 corridor includes the Portland International Airport, the Port of Portland, the Port of Astoria and the Port of Coos Bay. These features are illustrated in Table 4.4.

Columbia River Corridor

The Columbia River Corridor, including Interstate 84 (I-84) and Marine Highway 84 (M-84), is the primary link between western Oregon (including Portland) and the east and is one of the few transportation corridors in North America where truck, barge and rail transportation run parallel to one another. Eventually, I-84 links with I-80 in Utah, which connects to the large freight hub of Chicago. For most goods originating in the Portland and Willamette Valley region, I-84 is the route used to move goods to the Midwest and beyond. As a result, this is a heavily used freight corridor that is essential to the Oregon economy. Within Oregon, this corridor connects with Portland, the I-5 corridor, Portland International Airport, the Port of Portland and other ports on the Columbia River. In addition to the interstate, Oregon's major rail corridor that connects Portland and other West Coast cities with the Midwest runs along the Columbia River. Both Union Pacific and BNSF operate service that connects Portland with destinations in states to the east of Oregon. Noteworthy is the dependence of the computers and electronics manufacturing industry on the I-84 corridor; this is a high growth industry that makes up a large part of Oregon's expected future growth.

Central Oregon Corridor

This corridor is a major north-south corridor connecting central Oregon with markets in Washington State and California. The largest city in central Oregon is Bend, a metropolitan area with nearly 88,000 residents, which is connected by U.S. 97 to I-84. U.S. 97 is the only major north-south freight route east of the Cascades and acts as a relief highway to support I-5 in case of incidents on that interstate.

- In addition to the highway, a major BNSF and UP rail corridor runs parallel to U.S. 97; it is the major rail line that connects Oregon with California. The U.S. 97 corridor, similar to U.S. 20, connects a large portion of central Oregon that would have insufficient connectivity to major markets such as Portland and the interstate network without its existence. Businesses located in the South Central Oregon ACT and the Central Oregon ACT benefit from the connections to I-84 and California that this route provides. It also provides efficient access to U.S. 20, which allows businesses to move goods to I-5 and to the east.

Table 4.6 Central Oregon Corridor Freight Facilities, by ACT

ACTs	Facilities Providing Connectivity	Other Freight Facilities

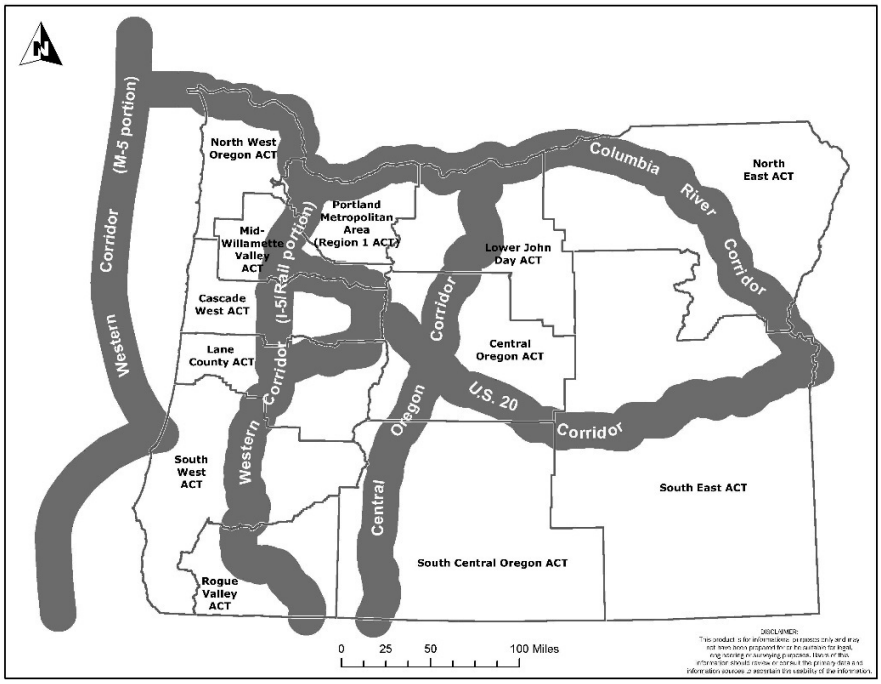
South Central Oregon ACT	· U.S. 20 · OR 58, OR 140	Class I rail: BNSF and UP Shortline rail: The Klamath Northern Railway, Lake Railway Major Commercial Port: Port of Umatilla, Port of Morrow Categories I, II and III Airports: Klamath Falls Airport, Lake County Airport

U.S. 20 Corridor

This is a major east-west connector corridor that runs through the middle of the state, from the Idaho border all the way to Newport on Oregon's Pacific Coast. The route ties together several important cities from Boise, Idaho to Bend. Further routes on OR 22 and OR 126 provide freight routes to Salem and

Eugene. One issue to consider with this route is that 53-foot trailers are currently not allowed between the U.S. 20/OR 22 junction and Sweet Home and between Newport and Corvallis. Trucks currently rely on OR 22, OR 126 and other routes to travel this area. The corridor concept allows the parallel facilities to carry the corridor traffic. In general, east-west connectivity in Oregon can be improved, especially between I-5 and U.S. 97.



In essence, U.S. 20 acts as the major east-west highway for central and eastern Oregon – interstates only exist in the northern and western sections of the state. No major rail corridors run parallel to U.S. 20. At the Idaho border, however, a Class I railroad intersects with U.S. 20; Class I railroads also intersect U.S. 20 in Bend and near Corvallis. Within Oregon, U.S. 20 connects the north-south corridors of U.S. 97, U.S. 395 and I-5. This is illustrated in Table 4.7. U.S. 20 is a major mover of agricultural products in the central and eastern one-half of the state. In the western one-half, the U.S. 20 Corridor is important to companies producing forest/wood products and clay/mineral/stone – 15 percent of the shipments from the former and 20 percent of the latter utilize U.S. 20.

This route is important in terms of connectivity because it connects a major area (Central Oregon) with two major interstates (I-84 and I-5). It also connects the freight-dependent industries in Bend with cities to the east and the I-5 Corridor to the west. Without this facility, businesses located near U.S. 20 in the South East Oregon ACT or Central Oregon ACT might struggle to compete because of high travel times and transportation costs to get goods to market. See Figure 4.13.

Figure 4.13 Freight Industries Strategic Corridors in Oregon

Source: Prepared by ODOT for the OFP

In summary, these corridors, when viewed as a system, provide cross-state or cross-regional access to the majority of the state. All of the roadways in Figure 4.12 above also have parallel Class I railroads except U.S. 20. Since the majority of the population in the state lives along the I-5 Corridor, a significant amount of inbound freight needs to be moved there. U.S. 20 and U.S. 97 connect remote, rural places with routes that connect with Portland; this allows goods to be moved to major markets. For further detail on important intermodal connectors in these corridors, a list of the official NHS Intermodal Connectors is available from FHWA.[75]

4.5 FREIGHT THROUGH MOVEMENTS

The Western Corridor and Central Oregon Corridor serve as the main north-south connections through Oregon between Washington and California. To the east the Columbia River Corridor is the main connection between Oregon and Idaho and eastern states. Goods move from the east and the Pacific through

75 FHWA Website : https://www.fhwa.dot.gov/planning/national_highway_system/intermodal_connectors/

Oregon's ports and to destinations outside of Oregon. As a result, significant "through" traffic exists on Oregon highways, railways, waterways and pipelines.

Truck Through Traffic

Oregon is a bridge state between Washington and California for numerous trucks traveling each day destined for locations outside of the state. Table 4.8 shows that about 2400 through-trucks cross the southern end of the Western Corridor, while about 3100 through-trucks cross the corridor from the north. Some of these trucks are likely eastbound within the Columbia Corridor. About 2100 through-trucks cross into the Columbia Corridor from Washington State in the vicinity of I-82, while about 2700 through-trucks cross the Oregon/Idaho border on an average day. About 600 to 800 through-trucks cross the border at the southern end of the Central Oregon Corridor a day. The through routes are varied and depend on their final destination outside of Oregon. The U.S. 20 Corridor does not appear to be a significant corridor for through-truck traffic. While these trucks have limited direct economic impact on Oregon, they contribute to congestion and environmental concerns in the state. These trucks also pay the Oregon weight mile tax.

Table 4.8 Average Annual Daily Through-Trucks Crossing Oregon Borders

Corridor Name	Through Trucks Entering or Exiting Corridor
Western Corridor	2400 – 3100
Columbia River Corridor	2100 – 2700
Central Oregon Corridor	600 – 800
U.S. 20 Corridor	not a significant through-trip corridor

Source: ODOT, 2009

Rail Through Traffic

Rail through movements make up the largest share of rail carloads, at over 600,000 carloads.[76] These are loads with rail origins outside of Oregon and rail movements through Oregon, during which time tracks in Oregon are used. This does not include shipments that come into Oregon ports and are transloaded to rail. Rail through movements mainly travel in the Western, Central Oregon and Columbia River Corridors.

[76] Carload Waybill, 2008: https://www.stb.gov/stb/industry/econ_waybill.html

Marine Through Traffic

For marine traffic, through movements refer to those commodities that are transferred on or off of ships or barges at Oregon ports, but have neither an Oregon origin nor destination. Many of these goods (especially bulk) arrive at the Portland harbor by rail and are loaded onto ships. The 2009 Oregon Commodity Flow Forecast (CFF) estimates that rail moved 565,000 tons of goods from locations outside of Oregon to the Port of Portland in 2010. This is only a small percentage of the total commodity volume that moves from outside of Oregon to the Portland area; the CFF estimates this volume to be 19 million tons in 2010. The CFF estimates that Portland harbor will move a total volume of 227,000 tons of marine imports to areas outside of Oregon in 2010.

Pipeline Through Traffic

The 2009 Oregon Commodity Flow Forecast shows that a significant amount of natural gas product moves through Oregon for use in other states. The total 2002 volume of natural gas that moved through Oregon was 13.7 million tons compared to 4.7 million tons imported to Oregon in 2002.

Freight and Climate Change

5.0 Freight and Climate Change

According to the U.S. Environmental Protection Agency (EPA), transportation sources account for one-third of carbon dioxide emissions which contribute to global climate change.[77] Research and policy have historically focused on reducing Green House Gas (GHG) emissions from passenger vehicles. However, freight sources are increasingly being considered due to their contribution to carbon dioxide, nitrogen oxides, sulfur dioxide and particulate matter emissions. The Transportation Research Board (TRB) found that the conveyance of freight—via rail, commercial trucks, ships, boats and pipelines—accounts for 38 percent of all transportation-related carbon dioxide emissions[78] or 12 percent of all man-made sources. Thus, addressing freight emissions and efficiency has the potential for long-term effects on GHG emissions and public health parameters.

The freight sector can take a number of actions to reduce the GHGs it produces. Low-cost, high-payoff actions that offer benefits for the freight sector are particularly attractive.

This chapter analyzes trends, actions and current policy as it relates to the freight sector and GHG emissions in the following sections:

- The Oregon policy context, summarizing relevant policies recently adopted in Oregon that are contributing to the GHG and climate change discussion;
- Technological and regulatory trends affecting freight GHG emissions and infrastructure;
- Potential opportunities to reduce GHG emissions from freight; and
- Impacts of climate change on freight.

Further details are contained in Freight and Climate Change: Background Paper for the *Oregon Freight Plan.*

5.1 THE OREGON POLICY CONTEXT

The State of Oregon is already actively combating climate change through targeted programs and policies, regulations and legislative initiatives, inter-agency coordination and collaboration with other western states. Some of these policies are related to freight and can be grouped into four areas:

---

77 EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2006, Table 2-14

78 "Potential Impacts of Climate Change on U.S. Transportation" (TRB 290), Table B-2

- Legislative initiatives. Several statutes addressing climate change and GHG emissions have been implemented in Oregon. These laws include provisions aimed at reducing GHG emissions from transportation. In 2007 the Oregon Legislature passed the Climate Change Integration Act, establishing the Oregon Global Warming Commission and setting statewide greenhouse gas reduction goals which call for reducing Oregon's emissions 10 percent below 1990 levels by 2020 and 25 percent below 1990 by 2050. Chapter 865 Oregon Laws 2009 requires Portland Metro to develop transportation and land use scenarios designed to reduce greenhouse gas emissions while accommodating population and economic growth. Enacted during the 2010 Special Session, Chapter 85 Oregon Laws 2010 directs ODOT and the Oregon Department of Land Conservation and Development (DLCD) to develop a state-level strategy to reduce greenhouse gas emissions from transportation, develop a toolkit to assist local governments and metropolitan planning organizations in reducing greenhouse gases from transportation, and develop guidelines for scenario planning. As part of this process, the Land Conservation and Development Commission (LCDC) will set transportation-related greenhouse gas reduction targets for light-duty vehicles in major metropolitan areas.

  The statutes address freight emissions by regulating shipboard engine usage in ports and setting minimum requirements for the amount of biodiesel contained in diesel fuel sold in Oregon.

- Funding programs. *Connect*Oregon I, II and III are lottery-backed bond funded programs exclusively dedicated to non-highway modes. As such, they improve or preserve modal alternatives that may reduce GHG emissions, as compared to trucking. There are also tax credits available through the Oregon Department of Energy to encourage reduced fuel use and through the Oregon Department of Environmental Quality to promote truck engine replacement.

- Partnerships. Oregon participates in a variety of partnerships with other western states and nonprofits to advance its GHG reduction goals. The Western Climate Initiative, a partnership of western states and Canadian provinces that cooperate on climate change issues, is exploring a regional target for GHG emissions reduction, as well as a market-based, cap-and-trade system. Oregon is also active in the Climate Registry, the International Carbon Action Partnership and the Climate Trust.

5.2 TRENDS AFFECTING FREIGHT GHG EMISSIONS

A number of technological innovations and regulatory actions are affecting freight-sector GHG emissions. This section highlights some of these technological trends by mode as well as some of the major regulatory actions that will impact GHG emissions from the freight sector in the future.

New Technologies

Freight engine and vehicle technologies continue to improve fuel efficiency and reduce GHG emissions per ton-mile. Table 5.1 provides estimates of the changes in GHG per ton-mile that could be achieved as the freight vehicle fleet is replaced.

Table 5.1 Range of Near-Term GHG per Ton-Mile Emissions for Freight Modes by Technology

Technology Option	Description	Emissions (g CO_2e/Ton-Mile)[79]		Percentage Reduction in GHG/Ton-Mile from Existing Fleet	
		Low	High	Low	High
Heavy-Duty Diesel Trucks					
Existing	Existing truck fleet (2008)	313			
New	New truck	310	310	1%	1%
Best available	Best available new truck, aerodynamic and weight reduction only	266	282	10%	15%
	Best available new truck, engine improvements only	284	287	8%	9%
	Best available new truck, combined	242	259	17%	23%
Rail					
Existing	Existing rail fleet (2008)	28			
New	New locomotive	27	27	3%	3%
	New locomotive, Tier 4-compliant	27	27	2%	2%
Best available	Best available new locomotive	25	25	12%	12%
	Best available new locomotive and cars	22	23	16%	21%
Marine					
Existing	Existing domestic marine fleet	54			
New	New engine	53	53	1%	2%
	New engine, Tier 4-compliant	53	55	-1%	1%
Best available	Best available engine (diesel-electric)	43	49	10%	20%
	Best available propeller (nozzle or winglets)	51	52	4%	5%
	Best available technology, combined	41	47	13%	25%
Air					

[79] This unit is grams of CO_2e per each mile traveled per ton.

Technology Option	Description	Emissions (g CO_2e/Ton-Mile)[79]		Percentage Reduction in GHG/Ton-Mile from Existing Fleet	
		Low	High	Low	High
Existing	Existing commercial aircraft fleet	1,472			
New	New commercial aircraft	1,407	1,407	4%	4%
Best available	Best available commercial aircraft	1,178	1,178	20%	20%

Sources: Cambridge Systematics analysis of Annual Energy Outlook, 2009; U.S. DOT Report to Congress Transportation's Role in Reducing U.S. Greenhouse Gas Emissions, 2010; U.S. EPA RIA for Diesel Engines less than 30L; Boeing; and General Electric.

The following technological trends by mode can impact GHG emissions from freight sources:

- Trucks. Heavy-duty truck[80] fuel efficiency can be improved through a variety of options, including aerodynamic improvements, weight reduction and engine improvements such as electrified accessory systems. Evidence suggests a combination of the best available new truck technologies, along with engine improvements, weight reduction and aerodynamic enhancements, could achieve an overall truck GHG reduction of 17 to 23 percent per ton-mile per truck.[81]
- Rail. Rail locomotives have demonstrated improved fuel economy over the past few decades mostly because the development of larger, more powerful line-haul locomotives results in fewer locomotives required per train. Other railroad technological and operational improvements also contributed to this trend. The combination of best available new locomotives and lightweight aluminum railcars could potentially lead to a 16 to 21 percent reduction in freight rail GHGs per ton-mile over the existing fleet. However, locomotives typically remain in service for 30 to 40 years, so it will likely take many decades before these new technologies penetrate the market completely.
- Marine diesel. GHG emissions are hard to track over time, because it is hard to differentiate between domestic and international sources. However, various technologies can help reduce GHG emissions from water sources, including diesel-electric engines, propeller nozzles and winglets and shore power systems. The combination of these and other technologies could yield GHG emissions per ton-mile improvements in the 13 to 25 percent range.

80 As used in this report, the term 'heavy duty truck' refers to Class 8 tractor-trailer combination trucks (Class 8: gross weight greater than 33,000 lbs.).

81 Freight and Climate Change: Background Paper for the Oregon Freight Plan, 2010, ODOT.

- Aircraft. GHG emissions from aircraft continue to improve because air carriers have strong incentives to cut operating costs and increase payload capacity with fuel-efficient aircraft. On average, a new jet is 4 percent more fuel efficient than the existing fleet while the best available new aircraft can be up to 20 percent more fuel efficient. However, like locomotives, commercial and cargo aircraft have very long service lives (up to 40 years or so), so it will take a long time before the best new technologies completely penetrate the fleet.

Regulatory Changes

Several states are phasing in new regulations to reduce GHG emissions from truck, locomotive and marine diesel engines. For example, California has a truck idling law, which restricts idling to five minutes for all trucks within the state's border. In Oregon, Chapter 754 Oregon Laws 2009 requires DEQ to form a workgroup and study idling regulations. Direct federal regulation of truck GHG emissions and/or fuel economy is also a possibility.

- Trucks. The 2007 Energy Independence and Security Act gave the U.S. DOT authority to regulate fuel consumption in medium- and heavy-duty trucks, starting with the 2016 model year.[82]
- Rail and marine. New locomotives and remanufactured line-haul locomotive and heavy-duty engines, including those used in marine vessels, will be subject to stricter U.S. EPA emissions requirements beginning in 2012.[83]
- Aircraft. Aircraft GHG emissions are currently not regulated, but the International Civil Aviation Organization does promulgate standards which control jet engine emissions of nitrogen oxides (NO_x), which is a GHG at altitude.[84] This has led to world-wide improvements in both engines and fuels used in aircrafts.

5.3 POTENTIAL ACTIONS TO REDUCE FREIGHT-RELATED GHG EMISSIONS

Several opportunities exist to reduce transportation-related GHG emissions from freight movements in Oregon beyond technology and regulatory strategies. In this section, two general categories of GHG reduction strategies are described:

---

82 Energy Independence and Security Act: https://www.congress.gov/bill/110th-congress/house-bill/6

83 EPA Website: https://www.epa.gov/vehicles-and-engines.

84 International Civil Aviation Society Website: https://icao.int/about-icao/Pages/default.aspx

- Operations improvements and education; and
- Mode shift.

Operations Improvements and Education

Many states, including Oregon, have realized environmental and economic benefits through the implementation of promising new freight operations and education ideas. These include three possible methods to reduce GHG emissions from freight:

- Port operations and equipment improvements. Ports and intermodal terminals are major freight nodes. The presence of numerous mobile and stationary emissions sources at these facilities can often turn them into hot spots for emissions of GHG and other pollutants. This is particularly true because port equipment (e.g., drayage trucks and shunting locomotives) tends to be older and more polluting. A number of operational strategies can reduce emissions at ports. These include various strategies using computerized information systems to help spread port truck traffic into off-peak periods (reducing congestion and associated fuel usage), making more efficient use of trucking equipment in order to reduce empty trips, using electric and alternative fuel powered equipment within the marine terminals to reduce emissions from fossil fuels and using electronic tracking systems to more efficiently manage port-related trucking fleets to reduce trips and operations in congested conditions.
- Idling reduction strategies. Long-duration idling of trucks and trains in the U.S. consumes more than 1 billion gallons of diesel fuel annually and produces 11 million tons of CO_2, along with other emissions.[85] This estimate does not take into consideration short-term idling or marine vessel idling, which also contribute to freight GHG emissions. For each mode, several strategies can be implemented to reduce idling-related GHG emissions:
  - *Trucks.* Trucks tend to idle significantly at intermodal stations and at ports. Many of the strategies for reducing GHG emissions at ports are strategies that can be employed to reduce truck idling. Truck stop electrification and auxiliary power unit (APU) installations can create reductions in GHG emissions from idling of parked trucks. Efforts to electrify trucks stops are well underway in Oregon but could be expanded to increase emissions reductions benefits.
  - *Rail.* Emissions from locomotives can be reduced with newer locomotive technology, such as Genset locomotives. This technology uses multiple smaller engines to better match power output to demand and uses up to

[85] EPA Website: https://www.epa.gov/air-pollution-transportation

37 percent less fuel than older locomotives.[86] Another strategy is to use idling limit devices, which automatically turn off a locomotive's engine if it is idle for a certain period.

- *Marine.* One solution is to install shore power systems that provide electricity to the ships while docking. This would result in less fuel consumed by the ships, which equates to lower GHG emissions.

· Improved driving and routing efficiency. Vehicle driving and routing efficiency improvements are important to reducing GHGs from the freight sector. Methods to improve operations efficiency include:

- *Virtual weigh stations.* These utilize technology, such as weigh-in-motion (WIM) devices, to detect truck weight without requiring that the driver stop at an actual weigh station. This reduces idling and fuel consumption that would occur in the weigh station. Oregon currently utilizes WIM devices throughout the state.
- *Speed reduction.* Freight operators will generally go as fast as the speed limits allow. While this may make sense from a time perspective, fuel economy usually decreases rapidly at speeds above 60 miles per hour.[87] The current maximum truck speed limit in Oregon is 55 miles per hour.
- *Driver training efforts.* Driver training programs can be used to educate truck drivers on "eco-driving" techniques to reduce emissions and save fuel, such as effective trip planning, use of cruise control, avoiding rapid acceleration, and deceleration and up shifting as soon as practicable. This strategy is often implemented by freight carriers themselves, as they result in fuel cost savings and cost reduction for carriers.
- *Signal optimization and signage.* Adjusting signal timing to optimize traffic flow on busy truck routes and improving signage near marine and intermodal facilities can improve emissions by freight. These are effective strategies to reduce freight emissions by reducing idling at signals and subsequent acceleration after the stop.

- *Congestion relief and bottleneck mitigation.* Congestion on roadways requires trucks to accelerate and idle more frequently, increasing truck emissions. In fact, a 2010 study by Portland State University found that fluctuations in speed during congestion on freight routes in the

[86] Union Pacific Railroad Website: https://www.uprr.com/newsinfo/releases/environment/2009/0611_genset.shtml

[87] U.S. EPA Fuel Economy Guide: https://www.fueleconomy.gov/feg/driveHabits.jsp

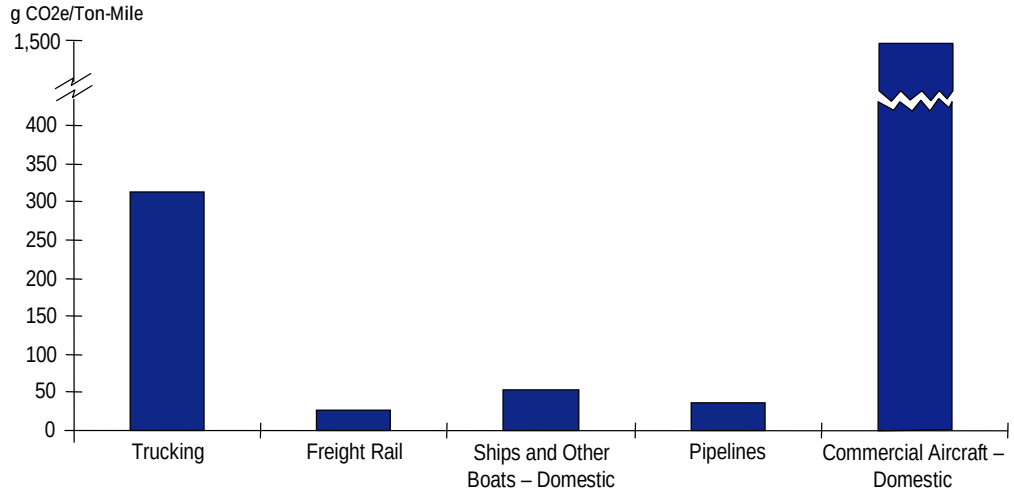
Portland Metropolitan Area correlated to increased emissions compared to free-flow conditions—a 50% increase in carbon dioxide, 65% rise in nitrogen oxides, 49% more sulfur dioxide and 13% rise in particulate matter.[88] Thus, addressing congestion has the potential for long-term effects on GHG emissions and public health parameters. However, it is important to consider the impacts of induced travel demand from passenger vehicles when considering an increase in capacity or improving traffic flow.[89] Improved transit also may help reduce congestion on major truck routes, thereby potentially contributing to reduced truck emissions.

Mode Shift

As shown in Figure 5.1, moving cargo by air has by far the highest GHG emissions per ton-mile of freight moved on average, more than four times those of truck. Trucking, in turn, emits GHGs at more than five times the rate of marine or rail modes on average.

It follows, then, that shifting freight to modes with lower emission rates can reduce GHG emissions. The major mode shifts that could result in reduced energy usage and GHG emissions reductions include the following:

- Truck to rail;
- Truck to short-sea shipping; and
- Air cargo to truck.



These mode shifts are not easy to implement in practice. Trucks offer flexibility and time savings that make it difficult for other modes to compete. In addition, the limited locations of rail infrastructure and remote locations of certain industries make many goods dependent on truck movements. However, some commodities in certain locations may see benefits from mode shifts to more energy efficient modes. To make sure a project is economically viable, an economic analysis should be completed prior to public sector investments that are intended to cause a mode shift.

---

88 Wheeler and Figiliozzi, Portland State University, Multi-Criteria Trucking—Freeway Performance Measures in Congested Corridors, August 2010

89 Induced travel demand refers to the concept that increasing roadway capacity and reducing congestion will result in additional vehicle traffic as a result of mode choice decisions. For example, a commuter who might have selected transit with congested roadways may instead select to drive, therefore increasing emissions. This generally does not apply to trucks. However, when implementing congestion mitigation measures, it is important to consider all system users.

Figure 5.1 Average GHG Emissions per Freight Ton-Mile by Freight Transportation Mode in the United States 2006

Source: U.S. EPA, 2008, *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 to 2006*; and Bureau of Transportation Statistics, National Transportation Statistics.

The following are examples of potential mode shift opportunities from truck to rail:

- Shipments arriving via water to the Port of Portland. The Port has on-dock rail and easy access to inland barges, so drayage emissions for transfers from ocean-going ships to rail or barge at Portland would be minimal, preserving the GHG benefits of rail and barge movements even within Oregon. However, there may still be a relatively high financial cost to the transfer that could discourage shippers. In addition, not all commodities are amenable to on-dock rail.
- Shipments moving between locations directly on the rail or waterway network. Where drayage moves are very short at both ends, it may be beneficial from both a financial and a GHG emissions point of view to shift to rail or water.

The following are examples of potential mode shifts from truck to short-sea shipping in Oregon:

- Container feeder service to Puget Sound. About one-half of the containers that arrive or depart the Columbia/Snake region by sea do so through Portland's Terminal 6,[90] but the remainder are sent by truck or rail to the

[90] Container service at Portland's Terminal 6 continued through 2014 as it had at the time this plan was adopted in 2011. However, by mid-2016, all container service had been discontinued.

Puget Sound's Ports of Seattle and Tacoma. Short-sea service has been suggested as a way to take some of those containers off the highways; however, the water route is almost double the distance of the overland route. Moreover, containers traveling down the Columbia by barge would need to be transshipped to an ocean-going barge to make the trip, adding significantly to the costs of such a move.[91]

- Coastal service to California. Coastal service to southern California could preserve some of the cost advantages of water transport due to the length of the haul. It could be most appropriate for movement of bulk agricultural and forest products from the Columbia River or southern Oregon. However, a suitable backhaul would also need to be found to make barge movement economically viable.
- Solid waste shipments. More than 500,000 tons of Portland area waste are trucked annually to the Columbia Ridge Landfill 140 miles east of Portland. Construction of a barge dock near the landfill could permit the waste to be sent by barge instead. It could also open up the possibility of taking waste by water from other areas, such as Seattle and California.[92] Rail service from Portland to the landfill with Oregon waste is also a possibility that should be explored to reduce emissions.

The public sector can play a role in encouraging the shifting of freight to less energy-intensive modes of transport. Possible strategies include investing in the rail and marine transportation systems, pricing and other incentives.

5.4 IMPACTS OF CLIMATE CHANGE ON FREIGHT

Climate change may have an impact on the freight sector in the following ways:

- Extreme temperatures. Climate change is expected to lead to an increase in the frequency of very hot days. As the number of very hot days rises, stress will increase on infrastructure. Infrastructure design changes may be required, pavement may wear faster and railroad tracks may be negatively impacted as a result of hotter weather. More information on the impact of extreme temperatures can be found in Freight and Climate Change: Background Paper for the Oregon Freight Plan.
- Changes in stream flow. The Northwest will experience major changes in stream flow patterns due primarily to changes in the timing of spring snowmelt in the mountains and an increase in winter precipitation falling as

[91] Center for Economic Development Education and Research (CEDER), 2005, *Columbia Snake River System and Oregon Coastal Cargo Ports Marine Transportation System Study*, prepared by Pacific Northwest Waterways Association, June 2005.

[92] Ibid.

rain instead of snow. In addition to earlier stream flow peaks, this will result in considerably lower summertime flows. A 30 percent reduction in warm season (April through September) runoff on the western slopes of the Cascades is projected by 2050. The marine freight system will be impacted by both higher and lower levels of stream flow; barge travel can be restricted as a result of either condition. During periods of low water levels, tonnage carried per barge may be limited.

- Increase in heavy precipitation. Between 1958 and 2007, there has been a 12 percent increase in days with very heavy precipitation in the Northwest; this trend is expected to continue.[93] In addition, increased winter rainfall instead of snowfall is expected to lead to more winter flooding on the west side of the Cascades. Increased heavy rainfall events may require redesign of stormwater management facilities for all transportation facilities. In addition, increased severe weather is correlated with increases in accidents and delays, impacting both freight safety and mobility.
- Sea level rise and coastal erosion. Global sea levels are projected to rise as little as 8 inches and as much as 4 feet by the end of this century. More southwesterly winter wind patterns, combined with higher sea levels, could accelerate erosion along the Pacific coast. Coastal port facilities and the roads and railways that serve them may be impacted by rising sea levels. Coastal areas may also become more vulnerable to surges from strong coastal storms, as these surges will now be overlaid onto higher water levels.
- Impacts to agriculture and forestry. Climate change also will impact demand for freight services by affecting agriculture and forestry production in Oregon. In the short run, high-elevation forests on the west side of the Cascades are expected to grow faster due to milder conditions, but in the long run all forests are projected to see decreased growth due to summertime soil moisture deficits. Agricultural production is likely to be negatively impacted by decreasing irrigation supplies during the summer growing season as well as increasing pests and weeds.

The likely impacts of climate change can be addressed in part through improved planning. The planning process should incorporate an understanding of expected future changes. For instance, future infrastructure might not be planned for locations such as floodplains and tsunami hazard zones. When designing new infrastructure, project managers will need to switch from designing with standards developed for historic climate trends to designing for future and uncertain climate projections. Operations are more easily adapted to a changing climate, but conditions should be monitored to plan for future operations in an effective manner rather than relying on past information.

93 Cambridge Systematics, Inc., 2007, *Cross Border Short-Sea Shipping Study: Phase II*, prepared for the International Mobility and Trade Corridor (IMTC) Project, January 2007.

Oregon has taken initial steps towards exploring climate change adaptation issues in *A Framework for Addressing Rapid Climate Change* (2008).[94] The Oregon Climate Change Research Institute administered by Oregon State University and the Oregon University System is charged with assessing the most current state of the science of the likely effects of climate change in Oregon every two years with the first report in December 2010.

In addition, in partnership with the Institute, the University of Oregon Climate Leadership Initiative is leading climate preparedness planning projects in regions throughout the state, including examinations of the impacts to built infrastructure such as transportation.[95]

94 Governor's Climate Change Integration Group, 2008, *A Framework for Addressing Rapid Climate Change: Final Report to the Governor*, State of Oregon, January 2008.

Funding

6.0 Funding

6.1 INTRODUCTION

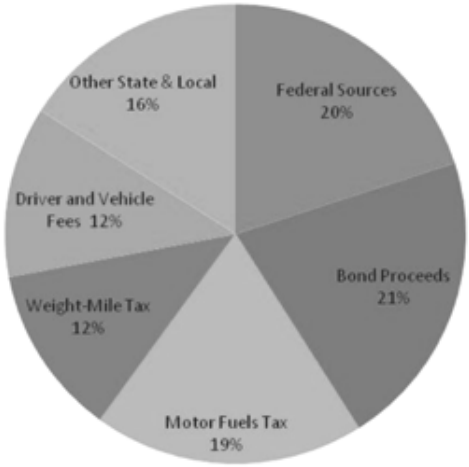
Federal, state and local governments provide much of the funding for freight transportation system improvements including highways, airports and certain marine port facilities. The private sector provides funding for those elements of the transportation system that are privately owned and operated, including marine terminals, pipelines and rail lines. Governments and the private sector sometimes work together in public-private partnerships to fund freight transportation improvements. In order to ensure that freight transportation system needs are adequately funded, states are actively seeking new methods and sources of project funding and finance. These include a wide variety of federal grant and loan programs, expanded user-pay programs and further development of partnering arrangements between the public- and private-sector investors.

The following topics are covered in this chapter:

- Public-sector funding for transportation in Oregon, along with how this funding is distributed to meet transportation needs;
- Summary of transportation funding needs as forecasted in the 2006 OTP; and
- Review of selected existing and potential initiatives for helping to fill the gap between funding needs and anticipated revenues.[96]

6.2 ODOT'S TRANSPORTATION FUNDS

It is anticipated that ODOT will receive $5.16 billion in funding during the 2009 to 2011 biennium.[97] Roughly 20 percent of this funding ($1.03 billion) is from federal government sources, as shown in Figure 6.1. The other 80 percent ($4.13 billion) is from state sources. These include a tax on motor fuels (19 percent), weight-mile tax (12 percent), driver and vehicle licenses and fees (12 percent) and other state and local sources (16 percent). A very small amount of revenue is derived from tolls (0.2 percent).



---

96 Chapter 9, Section 9.6 includes updated information regarding funding related to the FAST Act as well as Freight Investment Plan.

97 Oregon Department of Transportation Budget Booklet 2009-2011: http://library.state.or.us/repository/2010/201002171155453/ODOT_COMM_docs_BudgetBooklet_09-11.pdf

The single largest category of state funding (21 percent or $1.065 billion) is from the sale of bonds through programs such as the Oregon Transportation Investment Act and *Connect*Oregon. Bonds sold through these programs are repaid from revenues generated by various sources such as lottery revenues, weight-mile taxes, fuel taxes and vehicle license, registration and title fees.

Figure 6.1 ODOT's Revenue Sources – 2009 to 2011

Source: ODOT Budget Booklet 2009 to 2011.

Oregon has a constitutionally dedicated Highway Fund that requires all taxes levied on motor vehicle fuel and ownership, operation or use to be used exclusively for construction, reconstruction, improvement, repair, maintenance, operation and use of public highways, roads, streets and roadside rest areas. Oregon's constitution also requires that the legislature ensure that cars and trucks pay their fair and proportionate share of state motor vehicle taxes described above. This latter provision is unique among states and is accomplished by completion of a comprehensive cost allocation study every two years that includes a report to the legislature for appropriate action.

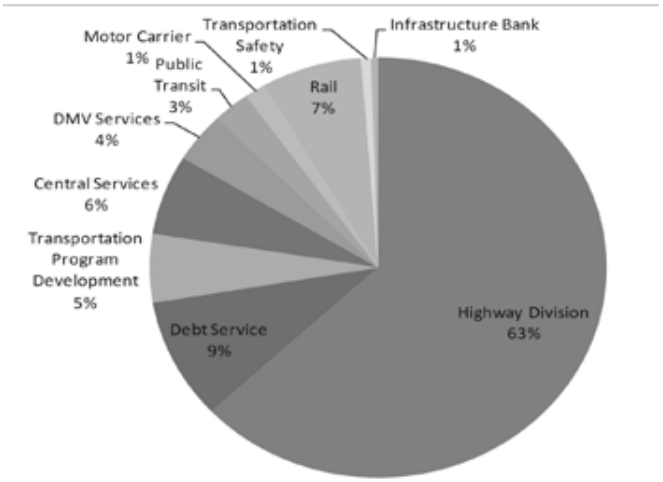
The share of funding from various sources, as shown in Figure 6.1, is likely to change in the future. Federal, state and local sources, including bond proceeds and vehicle taxes and fees, are all subject to fluctuation. The next 20 years are anticipated to see dramatic improvements in the fuel efficiency of vehicles. As these new vehicles replace the current vehicle fleet, large reductions in fuel consumption are possible. This will translate into a decrease in the amount of revenue derived from fuel taxes, even as vehicle miles traveled are projected to increase.[98]

[98] The Oregon Road User Fee task force researched possible alternatives to the fuel tax in their November 2007 report. Their findings show that many of the potential

About 16 percent of ODOT's total revenue is "passed through" to Oregon cities, counties and other agencies, as shown in Table 6.1. Per biennium, cities receive roughly $300 million and counties, roughly $450 million. These funds are derived from the state fuel tax, weight mile tax and licensing fees. Other state agencies, such as Oregon Parks and Recreation Department, Oregon Department of Aviation, and the Oregon State Marine Board, receive roughly $77 million. ODOT acts as a tax collector for these other agencies. ODOT itself is receiving approximately $4.3 billion for its 2009 to 2011 operating budget, from a total of $5.16 billion in revenue for the state.

Table 6.1 Distribution of ODOT's Pass-Through Revenue – 2009 to 2011

Recipient	Pass-Through Revenue
Cities	$ 303 Million
Counties	$ 452 Million
Other State Agencies	$ 77 Million
Total 2009-2011 Biennium	$ 832 Million



Source: Prepared by ODOT 2009

6.3 ODOT'S TRANSPORTATION BUDGET

Incoming revenues are used to support a wide variety of state and local transportation system needs. For the years 2009 to 2011, the Highway Division uses the largest portion ($2.63 billion or 63 percent), as shown in Figure 6.2 below, for programs such as the bridge program ($670 million), the highway maintenance and preservation programs ($789 million combined) and the highway modernization program ($348 million). The remaining 37 percent of expenses include debt servicing ($389 million or 9 percent) and the rail program ($296 million or 7 percent) and other smaller programs.

alternatives to the fuel tax are "not quite ready for broad scale implementation on a local, state, or national basis" (http://www.myorego.org/wp-content/uploads/2017/07/RUFPP_finalreport.pdf).

Figure 6.2 ODOT's Expenses 2009 to 2011

Source: ODOT Budget Booklet 2009 to 2011.

Table 6.3 summarizes 2030 transportation need forecasts from the 2006 OTP. By most estimates, trends such as a growing statewide population, industry activity and employment mean that the needs for the transportation system will likely grow in the future.

6.4 FREIGHT-SPECIFIC FUNDING OPPORTUNITIES

A variety of sources are necessary to fund Oregon freight projects, as shown in Table 6.2. These diverse funding sources are able to improve and maintain the freight system in many ways. However, as indicated in the table, the available revenue sources are not freight specific. Additionally, recent funding available for transportation in Oregon has been insufficient to meet all of the state's transportation needs. Public freight projects are funded from the same sources as all other public sector transportation programs.

To better understand why revenue sources are insufficient, funding needs and the impact of not meeting the state's freight funding needs are discussed in this section. The OFP does not develop specific freight funding needs forecasts. Instead, it relies on work completed for the OTP, the OHP and existing modal plans to develop a picture of future needs for selected components of the freight transportation system and funding gaps associated with these needs.

Table 6.2 Revenue Sources and Challenge for Freight Infrastructure

Freight Infrastructure	Revenue Sources	Challenges
Airports	Federal Airport and Airway Trust Fund	Programs are not freight specific
	Federal Airport Improvement Program	
	*Connect*Oregon funding	Program is not permanent and may fund non-freight programs
Connector Roads	Federal funds for connectors on the National Highway System	Connector projects compete for funding with freight and passenger projects on other local roads and highways; funding is insufficient to meet needs
	State funds for connectors that are state highways	
	Local funds for connectors that are local roads	
Highways (including bridges)	Federal and state (including OTIA and JTA) programs*	Programs are not freight specific
Natural gas and petroleum pipelines	Gas/petroleum companies' private funding	Private-sector priorities may differ from state priorities
Ports and waterways	Private-sector companies	Private-sector priorities may differ from state priorities
	Federal Inland Waterways Trust Fund and Harbor Maintenance Trust Fund	Funding is dependent on Congressional appropriations
	State business development programs	Programs are not freight specific
	*Connect*Oregon funding	Program is not permanent and may fund non-freight programs
Railroads (Class I and shortlines)	Private-sector companies	Private-sector priorities may differ from state priorities
	Federal Railroad Administration (FRA) programs	Programs are not freight specific
	*Connect*Oregon funding	Program is not permanent
Truck/rail transfer facilities	Private-sector companies	Private-sector priorities may differ from state priorities
	Federal and state business development (including brownfield) programs	Programs are not freight specific
	*Connect*Oregon state funding	Program is not permanent and may fund non-freight programs

* OTIA – Oregon Transportation Investment Act (2001, 2002 and 2003); JTA – Jobs and Transportation Act (2009).

Funding Needs as Identified in the OTP

The 2006 OTP identified feasible transportation needs of publicly and privately owned components of state, regional and local transportation systems from 2005

to 2030. These are summarized in Table 6.3. Though these are not freight-specific needs, they refer to components of the transportation system that are important for the movement of freight – the highways, intermodal connectors and other infrastructure that support efficient freight movement.

Table 6.3 OTP Investment Needs for Freight-Related Components of the Transportation System, 2005 to 2030[99]

Investment Needs	Current Annual Expenditures (in Millions Dollars)	Average Annual Realistic Needs* (in Millions Dollars)	Annual Gap (in Millions Dollars)	Forecasted Annual Growth Rate (Percentage)
State highway-related needs	787	1,278	491	1.4 (freight highway travel)
Intermodal connectors	n.a	11.3	n.a	1.35 (total highway travel)
Air freight and passenger				
Portland Intl	44.4	115.3	70.9	2.62 (freight tons)
Major modernization**	13.9	15.1	1.2	
Other airports	10.7	47.4	36.7	
Ports and waterways	51.3	56.2	4.9	0.97 (deep draft freight) 0.29 (shallow draft freight)
Natural gas and petroleum pipelines	n.a	n.a	n.a	n.a
Private rail facilities	More than 6.7	18.8	n.a	1.83 (freight tons)

Source: Oregon Transportation Plan, p. 83.

* "Realistic needs" referred to the amount of funding that would maintain the transportation system at a slightly more optimal level than 2005 levels, would replace infrastructure and equipment on a sensible and logical life cycle, and would bring facilities up to standard or add capacity in a prudent and practical way. The OFP references "realistic needs" in place of the OTP's "feasible needs".

** Needs identified for eight airports other than Portland International Airport where growth is expected to exceed capacity.

This assessment documents gaps in many of the investment categories. For example, state highway-related needs (including maintenance and capital improvements) are forecasted to face an annual shortfall of $491 million every year between 2005 and 2030.

[99] Freight transportation needs and revenues are further described in Chapter 9.

Potential Impacts of Not Meeting State Needs

With these modal needs and gaps in mind, the OTP also provides an investment scenario analysis. The goal of this analysis was to gauge the response of Oregon's transportation infrastructure to three hypothetical scenarios. The scenarios reflected the needs of publicly-supported transportation infrastructure and services, though they did include limited information on funding for freight rail. Briefly, the three scenarios were defined as follows:

- Level 1. The impacts of "flat funding" on the state's transportation system, where inflation causes a 40 to 50 percent loss in purchasing power by 2030;
- Level 2. A situation where transportation funding, while not providing for major capacity enhancements, keeps up with inflation and results in maintaining current performance levels on existing facilities and services; and
- Level 3. Funding that expands facilities and services including making major investments in new infrastructure, maintains the system at a slightly more optimal level than current levels, replaces infrastructure and equipment on a reasonable life cycle, and brings facilities up to standard or adds capacity in a reasonable way.

The OTP's analysis of these different levels of funding, which are assumed to be applicable for the OFP, suggested the following results including possible freight-related impacts:

Table 6.4 OTP Funding Levels and Impacts

Results of Funding	Freight-Related Impacts
Level 1	
This level of funding could be devastating to Oregon's economy.	· The ability to get to places by all forms of transportation would decline because of declining infrastructure conditions and services and lack of funding for projects that relieve congestion. · Deterioration of the state and local road and bridge system could not be avoided and would increase user costs. If bridges deteriorated to the point of load limits, then commerce would be interrupted. · Traffic congestion would hurt the local, state, regional and national economy because of longer travel times, reduced market areas, the need for duplicate inventories at more locations and the need for additional delivery fleet and drivers. · Reduction of intercity bus, rail freight, aviation and ports all would leave rural communities at an economic disadvantage. · Failure of the jetties at the mouth of the Columbia could leave Columbia River ports, including the Port of Portland, without access to ocean shipping. This would be devastating to industries dependent on ocean shipping and to Oregon's transportation and

Results of Funding	Freight-Related Impacts
	warehousing industry.
Level 2	
This level of funding would preserve existing facilities and services and keep up with inflation, at an estimated rate of 3.2 percent annually. Investments that kept up with inflation would keep existing facilities and services at their current performance levels to the extent possible. Funding at this level thus would avoid economic disaster but would not result in a competitive advantage for Oregon businesses.	· Rail freight shipping costs would be reduced by elimination of some bottlenecks. Preservation of rail services would assist job retention in rural areas and outside the Willamette Valley. · Funding would prevent further cutbacks of shortline rail service and maintain rural air service, maintaining rural access to freight and passenger services. · Ports would have the opportunity to deepen channels, protect jetties, and address truck and rail congestion around marine terminals. But the economy would not grow to full potential because congestion at truck, rail and port facilities would prevent expansion and efficient handling of growing amounts of cargo. · Some congestion would be addressed through improvements to bottlenecks and through more aggressive implementation of operational improvements, such as Intelligent Transportation Systems (ITS). · Major capacity needs for roads and highways would still go unaddressed. Road users would continue to experience rising costs from increased travel delay due to congestion. Freight accessibility would be lessened by lack of capacity-adding projects. The inability of local areas to expand arterial roads would hurt their development opportunities.
Level 3	
This level of funding would mean that major investments would enable feasible needs to be met over the OTP planning period, resulting in positive impacts on Oregon's economy.	· Statewide mobility would be enhanced by system-wide improvements. · Development of expanded road, transit, intercity passenger service, rail freight and airports would occur throughout the state. · Rural areas would be better able to retain air and rail services and related jobs. · Improved rail freight, marine port facilities and airports would enhance the economy in urban and rural areas. Truck congestion would not be eliminated, but it would no longer be a threat to the economy.

Following the results of this scenario analysis, the OTP recommended Oregon use traditional and new revenue sources to move toward funding at Level 3, using incremental steps over time.

Why Oregon Needs to Look for a Way to Close the Funding Gap

The OTP Investment Scenarios illustrate some of the potential dangers of continuing to under-invest in the state's freight transportation system. In

addition, other looming challenges will impact the performance of the state's freight transportation system and create a strong case for finding additional funding sources. Among these challenges are the following:

- Increasing wear and tear on the transportation infrastructure as Oregon's population and the economy grow;
- More congestion and crashes with growth in traffic volumes;
- Greater global competition, rising fuel prices and the need to have efficient, reliable and affordable freight transportation options so Oregon businesses can compete favorably with businesses in other states and nations;
- Global warming, greenhouse gas reduction and various other environmental issues and concerns;
- Community livability and land use issues and concerns; and
- Security issues and concerns.

These and other challenges suggest a compelling need to expand existing programs for financing freight transportation improvements, and to identify and implement new funding and finance sources, where feasible.

6.5 OPPORTUNITIES FOR ADDRESSING THE FUNDING GAP

Additional private- and public-sector funding is needed to address freight financing issues. Private-sector companies will continue to make transportation investments based on a variety of considerations to help maintain and improve their competitiveness regionally, nationally and internationally. Market conditions are a primary factor in private-sector decision-making, so efforts to strengthen economies at all geographic levels are critical to private-sector investments in the freight transportation system.

Private-sector companies also will continue to pay specific fees that governments, port authorities and other entities will use for a variety of purposes including freight infrastructure improvements. Opportunities may exist for enhancing existing fee structures or implementing additional fees to help reduce the funding gap. Federal, state and local governments, including port authorities, may identify ways to broaden or improve existing or establish new, freight financing programs. The following discussion summarizes some of the private- and public-sector opportunities for addressing the funding gap through user fees and government programs.

User Fees

Freight shippers and carriers currently pay user fees such as federal, state and local fuel taxes. In a few states, including Oregon, trucking companies pay a weight-distance tax based on mileage driven for various weight classifications of truck configurations. Shippers and carriers for other modes pay user fees specific to their type of freight haulage. Any Oregon-specific fees that do not produce transportation system improvements that would offset the costs to businesses that pay the fees could result in reduced competitiveness of Oregon businesses. In the most extreme case, businesses could choose to move to other states where costs are lower.

Airport and Port Fees

Airports and port authorities generate revenues in a variety of ways including grants, loans, tariffs, taxes and user fees. User fees for airports include passenger facility charges, aircraft registration fees, landing fees, terminal and gate lease fees, and parking fees. Most of these fees relate to passenger usage of airport facilities. User fees for port facilities include berthing fees, security fees, fees related to servicing vessels and fees for loading and unloading cargo. Fees may be dedicated to specific projects whereby the fees are used to repay the project costs.

Container Fees

Container fees represent a type of user fee sometimes used to help repay project-specific costs. These fees on import and export container movements at U.S. ports represent a potentially large source of revenue. Although the use of container fees or other direct user fees present promising opportunities to address the freight transportation funding gap, several institutional and operational challenges must be addressed before these strategies can be effectively implemented more broadly. There may be significant institutional resistance to levying new container or user fees or diverting existing user fees to fund freight transportation improvements. The private sector freight community, for instance, will want assurances that efficiency and reliability gains are proportional to the user fees that will be collected.

The regional, national and international nature of freight shipments also presents a challenge. Freight movements often affect the transportation systems of multiple states and metropolitan planning organizations, and it is critical to ensure that costs and benefits of container fees or other direct user fees are allocated appropriately across jurisdictional boundaries. Container fees rely on non-discretionary traffic levels that may not be generated through one state's infrastructure. A regional or national approach may be necessary.

Infrastructure Surcharges

Infrastructure surcharges are special assessments that governments or businesses impose on taxpayers or customers to help pay for infrastructure improvements. Numerous utilities have assessed surcharges on their customers in order to recoup the costs of infrastructure investments such as pipelines and related equipment and facilities.

Similar types of surcharges may be used to pay for transportation improvements. An example would be a surcharge placed on the number of employees at businesses in a taxing district such as a county or city (see the Special Districts discussion below). Revenues generated from the surcharge would be used to help pay for transportation improvements within the taxing district. Another type of surcharge might be a fee on tonnage of cargo shipped through a terminal or other freight facility. Surcharges could be targeted to pay for transportation improvements that benefit the payers of the surcharge.

Special Districts

According to the 2007 U.S. Census of Governments, special district governments are "all organized local entities (other than counties, municipalities, townships or school districts) authorized by state law to provide only one or a limited number of designated functions, and with sufficient administrative and fiscal autonomy to qualify as separate governments, known by a variety of titles, including districts, authorities, boards and commissions."[100] A freight special district would focus on freight-related functions such as the provision of infrastructure to support freight movements. Special districts typically are financed through taxes on district properties, other taxes, special assessments, grants or loans from governmental entities, or fees for services imposed on property owners or service users within the district's boundaries. However, getting voters to approve increased taxes or fees associated with special districts would be a challenge, as higher taxes are rarely popular.

Oregon statutes authorize 28 types of special districts, including several that finance activities that may support freight improvements.[101] These include port districts,[102] road assessment districts and special road districts. Some states authorize local transportation improvement districts to identify planning, funding and other resources for local transportation projects, usually associated with roadway improvements. In Oregon, local improvement districts serve this purpose.

100 https://www.census.gov/govs/definitions/index.html#s.

101 http://landru.leg.state.or.us/ors/198.html.

102 Legally in Oregon port districts are municipal corporations, like cities and counties.

Tolls

Tolling is a form of financing where transportation system users pay for using specific roads, bridges, tunnels or other facilities. The only tolled facilities in Oregon currently are two tolled bridges that together contribute 0.2 percent of the state's transportation revenue:

1. The Bridge of the Gods, operated by the Port of Cascade Locks and connecting Cascade Locks, Oregon, to Stevenson, Washington; and
2. The Hood River Bridge, operated by the Port of Hood River and connecting Hood River, Oregon, to White Salmon, Washington.

Both of these facilities are locally owned and operated. However, Oregon could consider other types of toll facilities including turnpikes and priced lanes. Many other states have instituted tolled facilities that are under either state or private operation.[103] Similar arrangements may be possible in Oregon in the future. For example, the I-5 Columbia River Crossing project's Tolling Study Committee reviewed the potential of several different tolling scenarios to help fund the project.[104] In addition, ODOT's Office of Innovative Partnerships and Alternative Funding has investigated the feasibility of several highway projects, where tolls are one of the potential funding mechanisms.[105] Tolls, though, increase costs to freight providers and have an impact on the economy as a result of increased transportation costs.

Congestion Pricing

Congestion pricing, closely related to tolls, involves offering incentives to use transportation facilities in off-peak hours or charging extra to use them during peak hours. Prices can vary based on a fixed schedule, or they can be dynamic, meaning that rates change depending on the level of congestion that exists at a particular time. A fixed-rate, off-peak congestion pricing strategy is currently being used to mitigate congestion and improve air quality as part of the Ports of Los Angeles and Long Beach PierPASS program. Use of congestion pricing strategies at freight facilities or corridors could represent a potential source of revenue to offset freight infrastructure investments. Though most commonly

---

[103] For more information on toll facility ownership in other states see: http://www.financingtransportation.org/funding_financing/funding/state_funding/tolls.aspx

[104] Columbia River Tolling Study Website: https://web.archive.org/web/20111019064836/http://tolling.columbiarivercrossing.org/.

[105] A series of tolling reports and white papers prepared for ODOT is available at https://web.archive.org/web/20100531214646/http://www.oregon.gov/ODOT/TD/TP/Tolling_Background.shtml.

used as a congestion mitigation tool, surplus revenue from congestion pricing programs could be used to support other freight improvements. However, this option is unlikely and would be politically difficult.

Selected Federal Opportunities

A number of financing mechanisms at the federal level represent existing and potential opportunities for funding freight transportation system improvements in Oregon. Several such mechanisms are summarized briefly below. It is important to note that while the programs presented below create opportunities for financing of critical transportation programs in Oregon, these options do come at a cost in the form of debt service. As a result, when these options are considered for funding transportation projects, it is necessary to weigh the implications and future costs of these alternatives.

Build American Bonds

Build American Bonds (BAB) are tax credit bonds that provide federally-subsidized debt financing to reduce borrowing costs for transportation investments. Authorized by the American Recovery and Reinvestment Act of 2009,[106] BABs allow state or local governments issuing bonds to elect to make the bond interest taxable in exchange for a federal interest subsidy. Bond proceeds must be used for governmental purposes, which include transportation investments.

In the spring of 2010, the State of Oregon completed the sale of $580 million of new bonds, 93 percent of which were BABs.Revenues from the sale will be used to fund projects identified through the Oregon Transportation Investment Act III program. Financing via BABs is reported to have enabled the state to save $56 million in financing costs. The BAB program expired on December 31, 2010, and has not been re-authorized.

CFR Title 23, Section 129 Loans

Section 129 of the Code of Federal Regulations Title 23 allows federal-aid highway apportionments to fund direct loans to projects with dedicated revenue streams. Dedicated revenues may include tolls, excise taxes, sales taxes, property taxes, motor vehicle taxes and other beneficiary fees. Proceeds from Section 129

[106] The American Recovery and Reinvestment Act of 2009, also known as the Recovery Act, utilized $787 billion to reduce unemployment and spur economic growth in the wake of the recession at this time. This bill included funding for transportation construction and maintenance projects.

loans can fund the costs of engineering, right-of-way acquisition and physical construction.

Any federal-aid highway project is a potential candidate for a Section 129 loan provided that the recipients pledge revenues from a dedicated source to repayment of the loan. Loans can be in any amount of up to 80 percent of the project cost, provided that a state has sufficient obligation authority to fund the loan.

Use of Section 129 loans for project financing has been very limited. One reason for this is that the Transportation Infrastructure Finance and Innovation Act program (described below) is generally available for the same kinds of projects that would likely use Section 129 loans. However, for projects that do not fit the profile of TIFIA projects, Section 129 loans remain a good alternative.

Transportation Infrastructure Finance and Innovation Act

The Transportation Infrastructure Finance and Innovation Act (TIFIA) of 1998 is a federal program through which the U.S. DOT provides credit assistance in the form of direct loans, loan guarantees and credit assistance to major surface transportation projects with dedicated revenue streams. In 2005, the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) opened the TIFIA program to freight projects. Several states have received TIFIA credits for projects that could be significant to freight, such as the Maryland Intercounty Connector and the Reno Rail Corridor in Nevada.

TIFIA has provided credit assistance to state DOTs, transit operators, special authorities, local governments and private entities undertaking highway, transit, rail and intermodal improvements. Rather than providing grant funding, TIFIA provides projects with supplemental or subordinate debt in order to leverage available federal resources. As of March 2009, the TIFIA program had provided $5.8 billion in credit assistance, leveraging projects with a construction value of $21.8 billion nationally.[107]

Oregon has not yet taken advantage of the TIFIA program. This may be a consideration for ODOT in coming years, in particular, to fund those projects occurring on the Strategic Freight System.

Grant Anticipation Revenue Vehicles Bonds

Grant Anticipation Revenue Vehicles or "GARVEE" is the name given to the process where states utilize bond or other debt instrument financing mechanisms

[107] http://www.financingtransportation.org/funding_financing/financing/credit_assistance/tifia.aspx.

involving the payment of future federal-aid highway funds to retire debt. Therefore, GARVEE bonds are backed by a pledge of future federal-aid from the U.S. DOT. GARVEEs generate upfront funding for major capital projects that a state would likely be unable to construct in the near term using traditional funding approaches. Bond-related costs eligible for federal-aid reimbursement include interest payments, retirement of principal and any other cost incidental to the sale of an eligible bond issue. States, political subdivisions and public authorities have issued GARVEE debt, including Oregon neighbors California and Idaho.

Looking Ahead to the Future Surface Transportation Reauthorization[108]

Individual states can help influence federal policy by making freight funding and finance a top priority in their discussions with congressional representatives. The last surface transportation authorization in 2005, SAFETEA-LU, created several new opportunities for freight funding and finance. Early indications are that the future of surface transportation funding legislation will include an even greater focus on freight. Ongoing state agency coordination with Oregon's congressional delegation is critical in showing support for maintaining and expanding current programs for funding freight projects, as well as identifying potential new sources of freight funding in federal transportation and other legislation.

State and Multimodal Opportunities

At the state level, state gas taxes and a variety of fees have been used in support of freight infrastructure and other improvements. In recent years, these have been extended by other programs, such as the Oregon Transportation Investment Act, which has been instrumental in providing funding to fix or replace bridges important for truck freight movements. OTIA also has provided funding for road modernization improvements, preservation and maintenance.

More recently, the *Connect*Oregon program and the Jobs and Transportation Act have established funding for freight projects on and off roads. The following discussion summarizes opportunities associated with these and other selected state and multimodal programs.

[108] Chapter 9, Section 9.6, includes updated information regarding funding related to the Fast Act as well as a Freight Investment Plan.

Oregon Multimodal Transportation Fund

The Multimodal Transportation Fund (also known as *Connect*Oregon) is a lottery-backed bond program that generates revenues to invest in air, marine, rail and transit infrastructure. Public road and highway projects that are eligible for funding through the State Highway Trust Fund are not eligible for funding through the Multimodal Transportation Fund. The *Connect*Oregon program received $100 million in the 2005 legislative session and another $100 million in the 2007 legislative session. In 2009, the Oregon Jobs and Transportation Act (JTA) authorized another $100 million for *Connect*Oregon. It is not a dedicated program, and each bond sale must be authorized by the state legislature. Proceeds from the Oregon State Lottery are used to pay back the bonds issued for the *Connect*Oregon program.

Establishing dedicated funding for *Connect*Oregon would help to provide a steady stream of funding that supports multimodal freight efficiency and mobility goals. Dedicated funding also might promote more cohesive statewide and regional freight planning, as regional governments could devote more time to working with their neighboring regions and the state to define projects that best support the movement of freight.

Oregon Jobs and Transportation Act

The Oregon Jobs and Transportation Act (JTA), enacted by the 2009 Oregon Legislature, represents an important source of new financing for investments in Oregon's transportation infrastructure. The legislation includes funding to relieve key bottlenecks, improve existing facilities and address safety concerns and deferred maintenance for roads and bridges.[109] Further, the JTA authorizes a third round of *Connect*Oregon funding, along with funding for city streets and county roads. Thirty-seven highway projects are to receive funding for addressing bottlenecks or improving safety; many of these projects are on major freight routes. Roadway improvements are financed through revenues generated by increases in various fees and in gasoline and diesel taxes. An estimated 40,000 jobs are expected to be created over 10 years through expenditures associated directly or indirectly with the JTA.

[109] https://www.oregon.gov/odot/pages/jta.aspx.

Public-Private Partnerships

Public-private partnerships (PPP) help accelerate development of critical transportation infrastructure, thereby, realizing benefits before the public or private sectors could do so on their own. From a goods movement perspective, rail PPP arrangements have thus far been the focus of many transportation PPP projects, possibly because of the frequent interaction between private railroads and government agencies. However, other types of projects also make potential PPPs, such as the development of intermodal centers or tolled/priced facilities.

ODOT's Office of Innovative Partnerships and Alternative Funding offers a unique support system to plan, fund and implement PPPs. In the past, the office has played a role in projects which brought together public and private partners, including the Road User Fee Pilot Program and Oregon's Solar Highway project. This office may be able to facilitate the development of freight-related projects using a combination of public and private sources of funding.

Implications for Future Freight Funding

While assumed values such as growth rates, the inflation rate and the like have changed since estimates and forecasts were made for the OTP, the general trends have not changed much. OTIA, *Connect*Oregon and the JTA have resulted in significant new state revenues to improve freight and passenger transportation facilities, but a major funding gap remains. Continuation of existing funding sources such as *Connect*Oregon and the creation of new state funding sources would help reduce the gap and support Oregon's economy. A similar effect may occur if reauthorization of federal surface transportation funding legislation or other freight-related federal legislation results in extending existing, and providing new, freight funding programs. Ongoing comparisons of freight funding needs to available revenues in relation to Oregon's economy and the demand for goods movement will be important to decision-makers when developing legislative proposals.

Alternative Scenarios

7.0 Alternative Scenarios

The strategies recommended to support the development of the Oregon freight system described in Chapter 8 are based on analysis of several possible future economic and policy scenarios. The Reference Case (discussed below) portrays the future Oregon freight system based on current expectations. It assumes economic conditions and policy directions that seem to be most likely in the future. Recognizing, however, that the future is sure to be different from what we can now foresee, the broad-brush implications for Oregon's freight system under a range of other plausible economic and policy conditions were also considered.

In order to understand the implications of different future economic scenarios for freight, Oregon's Statewide Integrated Model (SWIM2) was used to evaluate the spatial dimension of future economic and population growth and the commodity flow and travel patterns stemming from this future demand. The alternative scenarios presented below were selected using expert input from the Steering Committee and data from the Oregon Office of Economic Analysis. As a result of continued economic volatility, it is important to continue to monitor changes in economic projections and incorporate new economic data into future plans.

This chapter provides an overview of the modeling methods and results conducted by ODOT modeling staff. For more detail on the modeling results of the analysis, see Oregon Freight Plan *Modeling Analysis Technical Memorandum* on ODOT's website.[110]

7.1 Reference Case and Alternative Scenarios

The first step in analyzing the impact of alternative future scenarios on the freight system is to define the scenarios that need to be modeled, aside from a Reference Case which will serve as the baseline. Multiple factors could change economic conditions and markedly affect the demand for transportation, especially freight transportation. However, regardless of the future economic scenario, it is likely that the primary factors that will impact freight demand will be changing energy prices, greenhouse gas regulations, evolving business and carrier logistics strategies, international competition for resources, and state and national tax and transportation policies. Federal and state economic policies, U.S. trade programs and natural resource policies and legislation also will have a significant impact. The following scenarios were selected for analysis:

[110] ODOT website: https://www.oregon.gov/ODOT/Planning/Pages/Guidance.aspx

- Reference Case,
- Optimistic Scenario,
- Pessimistic Scenario,
- High Transportation Cost Scenario, and
- National Transportation Policy and Funding Shortfall Scenario (not a modeling scenario).

The Reference Case is consistent with the OTP, but uses the current economic forecast for Oregon. The five modeling analysis scenarios reflect different assumptions about future population, economic growth, land use and transportation trends. Alternative scenarios are generally considered less likely to occur than the OFP Reference Case. The alternative scenarios provide a framework to test the flexibility of OFP strategies in the event that the future is significantly different from that anticipated in the Reference Case. They also help evaluate possible unintended consequences of OFP strategies. More detail about these scenarios and how they were developed is presented below.

Despite expected economic growth under all scenarios; there are major differences in the levels of economic growth. If the Pessimistic Scenario were to become reality instead of the Optimistic Scenario, for example, Oregon's economy and freight system would feel the impacts. As previously noted, it is also important to recognize that the scenarios presented above are not all-encompassing. Future economic conditions, industry composition, and freight demand levels may differ substantially from those presented here. It is important, therefore, to monitor economic and policy developments for possible reevaluation of freight strategies in Oregon, and to feed this information on changing conditions back into the planning process.

The Reference Case

The Reference Case, or the business-as-usual scenario, highlights future freight movements consistent with current laws, most recent state economic forecasts, land use patterns and transportation system investments.[111] It is considered the most realistic future scenario with current information and has several key assumptions, including the following:

- Oregon's economy will grow as forecasted by the OEA, while the rest of the world economy will grow at rates consistent with national forecasts.
- Employment figures and forecasts are consistent with OEA values from March 2009.

[111] An example of another statewide scenario analysis can be found in the *Oregon Transportation Plan*, adopted September 20, 2006.

- Commodity flows are consistent with the data in the Oregon Commodity Flow Forecast, October 2009.
- Urban growth boundaries maintain 20-year land supplies.
- Transportation system maintenance, preservation and improvement assumptions are consistent with the current Statewide Transportation Improvement Program, Metropolitan Transportation Improvement Programs and local capital improvement plans. Longer-term investment assumptions are consistent with the OTP and transportation system plans.
- Transportation costs remain stable.
- The economy will suffer no major shocks over the next 25 years; it will grow at a stable rate and follow a similar pattern of long-run activity observed over the past 20 years. The dampening effects of the current recession are accounted for.

Many of the assumptions in the Reference Case include information discussed in the previous sections of this chapter, including the following:

- Oregon's population will grow and age,
- Consumption will increase with the increase in population,
- Workforce productivity will remain competitive, and
- Trade will increase.

In addition, the Reference Case assumes that there will be no major changes in statewide and metropolitan land use beyond those reflected in the local and state plans. Zoning decisions within urban growth boundaries are assumed to drive the location of businesses and major freight facilities, such as distribution centers, warehouses and terminals. Consistent with the OTP, the Reference Case assumes no major changes in national and Oregon transportation policies and funding programs.

Alternative Future #1: Optimistic Scenario

This alternative examines the condition and performance of the Oregon freight system, assuming that Oregon's total economy and population grow more rapidly than projected in the Reference Case.

The factors that might lead to higher economic and population growth in the state include the following:

- Improved productivity across a range of Oregon industries as a result of the introduction of new technologies,
- Changes in the value of the dollar that increase national and global demand for Oregon products,

- Changes in energy or transportation costs that make Oregon industries significantly more cost-competitive in national and global markets, and
- Climate changes that favor economic activity and settlement in Oregon.

Alternative Future #2: Pessimistic Scenario

This alternative examines the condition and performance of the Oregon freight system assuming that Oregon's total economy and population grow slower than projected in the Reference Case.

The factors that might lead to lower economic and population growth in the state include the following:

- Unfavorable trade policies;
- Slower gains in manufacturing productivity;
- Higher inflation rate, higher interest rates;
- Lower investment by companies in research and development or less technology innovation;
- Lower domestic and/or global consumption, leading to a decrease in exports of Oregon goods to trading partners; and
- Global wage equalization, which would raise the cost of imported goods and decrease the purchasing power of Oregon residents and their ability to consume goods.

Alternative Future #3: High Transportation Cost Scenario

This alternative examines the condition and performance of the Oregon freight system. It builds off the Pessimistic Scenario and adds the assumption that transportation costs are three times higher than projected in the Reference Case. This case assumes that the transportation cost increase is applied globally and does not put Oregon at an economic disadvantage.

The factors that might lead to considerably higher transport costs in Oregon include:

- High fuel cost for a variety of reasons;
- Global energy demand that outpaces supply, forcing higher prices;
- Greenhouse gas emissions regulations and/or carbon pricing regulations that force petroleum prices up and accelerate a shift to nonpetroleum energy sources (e.g., biofuels, hydroelectric, nuclear, etc.); and
- Fuel shortages caused by war or political crises.

Alternative Future #4: National Transportation Policy and Federal Funding Shortfall Scenario

This scenario is a policy scenario based on the modeled Reference Scenario. The alternative examines the condition and performance of the Oregon multimodal freight system assuming that national transportation policies in the future are significantly different from those of recent federal surface transportation programs. This alternative is the result of a policy analysis process and not a specific SWIM2 model run.

The factors that might lead to a change in national transportation policies affecting Oregon include:

- Greater devolution of highway funding responsibility to states and local governments;
- Declining federal and state revenue yields from motor fuel taxes;
- Shift from motor fuel taxes to state and local vehicle miles traveled (VMT) user fees because of national policies to "de-carbonize" transportation fuels;
- Failure to achieve national consensus on necessary investment in freight transportation facilities to support domestic and national trade;
- Preoccupation with metropolitan congestion at the expense of investments in interstate/global trade freight transportation services and facilities; and

Under the low funding levels examined in this scenario, a major shortfall in federal aid for highways will occur. Potentially, this shortfall in funding would have to be covered by increased taxes or other revenues. A shift in capital, maintenance and operations funding priorities may also be required under this scenario.

7.2 MODELING RESULTS

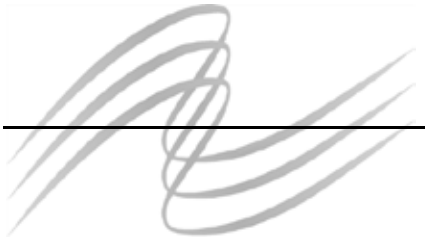
The results of running the SWIM2 model for each of the four analysis scenarios provided insight on how freight would be impacted when taking each of these alternate futures into consideration. This section contains a brief description of highlights from the modeling results. For a complete review of the modeling results, see Oregon Freight Plan *Modeling Analysis Technical Memorandum* on ODOT's website.[112] This technical memorandum provides substantial detail about the modeling analysis and results. Significant findings that relate to freight demand include the following:

[112] ODOT website: http://www.oregon.gov/ODOT/Planning/Pages/Guidance.aspx

Increased freight flows. Regardless of which scenario occurs in reality, Oregon is expected to see significant increases in freight flows in the future. The modeling results only highlight potential deviations from the Reference Case. Even under the Pessimistic Scenario described, freight demand will continue to increase and require a suitable freight network to move goods into, out of, within and through Oregon.

Highest freight demand under Optimistic Scenario. The Optimistic Scenario, which anticipates a period of higher than expected growth in the economy, will result in increased levels of freight demand. Freight demand will increase 21 percent more in terms of tonnage and 18 percent more in terms of value under the Optimistic Scenario when compared with the Reference Case. Under the Pessimistic Scenario, total freight demand will decrease when compared with the Reference Case. Value of goods moved could decrease by 22 percent while tonnage may decrease 26 percent. The High Transportation Cost Scenario creates results similar to the Pessimistic Scenario.

Less industry diversity make regions susceptible to economic risk. Some regions have dominant industries, making them more susceptible to economic risk associated with these industries. This is evident for the dominant urban industry of Machinery, Instruments, Transportation Equipment and Metals, and the Eastern Oregon dominance of Food or Kindred Products.



7.3 CONCLUSION

Using the Oregon Commodity Flow Forecast, October 2009, under all modeled scenarios, Oregon's economy and key industries will continue to grow, albeit at different rates. Many of Oregon's major freight dependent industries, such as Food Manufacturing, and Computers and Electronics are more susceptible to economic volatility because they are exported while Wholesale Trade and others are less susceptible. As a result of this relative stability in major Oregon industries, the OFP strategies can be expected to be applicable over the life of the plan. However, Oregon depends on federal funding for transportation system investment and maintenance. A reduction in federal funds, as described in Alternative Future #4, would be troubling for the freight system and Oregon's economy. In this case, core strategies discussed in Chapter 8 that focus on operations improvements would become even more relevant, as operations improvements require less investment to achieve travel time improvements and other benefits. As a result, where appropriate, operations improvements may be a method to keep freight moving effectively during times of reduced federal investment.

The primary indicators are derived from the assumptions that define the Reference Case and are listed here.

- Economic growth changes significantly. It is essential to continually evaluate economic growth, both past and future projections presented by the OEA. If actual and projected Oregon GSP and employment figures deviate significantly from those presented in this freight plan, reevaluation may be required.
- Long-term investment in the transportation system changes significantly. If investment in the transportation system increases or decreases substantially from what is presented in the OTP, re-evaluation may be required.
- Transportation costs increase or decrease significantly. If a large increase or decrease in freight provider transportation costs occurs over the long term, reevaluation may be required.
- Consumption and trade activity decreases over the long term. If total consumer consumption decreases over the long term (either as a result of declining population or for economic reasons), re-evaluation may be required. In addition, if trade activity decreases substantially, this would change some of the assumptions made.
- Projected demographics change significantly. Currently, Oregon's population is expected to age and increase. If forecasts change, re-evaluation may be required.

Freight Issues and Strategies

8.0 Freight Issues and Strategies

8.1 PURPOSE OF ISSUES AND STRATEGIES

Analysis and outreach efforts supporting the development of the OFP have identified a number of issues that need to be addressed in order to ensure that Oregon has an efficient and sustainable freight transportation system that continues to support economic growth and livability of Oregon communities. This chapter presents these issues and formulates strategies that ODOT, tribal governments and other governmental agencies and jurisdictions can implement in order to realize the state's freight transportation goals.

These strategies would do the following:

- Define a strategic freight system and establish a process for updating the definition of the system;
- Describe how the strategic system should be preserved;
- Periodically revisit existing processes and criteria for determining critical investment needs for the freight system;[113]
- Describe how ODOT can work with partner agencies and other states, local agencies and the private sector to ensure a coordinated approach to freight transportation system planning;
- Establish procedures to ensure the system operates safely and efficiently;
- Identify actions that can be taken to coordinate land use and freight transportation planning decisions;
- Describe how regulatory programs can be coordinated with freight transportation needs; and

[113] Section 9.5 evaluates freight mobility issues and includes strategies to address those issues as required by the FAST Act.

- Describe approaches to addressing long-term funding needs for the freight transportation system.

8.2 STRATEGY METHODOLOGY

Methodology to Create the OFP Issues and Strategies

The issues and strategies presented in this chapter were developed with input from two primary sources:

- Analysis described in a series of technical memoranda on freight transportation topics. Experts within the stakeholder community who participated in a series of Working Groups and the OFP Steering Committee reviewed these technical memoranda. The technical memoranda also provided extensive data that were used in subsequent analyses included in the preceding chapters of this plan. The technical memoranda prepared to support the OFP can be found in Freight Plan Publications on the ODOT website.[114]
- Discussions with the OFP Steering Committee. As described in Chapter 1, the OFP Steering Committee included executive-level freight industry, community and transportation professionals from around the state. The Steering Committee received all of the technical memoranda and then spent a number of meetings discussing issues and formulating strategies based on the technical information and their own expertise.

8.3 OFP ISSUES AND STRATEGIES

Freight Issue #1: *A clearly defined, multimodal "Strategic Freight System," is essential in order to focus freight system improvements, maintenance and protection on the freight corridors that play the most critical role in supporting the state's economy. Currently, this does not exist.*

Strategy 1.1:

Establish a Strategic Freight System building on the system defined by the commodity flows of Oregon's major industries. This system should include those elements of the transportation infrastructure that best support the state's key industries. This system should be multimodal, when viable, and exist in both urban and rural areas as appropriate.

[114] Contact the ODOT Freight Planning Unit to obtain copies of the technical memos. [115] Refer to Chapter 9.3 for updated performance measures required by the FAST Act.

- Action 1.1.1. Monitor and maintain freight systems identified in modal plans. Update modal plans to meet identified strategic needs and incorporate analysis of current economy and economic forecasts periodically.
- Action 1.1.2. Use the methodology resulting from this plan to update the definition of the strategic freight infrastructure system. The methodology includes both quantifiable and qualitative data elements.
- Action 1.1.3. Develop performance measures and gather necessary data on an ongoing basis to support continued updating of identified freight routes as Oregon's economy evolves and the state reacts to changing economic conditions.[115]

Strategy 1.2:

Support freight access to the Strategic Freight System. This includes proactively protecting and preserving corridors designated as strategic.

- Action 1.2.1. Preserve freight facilities included as part of the Strategic Freight System from changes that would significantly reduce the ability of these facilities to operate as efficient components of the freight system unless alternate facilities are identified or a safety-related need arises.
- Action 1.2.2. When a change of use or classification of any facility on the Strategic Freight System is considered, seek to ensure that continuity of the Strategic Freight System is maintained.

Strategy 1.3:

Improve understanding of the economic benefits of freight improvement projects or programs to Oregon's residents and businesses. This means understanding both the direct benefits and secondary benefits such as induced job growth.

- Action 1.3.1. Develop mechanisms to measure the potential benefits of freight projects or programs. Measures should include quantifiable economic benefit as well as non-quantifiable benefits such as improvements to public health, safety and quality of life.
- Action 1.3.2. Establish mechanisms to measure appropriate comparative economic returns of different freight projects or programs. When multiple projects are reviewed, provide decision makers with information regarding return on investments.

[115] Refer to Chapter 9.3 for updated performance measures required by the FAST Act.

- Action 1.3.3. Use relevant freight benefit and freight mobility measures during project prioritization and selection. Use the economic benefit and economic return information to support freight projects to achieve project funding during the selection process.

Freight Issue #2: *Capacity constraints, congestion, unreliability and geometric deficiencies in key highway, rail, air and marine freight corridors cause inefficiencies in statewide freight movement.*

Strategy 2.1:

Define and establish criteria to identify freight constraints and deficiencies.

- Action 2.1.1. Create quantitative definitions for the types of constraints existing on the Oregon transportation system: capacity-related congestion points, operational chokepoints, deficient infrastructure conditions or geometry and weather-related closures. Define these constraints and deficiencies at a corridor level. Base performance and prioritization criteria on multiple factors, including delay, value of cargo and industries affected, degree of weather-related impacts, availability of alternate routes and OHP mobility standards.[116]

Strategy 2.2:

Develop a process for identifying, measuring and monitoring system constraints and deficiencies.

- Action 2.2.1. Develop and use performance measures/factors to identify corridor performance constraints, system deficiencies and affected industries. Apply the criteria to identify system constraints on an ongoing basis. Base performance measures on research conducted by ODOT and reported in "Freight Performance Measures: Approach Analysis."[117,118]

---

[116] Chapter 9, Section 9.5, summarized the Freight Highway Bottlenecks Project that identified and prioritized truck delay areas in response to this strategy and FAST Act requirements.

[117] Starr McMullen and Christopher Monsere, "Freight Performance Measures: Approach Analysis," prepared for the Oregon Department of Transportation and the Oregon Transportation Research and Education Consortium (OTREC), May 2010.
https://www.oregon.gov/ODOT/Programs/ResearchDocuments/Freight_Perform ance_Measures.pdf

Strategy 2.3:

Identify and rank freight bottlenecks, corridor constraints or chokepoints, in particular those located on the strategic system. Update the ranked list periodically.[119]

- Action 2.3.1. Create a set of freight planning guidelines to use for developing transportation system plans. Recommend the adoption of ranking and prioritization procedures for evaluating freight system performance as part of TSPs. In the guidelines, recommend that the TSPs detail how plans will eliminate or significantly reduce bottlenecks and constraints.
- Action 2.3.2. Prioritize freight system needs on a regular basis. This list should include all modes and be flexible enough to be adaptable to different funding sources.

Strategy 2.4:

Coordinate freight improvements and system management plans on corridors comprising the Strategic Freight System with the intent to improve supply chain performance.

- Action 2.4.1. Define freight improvement projects specifically as those projects that support goods movement efficiency, using quantitative criteria as defined in Action 2.1.1.[120]

Strategy 2.5:

Enhance Intelligent Transportation Systems (ITS) applications (such as traveler information programs and transportation demand management systems) that are effective and useful to freight. Prioritize strategic

118 Chapter 9, Section 9.3, implements required performance measures and monitoring.

119 Chapter 9, Section 9.5, summarizes the Freight Highway Bottlenecks Project that identified and prioritized bottlenecks in response to this strategy and the FAST Act.

120 Refer to Chapter 9 for the freight investment plan required by the FAST Act.

locations for ITS applications. This should include intermodal connector facilities.

- Action 2.5.1. Evaluate the effectiveness of existing programs and explore opportunities to expand the programs to new facilities, in particular those that are part of the Strategic Freight System.
- Action 2.5.2. Target key intermodal connectors as well as possible alternate routes to those intermodal connectors that tend to be congested.
- Action 2.5.3. Interview freight users (motor carriers, private fleets and shippers) to determine types of travel information most useful to them and identify best methods of delivery. Conduct demonstrations of public-private information sharing partnerships linking public Traffic Management Centers (TMC)/Trip Check systems to private dispatch and scheduling systems.
- Action 2.5.4. Coordinate with local Transportation Demand Management (TDM) programs on or near congested freight corridors to reduce discretionary auto trips**.**

Strategy 2.6:

In order to increase modal alternatives on key freight corridors in the strategic system, encourage development of carload transload/consolidation facilities where there is market support for such facilities.

- Action 2.6.1. Since railroad business models have evolved to emphasize efficiency through unit train and expedited service models (for intermodal trains) that benefit shippers who can consolidate loads, consider developing programs to help shippers develop transload/consolidation facilities where there is market support for such facilities. Build this strategy on a compelling public benefits analysis and demonstration of potential market feasibility.

Freight Issue #3: *Congestion and unreliable travel time on roads to access major intermodal facilities can cause disruptions to freight movement and industry supply chains.*

Strategy 3.1:

Establish a procedure for monitoring the mobility, infrastructure conditions, and performance of intermodal connector roads on the National Highway System and other last-mile connections to important freight generation sites.

- Action 3.1.1. Develop and maintain measures monitoring intermodal connection performance at key intermodal facilities in terms of traffic volumes, delays and infrastructure conditions.

Strategy 3.2:

Partner with local government agencies and tribal governments to identify intermodal connectors that provide "last mile" connectivity to freight-generating businesses or locations and are not currently classified as NHS Connectors. Use this information to update the NHS connector list, when requested by the federal government, and to establish an additional list of secondary connector routes as appropriate. Highlight the importance to local governments of the role they have in making the freight system function effectively for businesses across the state.[121]

- Action 3.2.1. Working with local and regional jurisdictions, develop guidance documents for local agencies that identify how to define and designate local freight connectors.
- Action 3.2.2. Compile a list of local freight connectors once they have been identified by local and regional jurisdictions and tribal governments.
- Action 3.2.3. Request local governments to document how they have addressed last mile local freight connector needs in their TSPs.

Strategy 3.3:

Encourage inclusion of connector roads in local transportation system plans.

- Action 3.3.1. Review TSP guidelines and make recommendations about identifying connector roads including any NHS

[121] Chapter 9, Section 9.5, summarizes the Oregon Freight Intermodal Connector System Study that identified intermodal connectors in response to this strategy and the FAST Act.

and non-NHS, local freight connectors or secondary freight routes in the local TSP process. Place special emphasis on those facilities that serve as important links to businesses, industrial lands and freight generators of statewide economic importance.

Freight Issue #4: *Improvements to the efficiency, reliability and safety of long-haul freight corridors require collaboration between Oregon and neighboring states.*

Strategy 4.1:

Prioritize efforts to create and maintain strategic relationships with multistate coalitions and freight groups in neighboring states to identify freight transportation issues, concerns and needs of mutual interest. Continue to advocate for multistate planning opportunities. Work with trading partners and freight destinations and origins on identifying supply chain issues that affect whole industries.

- Action 4.1.1. Take a strong role in supporting the activities of established multistate coalitions as well as coordinating freight initiatives with transportation agencies in California, Idaho, Nevada and Washington. Build strong ties with Washington State and seek opportunities to work on cross-border planning initiatives, rail issues and capacity issues in the Columbia River Gorge and on the Columbia River Crossing. Build relationships with major trading partners to identify freight supply chain issues.
- Action 4.1.2 Coordinate with neighboring states to reduce discretionary auto trips in congested interstate corridors at peak hours.

Freight Issue #5: *Changes to the physical dimensions of a highway may either accommodate or restrict permitted loads throughout the entire state and can cause connectivity issues to key businesses and freight generating activities.*

Strategy 5.1:

Monitor, preserve and improve highway freight facilities that accommodate truckloads requiring a permit.

- Action 5.1.1. Preserve the ability of highway facilities and locations that are utilized by heavy and over-dimensional trucks to accommodate these loads. Identify freight mobility needs and avoid loss of physical capacity for these trips unless an existing feasible route is identified. If a conflicting policy limits the application of this action, seek to balance the transportation needs of all highway users while managing the statewide transportation system.[122]
- Action 5.1.2 Target highway facilities and locations that are utilized by heavy and over-dimensional loads for improvements through a systematic process that identifies centers of economic activity for industries generating these loads and the corridors in which they operate. Create connections between the motor carrier permitted load routes and project selection processes.
- Action 5.1.3 When applying Actions 5.1.1 and 5.1.2, engage in early public outreach to the affected communities, local governments, shippers of oversize and over-weight loads and motor carriers.

Strategy 5.2:

Identify routes that have length, weight, or height restrictions and include these routes, as appropriate, in the state's assessment of needed highway improvements.[123]

- Action 5.2.1. Use a data-driven process to identify highway improvement needs and to conduct an economic analysis of over-size, over-weight truck corridor improvement needs. Some criteria that could be considered as part of this identification and assessment process include:

[122] Oregon Revised Statutes (ORS) 366.215 stipulates that the Oregon Transportation Commission (OTC) may not permanently reduce the vehicle-carrying capacity of an identified freight route when altering, relocating, changing, or realigning a state highway unless safety or access considerations require the reduction. Local governments may apply to the OTC for an exemption to prohibitions to reductions in capacity.

[123] Chapter 9, Section 9.5, summarizes the needs related to highway over-dimensional load pinch points in response to this strategy and the FAST Act.

- The number of requests for permits on the route.
- Input from stakeholders and periodic shipper surveys to identify latent demand for commodity shipments requiring over-size, over-weight truck configurations.
- Analysis of corridor-level data and forecasts to determine where demand for over-size, over-weight loads is likely to increase.
- Analysis of emergency preparedness plans as certain events will require viable routes to deploy larger and heavier trucks that require a permit.

Strategy 5.3:

Consider targeting financial support to strategic non-highway modal infrastructure such as shortline rail and barge for shipment of nondivisible loads.

· Action 5.3.1. Identify other transportation modal options, including shortline rail service or barge, in each of the key corridors that need to be protected for over-size and over-weight commodity movements, as well as the "last mile" connections to industrial and freight–generating land uses. If rail or barge infrastructure is available, consider targeting financial support into upgrading or maintaining the infrastructure as an alternative to truck transportation.

In all cases, the state's participation in supporting infrastructure owned by private entities should only be contemplated if there is significant public interest or economic incentive to do so. Subsidies to the private sector should only be provided where there is an acceptable business plan for ongoing operation and maintenance of facilities and where a public benefit is clearly documented. Identified matching funds should also be considered as a necessary condition for state investment in private modal services.

Freight Issue 6: *Freight needs to be able to move throughout the state in a manner that is as safe as possible. Its movement may impact safety in Oregon communities and risk to the environment.*

Strategy 6.1:

Partner with local, statewide, tribal and federal partners to monitor and manage the safety performance of the statewide freight system.

- Action 6.1.1. Work with the ODOT Motor Carrier Transportation Division, Rail Division and other programs within state agencies to advance freight issues for consideration in safety plans. This should include continued monitoring of locations on state highways for high incidence of truck-involved crashes to identify any emerging safety issues and continued evaluation of rail grade crossing safety through the Oregon Operation Lifesaver program.
- Action 6.1.2. Continue leveraging the knowledge and support on safety matters offered by federal public agencies as well as private-sector freight partners.
- Action 6.1.3. Review programs and manuals offered by the state to include the most recent technological and operational freight and logistics developments.
- Action 6.1.4. Review existing hazardous transportation routes to determine whether their location is optimal to provide mobility while minimizing potential impacts to the environment and communities.

Strategy 6.2:

Use state-of-the-art crash statistics and data tracking methods to monitor the safety performance of the system and to track system performance over time.

- Action 6.2.1. The state will develop and use up-to-date local and national freight related crash data. Adjust the data types if necessary to respond to changes in logistics supply chains or transportation modes.

Strategy 6.3:

Build freight safety considerations into the system monitoring, project selection and prioritization processes.

Freight Issue #7: *Industrial land supply for freight-dependent land uses may be insufficient to meet future demand. Lack of necessary land use protections may threaten the viability of freight transportation systems.*

Strategy 7.1:

Work to better integrate freight into the land use planning process and to protect the existing supply of industrial (freight-dependent) land uses and freight terminals.

§ Action 7.1.1. Support better integration of freight into the regional and local land use planning processes. Encourage local governments to integrate industrial land use planning into comprehensive plans and all other plans and actions relating to land use controls.

§ Action 7.1.2 Work with regional and local land use planning agencies to protect existing industrial land from encroachment from incompatible land uses. This could be accomplished by including industrial-zoned lands adjacent to freight facilities (including such facilities as intermodal yards, freight terminals, marine and others) for future freight expansion. Encourage the development of buffers between freight facilities and incompatible uses. Transportation infrastructure connecting to terminals, ports, airports, and other freight-generating land uses should be included in these discussions.

§ Action 7.1.3 Work with local and regional governments to encourage that properties designated as industrial lands in a comprehensive plan are reasonably developable. Land selected for industrial uses should not have significant constraints that would make it unduly difficult or costly to develop.

§ Action 7.1.4 Encourage the development of freight transportation facilities and other industrial land uses at brownfield locations.

Strategy 7.2:

Work with local and regional agencies and tribal governments to develop best practices for integrating freight generating land uses into the urban fabric in a manner that minimizes the impact on surrounding communities and the environment.

· Action 7.2.1. Support local and regional land use agency efforts to create a set of freight generating land use design standards including information to educate private sector developers and public sector planners. Distribute the standards to potential developers of freight-dependent businesses and local land use planners. Support adoption of strategies such as Cargo-Oriented Development (COD)[124] and Smart Industrial Growth in local and regional plans.

[124] See Appendix E – Glossary for definition of Cargo-Oriented Development.

Freight Issue #8: *Freight emissions include pollutants such as greenhouse gases and particulate matter that contribute to climate change and health risk concerns.*

Strategy 8.1:

Research strategies to reduce pollutants and greenhouse gas emissions from freight sources that are active within Oregon, focus on strategies that have been implemented with success in regions that have similarities to Oregon.

- Action 8.1.1. Build on work completed in the OFP to research methods for emissions reduction. These methods may include behavioral changes, technology improvements or methods that increase the efficiency of freight supply chains.
- Action 8.1.2. Work in coordination with private sector freight stakeholders to identify the most cost-effective approaches to address climate change impacts from freight, in particular those strategies that also support and benefit shippers.

Strategy 8.2:

Consider climate change impacts in freight transportation planning activities.

- Action 8.2.1. Incorporate methods of considering greenhouse gas impacts in freight transportation planning and decision-making processes.
- Action 8.2.2. Support congestion relief and idling reduction activities such as weigh-in-motion technology and the provision of electricity at truck stops for parked trucks.

Freight Issue #9: *National Environmental Policy Act (NEPA) review procedures and permitting requirements for freight projects involve complexities that, if overlooked, can result in negative impacts to project development and implementation cycles.*

Strategy 9.1:

Reduce inefficiencies in the NEPA process as well as other environmental permitting processes by considering actions that encourage early consultation with federal, state, and local agencies.[125]

- Action 9.1.1. Review the state's natural resource and environmental permitting program for highway projects and assess its potential applicability for freight transportation projects for other modes. For all environmental review and NEPA projects, engage the necessary internal and external agency stakeholders early in the planning process in order to secure the required permits and speed project delivery. Work with resource agencies to arrange for concurrent reviews wherever possible.

Freight Issue #10: *New and emerging safety, security, and environmental regulations, though beneficial, can be confusing to shippers and carriers and be expensive to implement.*

Strategy 10.1:

Work with shippers, carriers and terminal operators to increase the knowledge of the costs, consequences and requirements of new safety, security and environmental regulations.

Freight Issue #11: *The freight system in Oregon lacks system redundancy in several key locations. This leaves it vulnerable to disruptions that threaten freight system continuity, especially during emergencies.*

Strategy 11.1:

Create a statewide emergency management plan that identifies critical vulnerable points from a freight mobility perspective and places where there is a lack of

[125] To review major transportation projects, ODOT and federal and state natural resource-related agencies use the Collaborative Environmental and Transportation Agreement for Streamlining (CETAS) process. CETAS relies on its agency representatives working together early in project development to collaboratively solve problems, potentially resulting in quicker permitting decisions than the traditional environmental review process.

system redundancy. Create freight movement emergency plans for disruptions at these locations that include information about possible alternatives routes.

- Action 11.1.1. Create an emergency transportation system map that includes alternative route identification as well as transportation modal alternative information. The map should be flexible enough to be used when single transportation components are compromised or when entire portions of the system have suffered a disruption.
- Action 11.1.2. Identify and track those places where disruptions would be most acutely felt. This includes those places where there are no, or few, parallel route options, so a disruption means a lack of connectivity. This also means places that tend to be subject to natural or weather-related disruptions including mountain passes, single-lane infrastructure, rail tracks that tend to be affected by heavy rains and snows, and inland waterway passages that are heavily influenced by water levels and drought.
- Action 11.1.3. Create plans that facilitate the movement of goods on alternative routes.

Strategy 11.2:

Develop and maintain transportation models that account for freight logistics and routing behavior in order to evaluate effects of disruptions on freight movement at the state, regional and urban levels.

Strategy 11.3:

Retain critical existing redundancy elements (for example, rail lines currently not in use, but parallel to a highway facility). Infrastructure that is currently under-utilized may become the primary link in the case of serious disruption on the primary facility.

Freight Issue #12: *Lack of a sustained source of statewide freight funding decreases the ability of the public sector to plan for long- and medium-term freight needs in a comprehensive manner.*

Strategy 12.1:

Work with elected officials, carriers, shippers and other stakeholders to study the potential for, and implications of, a statewide freight fund. The fund would have a selective, criteria-driven process to prioritize and fund projects in all modes of freight transportation. The process would be needs-based and focus on projects located on the Strategic Freight System.

Strategy 12.2:

On a regular basis, create a package of statewide freight improvements that best support efficient statewide freight movement. Share this statewide package with local and regional governments and agencies to assist them in selecting projects to forward through the multimodal transportation improvement selection processes.

Strategy 12.3:

Advocate establishing sources of funding for improvements on intermodal connectors.

· Action 12.3.1. Explore establishing mechanisms to maintain and improve intermodal connectors, focusing on publicly owned infrastructure such as the roads and railways that connect private intermodal warehouse/industrial facilities. This could include options for those problem intermodal connectors that are not NHS designees or for supplementing the funds available through the NHS program. Funding could be provided through an existing or new state funding source.

Freight Issue #13: *Limited availability of state transportation funds means that use of existing sources of funding must be effectively optimized.*

Strategy 13.1:

Before embarking on capital improvement projects, explore lower cost solutions, including operational upgrades or institutional changes, consistent with least cost planning principles.

· Action 13.1.1. Investigate freight operational upgrades or institutional changes prior to engaging in a capital improvement project, particularly during times of significant economic hardship.

Strategy 13.2:

When a public benefit can be achieved, work together with private sector multimodal freight stakeholders to pool resources and optimize funding efficiencies. This may include investing in transportation improvements that are multimodal and privately owned, and include improvements to all freight modal infrastructures.

- Action 13.2.1. Develop the tools necessary to incorporate the breadth of transportation modes into the state transportation planning process. Develop an understanding of criteria such as multimodal transportation performance measures, costs and benefits for all transportation modes if they are to be considered as part of the transportation planning process.

Strategy 13.3:

Seek projects to advance as potential public-private partnerships through the planning and programming process.

- Action 13.3.1. Actively pursue public-private partnerships, where appropriate, and use capabilities already developed to help manage them, such as the Office of Innovative Partnerships Program.

Freight Issue #14: *The lack of a continuous federal freight funding source makes it very challenging for Oregon to implement the ongoing planning and programming of freight projects. Those projects that are of regional or national significance should be eligible for federal participation and funding.*

Strategy 14.1:

Work through Oregon's congressional delegation to urge the federal government to develop a coherent national freight strategy.[126]

- Action 14.1.1. Work toward influencing national policy by stressing the urgency of freight funding and financing in discussions with congressional representatives.

Strategy 14.2:

Work with partner states to identify projects that are of national significance to elevate to the federal level for funding consideration.[127]

[126] Chapter 9 describes the steps taken in the FAST Act and with the National Highway Freight Program to develop a national freight strategy and funding source.

[127] Section 9.6 lists projects in an investment plan that describes how formula freight funding will be expended and matched during federal fiscal years 2016-2020.

- Action 14.2.1. Continue to work with partner agencies and other states to identify projects that are important to regional and statewide economies and also important at the national scale. State or local contributions may also be needed for these projects to the extent that they benefit the state or local communities.

Freight Issue #15: *The economic importance of freight is not always understood or appreciated by the public.*

Strategy 15.1:

Continue to create opportunities for positive interaction between freight industry representatives and community stakeholders, including long-range planning or other community planning activities.

- Action 15.1.1. Continue to include shippers, carriers and private-sector developers in regional and statewide outreach efforts and on advisory groups such as the one created for this OFP to promote an understanding of the needs of freight-related businesses.
- Action 15.1.2. Explore additional opportunities for promoting the understanding of freight issues, such as the participation of ODOT freight staff, carriers and shippers in Area Commission on Transportation meetings.
- Action 15.1.3. Educate the public about the importance of statewide freight issues through increased coverage on the ODOT website and through other forums.

8.4 IMPLEMENTATION

Implementation of the OFP strategies and actions will build on the planning framework established in the OTP and other modal and topic plans. This will include working with a variety of public agencies and private sector stakeholders through existing and new partnerships. Implementation of some of the strategies and actions can be accomplished in the short term while others will require commitments over the longer term. Some may require legislative action or action by other governmental entities. Implementation will occur in phases and will require coordination with efforts to update other plans such as the modal and topic plans as well as regional and local transportation system plans. Funding availability will be important to implementing many of the strategies and associated actions.

OTP Key Initiatives

The OTP implementation identifies a set of Key Initiatives that provide implementation guidance for the OTP and the modal and topic plans. These key initiatives include directions related to system optimization, integration of transportation modes, integration of transportation, land use, the environment and the economy, and the need to make strategic investments using a sustainable funding structure.

The purpose of the key initiatives is to frame plan implementation, along with updating the modal/topic plans, not to override the direction of the goals and policies. Implementation of the OFP will be consistent with all OTP Key Initiatives and advance several of them. These are the OTP Key Initiatives:

- Maintain the existing transportation system to maximize the value of the assets. If funds are not available to maintain the system, develop a triage method for investing available funds.
- Optimize system capacity and safety through information technology and other methods.
- Integrate transportation, land use, economic development and the environment.
- Integrate the transportation system across jurisdictions, ownerships and modes.
- Create a sustainable funding plan for Oregon transportation.
- Invest strategically in capacity enhancements.

Implementation Steps

Implementation of the OFP will require coordination between and within governments, agencies, and the private sector, integration of the OFP strategies into subsequent planning efforts and public involvement in discussions of freight needs.

Coordination

Implementation will require involvement and coordination among a variety of ODOT business units. This includes the ODOT modal divisions and the Transportation Development Division. The involvement of ODOT Region staff will be critical to the implementation of some strategies and actions.

Implementation also will require involvement and coordination with other state agencies such as the Department of Aviation, Business Development Department, Department of Land Conservation and Development and various resource and other agencies as well as the Federal Highway Administration, Federal Aviation Administration and other federal modal administrations and agencies.

Coordination with transportation and other agencies in neighboring states can further implementation of several strategies and actions.

Planning

Oregon's statutes and administrative rules promote planning consistency among state, regional and local governments. The Transportation Planning Rule (TPR) requires state, regional and local governments to address goods movement issues in the development of transportation system plans. The TPR also requires regional and local government transportation system plans to be consistent with the state transportation system plan. Since the OFP is part of the state transportation system plan, its strategies will provide guidance to regional and local freight planning and system management.

The OFP supports several elements of planning and system management including:

- State transportation facility plans such as specific area plans, interchange area management plans, expressway management plans and corridor plans;
- Regional and local transportation system plans developed through MPO, city or county processes;
- Plans developed by tribal governments;
- Plans developed by ports or special districts; and
- System management by ODOT, other state agencies, MPOs, cities and counties that may include management of roadway pavement, bridges, safety, operations, maintenance, congestion and public transportation.

Public Involvement

Public involvement and coordination will be critical to OFP implementation. This will include seeking input from a variety of community and freight stakeholders, such as the Oregon Freight Advisory

Committee as well as other tribal, state, regional and local advisory committees.

Input from various public agencies and freight stakeholders will help guide preparation of a more detailed analysis of the work needed to implement specific OFP strategies and actions. Completion of the analysis is expected to result in a guidance document identifying short-term priorities, medium-term priorities and long-term priorities, similar to the way these are identified in the OTP Implementation Work Program. Implementation of OFP priorities will need to be consistent with implementation of priorities in the OTP work program as well as other planning work programs.

Steps Following Plan Adoption

Some implementation actions can start soon after the OFP is adopted.[128] These include the following:

- Develop an Implementation Plan using the OTP Key Initiatives and Freight Plan purpose statement to provide a framework.
- Continue discussions to update Oregon's transportation finance structure with stakeholders and the public.
- Develop performance measures and analytical tools for plan implementation.
- Develop freight stakeholder input on bottlenecks or choke points on the Strategic Freight System.
- Communicate the bottlenecks or choke point locations to infrastructure owners and stewards.

[128] Refer to Chapter 9 for an update on implementation activities related to system needs, performance, network designations, and funding.

Federal Compliance

9.0 Federal Compliance

9.1 BACKGROUND

Moving Ahead for Progress in the 21st Century Act, or MAP-21[129], was signed into law on July 6, 2012. Among other things, it contained a number of provisions related to freight and performance management. It required the U.S. Department of Transportation (USDOT) to establish a national freight network to help states strategically direct resources toward improved freight system performance. It also required the USDOT to develop a National Freight Strategic Plan. It continued the Projects of National and Regional Significance program and, in order to encourage investment in freight projects, allowed for reduced non-federal matching share for freight projects.

MAP-21 encouraged each state to develop a comprehensive state freight plan that would:

- identify significant freight system trends, needs and issues;
- include freight policies, strategies and performance measures to guide the state's investment decisions;
