- improve the ability of the state to meet national freight goals;
- consider innovative technologies and operational strategies, including intelligent transportation systems, that improve the safety and efficiency of freight movement;
- describe improvements that may be required to reduce or impede the deterioration, where travel by heavy vehicles is projected to substantially deteriorate the condition of roadways; and
- inventory facilities with freight mobility issues, such as truck bottlenecks, and identify strategies to address those mobility issues.

MAP-21 also encouraged each state to establish a freight advisory committee containing a representative cross section of public- and private-sector freight stakeholders.

The Oregon Freight Plan (OFP) was developed in parallel with MAP-21 and is consistent with much of the impetus behind the law. However, the OFP was adopted prior to the finalization of MAP-21. Additionally, on December 4, 2015,

[129] Public Law No. 112-114

President Barack Obama signed the Fixing America's Surface Transportation (FAST) Act into law.

The FAST Act builds on MAP-21's freight requirements. At a national level, it clarified and amended the national freight network and planning requirements. It brings a greater focus on multimodal freight planning by establishing a National Multimodal Freight Policy (NMFP) and requiring the creation of a National Multimodal Freight Network (NMFN). It requires the USDOT to establish both an interim and final network.

It also established a new funding program, the National Highway Freight Program (NHFP), and provided formula funds over Federal FY 2016 to 2020 for states to invest in freight projects on the National Highway Freight Network (NHFN).

The FAST Act further requires that states develop a freight plan that comprehensively covers short- and long-term freight planning activities and investments. The plan must:

- Cover a five-year forecast period
- Be fiscally constrained
- Include a freight investment plan with a list of priority projects
- Describe how the state will invest and match its NHFP funds.

The FAST Act continues to encourage states to form freight advisory committees and clarifies their role. It requires the USDOT to develop new tools to support an outcome-oriented, performance-based approach to evaluating proposed projects, and continues the requirement to report on the NHFN's condition and performance.

This chapter has been developed to meet the federal freight provisions under MAP-21 and FAST Act. The FAST Act lists 10 required elements that all state freight plans must address.[130] Many of these requirements (including freight trends, needs and issues, policies, strategies, innovative technologies and State of Good Repair) are addressed in the previous chapters of the OFP, the Oregon Transportation Plan (OTP), and other modal/topic policy plans. This chapter will cover the outstanding requirements that relate to:

- Freight-related performance measures
- Designation of critical rural and urban freight corridors

[130] 49 U.S.C. 70202: State freight plans

- A description of how the OFP will improve the State's ability to meet the NMFP goals and the NHFP goals
- An inventory of facilities with freight mobility issues and a description of the strategies the State is employing to address those issues
- Consideration of any significant congestion or delay caused by freight movements and strategies to mitigate those impacts
- A freight investment plan
- A description of the consultation with the Oregon Freight Advisory Committee (OFAC)

These requirements and how the plan addresses them are detailed in the sections that follow. The extensive consultation used to develop both the original plan and this chapter is detailed in a revised Appendix A.

9.2 COMPARISON WITH NATIONAL FREIGHT GOALS

The FAST Act established the NMFP, which includes national goals to guide decision-making. The NHFP also includes goals to guide investment in freight. While one is geared to drive decision-making for all modes and the other focused on highway investments, there is a great deal of similarity in their goals.

The national highway freight program goals are—

1. *To invest in infrastructure improvements and to implement operational improvements on the highways of the United States that—*
    a. *strengthen the contribution of the National Highway Freight Network to the economic competitiveness of the United States;*
    b. *reduce congestion and bottlenecks on the National Highway Freight Network;*
    c. *reduce the cost of freight transportation;*
    d. *improve the year-round reliability of freight transportation; and*
    e. *increase productivity, particularly for domestic industries and businesses that create high-value jobs;*
2. *To improve the safety, security, efficiency, and resiliency of freight transportation in rural and urban areas;*
3. *To improve the state of good repair of the National Highway Freight Network;*
4. *To use innovation and advanced technology to improve the safety, efficiency, and reliability of the National Highway Freight Network;*
5. *To improve the efficiency and productivity of the National Highway Freight Network;*
6. *To improve the flexibility of States to support multi-State corridor planning and the creation of multi-State organizations to increase the ability of States to address highway freight connectivity; and*
7. *To reduce the environmental impacts of freight movement on the National Highway Freight Network.*

Source: 23 U.S.C. 167: National highway freight program

The national multimodal freight policy goals are:

1. *To identify infrastructure improvements, policies, and operational innovations that—*
    a. *strengthen the contribution of the National Multimodal Freight Network to the economic competitiveness of the United States;*
    b. *reduce congestion and eliminate bottlenecks on the National Multimodal Freight Network; and*
    c. *increase productivity, particularly for domestic industries and businesses that create high-value jobs;*
2. *To improve the safety, security, efficiency, and resiliency of multimodal freight transportation;*
3. *To achieve and maintain a state of good repair on the National Multimodal Freight Network;*
4. *To use innovation and advanced technology to improve the safety, efficiency, and reliability of the National Multimodal Freight Network;*
5. *To improve the economic efficiency and productivity of the National Multimodal Freight Network;*
6. *To improve the reliability of freight transportation;*
7. *To improve the short- and long-distance movement of goods that—*
    a. *travel across rural areas between population centers;*
    b. *travel between rural areas and population centers; and*
    c. *travel from the Nation's ports, airports, and gateways to the National Multimodal Freight Network;*
8. *To improve the flexibility of States to support multi-State corridor planning and the creation of multi-State organizations to increase the ability of States to address multimodal freight connectivity;*
9. *To reduce the adverse environmental impacts of freight movement on the National Multimodal Freight Network; and*
10. *To pursue the goals described in this subsection in a manner that is not burdensome to State and local governments.*

Source: 49 U.S.C. 70101 (b)

Appendix G contains a matrix that cross-references the national goals to the specific Oregon state plan policies, strategies and actions. In general, there is strong correlation and connection between the OFP strategies and the actions and the goals outlined in the NHFP and NMFP. Additionally, the OFP is one of several statewide transportation plans that implement the OTP's goals and define

the state's multimodal transportation system.[131] Several of these other statewide plans, including the Oregon State Rail Plan and the OTP, have numerous connections to the federal goals as further set forth, below.

In keeping with the national goals, the OFP purpose statement strongly connects the reliability, safety and efficiency of the multimodal freight system with economic competitiveness. This plan and the OTP contain numerous strategies and actions related to increasing economic competitiveness, and addressing reliability and safety. In addition, OFP implementation strategies include the recently completed inventory of needs for all modes, including the recent freight highway delay areas and intermodal connectors studies, along with similar inventories for other freight modes. These inventories of mobility issues are further discussed in Section 5 of this chapter (Freight Mobility Issues), which outlines specific areas of need that are critical to the strategic freight system.

Preserving and maintaining a state of good repair is a foundational element of the OFP. Numerous actions and strategies address this goal, relying on data processes to identify the most critical areas on the strategic freight system. The plan also recognizes the importance of multi-state and multi-agency coordination to improve freight system efficiency. Further, the OFP underscores the impact of the freight system on the environment and provides many actions to reduce this impact.

Security is a key topic in the OTP. Strategy 5.2.1 addresses the need for security plans for all transportation modes. Strategy 5.2.4 specifically addresses the potential impact of security measures on managing transportation facilities to minimize delays in the movement of people, goods and services. The OFP also has several actions related to improving connections between urban and rural areas.

While goals directed to using innovation and technology are less abundant in the OFP, technology is a strong theme, consistent with the national freight goals. The OFP outlines several key strategies and actions directed at implementing advanced technology to improve freight system efficiencies. And the OFP's focus on cost-effectiveness and use of the best opportunities available to maximize system efficiency encourages the use of innovative technologies to achieve these goals. ODOT has completed many ITS projects that benefit truck freight. The State will continue to capitalize on opportunities for using innovation and technology to develop applications such as Oregon's Green Light Program. Over the course of the last 15 years, Green Light has saved operators of commercial vehicles some 1.5 million hours of travel time and $180 million in operating costs as they cleared Oregon weigh stations without having to slow or

[131] The relationship between the OFP, the OTP and the various statewide modal and topic plans is further explained in Section 1.2.

stop. In addition, the increase in operational capacity afforded by Green Light has reduced the need to build new weigh station facilities or expand existing ones.

The strategies and actions outlined in the OFP and the OTP formalize Oregon's commitment to multimodal freight system improvement by helping define system needs. Nearly every strategy and action in the OFP supports multiple national freight goals. Extensive implementation efforts have led to the identification of critical areas of need and will provide Oregon with the information necessary to meet to the OFP and national freight goals.

More detail on how the specific strategies and actions in Oregon plans line up with the federal freight goals is contained in Appendix G.

9.3 PERFORMANCE MEASURES

MAP-21 established seven national performance goals and a performance management system. It required the Federal Highway Administration (FHWA), in consultation with the states, to establish measures and required each state to establish performance targets in the following areas:

- Pavement condition on the Interstate System and on the remainder of the National Highway System (NHS)
- Performance of the Interstate System and the remainder of the NHS
- Bridge condition on the NHS
- Fatalities and serious injuries—both number and rate per vehicle mile traveled (VMT)—on all public roads
- Traffic congestion
- On-road mobile source emissions
- Freight movement on the Interstate System

The FAST Act continued this program with some limited adjustments. If the USDOT Administrator determines that a state has failed to make significant progress toward meeting its freight performance targets within two years after establishing the targets, the state must describe the actions it will take to achieve these targets in its next performance report to USDOT.[132]

USDOT has established national performance measures in response to the requirements of MAP-21 and the FAST Act.[133] The performance measure to

[132] FAST Act § 1116; 23 U.S.C. 167(j)

[133] 23 CFR Part 490 – Subpart F

assess freight movement on the Interstate is Percentage of the Interstate System Mileage providing for Reliable Truck Travel Times, or Truck Travel Time Reliability (TTTR) Index (the Freight Reliability measure). This measure is calculated using the National Performance Management Research Data Set (NPMRDS), which was developed by the FHWA to provide a comprehensive picture of travel times throughout the National Highway System, for both passenger vehicles and trucks. It is a ratio of the median to the 95th percentile travel time and is calculated for each segment throughout the state system for five time periods. The worst time period for each segment is selected and then an average developed for the entire system based on the segment length.

In addition to this federally required performance measure, Oregon will track and report on three safety performance indicators. All three of these indicators are included as part of the Oregon Transportation Safety Action Plan and are currently measured and reported through the ODOT Safety Division and the Rail and Public Transit Division. These indicators are:

- Large truck at-fault crashes: number of large truck at-fault crashes per million VMT[134]
- Rail crossing incidents: number of highway-railroad at-grade incidents
- Derailment incidents: number of train derailments caused by human error, track, or equipment.

ODOT will continue to work with the OFAC to evaluate and explore other potential freight performance measures and indicators that may help inform future system needs and priorities.

9.4 FREIGHT NETWORK DESIGNATIONS

Existing Federal Networks

The FAST Act requires FHWA to establish a NHFN. This network is the focus of funding under the NHFP and the FASTLANE Grants program. The NHFN consists of four subsystems:

1. The Primary Highway Freight System (PHFS)
2. Portions of the Interstate System that are not part of the PHFS
3. Critical Rural Freight Corridors (CRFCs), and
4. Critical Urban Freight Corridors (CUFCs)[135]

[134] Trucks with five or more axles are commonly considered large.

[135] 23 U.S.C. 167(c)

The FAST Act limited the PHFS to 41,518 centerline miles nation-wide. FHWA designated these in October 2015. Including the portions of the interstate system that are not part of the PHFS, the current NHFN for Oregon is shown in Figure 9.1. The State is responsible for designating CRFCs. The FAST Act allows states to designate CUFCs, in consultation with metropolitan planning organizations (MPOs), for urbanized areas with populations more than 50,000, but less than 500,000. MPOs may designate CUFCs, in consultation with the state, in urbanized areas with populations of 500,000 or more. The federal legislation allows Oregon to designate 155 miles as CRFC and 77 miles of CUFC. Once designated, ODOT can ask FHWA to remove or add segments within the total mileage limit. The rules also provide a mechanism for state mileage to increase over time.

Adding mileage to the NHFN allows the state to expand the facilities it can strategically direct federal resources toward. ODOT has worked with stakeholders to develop recommended CUFCs and CRFCs, which are discussed later in this section.

Figure 9.1 Existing National Highway Freight Network in Oregon

The FAST Act also required the USDOT to develop a National Freight Strategic Plan within two years of enactment that would identify and assess the demands on, and the condition and performance of, the nation's multimodal freight system. The draft plan, released in early 2016, identified barriers and opportunities as well as best practices for improving multimodal freight network performance. It also contained strategies for mitigating the impacts of freight on communities and for improving multistate and multimodal connectivity.

The FAST Act required the USDOT to establish a NMFN to inform stakeholders where major freight flows occur and where special attention to freight issues may be most warranted. The NMFN will include the following elements:

- The NHFN
- The Class 1 railroads as well as other freight rail systems
- U.S. public ports
- U.S. inland and intra-coastal waterways
- The Great Lakes, the St. Lawrence Seaway, and coastal and ocean domestic freight routes
- The 50 largest U.S. airports by landed weight
- Other strategic freight assets, including intermodal facilities

In May 2016, USDOT released an interim NMFN for comment. ODOT provided comments and asked that a number of facilities be added.

Beyond that, FAST Act allows the addition of up to 20% of mileage to the NMFN. Designation on the NMFN is not required for freight funding under the Act. Further, the State of Oregon and others are seeking clarification as to the process for identifying and apportioning between modes. Finally, these designations are not required to be part of the state freight plan under the FAST Act. Therefore, this section does not contain recommended additions to the NMFN, but ODOT will consider additional designations as a part of future processes.

State Networks

Chapter 4 describes the freight networks for all modes in Oregon. It examined commodity flows and identified a network of highways and other modal facilities that provide critical connections to centers of freight-dependent economic activity in the state. The designated Strategic Freight Corridors comprise four primary (trunk) corridors and multimodal connecting routes:

- The Western Corridor (I-5);
- Columbia River Corridor (I-84);
- U.S. 20 Corridor; and
- The Central Oregon corridor (U.S. 97).

The Strategic Freight Corridors are shown in Figure 4.13.

OHP Freight Routes

The Oregon Highway Plan (OHP) contains policies and actions to balance the need for efficient movement of goods and support of the economy with the movement of other modes. In order to facilitate efficient and reliable interstate, intrastate and regional truck movement, the OHP designated a freight system: the State Highway Freight System.[136] This system comprises interstate highways and certain statewide, regional and district highways, the majority of which are on the NHS, and includes routes that carry significant tonnage of freight by truck and serve as the primary interstate and intrastate highway freight connection to ports, intermodal terminals, and urban areas. The State Highway Freight System designation does not guarantee additional state investment in these routes. However, the OHP outlines special management strategies that are available.[137]

The 2003 Oregon Legislature adopted changes to Oregon Revised Statutes (ORS) 366.215. In order to protect the routes that are necessary for the movement of freight, it limited the situations in which the state could reduce the carrying capacity (defined as the horizontal or vertical clearance) on these routes. Oregon Administrative Rule (OAR) 731-012-0010 implements ORS 366.215 and details the review of potential reductions of vertical and horizontal clearance and the process for stakeholder involvement. The Reduction Review Routes where the Department will apply the rule are depicted in Figure 10c of the OHP.

Critical Urban Freight Corridors

CUFCs must be a public road in an urbanized area (more than 50,000 population) that either:

- Connects an intermodal facility to the PHFS, the Interstate System, or an intermodal freight facility;
- Is located within a corridor on the PHFS and provide an alternative highway option important to goods movement;
- Serves a major freight generator, logistic center or manufacturing and warehouse industrial land; or
- Is important to freight movement within the region as determined by the MPO or the state.

The FHWA encourages the consideration of first or last mile connector routes from high-volume freight corridors to freight-intensive land and key freight facilities, including ports, rail terminals and other industrially zoned land.

136 1999 OHP (including amendments November 1999 through May 2015), Figure 10

137 1999 OHP, p. 61

Based upon federal legislation, USDOT allotted 77 miles to Oregon for CUFCs. As a result of the limited mileage, USDOT encourages states to focus strategically on segments in which improvement projects in need of federal funding are anticipated in the near term.

The recommended designations are listed in Appendix H.

Critical Rural Freight Corridors

Based upon federal legislation, USDOT has allocated 155 miles to Oregon for CRFCs. CRFCs must be a public road that is not within an urbanized area and meets one or more of the following criteria:

- Is a rural principal arterial roadway with a minimum of 25% of the annual average daily traffic of the road measured in passenger vehicle equivalent units from trucks
- Provides access to energy exploration, development, installation, or production areas
- Connects the PHFS or the Interstate System to facilities that handle more than:
  - 50,000 20-foot equivalent units per year; or
  - 500,000 tons per year of bulk commodities;
- Provides access to a grain elevator, an agricultural facility, a mining facility, a forestry facility, or an intermodal facility
- Connects to an international port of entry
- Provides access to significant air, rail, water, or other freight facilities
- Is a corridor that is vital to improving the efficient movement of freight that is important to the state's economy

ODOT developed the list of potential segments based on the inventories of need that are further described in the next section of this chapter. Locations outside of urbanized areas and not already on the NHFN were considered from the following inventories:

1. Freight Highway Delay Areas
2. Freight Intermodal Connectors – Tier 1
3. Highway Over-dimension Load Pinch Points – High Priority
4. Regional Highway System Needs
5. Seismic Bridges – Phase 1 & 2 Unfunded
6. Seismic Landslides – Phase 1 Tier 1 Selection

ODOT then considered state designations. Segments that are on the following routes were prioritized as follows:

1. OFP Strategic Freight System
2. OHP Freight Routes
3. Seismic Phase 1 & 2 Routes
4. ORS 366.215 Reduction Review Routes

The CRFC designations are listed in Appendix H.

9.5 FREIGHT MOBILITY ISSUES

The OFP identifies "significant freight system trends, needs and issues with respect to the State" as required by the FAST Act. The OFP and the OTP contain numerous strategies and actions to address those needs. In 2011, the OFP incorporated a strategic implementation initiative 2.3, which directs the state to "identify and rank freight bottlenecks…in particular those located on the strategic system. Update the ranked list periodically."[138] The FAST Act also calls for an "inventory of facilities with freight mobility issues, such as bottlenecks, within the State, and for those facilities that are State owned or operated, a description of the strategies the State is employing to address those freight mobility issues."

This section describes the inventories of facilities with freight mobility issues, particularly bottlenecks, and generally outlines the strategies in the OFP and OTP that address the needs identified in those inventories.

Freight Needs

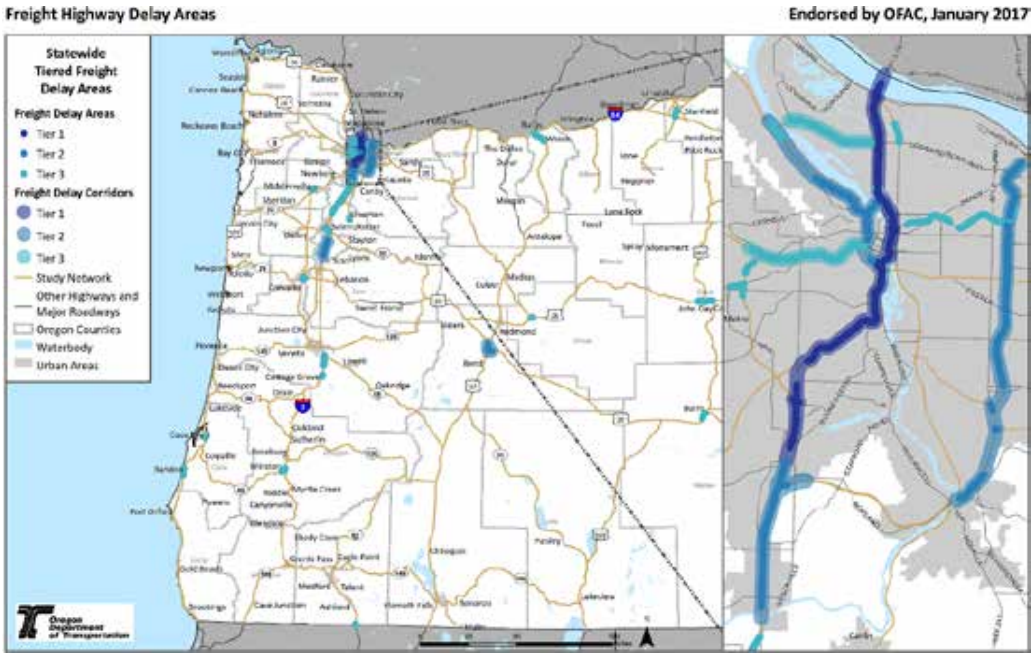
Highway Freight Needs

Freight Highway Delay Areas: Studies of existing freight highway conditions in Oregon identified that congestion from bottlenecks is a major issue, impacting Oregon's economy with variations in travel time reliability and rising travel costs. The 2017 Freight Highway Bottlenecks Project (FHBP) was initiated to identify locations on Oregon's highway network that were experiencing significant freight truck delay, unreliability and increased transportation costs. The FHBP looked at a variety of key measureable indicators to identify locations on the state freight highway network, specifically those routes identified as ORS 366.215 restriction review routes. The project identified areas that imposed higher than usual transportation costs on the freight user. The FHBP identified

[138] ODOT, 2011 Oregon Freight Plan

where impacts are felt but does not diagnose the cause of the freight delay area or prescribe the solution.

Indicators were primarily elements such as:



- Delay – The annual hours of delay that trucks accumulate on each segment.
- Unreliability – The unreliability of shipment travel times.
- Geometric Issues – Percent grade, degree curvature or shoulders.
- Volume – Volume-to-capacity ratio and percentage of travel in congested conditions.
- Incident-Related – Frequency, and clearance times, of various collision types.
- Cost – Transportation delay costs, inventory delay costs, and unreliability costs.

This project was supported by a significant stakeholder process, which included the Project Management Team (PMT), the Technical Advisory Committee (TAC) and OFAC, as well as ODOT regional managers and staff.

There were clear series of delay areas, particularly in the Portland metro area, that should be considered as corridors rather than individual delay areas. This reflects the cumulative impact that longer segments have on freight movements. It also acknowledges the need to consider the entire corridor when developing solutions.

Tiers were established to identify the severity of the problem. The total transportation costs, along with the freight designation on the corridor or segment, were key factors used to determine the tiers for the delay areas and corridors. The final tiered freight highway delay area map is presented in Figure 9.2. These tiers, together with costs, available funding, feasibility and other factors, can help inform decision-makers when considering project investments.

Figure 9.2 Freight Highway Delay Areas

Intermodal Connectors: The 2017 Oregon Freight Intermodal Connector System (OFICS) study was developed by ODOT to help implement strategies in the OFP related to identification of connectors that provide "last mile" connectivity to freight locations that are not currently classified as NHS connectors.[139] NHS connectors are the public roads leading to major intermodal terminals. Although they account for less than 1% of NHS mileage, NHS connectors are key conduits for the timely and reliable delivery of goods. [140]

NHS intermodal connectors that primarily service freight terminals are designated as NHS freight intermodal connectors. Marine terminals, truck-rail facilities, pipeline terminals, and airports are the primary types of intermodal freight facilities operating in Oregon. The OFICS study identified additional freight intermodal connectors in the state besides the existing designated NHS freight intermodal connectors.

Intermodal connectors are important because they are critical components of the state and national intermodal freight system that enable more efficient use of all

139 OFP Strategy 3.2.

140 Intermodal connectors are roads that provide access between major intermodal facilities and the other four subsystems making up the National Highway System. https://www.fhwa.dot.gov/planning/national_highway_system/intermodal_connectors/

freight modes. These intermodal connectors serve as the first and last mile for many of the state's manufacturing and industrial businesses. In order for Oregon to remain competitive, the connectors must be able to efficiently move raw materials, partially assembled products and finished goods to and from all areas of the state for national and international markets.

In order to identify intermodal connectors beyond the existing NHS Intermodal Connectors, it was necessary to locate intermodal terminals/businesses (ITB) first. Freight intermodal terminals are defined as facilities, which provide for the transfer of freight from one mode to another. The study identified approximately 200 ITBs. A majority of these are in Portland, the Willamette Valley and along the Columbia River. After the ITB were identified, the new intermodal connectors were located by identifying the public street segments that connect to the closest state highway. The full list of intermodal connectors, including those currently designated as NHS freight intermodal connectors, is in Appendix I.

The intermodal connectors were tiered. Tier 1 connectors are considered primary intermodal connectors and meet all of the NHS intermodal connector criteria for volume of traffic and need. Tier 2 roads are secondary intermodal connectors, which generally serve an important state need. They must be a public road that serves as a primary access between an intermodal terminal and a state highway or NHS connector and carry a certain amount of truck traffic or serves significant intermodal terminal or air cargo business. The Tier 3 minor intermodal connectors serve more of a regional need. They serve fewer than 50 trucks a day in each direction and typically serve only one smaller ITB.

Over-Dimensional Load Pinch Points: The 2016 Highway Over-dimensional Load Pinch Points (HOLPP) study was developed by ODOT to help implement strategies in the OFP pertaining to the efficient movement of over-dimensional (OD) loads. The study identified highway pinch points that restrict the movement of OD loads. OD load pinch points are due to height, width, weight or length constraints, and can include low overpasses, narrow roadways or intersections, sharp curves, weight-restricted bridges, bridges with low overhead clearance, sign bridges, tunnels and other features.

The study prioritized pinch points based on the degree to which resolving a pinch point would open up an entire corridor for OD loads. The study identified 381 pinch points statewide, with 92 of them classified as high-priority pinch points and 289 low-priority pinch points.

Seismic: ODOT undertook an analysis of the seismic resiliency of the Oregon Highway System to address OFP strategies that called for creation of a statewide emergency management plan that identifies critical vulnerable points from a freight mobility perspective. That analysis identified key lifeline routes and established a strategic program to prioritize and systematically retrofit all seismically vulnerable bridges and address unstable slopes on key lifeline routes.

This would allow for rescue and recovery following a major earthquake. Seismic resiliency is critical to freight mobility.[141]

The top-priority bridge and landslide locations identified through this effort are listed in Appendix I. These include the Phase 1 and 2 bridges and the High-Priority Phase 1 and 2 landslides. More information is contained in the 2014 Seismic Plus Report.

Regional Needs to Address Freight Impacts: The FAST Act also requires states to identify areas where freight may be creating performance issues for other users, such as mobility, reliability, and safety. ODOT regions helped prepare a list of these freight issues based upon past planning actions and operational knowledge. Projects include climbing and through lanes, pavement condition, intersection widening, additional or longer turning lanes, truck parking, shoulder improvements, grade separation and signage.

The full list of regional highway system needs identified by ODOT region staff related to freight impacts is contained in Appendix I.

Non-Highway Freight Needs

Chapter 4 provides an overview of the multimodal freight transportation network and systems that support industries that depend on efficient freight movement. This section provides an inventory of the non-highway facilities and components of the multimodal freight system that have demonstrated freight mobility issues. Specifically, this section includes needs inventories for facilities associated with the rail and marine systems[142] that contribute to the state's multimodal freight transportation network.

Rail: The 2014 Oregon State Rail Plan (SRP) contains a description of the key needs and opportunities for freight rail, including the physical needs of the freight rail system relating to capacity constraints and bottlenecks. ODOT's Rail and Public Transit Division and Freight Planning Program used information from the needs assessment conducted for the SRP and identified facilities with current freight mobility issues. The improvements to address capacity constraints and bottlenecks on the mainline rail network include siding and track upgrades, signal system upgrades, and speed increases. For the Class III railroads (short lines) in Oregon, needs include track upgrades to serve increased train weight and speed, infrastructure improvements such as bridge upgrades, and consideration of the carload volume and vulnerability of short-line railroads to

[141] ODOT, Oregon Highways Seismic Report, October 2014.

[142] Aviation needs are currently being updated as part of the Aviation Plan and were not available at time of publication. Access to airports was addressed as part of the OFICS study.

abandonment. Generally, freight rail system preservation priorities include maintenance of rail functionality to current operating standards, preservation or improvements of critical bridge, tunnel or other structures, maintenance of rail lines serving key intermodal terminals and that provide significant economic value, and protection of critical rail infrastructure from seismic vulnerability. The prioritized list of rail facilities with freight mobility issues in Oregon is contained in Appendix J.

Marine: Marine system components of the freight transportation network include marine highways, marine ports, and intermodal terminals. System preservation priorities include maintenance and improvement of marine highway channel depth, preservation of docks and piers to support cargo activity or deep draft shipping, maintenance of intermodal connections to port facilities (e.g., rail or highway), preservation of equipment, and improvements that address seismic resilience. Enhancement priorities beyond system preservation include improvements to deep water ports, intermodal connections, port operations, port accessibility, and port safety. ODOT Freight Planning Program staff coordinated with the Oregon Public Ports Association, the Oregon Business Development Department, and marine port district representatives to develop a prioritized list of marine facilities with freight mobility issues. The marine transportation system needs list is contained in Appendix J.

Strategies to Address Freight Needs

Chapter 8 lists a number of actions and strategies to address freight system needs. Strategies that are relevant to the identified mobility issues above include preserving freight facilities; reducing capacity constraints, congestion, unreliability and geometric deficiencies in all modes; and improving safety. There are specific actions and strategies targeted to improving the efficiency, reliability and safety of long-haul freight corridors and preserving capacity for over-dimensional loads. Finally, the OFP recognizes the significant funding needs for addressing freight issues, and includes strategies and actions geared toward maximizing and leveraging funding for freight, including establishing a statewide freight fund.

The OTP includes policies and strategies that will guide freight related investment. Under Goal 1, Mobility and Accessibility, Policy 1.1 calls for an integrated transportation system with modal choices and related strategies and specifically mentions individual freight modes. Goal 2, Management of the System, Policy 2.1, calls for improving transportation capacity and operational efficiency. Related strategies include incident management and reducing bottlenecks and geometric constraints. Under Goal 3, Economic Vitality, Policy 3.1 addresses creating an integrated efficient and reliable freight system. It includes developing strategies around innovative technology; addressing barriers to efficient truck movements; giving priority to projects on identified freight

routes; and supporting strategic investment in marine, air cargo and pipeline transportation.

The OHP contains policies and associated actions to consider a broad range of intelligent transportation system (ITS) solutions: improving safety, reducing conflicts between rail and highways, improving the efficient movement of freight, and managing congestion through managing access and using transportation demand management (TDM) techniques.

Prioritization is needed because limited funding prohibits the ability to address all of the freight needs at once; most inventories are tiered or prioritized in some way. However, the planning and scheduling of transportation improvements is complex and involves a variety of funding sources, scheduling issues and jurisdictional interests. Additionally, there are multiple lists of needs that represent a variety of modes, issues and prioritization processes. While investments should generally be focused on addressing higher tier or priority needs, investment in projects that address lower tier needs may be justified depending on opportunities to leverage public or private funds, readiness, benefits, costs and other factors.

9.6 FREIGHT INVESTMENT PLAN

Purpose and Requirements

The FAST Act instituted a new requirement for state freight plans to include a freight investment plan. The plan must list priority projects and describe how funds made available to carry out Section 167 of Title 23 (the National Highway Freight Program[143]) would be invested and matched over a five year period. The freight investment plan must be fiscally constrained.[144] In addition, these federal funds may be obligated for projects on the NHFN, which is described in greater detail in Section 9.4 of this chapter and consists of the PHFS, portions of the interstate system not designated as part of the PHFS, CUFCs, and CRFCs.

It is anticipated that ODOT will receive approximately $75.7 million in federal formula freight funds for federal fiscal years 2016-2020 authorized and allocated by USDOT via the FAST Act. Such funds have been authorized by Congress

[143] 23 U.S.C. 167: https://www.gpo.gov/fdsys/pkg/USCODE-2015-title23/html/USCODE-2015-title23-chap1-sec167.htm

[144] 49 U.S.C. 70202(c)(2) states "the freight investment plan component of a freight plan shall include a project, or an identified phase of a project, only if funding for completion of the project can reasonably be anticipated to be available for the project within the time period identified in the freight investment plan."

through fiscal year 2020 with an annual allocation to the states delineated for fiscal years 2016-2020.

Table 9.1 represents the state investment plan for freight funds from the FAST Act. Projects listed in the freight investment plan are expected to contribute to the efficient movement of freight on the NHFN and may address one or more of the following: development phase activities, construction and rehabilitation of facilities, property and equipment acquisition, operational improvements, ITS, environmental and community impacts of freight movement, transportation system and work zone management systems, and several additional issues listed in the NHFP.

Investment Plan

Table 9.1 FAST Act Formula Freight Funds Investment Plan (federal fiscal year 2016–2020)

Project Name	Freight Funds	Freight Funds Match	Phase	Work Type	Fed Fiscal Year	Project Total
I-205 Stafford Rd - OR99E - Planning	$2,305,500.00	$194,500.00	Planning	Modernization	2016	$2,500,000.00
I-5 Delaney Rd to Albany - Third lane	$2,766,600.00	$233,400.00	Preliminary Engineering	Modernization	2017	$3,000,000.00
I-5 Kuebler Blvd to Delaney Rd Widening	$4,607,311.20	$388,688.80	Preliminary Engineering	Modernization	2017	$4,996,000.00
	$16,630,295.00	$1,402,989.54	Right of Way	Modernization	2018	$18,033,284.54
I-5 Roberts Mtn-S Umpqua R Paving & Climbing Lane	$6,455,400.00	$544,600.00	Construction	Preservation	2018	$22,139,516.00*
I-205 corridor bottleneck project Powell Blvd to I-84	$15,500,000.00	$1,307,633.92	Construction	Operations	2019	$16,807,633.92
I-205 active traffic management project	$15,200,000.00	$1,282,324.88	Construction	Operations	2019	$16,482,324.88
Total	$70,289,386.20					

Note: Federal freight fund total shown in Table 9.1 is an estimate subject to annual federal authorization and is not a guaranteed amount for programming. Additional details on project funding are included in Oregon's Statewide Transportation Improvement Program. Remaining National Highway Freight Program funds allocated in 2020 that are not shown in Table 9.1 will go towards projects planned for fiscal years 2021 and 2022.

**Project total shown is for all project phases.*

Appendix A – Stakeholder Consultation

Freight Plan Steering Committee and Working Group members for the development of the 2011 OFP are listed below. Following that is an overview of the stakeholder process for the 2017 amendment.

A.1 Freight Plan Steering Committee

- Dave Lohman, OTC Commissioner
- Mike Burton, Director - Affiliated Tribes of NW Indians
- Scott Cantonwine, President and CEO - Cascade Warehouse
- Mike Card, President, Combined Transport
- Gary Cardwell, Divisional Vice President - Northwest Containers, Inc.
- Peter Kratz, Executive Vice President of Operations - Harry & David's
- David Kronsteiner, Port Commission President, Int'l Port of Coos Bay
- Susie Lahsene, Manager, Transportation and Land Use Policy - Port of Portland
- Robin McArthur, Director of Planning and Development, Metro
- Linda Modrell, County Commissioner - Benton County
- Mike Montero, Partner - Montero & Associates
- Brock A. Nelson, Director of Public Affairs - Union Pacific Railroad
- Mike Noonan, President - Oregon Wheat Grower's League
- John Porter, President - AAA Oregon-Idaho
- Bob Russell, President - Oregon Trucking Associations
- Tom Zelenka, Vice President, Environmental and Public Affairs - Schnitzer Steel Industries, Inc.

A.2 Freight Infrastructure and Traffic Issues Working Group

- Mike Montero, Partner - Montero & Associates
- Bob Russell, President - Oregon Trucking Associations
- Kim B. Puzey, General Manager - Port of Umatilla
- Dan Clem, Director - Oregon Department of Aviation
- Terry Finn, Director of Government Affairs - BNSF Railway
- Steve Bates, Vice President -Redmond Heavy Hauling
- Jon Oshel, County Road Program Manager - Association of Oregon Counties
- Terry Tallman, Judge – Morrow County
- Joel Halloran, Senior Transportation Manager - Fred Meyers Inc.
- Ric Young, District Manager - ODOT

A.3 Policy and Process Working Group

- Linda Modrell, County Commissioner - Benton County
- Susie Lahsene, Manager, Transportation and Land Use Policy - Port of Portland
- Steve Greenwood, Environmental and Public Policy Consultant - Oregon Solutions
- Glenn Vanselow, Executive Director - Pacific NW Waterways Association
- Dan Lovelady, Manager - City of Prineville Railroad
- Robin McArthur, Director of Planning and Development - Metro
- Richard W. Schmid, Transportation Program Director - Mid-Willamette Valley Council of Governments (COG)
- Rob Hallyburton, Planning Services Division Manager – DLCD
- Nick Fortey, Traffic Safety Engineer - FHWA Oregon Division
- Erik Havig, Region 2 Planning Manager - ODOT

A.4 Freight and the Economy Working Group

- Mike Burton, Director - Affiliated Tribes of NW Indians
- Martin Callery, Director of Communications & Freight Mobility - International Port of Coos Bay
- Gary Cardwell, Divisional Vice President - Northwest Containers, Inc.
- Tammy Dennee, Executive Director - Oregon Wheat Growers League
- Monte Grove, Region 5 Manager - ODOT
- Dave Harlan, Ports Program Manager – Business Oregon
- Shirley Kalkhoven, Mayor - City of Nehalem
- Peter Kratz, Executive VP Operations - Harry & David’s
- Carrie Novick, Airport Manager - Redmond Municipal Airport
- Jonathan Schlueter, Executive Director - Westside Economic Alliance
- Brad Winters, Commissioner - South Central Oregon ACT

The Oregon Freight Advisory Committee served as the primary advisory committee during the development of the 2017 OFP amendment. A number of stakeholder and advisory groups were consulted as part of the 2017 amendment. The following is a description of those groups and processes.

A.5 Oregon Freight Advisory Committee (2017)

- David Anzur - Anzur Logistics, LLC
- Wayne Bauer – WH Pacific and Westside Economic Alliance
- Jonathon Berndt - Expeditors Portland
- Gary Cardwell - Northwest Container Services
- Martin Callery - Citizen at large
- Timothy Collins - Metro
- Kevin Downing - Oregon Department of Environmental Quality
- Scott Drumm - Port of Portland
- Michael Eliason - Association of Oregon Counties
- Terry Fasel - Oregon Department of Agriculture
- Kristal Fiser - United Parcel Service
- Nick Fortey - Federal Highway Administration
- Greg Gilmer - NORPAC
- Jerry Grossnickle - Bernert Barge Lines, Inc.
- Dave Harlan - Oregon Business Development Department
- Brodie Harvey - Knife River Corporation
- Salvador Hernandez - Oregon State University
- Robert Hillier - City of Portland Bureau of Transportation
- Jana Jarvis - Oregon Trucking Associations
- Susie Lahsene - Port of Portland
- Mark Landauer - Oregon Public Ports Association
- Michael Montero - Montero & Associations, LLC
- Scott Parkinson - ARG Transportation Services
- Deena Platman - DKS Associates
- Mike Quilty - Rogue Valley Metropolitan Planning Organization
- Jeff Stone - Oregon Association of Nurseries
- Mitch Swecker - Oregon Department of Aviation
- Colleen Weatherford - Burlington Northern Santa Fe Railway
- Lonny Welter - Columbia County Road Department

A.6 Critical Rural Freight Corridor (CRFC) Working Group

ODOT established the Working Group to provide review and advice on the Critical Rural Freight Corridor (CRFC) designation process. The group met twice in spring 2017 to review the federal requirements, proposed criteria and evaluation. It endorsed the recommended list of CRFCs at its final meeting. The group included the following members:

- Martin Callery - Oregon Freight Advisory Committee (OFAC)
- Mike Eliason - Association of Oregon Counties

- Tom Fellows - Umatilla County
- Thomas Gennarelli - Roseburg Forest Products
- Kevin Haugh - Portland & Western (Genessee & Wyoming)
- Gary Neal - Port of Morrow
- Bob Russell - Oregon Trucking Association
- Diane Schyler - Lowes
- Mitch Swecker - Oregon Department of Aviation
- Pia Welch - FedEx

A.7 Consultation with MPOs regarding Critical Urban Freight Corridors (CUFCs)

ODOT provided information about the FAST Act requirements for designation of CUFCs to the metropolitan planning organizations (MPOs) at a meeting and distributed fact sheets in the fall of 2016. ODOT consulted with Metro several times as Metro developed its recommendation.[1] ODOT hosted a meeting in winter 2017 of all of the MPOs, at which it reviewed the FAST Act requirements, obtained input on potential criteria for designation and discussed MPO proposed route designations. Based on feedback from the MPOs, ODOT assigned mileage targets to each MPO based primarily on OHP Freight Route miles. It then worked individually with the various MPOs to finalize their recommendations.

A.8 Freight Highway Bottleneck Project Technical Advisory Committee (TAC)

This group met three times to provide input and guidance to the Freight Highway Bottleneck Project. It provided input on the approach and results, and endorsed the tiered bottleneck list at its final meeting. Membership was as follows:

- Emily Ackland - Association of Oregon Counties
- Steve Akre - OIA Global Logistics
- Steve Bates - V. Van Dyke Incorporated
- Shelly Boshart Davis - Boshart Trucking
- Martin Callery – OFAC
- Scott Drumm - Port of Portland
- Charlie Every - Every Trucking
- Jeremy Foreman – Walmart
- Nick Fortey - FHWA

[1] Under the FAST Act, MPOs in urban areas with populations of 500,000 or more may designate CUFCs, in consultation with the state.

- Chuck Ireland - Ireland Trucking
- Don McGinn -McGinn Brothers Trucking
- Amy Ramsdell - ODOT Motor Carrier Division
- Bud Reiff – Metro
- Bob Russell - Oregon Trucking Association
- Diane Schyler - Lowes

A.9 Oregon Freight Intermodal Connector System Technical Advisory Committee (OFICS TAC)

The OFICS TAC met throughout the course of the OFICS study to provide advice and guidance on methodology, review results and make recommendations. The group included the following members:

- Shelly Boshart Davis - Boshart Trucking
- Martin Callery - OFAC
- Kelly Clarke - Central Lane MPO
- Mike Eliason - Union Pacific Railroad
- Jeremy Foreman - Walmart
- Nick Fortey - FHWA
- Phil Healy - Port of Portland
- Bob Hillier - City of Portland
- Jim Irvin - Portland & Western Railroad Inc
- Karl MacNair - City of Medford
- Gary Neal - Port of Morrow
- Bob Russell - Oregon Trucking Association
- Matt Wiederholt - City of Prineville Railway

A.10 Highway Over-dimension Load Pinch Points (HOLPP) Study

The primary source of data for the HOLPP study came from ODOT maintenance district staff as they coordinate the daily routing of over-dimension (OD) loads with the Motor Carrier Transportation Division.

A.11 Marine Needs Inventory

ODOT consulted with the Oregon Business Development Department and Oregon Public Ports Association (OPPA) to develop the list of marine needs. In January 2017, a questionnaire was distributed through the OPPA that provided an opportunity for port districts and other marine transportation stakeholders to submit information about specific facilities with freight mobility

issues or that are forecast to have issues or constraints in the near future. Responses included information drawn from port district Strategic Business Plans and Capital Facilities Plans. The questionnaire responses, combined with the expertise of agency staff, led to the development of the marine transportation needs list, which was shared with the OFAC in June 2017.

A.12 Rail Needs Inventory

ODOT staff received input from the Oregon Rail Advisory Committee and subsequently presented the list to OFAC. OFAC members provided feedback to help refine the description of needs for both the marine and rail transportation systems and it is expected that comments received during the public review period may also be incorporated into the needs lists, as appropriate.

Appendix B – ACTs and MPOs

B.1 ACTs

Area Commissions on Transportation (ACT) are advisory bodies chartered by the Oregon Transportation Commission. ACTs address all aspects of transportation (surface, marine, air, and transportation safety) with primary focus on the state transportation system.

B.1.1 Oregon ACTs

- Northwest Oregon ACT
- Mid-Willamette Valley ACT
- Lane ACT
- Cascades West ACT
- South West ACT
- Rogue Valley ACT
- Lower John Day ACT
- Central Oregon ACT
- South Central Oregon ACT
- North East ACT
- South East ACT

The Portland metropolitan region elected not to establish an ACT for the urban portion of Multnomah, Washington and Clackamas counties that is governed by Metro. Outside Metro's boundaries, ODOT works with various county coordinating committees to coordinate transportation project planning and construction.

B.2 MPOs

Metropolitan Planning Organizations are responsible for planning, programming and coordination of federal highway and transit investments in urbanized areas.

The six Oregon MPOs are:

- Portland Metropolitan Planning Organization
- Salem/Keizer Metropolitan Planning Organization
- Eugene/Springfield Metropolitan Planning Organization
- Rogue Valley Metropolitan Planning Organization
- Corvallis Area Metropolitan Planning Organization
- Bend Area Metropolitan Planning Organization

Appendix C – Consistency Analysis

C.1 OFP Consistency with the OTP and Statewide Mode and Topic Plans

The Oregon Freight Plan (OFP) is a multimodal topic plan called for in the 2006 Oregon Transportation Plan (OTP). The OTP requires mode and topic plans to show consistency with the OTP, which along with mode and topic plans comprises the state transportation system plan (see Figure 1.3). The discussion below shows how the OFP is consistent with the OTP and the following statewide mode and topic plans: 1999 Oregon Highway Plan, 2001 Oregon Rail Plan, 2004 Oregon Transportation Safety Action Plan, 2007 Oregon Aviation Plan, and 2010 Oregon Statewide Port Strategic Plan.

C.2 Oregon Transportation Plan

The 2006 Oregon Transportation Plan identifies seven goals:

- Mobility and Accessibility,
- Management of the System,
- Economic Vitality,
- Sustainability,
- Safety and Security,
- Funding the Transportation System, and
- Coordination, Communication, and Cooperation.

The OTP develops policies and strategies to further define each goal. A number of these policies and strategies address freight or goods movement. The OFP builds on this discussion by identifying strategies and actions that further define policies and strategies in the OTP. Together, the OFP strategies and actions address all seven OTP goals and many of its policies and strategies. Table C-1 provides a crosswalk between OFP strategies and selected OTP policies and strategies. For several OFP strategies, more than one OTP policy or strategy applies. Similarly, several OTP policies or strategies apply to multiple OFP strategies. The table establishes consistency between strategies in the OFP and selected strategies and policies in the OTP.

Table 9-2 OFP Strategies and Selected OTP Policies and Strategies

Oregon Transportation Plan (OTP)	Oregon Freight Plan (OFP)
Policy 1.1 – Development of an Integrated Multimodal System	Strategy 3.2 Strategy 3.3 Strategy 4.1 Strategy 13.1
Policy 1.2 – Equity, Efficiency and Travel Choices	No freight Plan Strategy. The State will apply the applicable OTP strategies.
Policy 1.3 – Relationship of Interurban and Urban Mobility	No freight Plan Strategy. The State will apply the applicable OTP strategies.
Policy 2.1 – Capacity and Operational Efficiency	Strategy 2.4 Strategy 2.5 Strategy 6.1 Strategy 6.2 Strategy 11.1 Strategy 11.2 Strategy 11.3
Policy 2.2 – Management of Assets	Strategy 5.3 Strategy 10.1
Policy 3.1 – An Integrated and Efficient Freight System	Strategy 1.1 Strategy 1.2 Strategy 2.1 Strategy 2.2 Strategy 2.3 Strategy 2.6 Strategy 3.1 Strategy 5.1 Strategy 5.2 Strategy 5.3 Strategy 6.1 Strategy 7.1 Strategy 7.2 Strategy 11.1 Strategy 11.2 Strategy 11.3
Policy 3.2 – Moving People to Support Economic Vitality	No freight Plan Strategy. The State will apply the applicable OTP strategies.

Oregon Transportation Plan (OTP)	Oregon Freight Plan (OFP)
Policy 3.3 – Downtowns and Economic Development	No freight Plan Strategy. The State will apply the applicable OTP strategies.
Policy 3.4 – Development of the Transportation Industry	Strategy 8.1 Strategy 8.2
Policy 4.1 – Environmentally Responsible Transportation System	Strategy 8.1 Strategy 8.2 Strategy 9.1
Policy 4.2 – Energy Supply	No freight Plan Strategy. The State will apply the applicable OTP strategies.
Policy 4.3 – Creating Communities	No freight Plan Strategy. The State will apply the applicable OTP strategies.
Policy 5.1 – Safety	Strategy 6.1 Strategy 6.2 Strategy 6.3 Strategy 10.1

Oregon Transportation Plan (OTP)	Oregon Freight Plan (OFP)
Policy 5.2 – Security	Strategy 10.1 Strategy 11.1 Strategy 11.2 Strategy 11.3
Policy 6.1 – Funding Structure	Strategy 12.1 Strategy 12.2 Strategy 12.3
Policy 6.2 – Achievement of State and Local Goals	Strategy 1.1 Strategy 1.2 Strategy 2.1 Strategy 2.2 Strategy 2.3 Strategy 12.1 Strategy 12.2 Strategy 12.3 Strategy 13.2 Strategy 13.3
Policy 6.3 – Public Acceptability and Understanding	Strategy 15.1
Policy 6.4 – Beneficiary Responsibilities	Strategy 12.3
Policy 6.5 – Triage in the Event of Insufficient Revenue	Strategy 13.2 Strategy 13.3
Policy 7.1 – A Coordinated Transportation System	Strategy 14.1 Strategy 14.2
Policy 7.2 – Public/Private Partnerships	Strategy 13.2 Strategy 13.3
Policy 7.3 – Public Involvement and Consultation	Strategy 15.1
Policy 7.4 – Environmental Justice	No freight Plan Strategy. The State will apply the applicable OTP strategies.

C.3 Oregon Highway Plan

The 1999 Oregon Highway Plan (OHP) and subsequent amendments to the plan reference five goals and a number of policies and actions for each goal. The goals are System Definition, System Management, Access Management, Travel Alternatives, and Scenic and Environmental Resources. The OFP identifies Strategies and Actions that further define policies and actions for four of the five OHP goals. Specifically, Strategies within OFP address the OHP goals as follows: System Definition (OFP Strategies 1.1, 1.2, 2.2, 6.1, 6.2, 6.3, 11.1, 12.1), System Management (OFP Strategies 2.5, 4.1, 13.2, 13.3, and 15.1), Travel Alternatives (OFP Strategies 2.1, 2.2, 2.3, 3.1, 3.2, 5.1, 5.2, 5.3 12.1, 12.2 and 12.3), and Scenic and Environmental Resources (OFP Strategies 8.1, 8.2 and 9.1).

C.4 Oregon Rail Plan

The 2001 Oregon Rail Plan (ORP) references four policies and several actions for each policy. The policies are as follows:

- Policy 1: Increase economic opportunities for the State by having a viable rail system,
- Policy 2: Strengthen the retention of local rail service where feasible,
- Policy 3: Protect abandoned rights-of-way for alternative or future use; and
- Policy 4: Integrate rail freight considerations into the States land use planning process.

The OFP identifies strategies that further define actions for all ORP policies.

C.5 Oregon Transportation Safety Action Plan

The 2004 Oregon Transportation Safety Action Plan (OTSAP) reinforces OTP safety goals, policies, and actions through 69 actions. Two actions address truck safety; five actions address rail safety, and one action addresses navigational conflicts. The OFP discusses safety in various issues, strategies and actions of the Chapter 8 “Freight Issues and Strategies” including:

Freight Issue #4: Improvements to the efficiency, reliability and safety of long-haul freight corridors require collaboration between Oregon and neighboring states.

Freight Issue #6: Freight needs to be able to move throughout the state in a manner that is as safe as possible. Its movement may impact safety in Oregon communities and risk to the environment.

Freight Issue #10: New and emerging safety, security, and environmental regulations, though beneficial, can be confusing to shippers and carriers and be expensive to implement.

The strategy and action for Issue #4 primarily focuses on coordinating freight initiatives, multistate coalitions, and freight groups in neighboring states. Strategies and actions in Issue #6 concern the safe movement of goods and future actions to monitor and enhance freight safety considerations throughout Oregon’s planning efforts. The strategy for Issue #10 focuses on understanding the costs, unintended consequences, and requirements of new safety, security, and

environmental regulations. These strategies and actions are peripherally related to freight-related actions in the OTSAP.

C.6 Oregon Aviation Plan

The 2007 Oregon Aviation Plan (OAP) identifies 15 policies intended to guide state-level aviation related actions and to provide assistance to local airport sponsors, Oregon Department of Aviation staff, and the State Aviation Board with future decisions regarding the state's aviation system. Various actions are identified for each OAP policy. The OFP identifies 9 strategies that correspond to 6 of the OAP's 15 policies. OAP policies and corresponding actions further defined by OFP strategies include Preservation (OFP Strategy 13.1), Protection (OFP Strategy 7.1), Safety (OFP Strategies 6.1, 6.2, 11.1, 11.3), Intermodal Accessibility (OFP Strategies 1.1,1.2), Funding (OFP Strategy 12.1), and Advocacy and Technical Assistance (OFP Strategy 2.3, 15.1).

C.7 Oregon Statewide Port Strategic Plan

The purpose of the 2010 Oregon Statewide Port Strategic Plan, also known as *A New Strategic Business Plan for Oregon's Statewide Port System*, is to

> *"Define the State of Oregon's future role, interest and investment in the statewide port system based on a realistic assessment of port markets, and economic and business development opportunities. It will identify infrastructure, equipment, administrative, regulatory and governance needs of the ports, and also identify ways that Oregon's port system can best serve the interest of the State of Oregon and its residents."*

The strategic plan defines the framework for a new business relationship between the Oregon Business Development Department (OBDD) and each Oregon port. The plan recommends a number of changes to Oregon's state government institutional structure as it relates to ports, a change in how the ports and state agencies interact and coordinate, a new centralized infrastructure finance program, and a new marine transportation modal program. Regarding the later, the plan recommends the creation of a Marine Transportation Mode Program within state government. One of the responsibilities of program staff would be to prepare a Marine Transportation Modal Plan similar to modal plans noted above for freight, highway, rail, and air. The port strategic plan includes a set of goals and objectives but does not include policies, strategies, and actions similar to those noted above for mode and topic plans.

C.8 OFP Compliance with Federal and State Regulations

The Oregon Freight Plan is required to comply with various federal and state regulations. At the Federal level, requirements include those in the Safe, Accountable, Flexible Transportation Equity Act: A Legacy for Users (SAFETEA-LU) and the Code of Federal Regulations. Other freight-related requirements at the Federal level include those stipulated in the Passenger Rail Investment and Improvement Act of 2008, and Federal Aviation Administration policy and guidance for aviation system planning.

At the state level, the OFP is an element of the statewide transportation plan, and is subject to requirements that apply to the statewide planning process. This includes meeting requirements of the State Agency Coordination (SAC) agreement and with statewide land use planning goals, particularly Goal 12, and the Transportation Planning Rule (TPR).

OFP compliance with Federal and state regulations is discussed in more detail below.

C.9 Federal Planning Regulations

C.9.1 SAFETEA-LU and the Code of Federal Regulations

SAFETEA-LU, in Section 6001.135, requires states to develop statewide transportation plans. In developing these plans, states are required to conduct a transportation planning process that addresses a number of considerations, several of which are freight related as follows:

- Increase the accessibility and mobility of people and freight; and
- Enhance the integration and connectivity of the transportation system, across and between modes throughout the State, for people and freight.

Additionally, SAFETEA-LU requires that various groups are provided with a reasonable opportunity to comment on the proposed plan. Included in these groups are freight shippers and providers of freight transportation services.

The Code of Federal Regulations implements SAFETEA-LU provisions for statewide planning in Title 23, Part 450, which includes freight-related planning requirements identical to those stated above for SAFETEA-LU.

Neither SAFETEA-LU nor the Code of Federal Regulations requires the development of a statewide stand-alone freight or goods movement transportation plan. As an element of the statewide transportation plan, however, the Oregon Freight Plan is required to meet the above federal regulations.

> *FINDING: Accessibility and mobility of freight, along with integration and connectivity of the transportation system, are discussed in numerous parts of the OFP, including various strategies and actions in Chapter 8. See the OFP discussion on plan consistency for more detail. The public involvement process for the plan has provided opportunities for freight shippers and providers of freight transportation services to provide comments on the proposed OFP. The Oregon Freight Advisory Committee, comprised of shippers, transportation providers, and other freight stakeholders, is among the groups providing comments on the plan.*
>
> *The OFP is in compliance with and supportive of federal transportation planning regulations as stated in SAFETEA-LU and the Code of Federal Regulations.*

C.9.2 MAP-21 and the FAST Act

Moving Ahead for Progress in the 21st Century Act, or MAP-21,[1] was signed into law on July 6, 2012. Among other things, it contained a number of provisions related to freight and performance management. MAP-21 encouraged each state to develop a comprehensive state freight plan. The Oregon Freight Plan (OFP) was developed in parallel with MAP-21 and is consistent with much of the impetus behind the law. However, the OFP was adopted prior to the finalization of MAP-21.

Additionally, on December 4, 2015, President Barack Obama signed the Fixing America's Surface Transportation (FAST) Act into law. The FAST Act builds on MAP-21's freight requirements. At a national level, it clarified and amended the national freight network and planning requirements. It brings a greater focus on multimodal freight planning by establishing a National Multimodal Freight Policy (NMFP) and requiring the creation of a National Multimodal Freight Network (NMFN). It requires the USDOT to establish both an interim and final network.

It also established a new funding program, the National Highway Freight Program (NHFP), and provided formula funds over Federal FY 2016 to 2020 for states to invest in freight projects on the National Highway Freight Network (NHFN). The FAST Act further requires that states develop a freight plan that comprehensively covers short- and long-term freight planning activities and investments.[2] The plan must:

- Cover a five-year forecast period;
- Be fiscally constrained;
- Include a freight investment plan with a list of priority projects; and
- Describe how the state will invest and match its NHFP funds.

> *FINDING: ODOT developed Chapter 9 Federal Compliance, to meet the federal freight provisions under MAP-21 and FAST Act. Section 9.1 describes the federal requirements and the rest of the Chapter (sections 9.2-9.6) details how those requirements were met. Chapter 9 was adopted by the OTC in November 2017.*
>
> *The OFP is in compliance with and supportive of federal transportation planning regulations as stated in MAP-21 and the FAST Act.*

C.9.3 Passenger Rail Investment and Improvement Act of 2008

The PRIIA of 2008 includes a provision that states may prepare and maintain a State rail plan in accordance with provisions of the PRIIA of 2008. The purposes of such a plan would be to:

- *Set forth State policy involving freight and passenger rail transportation, including commuter rail operations, in the State.*

[1] Public Law No. 112-114.

[2] 49 U.S.C. 70202: State freight plans.

- *Establish the period covered by the State rail plan.*
- *Present priorities and strategies to enhance rail service in the State that benefits the public.*
- *Serve as the basis for Federal and State rail investments within the State.*

The State of Oregon has prepared several state rail plans, the most recent of which is the 2001 Oregon Rail Plan. In 2010 an Oregon Rail Study was conducted and an update of the Oregon Rail Plan is scheduled to begin in 2011.

> *FINDING: Various strategies and actions in the OFP are consistent with the existing rail plan policies and actions, as shown in the OFP discussion on plan consistency. As an effort separate from the Oregon Rail Plan, the OFP is not subject to provisions in the PRIIA of 2008.*

C.9.4 Federal Aviation Policy and Guidance for Aviation System Planning

The Federal Aviation Administration coordinates and partners with airport authorities on various planning activities. This includes the provision of funding for planning activities, such as the preparation of statewide aviation plans addressing the mobility of people and freight, funding needs, and a variety of other topics. In Oregon, coordination occurs primarily through the Oregon Department of Aviation. The 2007 Oregon Aviation Plan is the latest statewide aviation plan.

> *FINDING: Various strategies and actions in the OFP are consistent with the existing aviation plan policies and actions, as shown in the OFP discussion on plan consistency. The OFP is an effort separate from the Oregon Aviation Plan.*

C.10 Oregon State Planning Regulations

C.10.1 State Agency Coordination Agreement

ODOT's State Agency Coordination (SAC) Agreement requires that the Oregon Transportation Commission (OTC) adopt findings of fact when adopting long-range policy plans (OAR 731-015). Pursuant to these requirements, the following findings support OTC adoption of the Oregon Freight Plan (OFP). The SAC program describes what agencies will do to comply with Oregon's land use planning program. Specifically, it describes how an agency will meet its obligations under ORS 197.180 to carry out its programs affecting land use in compliance with the statewide planning goals and in a manner compatible with acknowledged comprehensive plans.

C.10.2 Coordination Procedures for Adopting Final Modal Systems Plans, OAR 731-015-0055

(1) Except in the case of minor amendments, the Department shall involve DLCD, metropolitan planning organizations, and interested cities, counties, state and federal agencies, special districts and other parties in the development or amendment of a modal systems plan. This involvement

may take the form of mailings, meeting, or other means that the Department determines are appropriate for the circumstances. The Department shall hold at least one public meeting on the plan prior to adoption.

FINDING: The development of the OFP used an open and ongoing public and agency involvement process which included the Department of Land Conservation and Development (DLCD), the metropolitan planning organizations (MPOs), Area Commissions on Transportation (ACTs), cities, counties, state and federal agencies, stakeholder interest groups, and interested citizens.

(2) The Department shall evaluate and write draft findings of compliance with all applicable statewide planning goals.

FINDING: The OFP discussion below on "Oregon's Statewide Planning Goals" contains draft findings of compliance.

(3) If the draft plan identifies new facilities which would affect identifiable geographic areas, the Department shall meet with the planning representatives of affected cities, counties and metropolitan planning organization to identify compatibility issues and the means of resolving them. These may include:

(a) Changing the draft plan to eliminate the conflicts;

(b) Working with the affected local governments to amend their comprehensive plans to eliminate the conflicts; or

(c) Identifying the new facilities as proposals which are contingent on the resolution of the conflicts prior to the completion of the transportation planning program for the proposed new facilities.

FINDING: The draft OFP does not identify new facilities.

(4) The Department shall present to the Transportation Commission the draft plan, findings of compatibility for new facilities affecting identifiable geographic areas, and findings of compliance with all applicable statewide planning goals.

FINDING: The draft findings were presented to the Commission for review at the December 15, 2010 OTC meeting.

(5) The Transportation Commission, when it adopts a final modal systems plan, shall adopt findings of compatibility for new facilities affecting identifiable geographic areas and findings of compliance with all applicable statewide planning goals.

FINDING: Final findings were presented at the June 15, 2011 OTC meeting for Commission consideration for adoption. The OFP does not identify any new facilities.

(6) The Department shall provide copies of the adopted final modal systems plan and findings to DLCD, the metropolitan planning organizations, and others who request to receive a copy.

FINDING: The final Oregon Freight Plan and final findings will be available on the OFP web page and will be distributed to DLCD, the metropolitan planning organizations, and others who request a copy following adoption.

C.11 Oregon's Statewide Planning Goals

The State of Oregon has established 19 statewide planning goals to guide state, local and regional land use planning. The goals express the state's policies on land use and related topics. The findings are based on the content of the Oregon Freight Plan (OFP). Included in the OFP are background information, issues, strategies, and actions. The OFP policies are expressed by the strategies and actions. The discussion for Goal 12 includes findings of compliance with the applicable provisions of the Transportation Planning Rule (TPR), OAR 660-012.

1. **Citizen Involvement** - Goal 1 calls for "the opportunity for citizens to be involved in all phases of the planning process." The purpose of Goal 1 (OAR 660-015-0000(1)) is "To provide a citizen involvement program that ensures the opportunity for citizens to be involved in all phases of the planning process."

   FINDING: The development and review of the OFP provided a variety of opportunities for citizen involvement as described in the "Plan Development" section of Chapter 1. OFP Strategy 15.1 and associated actions support Goal 1 by calling for ongoing interaction between freight industry representatives and community stakeholders in long-range planning and other community planning activities.

   > *OFP Strategy 15.1: Continue to create opportunities for positive interaction between freight industry representatives and community stakeholders, including long-range planning or other community planning activities.*

   The OFP is in compliance with and supportive of Goal 1, Citizen Involvement.

2. **Land Use Planning** - The purpose of Goal 2 (OAR 660-015-0000(2)) is "To establish a land use planning process and policy framework as a basis for all decisions and actions related to use of land and to assure an adequate factual base for such decisions and actions." Goal 2 outlines the basic procedures of Oregon's statewide planning program.

FINDING: OFP Strategy 7.1 and Action 7.1.1 address the integration of freight into the land use planning process. This includes protecting industrial (freight-dependent) land uses and freight terminals.

> *Strategy 7.2: Work with local and regional agencies and tribal governments to develop best practices for integrating freight land uses into the urban fabric in a manner that minimizes the impact on surrounding communities and the natural environment.*

The OFP is in compliance with and supportive of Goal 2, Land Use Planning.

3. **Agricultural Lands** - The purpose of Goal 3 (OAR 660-015-0000(3)) is "To preserve and maintain agricultural lands." It requires counties to inventory such lands and to "preserve and maintain" them through exclusive farm use (EFU) zoning (per ORS Chapter 215).

FINDING: The OFP does not plan for uses on EFU lands. Oregon agricultural goods move by barge, rail, ship, truck, and airplane. The OFP includes a number of strategies and actions supporting development and improvement of a multimodal transportation system for the movement of agricultural goods as well as other commodities. Strategy 1.1 below is an example of OFP policy support pertaining to a multimodal transportation system.

> *Strategy 1.1: Establish a Strategic Freight System building on the system defined by the commodity flows of Oregon's major industries. This system should include those elements of the transportation infrastructure that best support the state's key industries. This system should be multimodal, when viable, and exist in both urban and rural areas as appropriate.*

The OFP is in compliance with and supportive of Goal 3, Agricultural Lands.

4. **Forest Lands** – The purpose of Goal 4 (OAR 660-015-0000(4)) is "To conserve forest lands by maintaining the forest land base and to protect the state's forest economy by making possible economically efficient forest practices that assure the continuous growing and harvesting of forest tree species as the leading use on forest land consistent with sound management of soil, air, water, and fish and wildlife resources and to provide for recreational opportunities and agriculture."

FINDING: The OFP does not propose specific uses to be located on forest lands. Oregon forest products move primarily by barge, rail, ship, and truck. The OFP includes a number of strategies and actions supporting development and improvement of a multimodal transportation system for the movement of timber products as well as other commodities. Strategy 1.1 below is an example of OFP policy support pertaining to a multimodal transportation system.

> *Strategy 1.1: Establish a Strategic Freight System building on the system defined by the commodity flows of Oregon's major industries. This system should include those elements of the transportation infrastructure that best support the state's key industries. This system should be multimodal, when viable, and exist in both urban and rural areas as appropriate.*

The OFP is in compliance with and supportive of Goal 4, Forest Lands.

5. **Open Spaces, Scenic and Historic Areas, and Natural Resources** - The purpose of Goal 5 (OAR 660-015-0000(5)) is "To protect natural resources and conserve scenic and historic areas and open spaces." Goal 5 encompasses 12 different types of resources, including wildlife habitats, mineral resources, wetlands, and waterways.

FINDING: The OFP does not plan for specific uses that would be located on lands protected by Goal 5. In Strategy 7.1 and Action 7.1.1, the OFP recognizes the need to protect the existing supply of industrial land and preserve undeveloped land adjacent to freight facilities. Action 7.1.1 also calls for comprehensive plans to include actions to prevent the encroachment of incompatible land uses. The uses may include lands protected by Goal 5.

> *OTP Action 7.1.1: Support better integration of freight into the regional and local land use planning processes. Encourage local governments to integrate industrial land use planning into comprehensive plans and all other plans and actions relating to land use controls.*

The OFP is in compliance with and supportive of Goal 5, Open Spaces, Scenic and Historic Areas, and Natural Resources

6. **Air, Water and Land Resources Quality** - The purpose of Goal 6 (OAR 660-015-0000(6)) is "To maintain and improve the quality of the air, water and land resources of the state."

FINDING: The OFP addresses Goal 6 primarily through Strategy 8.1, 8.2, and associated actions, which deal with climate change and pollutants from freight emissions, as shown below.

> *Strategy 8.1: Research strategies to reduce pollutants and greenhouse gas emissions from freight sources that are active within Oregon. Focus on strategies that have been implemented with success in regions that have similarities to Oregon.*
>
> *Action 8.1.1: Build on work completed in the OFP to research methods for emissions reduction. These methods can include*

behavioral changes, technology improvements or methods that increase the efficiency of freight supply chains.

Action 8.1.2: Work in coordination with private sector freight stakeholders to identify the most cost-effective approaches to address climate change impacts from freight, in particular those strategies that also support and benefit shippers.

Strategy 8.2: Consider climate change impacts in freight transportation planning activities.

Action 8.2.1: Incorporate methods of considering greenhouse gas impacts in freight transportation planning and decision-making processes.

Action 8.2.2: Support congestion relief and idling reduction activities such as weigh-in-motion technology and the provision of electricity at truck stops for parked trucks.

The OFP is in compliance with and supportive of Goal 6, Air, Water and Land Resources Quality.

7. **Areas Subject to Natural Disasters and Hazards** - The purpose of Goal 7 (OAR 660- 015-0000(7)) is "To protect people and property from natural hazards." This goal deals with development in places subject to natural hazards such as floods or landslides.

FINDING: While the OFP does not specifically address natural hazards, it recognizes the need for transportation system redundancy when disruptions occur, for example, during emergencies. Natural hazards may be a cause of such disruptions. Strategies 11.1 and associated actions address the need to identify critical locations that are vulnerable from a freight mobility perspective, and the identification of alternative routes where disruptions would be most acutely experienced.

Strategy 11.1: Create a statewide emergency management plan that identifies critical vulnerable points from a freight mobility perspective and places where there is a lack of system redundancy. Create freight movement emergency plans for disruptions at these locations that include information about possible alternative routes.

Action 11.1.1: Create an emergency transportation system map that includes alternative route identification as well as transportation modal alternative information. The map should be flexible enough to be used when single transportation components

are compromised or when entire portions of the system have suffered a disruption.

Action 11.1.2: Identify and track those places where disruptions would be most acutely felt. This includes those places where there are no, or few, parallel route options, so a disruption means a lack of connectivity. This also means places that tend to be subject to natural or weather-related disruptions including mountain passes, single-lane infrastructure, rail tracks that tend to be affected by heavy rains and snows, and inland waterway passages that are heavily influenced by water levels and drought.

Action 11.1.3: Create plans that facilitate the movement of goods on alternative routes.

The OFP is in compliance with and supportive of Goal 7, Areas Subject to Natural Disasters and Hazards.

8. **Recreational Needs** - The purpose of Goal 8 (OAR 660-015-0000(8)) is "To satisfy the recreational needs of the citizens of the state and visitors and, where appropriate, to provide for the siting of necessary recreational facilities including destination resorts." This goal calls for each community to evaluate its areas and facilities for recreation and develop plans to deal with the projected demand for them.

FINDING: The OFP does not address Goal 8, Recreational Needs.

9. **Economic Development** - The purpose of Goal 9 (OAR 660-015-0000(9)) is "To provide adequate opportunities throughout the state for a variety of economic activities vital to the health, welfare, and prosperity of Oregon's citizens." This goal calls for diversification and improvement of the economy. Under this goal communities are required to inventory commercial and industrial lands, project future needs for such lands, and plan and zone enough land to meet those needs.

FINDING: The OFP includes several strategies and actions that recognize the importance of an efficient transportation system for helping Oregon businesses to more effectively compete in the world economy. This includes helping increase the public's understanding of freight's economic importance. Several of these policies and actions are as follows.

Action 1.1.1: Monitor and maintain freight systems identified in modal plans. Update modal plans to meet identified strategic needs and incorporate analysis of current economy and economic forecasts periodically.

Action 1.1.3: Develop performance measures and gather necessary data on an ongoing basis to support continued updating of identified freight routes as the Oregon's economy evolves and the state reacts to changing economic conditions.

Strategy 7.1: Work to better integrate freight into the land use planning process and to protect the existing supply of industrial (freight-dependent) land uses and freight terminals.

Strategy 15.1: Continue to create opportunities for positive interaction between freight industry representatives and community stakeholders, including long-range planning or other community planning activities.

The OFP is in compliance with and supportive of Goal 9, Economic Development.

10. **Housing** - The purpose of Goal 10 (OAR 660-015-0000(10)) is "To provide for the housing needs of citizens of the state." This goal specifies that each city inventory its buildable residential lands, project future needs for such lands, and plan and zone enough buildable land to meet those needs.

FINDING: The OFP does not address Goal 10, Housing.

11. **Public Facilities and Services** - Goal 11 calls for efficient planning of public services such as sewer, water, law enforcement and fire protection. The stated purpose of Goal 11 (OAR 660- 015-0000(11)) is "To plan and develop a timely, orderly and efficient arrangement of public facilities and services to serve as a framework for urban and rural development."

FINDING: The OFP does not include project proposals for public facilities and services as addressed in Goal 11. The OTP does, however, include a strategy for better integrating freight into the land use planning process. This could include integration with planning for public facilities and services.

Strategy 7.1: Support better integration of freight into the regional and local land use planning process. Encourage local governments to integrate industrial land use planning into comprehensive plans and all other plans and actions relating to land use controls.

The OFP is in compliance with and supportive of Goal 9, Economic Development.

12. **Transportation** - The purpose of Goal 12 (OAR 660-015-0000(12)) is "To provide a safe, convenient and economic transportation system."

FINDING: The OFP addresses the provision of a safe, convenient, and economic freight transportation system through a number of OFP strategies and actions. The OFP does not include project proposals for specific transportation improvements.

> *Administrative Rule 660-012, also known as the Transportation Planning Rule (TPR), implements Goal 12, Transportation. Much of the TPR applies to regional and local transportation planning, planning for transportation facilities, or planning for people movements. One of the purposes of the TPR is specifically freight related:*
>
> *(1)(d): Facilitate the safe, efficient and economic flow of freight and other goods and services within regions and throughout the state through a variety of modes including road, air, rail and marine transportation.*

The following discussion shows how the OFP addresses applicable sections of the TPR.

> *Section 660-012-0015 calls for the preparation and coordination of Transportation System Plans. This includes the preparation and coordination of a state Transportation System Plan (TSP). The OTP and statewide mode and topic plans comprise the statewide TSP. The Oregon Freight Plan is a multimodal topic plan that is an element of the state TSP.*
>
> *Section 660-012-0030 calls for determining transportation needs, including needs for movement of goods and services to support industrial and commercial development. Chapter 6 of the OFP addresses freight-related funding needs as developed for the 2006 OTP. The OFP also addresses needs in terms of freight demand, as discussed in Chapter 2.*

The OFP is in compliance with and supportive of Goal 12, Transportation, including applicable sections of the Transportation Planning Rule.

13. **Energy Conservation** - Goal 13 declares that "land and uses developed on the land shall be managed and controlled so as to maximize the conservation of all forms of energy, based upon sound economic principles." The purpose of Goal 13 (OAR 660-015- 0000(13)) is "To conserve energy."

FINDING: The OFP does not specifically address Goal 13. The OFP does, however, discuss reducing freight-related greenhouse gas (GHG) emissions and adverse climate change impacts, which may result in reduced energy consumption

for goods movement. The following OFP strategies and actions address GHG emissions and climate change impacts.

> *Strategy 8.1: Research strategies to reduce pollutants and greenhouse gas emissions from freight sources that are active within Oregon. Focus on strategies that have been implemented with success in regions that have similarities to Oregon.*
>
> *Action 8.1.1: Build on work completed in the OFP to research methods for emissions reduction. These methods can include behavioral changes, technology improvements or methods that increase the efficiency of freight supply chains.*
>
> *Action 8.1.2: Work in coordination with private sector freight stakeholders to identify the most cost-effective approaches to address climate change impacts from freight, in particular those strategies that also support and benefit shippers.*
>
> *Strategy 8.2: Consider climate change impacts in freight transportation planning activities.*
>
> *Action 8.2.1: Incorporate methods of considering greenhouse gas impacts in freight transportation planning and decision-making processes.*
>
> *Action 8.2.2: Support congestion relief and idling reduction activities such as weigh-in-motion technology and the provision of electricity at truck stops for parked trucks.*

The OFP is in compliance with and supportive of Goal 13, Energy Conservation.

14. **Urbanization** – *The purpose of Goal 14 (*OAR 660-015-0000(14)) is "To provide for an orderly and efficient transition from rural to urban land use, to accommodate urban population and urban employment inside urban growth boundaries, to ensure efficient use of land, and to provide for livable communities."

FINDING: The OFP does not address Goal 14, Urbanization.

15. **Willamette Greenway** - Goal 15 sets forth procedures for administering the 300 miles of greenway that protects the Willamette River. The purpose of Goal 15 (OAR 660-015-0005) is "To protect, conserve, enhance and maintain the natural, scenic, historical, agricultural, economic and recreational qualities of lands along the Willamette River as the Willamette River Greenway."

FINDING: The OFP does not address Goal 15, Willamette Greenway.

16. **Estuarine Resources** - The purpose of Goal 16 (OAR 660-016-0010(1)) is "To recognize and protect the unique environmental, economic, and social values of each estuary and associated wetlands; and to protect, maintain, where appropriate develop, and where appropriate restore the long-term environmental, economic, and social values, diversity and benefits of Oregon's estuaries."

    FINDING: The OFP does not address Goal 16, Estuarine Resources.

17. **Coastal Shorelands** - The purpose of Goal 17 (OAR 660-017-0010(2)) is "To conserve, protect, where appropriate, develop and where appropriate restore the resources and benefits of all coastal shorelands, recognizing their value for protection and maintenance of water quality, fish and wildlife habitat, water-dependent uses, economic resources and recreation and aesthetics. The management of these shoreland areas shall be compatible with the characteristics of the adjacent coastal waters; and to reduce the hazard to human life and property, and the adverse effects upon water quality and fish and wildlife habitat, resulting from the use and enjoyment of Oregon's coastal shorelands."

    FINDING: The OFP does not address Goal 17, Coastal Shorelands.

18. **Beaches and Dunes** - The purpose of Goal 18 (OAR 660-015-0010(3)) is "To conserve, protect, where appropriate develop, and where appropriate restore the resources and benefits of coastal beach and dune areas; and to reduce the hazard to human life and property from natural or man induced actions associated with these areas." Goal 18 sets planning standards for development on various types of dunes. It prohibits residential development on beaches and active foredunes, but allows other types of development if they meet key criteria.

    FINDING: The OFP does not address Goal 18, Beaches and Dunes.

19. **Ocean Resources** - The purpose of Goal 19 (OAR 660-015-0000(19)) is "To conserve marine resources and ecological functions for the purpose of providing long-term ecological, economic, and social value and benefits to future generations." It deals with matters such as dumping of dredge spoils and discharging of waste products into the open sea.

    FINDING: The OFP does not address Goal 19, Ocean Resources.

C.12 Conclusion

Based on the findings in this appendix, the Oregon Freight Plan complies with the applicable statewide planning goals.

Appendix D – Public Involvement Process

D.1 Outreach Strategy Goal

The Oregon Freight Plan Outreach Strategy has four primary purposes. First, to share the draft Oregon Freight Plan (OFP) with stakeholders and citizens in order to gain their ideas, concerns and comments and incorporate, as appropriate. Second, to coordinate plan elements with federal, state and local government partners. Third, to document compliance with federal and state public involvement requirements. Fourth, to publicize plan contents and information about the value of freight operations, services and infrastructure to Oregon businesses and citizens.

D.2 Outreach Strategy Timetable

Timeline	Outreach Activity
Nov. 2010	Create stakeholder communication loops through electronic media
Nov. 2010	Prepare public meeting materials—executive summary, freight fact sheets, visual displays, and power point presentation
Nov.-Dec. 2010	Organize two public meetings in each ODOT region coordinating with Metropolitan Planning Organizations and Area Commissions on Transportation; Craft multiple avenues to receive comments
Dec. 2010	Update Freight Plan website—post draft Oregon Freight Plan (OFP) upon Oregon Transportation Commission approval; use multiple social media avenues to point people to the draft plan on the website
Dec. 2010-Feb. 2011	Communicate with stakeholders and the public through electronic media
Dec. 2010	Send hard copy of plan by mail to stakeholders that do not have reliable access to computer service
Dec. 2010 – Feb. 2011	Media news releases- Work with statewide, local and foreign language media outlets to announce availability of draft Oregon Freight Plan for comment and to advertise public meetings
Jan. – Feb. 2011	Conduct public meetings in coordination with Metropolitan Planning Organizations (MPOs), Area Commissions on Transportation (ACTs), and local officials
Jan. – May 2011	Perform interagency consultation and coordination
Feb. - April 2011	ODOT staff and consultants review and respond to public comments; Share comments and responses with Freight Plan Steering Committee; Develop recommendations to revise Freight Plan based on comments
May 2011	Submit comment summaries, responses and plan revision recommendations to the Oregon Transportation Commission
June 2011	Oregon Transportation Commission action to adopt Oregon Freight Plan
July 2011	Implement Oregon Freight Plan
Summer/Fall 2016	Prepare and distribute informational materials regarding amendment to Oregon Freight Advisory Committee (OFAC), MPOs, ACTs and other stakeholders through electronic media and briefings
Winter/Spring 2017	Hold meetings with MPOs, Working Group and OFAC to obtain input on amendment.
July 2017	Oregon Transportation Commission briefing on amendment
July-Sept. 2017	Public Comment Period on amendment, including public hearing at September Oregon Transportation

Timeline	Outreach Activity
	Commission meeting
Sept.-Oct. 2017	ODOT staff and consultants review and respond to public comments, share comments and responses with OFAC; develop recommendations to revise amendment based on comments
Nov. 2017	Oregon Transportation Commission action to adopt Oregon Freight Plan amendment

D.3 Outreach Authorities, Policies and Requirements

The Oregon Freight Plan is a topic plan under the statewide Oregon Transportation Plan that must be developed in accordance with state and federal laws, administrative rules, Oregon Transportation Commission policies and Oregon Department of Transportation (ODOT) guidance. Below is a brief description of public involvement policies and regulations followed during development of the Oregon Freight Plan.

Under ODOT policies (Oregon Transportation Plan, Public Involvement and Consultation – Policy 7.3 and Public Involvement Policy, Oregon Transportation Commission-11), the Department must develop statewide transportation plans in consultation and cooperation with affected state and federal agencies, local jurisdictions, transportation system owners, advisory committees and other stakeholders. These policies further call for holding at least two public meetings in each of ODOT's five regions, providing a minimum of 45 days for public comment, and compels the Oregon Transportation Commission to consider and respond to written comments prior to plan adoption.

The *Oregon Transportation Planning Rule (OAR 660-012)* links the Oregon Freight Plan as a component of transportation system plans that identify a network of facilities and services to meet overall transportation needs. In turn, transportation system plans must be compatible with acknowledged local comprehensive plans. Further, under the rule governing *Coordination Procedures for Adopting the Final Modal System Plan* (*OAR 731-015-055),* an evaluation and findings of compliance with applicable statewide planning goals is required. Finally, federal *Title IV* requirements to evaluate the plan's impact on and proactively seek involvement from minority, disadvantaged and low income groups as well as *SAFETEA-LU engagement requirements* must be documented. The ODOT Freight Mobility Unit relied upon guidance provided in the *Public Involvement Policy Resources Handbook for Statewide Planning and STIP Development, ODOT Planning Section, August 2009* in performing outreach activities.

D.4 Outreach Activity Framework

- Post draft Oregon Freight Plan on ODOT Freight Plan website
- Notify stakeholders of draft Oregon Freight Plan availability; publicize comment process
- Use ODOT Freight Plan website, electronic media and news releases—including foreign language media outlets—to advertise public meetings and encourage public comment
- Hold at least two meetings in each ODOT region in consultation with Metropolitan Planning Organizations, Area Commissions on Transportation and local officials

- Confirm public meeting rooms are ADA accessible; Offer interpreters at public meetings upon advance request
- Record and respond to each comment received; Review comments and responses with Freight Plan Steering Committee; Recommend plan revisions, as appropriate
- Perform internal ODOT consistency review with the Oregon Transportation Plan
- Work with DLCD to evaluate and write draft findings of compliance with Statewide Planning Goals
- Retain public meeting sign-in sheets and cards designed to document compliance with federal Title IV and SAFETEA-LU requirements
- Report compliance with state and federal regulations
- Implement Oregon Freight Plan upon final OTC adoption
- Amend and update, as necessary

Appendix E – Glossary of Freight Transportation Terms

The definitions below are intended to provide clarification on freight-specific terms used throughout the Oregon Freight Plan (OFP). Many of the definitions used here were taken from the FHWA.[1]

Barge – The cargo-carrying vehicle that inland water carriers primarily use. Basic barges have open tops, but there are covered barges for both dry and liquid cargoes.

Bottleneck – A section of a highway or rail network that experiences operational problems such as congestion. Bottlenecks may result from factors such as reduced roadway width or steep freeway grades that can slow trucks.

Bulk shipments – Cargo that is unbound as loaded; it is without count in a loose unpackaged form. Examples of bulk cargo include coal, grain, and petroleum products.

Capacity – The physical facilities, personnel and process available to meet the product of service needs of the customers. Capacity generally refers to the maximum output or producing ability of a machine, a person, a process, a factory, a product, or a service.

Cargo-oriented development (COD) – The development of manufacturing and distribution businesses in select locations that benefit from access to multiple types of freight transportation, proximity to complimentary businesses, and a large local industrial workforce.

Carrier – An organization engaged in transporting goods for hire.

Class I railroad – A large freight railroad company having annual carrier operating revenues of $250 million or more.

Class II railroad – A (regional) mid-sized freight-hauling railroad having annual carrier operating revenues between $20 million and $250 million.

Class III railroad – A (local or shortline) small-scale freight hauling railroad with an annual operating revenue of less than $20 million.

Commodity – An Item that is traded in commerce. The term usually implies an undifferentiated product competing primarily on price and availability.

Commodity flow – the movement of commodities within a region or between regions.

Container – A "box"' typically ten to forty feet long, which is used primarily for ocean freight shipment. For travel to and from ports, containers are loaded onto truck chassis' or on railroad flatcars.

[1] FHWA website: https://ops.fhwa.dot.gov/freight/fpd/glossary/index.htm#u

Critical Rural Freight Corridors (CRFCs) – These are public roads not in an urbanized area that provide access and connection to the PHFS and the interstate with other important ports, public transportation facilities, or other intermodal freight facilities.

Critical Urban Freight Corridors (CUFCs) – These are public roads in urbanized areas (more than 50,000 population), which provide access and connection to the PHFS and the interstate with other ports, public transportation facilities, or other intermodal transportation facilities.

Distribution center (DC) – The warehouse facility that holds inventory from manufacturing pending distribution to the appropriate stores.

Dock – A space used or receiving merchandise at a freight terminal.

Drayage – Transporting of rail or ocean freight by truck to an intermediate or final destination; typically a charge for pickup/delivery of goods moving short distances (e.g., from marine terminal to warehouse).

Durables – Generally, any goods whose continuous serviceability is likely to exceed three years.

Freight Highway Bottlenecks Project (FHBP) – Initiated by ODOT to identify locations on Oregon's highway network that were experiencing significant freight truck delay, unreliability and increased transportation costs.

Freight movements – The transportation of goods between particular locations.

GSP – Gross State Product, a measure of the value added to products and services by all businesses within the state

GPS – Global Positioning System, is a radio navigation system that allows land, sea, and airborne users to determine their exact location, velocity, and time 24 hours a day, in all weather conditions, anywhere in the world.

Highway Over-dimensional Load Pinch Points Study (HOLPP Study) – A study developed by ODOT to identify highway "pinch points" or facilities that restrict movement of over-dimensional (OD) loads due to height, length, width, or weight constraints.

Hub – A common connection point for devices in a network. Referenced for a transportation network as in "hub and spoke" which is common in the airline and trucking industry.

Intermodal – Transferring from mode to another or between two modes.

Intermodal connectors – The links that facilitate transfers between modes, such as local roads between a designated freight route and a port or rail reload facility.

Intermodal terminal – A location where links between different transportation modes and networks connect. Using more than one mode of transportation in moving persons and goods. For example, a shipment moved over 1,000 miles could travel by truck for one portion of the trip, and then transfer to rail at a designated terminal.

Inventory – The number of units and/or value of the stock of good a company holds.

Just-in-Time (JIT) – Cargo or components that must be at a destination at the exact time needed. The container or vehicle is the movable warehouse.

Last Mile (Connectors) – The local streets that connect a designated freight route with a freight generating or receiving facility.

Line haul – The movement of freight over the road/rail from origin terminal to destination terminal, usually over long distances.

Lock – A channel where the water rises and falls to allow boats to travel a dammed river.

Logistics – All activities involved in the management of product movement; delivering the right product from the right origin to the right destination, with the right quality and quantity, at the right schedule and price.

Multimodal trip – Employing various modes of transport within a single trip.

National Freight Strategic Plan (NFSP) – Established by the U.S. Department of Transportation under MAP-21 requirements, the intent of the NFSP is to describe the existing U.S. freight transportation system and future demands on it, identify major corridors and gateways, assess barriers to improving the system, and specify best practices for enhancing it.

National Highway Freight Network (NHFN) – Established by the U.S. Department of Transportation under MAP-21 requirements, the NHFN comprises four subsystems of roadways intended to help states strategically direct resources toward improving performance of highway portions of the U.S. freight transportation system: the PHFS, portions of the interstate system not part of the PHFS, CRFCs and CUFCs.

National Highway Freight Program (NHFP) – Established by the FAST Act, the NHFP provides $6.3 billion in formula funds over five years for states to invest in freight projects on the NHFN.

National Multimodal Freight Network (NMFN) – Building upon the NHFN created by MAP-21, the FAST Act required the creation of an interim and final NMFN to bring greater focus on multimodal freight planning for the U.S.

National Multimodal Freight Policy (NMFP) – Established by the FAST Act, the NMFP sets national goals to guide decision-making to ensure the safe, efficient and reliable movement of freight in the U.S.

North American Industry Classification System (NAICS) – standard used by Federal statistical agencies in classifying business establishments.

Node – A fixed point in a firm's logistics system where goods come to rest; includes plants, warehouses, supply sources, and markets.

Nondivisible load – A load which is unable to be divided into smaller parts- like a piece of equipment or a steel beam.

Oregon Freight Plan (OFP) – Developed in parallel with MAP-21 and adopted in 2011 as an element of the Oregon Transportation Plan, the OFP is a resource designed to guide freight-related operation, maintenance and investment decisions.

Oregon Freight Advisory Committee (OFAC) – Formalized in 2001 through the passage of House Bill 3364 (now ORS 366.212), the OFAC advises the director of the Oregon Department of Transportation and the Oregon Transportation Commission on issues, policies and programs that impact multimodal freight mobility in the state.

Oregon Freight Intermodal Connector System (OFICS) Study– Identified additional freight intermodal connectors in the state besides the existing designated National Highway System freight intermodal connectors.

On-dock rail – Direct shipside rail service. Includes the ability to load and unload containers/breakbulk directly from rail car to vessel.

Primary Highway Freight System (PHFS) –The network of highways identified as the most critical highway portions of the U.S. freight transportation system determined by measurable and objective national data. The network consists of 41,518 centerlines miles, including 37,436 centerline miles of interstate and 4,082 centerline miles of non-interstate roads.

Rail carload – Quantity of freight (in tons) required to fill a railcar; amount normally required to qualify for a carload rate.

Rail mainline – The principal artery of a railway system.

Reliability – Refers to the degree of certainty and predictability in travel times on the transportation system. Reliable transportation systems offer some assurance of attaining a given destination within a reasonable range of an expected time. An unreliable transportation system is subject to unexpected delays, increasing costs for system users.

Shipper – An entity that prepares goods for shipment, by packaging, labeling, and arranging for transit, or who coordinates the transport of goods.

Short-sea shipping – Also known as coastal or coastwise shipping, describes marine shipping operations between ports along a single coast or involving a short sea crossing.

Shunting – Sorting rail cars into complete train sets.

State Highway Freight System – Freight system designated by the Oregon Highway Plan to facilitate efficient and reliable interstate, intrastate and regional truck movement. This system comprises interstate highways and certain statewide, regional and district highways, and includes routes that carry significant tonnage of freight by truck and serve as the primary interstate and intrastate highway freight connection to ports, intermodal terminals, and urban areas.

Supply Chain – Starting with unprocessed raw materials and ending with final customer using the finished goods.

Throughput – Total amount of freight imported or exported through a seaport measured in tons or TEUs.

"Through" tonnage – The amount (by weight) of goods transported that have neither an origin nor a destination within the state or region.

Ton-mile – A measure of output for freight transportation; reflects weight of shipment and the distance it is hauled; a multiplication of tons hauled by the distance traveled.

Transit time – The total time that elapses between a shipment's delivery and pickup.

Transloading - Transferring bulk shipments from the vehicle/container of one mode to that of another at a terminal interchange point.

Truck Travel Time Reliability Index (TTTR Index) – National performance measure established by the U.S. Department of Transportation to assess freight movement on interstate highways.

Truckload (TL) – Quantity of freight required to fill a truck, or at a minimum, the amount required to qualify for a truckload rate.

Rail unit trains – A train of a specified number of railcars handling a single commodity type which remain as a unit for a designated destination or until a change in routing is made.

Vehicle Miles Traveled (VMT) – A measurement of miles traveled by vehicles within a specified region for a specified time period..

Warehouse – Storage place for commodities. Principal warehouse activities include receipt of commodity, storage, shipment and order picking.

Winglets – Blade tip devices attached to the back doors of tractor-trailers that reduce drag, and improve fuel efficiency of heavy trucks in this context.

Appendix F – Commodity to NAICS Bridge

The table below is meant to highlight the commodities[1] used in production by certain industries, the volume results of which are presented in OFP Figure 3.1.

Table 9-3. Commodity to NAICS Table

Commodity	NAICS Industry Code (Manufacturing in NAICS3, Others in NAICS2)	Percent Distribution
Farm products	Agriculture, Forestry, Fishing (11)	79.8%
	Food Manufacturing (311)	17.9%
	Beverage and Tobacco Product Manufacturing (312)	0.2%
	Textile Mills (313)	1.7%
	Chemical manufacturing (325)	0.4%
Forest Products	Agriculture, Forestry, Fishing (11)	20.8%
	Textile Mills (313)	20.8%
	Chemical manufacturing (325)	58.3%
Fresh Fish	Agriculture, Forestry, Fishing (11)	100.0%
Metallic Ores	Mining, Quarrying, and Oil and Gas Extraction (211 & 212)	79.2%
	Nonmetallic Mineral Product Manufacturing (327)	1.4%
	Primary Metal Manufacturing (331)	19.4%
Coal	Mining, Quarrying, and Oil and Gas Extraction (211 & 212)	85.7%
	Petroleum and Coal Products Manufacturing (324)	14.3%
Crude Petroleum, Natural Gas	Mining, Quarrying, and Oil and Gas Extraction (211 & 212)	8.8%
	Petroleum and Coal Products Manufacturing (324)	91.2%
Nonmetallic Ores, Minerals	Mining, Quarrying, and Oil and Gas Extraction (211 & 212)	66.7%
	Beverage and Tobacco Product Manufacturing (312)	2.0%
	Chemical manufacturing (325)	7.1%
	Nonmetallic Mineral Product Manufacturing (327)	2.0%
	Primary Metal Manufacturing (331)	1.0%
	Fabricated Metal Product Manufacturing (332)	9.1%
	Computer and Electronic Product Manufacturing (334)	5.1%
	Miscellaneous Manufacturing (339)	7.1%
Ordnance or Accessories	Fabricated Metal Product Manufacturing (332)	79.5%
	Machinery Manufacturing (333)	11.5%
	Computer and Electronic Product Manufacturing (334)	1.3%
	Transportation Equipment Manufacturing (336)	7.7%
Food and Kindred Products	Agriculture, Forestry, Fishing (11)	14.6%
	Food Manufacturing (311)	76.6%
	Beverage and Tobacco Product Manufacturing (312)	4.8%
	Textile Mills (313)	0.2%
	Chemical manufacturing (325)	3.9%
Tobacco Products	Beverage and Tobacco Product Manufacturing (312)	100.0%

[1] Commodities are classified according to the Standard Transportation Commodity Code.

Commodity	NAICS Industry Code (Manufacturing in NAICS3, Others in NAICS2)	Percent Distribution
Textile Mill Products	Agriculture, Forestry, Fishing (11)	0.5%
	Textile Mills (313)	67.5%
	Textile Product Mills (314)	17.4%
	Paper Manufacturing (322)	2.6%
	Chemical manufacturing (325)	6.3%
	Plastics and Rubber Products Manufacturing (326)	5.0%
	Machinery Manufacturing (333)	0.2%
	Furniture and Related Product Manufacturing (337)	0.5%
Apparel/Finished Textile Products	Textile Mills (313)	3.5%
	Textile Product Mills (314)	1.4%
	Apparel Manufacturing (315)	62.3%
	Leather and Allied Product Manufacturing (316)	6.3%

Appendix G – Oregon Plan Implementation Support for Federal Freight Goals

National Multimodal Freight Policy Goals 49 USC 70101	OFP strategy and action that satisfies	National Highway Freight Program Goals 23 USC 167	OFP strategy and action that satisfies
1. To identify infrastructure improvements, policies, and operational innovations that: a) Strengthen the contribution of the National Multimodal Freight Network to the economic competitiveness of the United States; b) Reduce congestion and eliminate bottlenecks on the National Multimodal Freight Network; and c) Increase productivity, particularly for domestic industries and businesses that create high-value jobs	Action 1.1.1 Action 1.1.2 Action 1.1.3 Action 1.3.2 Action 2.1.1 Action 2.2.1 Action 2.3.1 Action 2.4.1 Action 2.5.2 Action 4.1.2 Action 5.1.2 Action 8.2.2 Action 11.1.3 Action 12.3.1 Strategy 2.3	1. To invest in infrastructure improvements and to implement operational improvements on the highways of the United States that: a) Strengthen the contribution of the National Highway Freight Network to the economic competitiveness of the United States; b) Reduce congestion and bottlenecks on the National Highway Freight Network; c) Reduce the cost of freight transportation; d) Improve the year-round reliability of freight transportation; and e) Increase productivity, particularly for domestic industries and businesses that create high-value jobs	Action 1.1.1 Action 1.1.2 Action 1.1.3 Action 1.3.2 Action 2.1.1 Action 2.2.1 Action 2.3.1 Action 2.4.1 Action 2.5.2 Action 4.1.2 Action 5.1.2 Action 8.2.2 Action 11.1.3 Action 12.3.1 Strategy 2.3
2. To improve the safety, security, efficiency, and resiliency of multimodal freight transportation	Action 2.1.1 Action 5.2.1 Action 6.1.1 Action 6.1.2 Action 6.2.1 Action 11.1.1 Strategy 6.1 Strategy 11.1 Strategy 11.3	2. To improve the safety, security, efficiency, and resiliency of freight transportation in rural and urban areas	Action 2.1.1 Action 5.2.1 Action 6.1.1 Action 6.1.2 Action 6.2.1 Action 11.1.1 Strategy 6.1 Strategy 11.1 Strategy 11.3
3. To achieve and maintain a state of good repair on the National Multimodal Freight Network	Action 1.2.1 Action 2.1.1 Action 5.2.1 Action 6.1.1 Action 7.1.2 Action 12.3.1 Strategy 1.2 Strategy 5.1 Strategy 5.2	3. To improve the state of good repair of the National Highway Freight Network	Action 1.2.1 Action 2.1.1 Action 5.2.1 Action 6.1.1 Action 7.1.2 Action 12.3.1 Strategy 1.2 Strategy 5.1 Strategy 5.2
4. To use innovation and advanced technology to improve the safety, efficiency, and reliability of the National Multimodal Freight Network	Action 6.1.3 Action 8.2.2 Strategy 2.5	4. To use innovation and advanced technology to improve the safety, efficiency, and reliability of the National Highway Freight Network	Action 6.1.3 Action 8.2.2 Strategy 2.5

National Multimodal Freight Policy Goals 49 USC 70101	OFP strategy and action that satisfies	National Highway Freight Program Goals 23 USC 167	OFP strategy and action that satisfies
5. To improve the economic efficiency and productivity of the National Multimodal Freight Network	Action 1.1.1 Action 1.1.2 Action 1.1.3 Action 1.3.2 Action 2.1.1 Action 2.4.1 Action 2.5.2 Action 4.1.2 Action 5.1.1 Action 5.1.2 Action 12.3.1 Strategy 5.3	5. To improve the efficiency and productivity of the National Highway Freight Network	Action 1.1.1 Action 1.1.2 Action 1.1.3 Action 1.3.2 Action 2.1.1 Action 2.4.1 Action 2.5.2 Action 4.1.2 Action 5.1.1 Action 5.1.2 Action 12.3.1 Strategy 5.3
6. To improve the reliability of freight transportation	Action 2.1.1		
7. To improve the short- and long-distance movement of goods that- a) Travel across rural areas between population centers; b) Travel between rural areas and population centers; and c) Travel from the Nation's ports, airports, and gateways to the National Multimodal Freight Network	Action 1.1.1 Action 1.1.2 Action 1.1.3 Action 2.5.2 Action 3.1.1 Action 3.2.2 Action 3.2.3 Action 3.3.1 Action 5.2.1 Action 5.3.1 Action 6.1.4 Action 7.1.2 Action 11.1.3 Action 12.3.1 Strategy 3.1		
8. To improve the flexibility of States to support multi-State corridor planning and the creation of multi-State organizations to increase the ability of States to address multimodal freight connectivity	Action 3.2.1 Action 3.2.2 Action 4.1.1 Action 4.1.2 Action 14.2.1 Strategy 2.4 Strategy 3.3 Strategy 4.1	6. To improve the flexibility of States to support multi-State corridor planning and the creation of multi-state organizations to increase the ability of States to address highway freight connectivity	Action 4.1.1 Action 4.1.2 Action 14.2.1 Strategy 2.4 Strategy 4.1
9. To reduce the adverse environmental impacts of freight movement on the National Multimodal Freight Network	Action 2.5.4 Action 2.6.1 Action 4.1.2 Action 6.1.4 Action 8.1.1 Action 8.1.2 Action 8.2.1 Strategy 2.6 Strategy 8.1 Strategy 8.2	7. To reduce the environmental impacts of freight movement on the National Highway Freight Network	Action 2.5.4 Action 2.6.1 Action 4.1.2 Action 6.1.4 Action 8.1.1 Action 8.1.2 Action 8.2.1 Strategy 2.6 Strategy 8.1 Strategy 8.2

National Multimodal Freight Policy Goals 49 USC 70101	OFP strategy and action that satisfies	National Highway Freight Program Goals 23 USC 167	OFP strategy and action that satisfies
10. To pursue the goals described in this subsection in a manner that is not burdensome to State and local governments	Action 1.3.1 Action 1.3.2 Action 2.3.1 Action 2.5.4 Action 3.2.1 Action 3.2.2 Action 3.2.3 Action 3.3.1		

Appendix H – Critical Freight Corridors

Table 9-4. Critical Rural Freight Corridors

State	Route[1]	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	U.S. 97	84.00	84.50	0.50	Guardrail too close to travel lane with frequent strikes by trucks.
OR	U.S. 97	118.25	118.75	0.50	Trans-shipment facility located 1/2 mile east of U.S. 97 on O'Neil Highway. O'Neil Highway Junction with U.S. 97 has exceeded statewide average crash rates. The 2015 crash rate was two times the statewide average. A closer review of the crash data suggested that it is concentrated at the intersection of U.S. 97 and O'Neil Highway. Side street approaches must wait for gaps in highway traffic. The volume-to-capacity ratio was over 1.0, which is significantly above the 0.70 to 0.75 standard for this area and causes delay to freight movement.
OR	U.S. 97	124.40	133.39	8.99	During the 10 years between 2009 and 2013, 12 serious injury and fatal crashes occurred on U.S. 97 between Bend and Redmond. Many of these were lane departure crashes, sometimes resulting in high-speed head on collisions. In addition, there are a number of driveways on U.S. 97 between Bend and Redmond, and as traffic volumes grow, there are fewer gaps in traffic to facilitate motorists entering and exiting the highway at driveways. These conflicting movements can result in crashes, and probably are responsible for the many of the 25 rear end crashes reported between 2009 and 2013. Significant delay to freight and passenger vehicles associated with crashes.
OR	U.S. 97	155.00	156.00	1.00	Highway U.S. 97 is the main north-south transportation corridor through Central Oregon and a critical part of the state's transportation system. Demand continues to increase along U.S. 97, with average traffic rates of over 12,000 vehicles per day. Safety is a concern due to limited passing opportunities, leading to lengthy following times that sometimes result in drivers making passing maneuvers with high speeds and limited sight distances.
OR	U.S. 97	173.70	172.70	1.00	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	192.20	193.20	1.00	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.

[1] Routes without mile start and end points in this table are intermodal connectors

State	Route[1]	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	U.S. 97	200.40	199.30	1.10	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	211.10	212.10	1.00	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	220.90	221.90	1.00	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	237.00	239.00	2.00	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	244.20	244.70	0.50	Wide/Long
OR	U.S. 97	256.50	255.40	1.10	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles.
OR	U.S. 97	259.32	262.77	3.45	Rockfall location above the highway
OR	U.S. 97	264.00	266.91	2.91	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement. Widen roadway to extend existing passing lanes from 1 mile to 2 miles. Rockfall location above highway at south end of segment.
OR	U.S. 97	272.69	272.89	0.20	Vertical Clearance
OR	U.S. 97	280.40	281.80	1.40	Wide/Long
OR	U.S. 730	168.20	168.30	0.10	Wide/Long

Table 9-5. Critical Urban Freight Corridors

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	OR 99E	OR 34 Interchange	Albany City Limits	1.68	This is a first/last segment linking industrial and distribution facilities to I-5. Segment is on the NHS. Lack of pedestrian facilities create safety concerns and opportunities for conflict with fast moving traffic and freight. Sidewalk infill projects as in the AAMPO RTP constrained project list will facilitate safe freight travel.
OR	Albany Ave SE	Old Salem Rd NE	OR 99E / Albany	0.30	Albany Ave SE and Old Salem Rd is a first/last segment connecting manufacturing and freight logistics facilities. It is also within a corridor of a route on the PHFS and is an alternate route.
OR	Old Salem Rd NE (At RR Trestle, junction with Century Drive)	South of I-5 MP 236	North of I-5 MP 235	0.30	Albany Ave SE and Old Salem Rd is a first/last segment connecting manufacturing and freight logistics facilities. It is also within a corridor of a route on the PHFS and is an alternate route.
OR	U.S. 20	Willamette River	North Albany Rd.	0.50	This is a first/last segment on U.S. 20 between Albany's urban downtown and the Coast. This segment is on an NHS route.
OR	U.S. 97	Bend north City Limits (MP 133.39)	Empire Ave (MP 135.46)	2.07	Important segment of the U.S. 97 Statewide freight corridor on the north end of Bend that connects U.S. 97 to the City's largest industrial area on Empire Ave. This area experiences congestion, delay and safety issues.
OR	Empire Avenue	U.S. 20 Connection	U.S. 97 NB ramps	0.25	Important freight corridor that connects U.S. 20 and U.S. 97 to the largest concentration of industrial land in Bend. This is a key first/last mile connection to distribution and industrial facilities.
OR	U.S. 20	Cooley Road (MP 17.40)	U.S. 97 SB on-ramp at Division (MP 19.76)	2.36	Important segment of the U.S. 20 Statewide freight corridor. Important connection to distribution and industrial facilities along Empire Ave in Bend. Additionally, there will be significant land use development (light industrial and mixed employment) along this highway segment.
OR	U.S. 20	Webster Street (MP 20.19)	Greenwood Ave (MP 20.99)	0.80	Important segment of the U.S. 20 Statewide freight corridor that experiences congestion and delay.

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	U.S. 20	3rd Street (MP 0.51)	8th Street (MP 0.94)	0.43	Important segment of the U.S. 20 Statewide freight corridor that experiences congestion and delay.
OR	U.S. 20	Old Bend-Redmond Highway intersection (MP 16.70)	Old Bend-Redmond Highway intersection (MP 16.79)	0.09	Important segment of the U.S. 20 Statewide freight corridor that experiences safety and congestion issues.
OR	Randy Pape Beltline	Prairie Road	Delta Hwy	3.60	Supports regional mobility, freight movement and access to the NHFS.
OR	OR 126	I-5	OR 126 WB off-ramp	1.30	Supports regional mobility, freight movement and access to the NHFS.
OR	OR 126 at 52nd Ave	West of 52nd Ave	East of 52nd Ave	0.20	Supports regional mobility, freight movement and access to the NHFS.
OR	42nd St (Springfield)	OR126	Rail line	1.10	Connects Lane Forest Product to NHS.
OR	OR 126 at Mohawk Blvd	West of OR126 WB on/off-ramp	East of OR126 EB on/off-ramp	0.40	Supports freight movement and access to the NHFS.
OR	OR 99 (Franklin Blvd) in Goshen	Franklin Blvd north of 30th Ave (at point of its east/west alignment)	I-5 NB off ramp at MP 188	1.20	Supports industrial land in Goshen and access to the NHFS.
OR	Eugene Airport	Airport Rd between Old Airport Rd and OR 99	Airport Rd between Old Airport Rd and OR 99	0.60	Connects Mahlon Sweet Municipal Airport to NHS. Currently a NHS Intermodal Connector and identified as a proposed Tier 1 Intermodal Connector in the ODOT Intermodal Connector Study.
OR	Eugene Airport	Green Hill Rd/Northrop Rd between Airport Rd and Lockheed Rd, Lockheed Dr between Greenhill Rd/Northrop Rd and the Passenger Terminal	Green Hill Rd/Northrop Rd between Airport Rd and Lockheed Rd, Lockheed Dr between Greenhill Rd/Northrop Rd and the Passenger Terminal	0.80	Connects Mahlon Sweet Municipal Airport to NHS. Currently a NHS Intermodal Connector and identified as a proposed Tier 1 Intermodal Connector in the ODOT Intermodal Connector Study.
OR	Irving Rd/Prairie Rd	OR 99 to Prairie on Irving; Irving Rd to OR 99 on Prairie	OR 99 to Prairie on Irving; Irving Rd to OR 99 on Prairie	1.50	Connects Kinder Morgan Eugene, Lane Forest Products, Jerry Brown Co. and Paktech intermodal facilities to the NHS. Identified as a proposed Tier 2 Intermodal Connector in the ODOT Intermodal Connector Study.

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	U.S. 20/OR 34 Interchange with OR 99W over Marys River	U.S. 20/OR 34 Inter Change over Mary's River	U.S. 20/OR 34 Interchange over Marys River	0.10	Add an off ramp to the existing interchange for eastbound traffic turning to south OR 99W. The Interchange is on FAU system and is a major missing link on the existing Freight Routes.
OR	U.S. 20/OR 34 (Philomath Blvd)	35th Street	Separation point of U.S. 20/OR 34 west of Philomath	4.50	The link is in FAU and is a major Freight Route for lumber trucks. Improve intersections and install dedicated truck signal (ITS).
OR	OR 199	MP 0.69	MP 4.29	3.60	Freight corridor serving industrial/commercial areas with connection to I-5. This project is ODOT RTP # 510, Key 20104 and is currently in the TIP. Grind out existing pavement and replace with asphalt. Note: Project 510 extends from MP 0.69 in Grants Pass, west along OR 199 to MP 6.92.
OR	Table Rock Road	Table Rock Road	Vilas Road	0.10	Freight corridor that connects major industrial area to OR62, a connector to I-5. This project is Central Point RTP # 219, widen and add turn lanes.
OR	OR 62	OR 62	Dahlia Terrace	0.50	Freight route that connects industrial/commercial area to OR 62, a connector to I-5. This project is Eagle Point RTP # 339, Urban upgrade (collector) with bike lanes and sidewalks.
OR	North Phoenix/Foothills Road	Dry Creek	Vilas Road	1.10	Identified as a regional priority as an alternative North/South route to I-5. Provides a connection from the south valley to OR 140. Identified by ODOT as part of a resiliency plan in case of a major disaster (i.e. Cascadia quake.) This project is Jackson County RTP # 859. Widen to rural major collector standards.
OR	North Phoenix/Foothills Road	Vilas Road	Corey Road	1.70	Identified as a regional priority as an alternative North/South route to I-5. Provides a connection from the south valley to OR 140. Identified by ODOT as part of a resiliency plan in case of a major disaster (i.e. Cascadia quake.) This project is Jackson County RTP # 860. Widen to rural major collector standards.

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	North Phoenix/Foothills Road	McAndrews	Delta Waters	1.30	Identified as a regional priority as an alternative North/South route to I-5. Provides a connection from the south valley to OR 140. Identified by ODOT as part of a resiliency plan in case of a major disaster (i.e. Cascadia quake.) This project is the City of Medford RTP # 5043. Widen to 3 lanes with bike lanes and sidewalks.
OR	OR 99	OR 99	I-5	0.50	Freight corridor serving industrial areas with connection to I-5. This project is ODOT project RTP #951. Realigns and widens Bear Creek Bridge, adds turn lanes to S.Valley View Rd.
OR	Salem Rivercrossing aka "3rd Bridge"	Liberty St	Wallace Rd	1.13	Proposed bridge will provide a route for freight movement between I-5, the Willamette Valley and the Oregon Coast that does not go through downtown Salem, reducing travel time.
OR	OR 22E	I-5	25th St	1.18	OR 22 is designated as an Oregon Highway Plan Freight Route and intersects with I-5 in Salem. OR 22 is also one of the major routes for freight between central Oregon, the Willamette Valley and the Oregon Coast. Part of this segment is identified as a corridor with high freight delay (#57 in the Freight Highway Bottlenecks List as part of the Oregon Freight Plan). ODOT has completed a Facility Plan that includes recommendations along OR 22E part of the proposed CUFC segment.
OR	Center St Bridge	Commercial St	Murlark Dr	0.70	The Center St bridge provides the main freight route between the Willamette Valley and the Oregon Coast. OR 22 is designated as an Oregon Highway Plan Freight Route. The SKATS MPO is funding a study by ODOT to determine the seismic upgrades (and the cost) needed on this regional and statewide significant bridge.
OR	25th St	OR 22E	Madrona Av	0.84	Connects a major industrial area (Fairview Industrial) and the airport (which includes industrial uses as well as air freight trans-shipment) to OR 22E, which then connects to the Primary Highway Freight System (PHFS).

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	McGilchrist St	12th St	25th St	1.00	Provides access to the surrounding industrial area, which is an enterprise and electronic commerce zone. Adding capacity and providing complete facilities is a high priority for the city of Salem, which is in the process of completing a street design for McGilchrist Street; the draft FY 2018-2023 SKATS TIP includes $3.6 million of federal and local match funds for right-of-way purchasing in 2018.
OR	Kuebler Blvd	I-5	Aumsville Hwy	2.12	Connects a major industrial area (Fairview Industrial) and a major logistic and industrial area (Mill Creek Corporate Center – a 500+ acre major logistic area and the largest "shovel ready" industrial site on I-5) to the Primary Highway Freight System (PHFS).
OR	Cordon Rd/OR 22E Interchange	Aumsville Hwy	Gaffin Rd	0.97	Proposed interchange will provide access to traffic from/to central Oregon and the Mill Creek Corporate Center, a 500+ acre major logistic area and the "largest shovel ready" industrial site on I-5 between Seattle and Sacramento. OR 22 is designated as an Oregon Highway Plan Freight Route. OR 22 is also one of the major routes for freight between central Oregon, the Willamette Valley and the Oregon Coast. Also, would provide a bypass to the OR 22E / I-5 interchange to reduce travel distance.
OR	Cordon Rd	Gaffin Rd	State St	1.34	Provides for an alternate route around Salem if I-5 is closed. Also, provides connections to central Marion County (via Hazelgreen Rd and Silverton Rd) and central Oregon (via proposed OR 22E/Cordon Rd interchange).
OR	OR 217	U.S. 26	I-5	7.20	On Regional Freight Network as a Main Roadway Route and is on the NHS. Included on an earlier draft of National Multimodal Freight Network. Origins and destinations of freight; corridor that MPO and state identify as important.

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	U.S. 26 (Sunset Hwy.)	I-405	Brookwood Parkway	12.70	On Regional Freight Network as a Main Roadway Route, is on the NHS, and connects to the region's high tech industries. Included on an earlier draft of National Multimodal Freight Network. Origins and destinations of freight; volume, value and strategic importance of freight; economic factors, including balance of trade.
OR	U.S. 30	NW Kittridge	St. Johns Bridge	2.80	U.S. 30 is on the National Highway System (NHS). U.S. 30 is the main freight highway to energy pipelines and installations. Access to seaports and pipelines; intermodal links that promote connectivity; access to energy installation and production areas.
OR	NW Kittridge Road	NW Front Ave	U.S. 30	0.20	Access to seaports and pipelines; Intermodal links that promote connectivity; access to energy installation and production areas.
OR	NW 26th Drive	NW Front Ave	Terminal 2 Access	0.10	Terminal 2 has direct ship to rail transfers and ships forest products, steel and bulk cargo. Economic factors including balance of trade; Volume, value, tonnage, and strategic importance of freight; Inland intermodal facilities, and first and last mile facilities
OR	OR 99E	SE Holgate Blvd.	SE Harold St	0.80	On Regional Freight Network as a Main Roadway Route and is on the NHS. Important connection to Brooklyn Rail Yard and other intermodal connections. Intermodal link that promotes connectivity; major distribution centers and first/last mile links; corridor that MPO and State of Oregon identify as important.
OR	OR 212/224	I-205	SE Foster Road	5.70	On Regional Freight Network as a Main Roadway Route and is on the NHS. Key last mile connection to distribution and industrial facilities along OR 212. Origins and destinations of freight; major distribution centers and first/last mile links; corridor that MPO and State of Oregon identify as important.

State	Route	Start Point	End Point	Length (Miles)	Description of Importance (Other Comments)
OR	NE Alderwood Road	NE Cornfoot Road	NE Columbia Blvd.	0.40	On Regional Freight Network as a road connector route. Provides freight connectivity to Portland International Airport and air cargo facility. Volume, value and strategic importance of freight; access to Portland International Airport and air cargo facility; intermodal link that promotes connectivity.
OR	Marine Drive	I-84 (west end of frontage road)	Sundial Road	1.00	Connects a major freight route and interstate highway (I-84) to major a distribution center and Troutdale Airport. Origins and destinations of freight; distribution centers and first/last mile links.
OR	238th/242nd/Hogan Road	I-84	Burnside Road	2.80	On Regional Freight Network as a road connector route and is on the NHS. Provides key north/south freight connection between U.S. 26 and I-84, Troutdale Airport, and key distribution centers in the Columbia Corridor. Intermodal link that promotes connectivity; origins and destinations of freight; corridor that MPO identifies as important.
OR	Boones Ferry Road/ Basalt Creek	Grahams Ferry Road	I-5 via Boones Ferry Road	1.00	

Appendix I – Highway Inventories of Need

Table 9-6. Freight Highway Delay Areas

Route	Beg MP	End MP[1]	City/County	ODOT Region	Needs	Tier
I-405	0.0	0.8	Portland	1	Delay and unreliability at I-5 interchange	1

U.S. 30	98.00	99.00	Astoria	2	John Day Bridge to Astoria City Limits/high truck volumes create safety and mobility problems for non-freight traffic.
I-5	16.70	16.70	Ashland	3	Mountain Avenue vertical height does not meet ODOT or trucking standards, requiring truck detours.
I-5	27.00	30.00	Medford	3	Medford Viaduct has narrow shoulders that are insufficient for vehicles to pull over onto in the event of a breakdown or crash, creating through lane blockage. Emergency Vehicle access restricted as a result.
I-5	68.90	71.30	Josephine County	3	Sexton Summit: Curves and slow trucks leads to quick deceleration; steep grades create congestion due to significant speed reductions by trucks. Safety/Operational problems due to these speed reductions and speed differentials between lanes.
I-5	72.00	75.80	Josephine County	3	Smith Hill: Curves and slow trucks leads to quick deceleration. Steep grades create congestion due to significant speed reductions by trucks. Safety/Operational problems due to these speed reductions and speed differentials between lanes.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
I-5	77.70	80.80	Josephine/Douglas County	3	Stage Rd Pass: Curves and slow trucks leads to quick deceleration. Steep grades create congestion due to significant speed reductions by trucks. Safety/Operational problems due to these speed reductions and speed differentials between lanes.
I-5	88.40	95.40	Douglas County	3	Canyon Creek Pass: Curves and slow trucks leads to quick deceleration. Steep grades create congestion due to significant speed reductions by trucks. Safety/Operational problems due to these speed reductions and speed differentials between lanes.
I-5	119.00	125.00	Roseburg	3	Congestion partially due to high truck % and weaving from closely spaced interchanges.
OR 140	-6.42	0.00	White City	3	Road built to narrow county standards. Jurisdiction transferred to ODOT.
OR 42	38.00	45.00	Coos County	3	Tight curves result in truck turnovers on OR 42.
OR 42	Various	various	Coos County	3	Lack of westbound passing lanes leads to crashes as people seek areas to maneuver (pass) trucks.
U.S. 199, OR 99, OR 238	Junction	Junction	Grants Pass	3	Intersection of highways creates confusion, capacity constraints and is difficult for freight to traverse.
OR 370 & U.S. 97	118.25	118.75	Redmond	4	Trans-shipment facility located 0.5 mile east of U.S. 97 on O'Neil Highway. O'Neil Highway Junction with U.S. 97 has exceeded statewide average crash rates. The 2015 crash rate was two times the statewide average. A closer review of the crash data suggested that it is concentrated at the intersection of U.S. 97 and O'Neil Highway. Side street approaches must wait for gaps in highway traffic. The volume-to-capacity ratio was over 1.0, which is significantly above the 0.70 to 0.75 standard for this area and causes delay to freight movement.
U.S. 20	13.22	103.02	Deschutes/Lake/ Harney County	4	Superload route with limited pull-outs. Freight and passenger vehicles delayed up to 20 minutes waiting for superloads to clear area.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
U.S. 20	18.70	21.00	Deschutes County	4	Narrow shoulders on steep grade in Horse Ridge fails to provide a safe recovery zone for vehicles which crash or spin out. Lack of operating room makes vehicle recovery difficult and leads to significant delays to freight movement.
U.S. 97	0.20	4.07	Sherman County	4	This section of highway is south of Biggs Junction. It is approximately 4 miles long and has rock walls, steep banks, sharp curves, narrow shoulders and guardrails.
U.S. 97	84.00	84.50	Jefferson County	4	Guardrail too close to travel lane with frequent strikes by trucks.
U.S. 97	124.40	133.39	Deschutes County	4	During the 10 years between 2009 and 2013, 12 serious injury and fatal crashes occurred on U.S. 97 between Bend and Redmond. Many of these were lane departure crashes, sometimes resulting in high-speed head on collisions. In addition, there are a number of driveways on U.S. 97 between Bend and Redmond, and as traffic volumes grow, there are fewer gaps in traffic to facilitate motorists entering and exiting the highway at driveways. These conflicting movements can result in crashes, and probably are responsible for the many of the 25 rear end crashes reported between 2009 and 2013. Significant delay to freight and passenger vehicles associated with crashes.
U.S. 97	155.00	156.00	Deschutes County	4	Highway U.S. 97 is the main north-south transportation corridor through Central Oregon and a critical part of the state's transportation system. Demand continues to increase along U.S. 97, with average traffic rates of over 12,000 vehicles per day. Safety is a concern due to limited passing opportunities, leading to lengthy following times that sometimes result in drivers making passing maneuvers with high speeds and limited sight distances.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
U.S. 97	172.70	173.70	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.
U.S. 97	192.20	193.20	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.
U.S. 97	199.30	200.40	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.
U.S. 97	211.10	212.10	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.
U.S. 97	220.90	221.90	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.

U.S. 97	255.40	256.50	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.
U.S. 97	264.00	265.10	Klamath County	4	Primarily a 2-lane highway with lack of passing opportunities resulting in platooning of traffic, unsafe passing, which contributes to crashes, and delay of freight movement.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
I-82	0.00	10.00	Umatilla County	5	Motorist rely on cameras and weather reporting stations to provide real time information during winter travel. When trucks are able to access real time information, they are able to make decisions about proceeding in the corridor or installing chains before entering into an area with inclement weather. Access to real time information allows them to avoid getting trapped in or contributing to an incident on the freeway.
I-82	1.00	1.00	Umatilla	5	Proximity of Port of Entry to I-82 EB off ramp creates truck stacking that blocks Hwy 2 and backs traffic up the I-82 EB off ramps onto the freeway.
I-84	160.00	378.00	Morrow/Umatilla/Union/Baker/ Malheur County	5	There are a number of bridges crossing over the freeway that create vertical clearance issues by having less than 17' 6".
I-84	160.00	378.00	Morrow/Umatilla/Union/Baker/ Malheur County	5	Motorists rely on cameras and weather reporting stations to provide real time information during winter travel. When trucks are able to access real time information, they are able to make decisions about proceeding in the corridor or installing chains before entering into an area with inclement weather. Access to real time information allows them to avoid getting trapped in or contributing to an incident on the freeway.
I-84	165.00	165.00	Boardman	5	WB interchange ramp congestion during peak usage with traffic backing onto interstate.
I-84	188.00	188.00	Stanfield/Echo	5	Interchange congestion during winter events and peak agricultural harvest traffic.
I-84	205.00	207.00	Umatilla County	5	The westbound grade between MP 205 and 207 is steep, dropping truck speeds and creating localized congestion on the freeway and safety issues. There is a large differential in speed between commercial traffic and light vehicles.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
I-84	209.00	210.00	Pendleton	5	The grade between MP 209 and 210 is steep, dropping truck speeds and creating localized congestion between the two interchange ramps that many locals use to access different parts of Pendleton. There is a large differential in speed between commercial traffic and light vehicles.
I-84	209.00	209.00	Pendleton	5	The U.S. 395/I-84 Interchange ramps no longer meet intersection function criteria. Traffic backs up the ramps to the freeway regularly. This affects the primary entrance to Pendleton's commercial district.
I-84	213.00	216.00	Umatilla County	5	Winter congestion/truck stacking blocking through traffic during winter events on freeway mainline. Highest District 12 priority for congestion.
I-84	216.00	252.00	Umatilla/Union County	5	Commercial vehicles failing to comply with chain restriction and resultant spin outs frequently closes the freeway.
I-84	268.00	268.00	Union County	5	Lack of chain sorting/compliance enforcement allows unchained commercial vehicles to proceed into Ladd Canyon, leading to spin out related closures in the winter.
I-84	374.00	378.00	Malheur County	5	During winter freeway closures, the Ontario area becomes congested as trucks run out of space to park. Traffic backs ups and blocks the freeway lanes preventing people from exiting during closures.
OR 201	30.00	30.00	Ontario	5	High accident intersection at OR 201/SW 18th and OR 201 @ RR Avenue (OR 201 connects U.S. 20 to I-84 and is on the I-84 paired route for over-dimensional loads) is a safety issue. Additionally, this location is a key transportation pinch point that complicates industrial development in the adjacent vacant lands.

Route	Beg MP[4]	End MP	City/County	ODOT Region	Needs (Facilities - Mobility Issues)
OR 237	17.20	28.80	Union County	5	Closures in Ladd Canyon due to weather related crashes, unchained trucks or visibility interrupts all travel in NE Oregon as there are no alternate routes available for freeway traffic.
OR 78	26.80	27.00	Harney County	5	When using this route as an alternate to I-84 during freeway construction projects, super loads back up traffic and have difficulty finding places to park or stage on this route.
OR 78	90.90	91.10	Malheur County	5	When using this route as an alternate to I-84 during freeway construction projects, super loads back up traffic and have difficulty finding places to park or stage on this route.
U.S. 20	193.74	216.87	Malheur County	5	Curves and narrow spots restrict over-dimension loads between Burns and Vale. Hwy 7 is the paired route to I-84 and frequently is used for over-dimensional loads when work is occurring on I-84.
U.S. 20	258.00	258.00	Malheur County	5	High accident intersection at Cairo Junction makes through freight and local agricultural freight movements dangerous.
U.S. 95	0.00	0.20	Malheur County	5	When using this route as an alternate to I-84 during freeway construction projects, super loads back up traffic and have difficulty finding places to park or stage on this route.

Appendix J – Non-Highway Inventories of Need

Table 9-12. Marine

Location	ODOT Region	Needs
Port of Portland	1	Grade separations: Marine Drive at BNSF Ford/Ramsey Lead in Rivergate. UPRR Kenton Line grade separations and double tracking from North Portland to Troutdale.
Port of Portland	1	Willamette River Channel Deepening of the portion of the Willamette River with deep draft infrastructure to -43 feet to take advantage of the Columbia River's controlling depth.
Port of Portland	1	Bonneville Rail Yard Build Out: Construct two interior yard tracks and complete the double track lead from Barnes Yard to add rail staging capacity for South Rivergate.
Port of Portland	1	Terminal 2: Terminal 2 Yard and Rail Improvements to increase rail and yard operating efficiencies at T2, reconstruct rail and yard pavement.
Port of Portland	1	Terminal 4 Pier 1 Site Preparation: Remove Berths 405 and 408, the grain leg platform and tower, and the grain elevator in the Pier 1 area of T4. This will facilitate redevelopment of approximately 30 acres of marine industrial property in the Portland Harbor.
Port of Portland	1	Terminal 4: T4 Capacity Expansion and Modernization needed to allow increase in rail capacity at T4, includes second entrance, rail at Berth 410-411, a third rail lead to Barnes Yard, and replacement of Lombard Bridge.
Port of Portland	1	Time Oil Road Reconstruction to provide improved access to the South Rivergate Industrial Area.
Portland	1	BNSF Columbia River Rail Bridge: change from swing span to lift span and align lift span location with I-5 Bridge high span and wide span to align barge traffic between the two bridges, reduce I-5 Bridge lifts needed for barge traffic, and reduce marine impacts to I-5 highway traffic.
Port of Portland	1	Marine Drive Interchange at Interstate 5: This interchange is an existing constraint and will need to be redesigned with or without a larger Columbia River Crossing project. This is a key bottleneck for access to and from Rivergate, the largest industrial district in Oregon. Possible solution is westbound Marine Drive to northbound I-5 flyover ramp.
Port of Portland	1	Cathedral Park Quiet Zone to address rail switching noise by improving multiple public rail crossings in the St. Johns Cathedral Park area.
Port of Portland	1	Terminal 6 Development Project includes additional scour protection, T6 entrance overcrossing, two new PPMX cranes, electrical upgrades, yard gantry cranes, and 6,800 and 8,500 departure tracks. Necessary to expand capacity to 1 million TEUs.
Port of Hood River	1	Replacement of Hood River Interstate Bridge.
Lower Columbia River	2	Lower Columbia River shipping channel: Anchorage deepening to allow loaded ships to anchor while waiting to time their arrival at the Columbia River Bar.
Lower Columbia River	2	Lower Columbia River shipping channel: Stern buoys for Lower Columbia River anchorages.
Port of Astoria	2	Major repairs needed at all port shipping docks.

Location	ODOT Region	Needs
Port of Newport	2	Port Dock 5 Pier Access, located at 210 Bay Blvd., Newport, OR. The sole connector between the commercial fishing fleet and shoreside services is via a 75-year-old access pier. Recent preliminary engineering study has shown that this critical infrastructure connector is in danger of failing and needs reconstruction.
Port of St. Helens	2	Portland & Western rail improvements - sidings, track improvements.
Port of St. Helens	2	Port Westward dock improvements and water system improvements.
Lower Columbia River	2	Jetties at the mouth of the Columbia River.*
Port of Astoria	2	Rail and truck access at Tongue Point.
Port of Newport	2	International Terminal Shipping Facility, located at 1510 Bay Blvd., Newport, OR. Construction of a laydown facility to consolidate imports and exports using U.S. 20/U.S. 101 and the Federal Marine Highway system. There is a demand for logging/wood products exports and waste paper imports from barges and handysized vessels onto the state highway system.
Port of Toledo	2	Boat yard expansion and upgrade.
Port of Newport	2	Channel deepening.*
Port of Astoria	2	Pier 3 (east) rebuild: Resurface docks and adjoining lay-down areas.
Port of Newport	2	Add new hoist to support commercial fishing fleet.
Port of St. Helens	2	Columbia City at-grade rail crossings with U.S. 30 and industrial site developments.
Port of Astoria	2	Stormwater management of all port pier structures: Expansion of new stormwater treatment facility, address future stormwater management and DEQ requirements.
Port of Astoria	2	Improve terminal lights and security fencing.
Port of Toledo	2	Intermodal rail connection improvement.
Port of Toledo	2	Additional transient and permanent moorage on the Downtown Waterfront.
Oregon International Port of Coos Bay	3	Coos Bay Rail Link improvements to bridges, spurs, tracks, transload sidings, at grade crossings and tunnels are needed to create or improve multi-modal business opportunities.
Oregon International Port of Coos Bay	3	Charleston boatyard (dock, travel lift etc.) improvements that include the Marine Ways.
Oregon International Port of Coos Bay	3	Oregon Gateway: North Spit improvements (ocean outfall, access roads etc.) to accommodate a multi-modal marine facility to handle bulk cargo, containers and an LNG export facility.
Oregon International Port of Coos Bay	3	Federal channel widening and deepening to accommodate larger ships and ensure safer operations.*
Oregon International Port of Coos Bay	3	Charleston dock replacements.
Port of Morrow	5	Current Port facilities need additional rail trackage to utilize transload opportunities - rail improvements in East Beach area.
Port of Morrow	5	Barge Terminals need additional expansion, both new and existing to accommodate multi cargo use, or dedicated new use.

Location	ODOT Region	Needs
Port of Morrow	5	Additional mainline access will be needed: Port of Morrow West Beach area does not have rail intermodal access because of constraints related to siding access and the only way to add rail to 4 Barge terminal locations is to have another mainline access.
Port of Morrow	5	Interconnecting roads need priority for freight.
Port of Umatilla	5	Rail access improvements to existing industrial lands and to U.S. Army Depot lands.
Port of Morrow	5	Access improvements.

*Federal agencies are responsible for maintenance and enhancements of federal channels and jetties

.

Table 9-13. Rail

Line Segment	Start	End	Miles	Operator	Owner	ODOT Region	Description of Need/Freight Mobility Issue with the Facility
Lakeview Branch	Lakeview	Alturas	55.5	Lake Railway	Lake County	4	Small rail and restricted-weight bridges preclude moving standard 286K GVW railcars critical for new industrial development; tie condition generally poor. The county acquired it 30 years ago to keep it from being abandoned.
Coos Bay Branch	W. Eugene	Coquille	133.4	Coos Bay Rail Link	Port of Coos Bay	3	This 100-year-old line is dealing with a significant backlog of deferred maintenance on tunnels, bridges and track, and an inadequate traffic base. Preservation of rail service is essential to support economic development at the Port of Coos Bay and south coast.
Astoria Branch	Port Westward	Wauna	15.7	Portland & Western	Portland & Western	2	Rail on this segment requires upgrading for efficient, long-term usage of this line in support of industrial development in Columbia and Clatsop counties. A hand-cranked drawbridge over the Clatskanie River needs to be electrified.
Union Pacific (Kenton line)	MP 0.32	MP 1.0	0.68	Union Pacific	Union Pacific	1	When long freight trains are navigating two 6 mph curves just north of the Steel Bridge, other trains, including passenger trains, can be delayed. Straightening track and easing curvature would permit more optimum speeds. This location has long been recognized as a significant Portland-area bottleneck.
Union Pacific (Kenton line)	Peninsula Jct.	Peninsula Jct.	0.5	Union Pacific	Union Pacific	1	Track upgrades and signal work is necessary at Peninsula Jct., for which preliminary plans, funded by a federal ARRA grant, were completed.
Fallbridge Subdivision	S. Lake Yard	N. Lake Yard	1.5	Burlington Northern Santa Fe	Burlington Northern Santa Fe	1	Install remotely controlled power switches and signals at both ends of Portland's Lake Yard to expedite ability of freight trains to arrive and depart the facility, reducing delays and interference between passenger and freight trains.
Fallbridge Subdivision	Willbridge	Willbridge	0.5	Burlington Northern Santa Fe	Burlington Northern Santa Fe	1	Using ARRA funding, ODOT completed 30% plans for replacing 10 mph crossovers at this junction with 30 mph crossovers for improving fluidity and reducing delays for passenger and freight trains.

Line Segment	Start	End	Miles	Operator	Owner	ODOT Region	Description of Need/Freight Mobility Issue with the Facility
Oregon Trunk Subdivision	Bend	Chemult	67.8	Burlington Northern Santa Fe	Burlington Northern Santa Fe	4	Between Bend and Chemult is "dark territory" with no signal system, whereas north of Bend has block signals. Ultimately installation of Centralized Traffic Control from the Columbia River to Chemult will significantly increase the capacity of this line.
Brooklyn Subdivision	Eugene	Eugene	0.5	Union Pacific/AMTRAK	Union Pacific/City	2	The ability to house state-supported Cascades passenger trains at Eugene's passenger depot between runs by building a layover track there (instead of moving trains to UP's freight yard as is current practice) would reduce operating costs and improve on-time performance. A federal ARRA grant has permitted ODOT to complete 30% preliminary plans and NEPA work for this two-phase project.
Brooklyn Subdivision	Brooks MP 725.8	Brooks MP 727.6	1.8	Union Pacific/AMTRAK	Union Pacific	2	Build 8,950-foot controlled siding between Quinaby Road and Tacoma Street crossings at Brooks to facilitate more efficient movement of freight and passenger trains between Salem and Portland. Siding will cross Brooklake Road at MP 726.9.
Astoria Branch	Wauna	Tongue Point	23.2	Portland & Western	Portland & Western	2	This segment has not been operated since the fall of 2005 and requires a tie program and surfacing to reopen. To efficiently carry 286K cars and significant volumes smaller rail must be replaced and hand-cranked drawbridges at Blind Slough and John Day River automated with electric motors. ODOT owns the right of way from Linnton to Tongue Point.
Dallas Branch	OR 99W	Dallas	4.3	Portland & Western	Union Pacific	2	The western 4 miles of this line serving the industrial section of Dallas has seen no traffic for several years, yet availability of rail is cited by the city in marketing the district. To resume service a tie and surfacing program would be necessary; longer term, the smaller rail would need to be replaced.
Klamath Northern Railway	Gilchrist	Gilchrist Jct.	11.0	Klamath Northern Railway	Klamath Northern Railway	4	Although KNOR handles 286K shipments, a significant portion of the railroad's trackage is comprised of small rail generally considered to be inadequate for safely carrying 286K.

Line Segment	Start	End	Miles	Operator	Owner	ODOT Region	Description of Need/Freight Mobility Issue with the Facility
Gateway Subdivision	Bieber Line Jct.	Bieber Line Jct.	0.5	Burlington Northern Santa Fe/Union Pacific	Burlington Northern Santa Fe/Union Pacific	4	This project signalizes and remotely controls the junction switch in Klamath Falls where BNSF trains leave/enter Union Pacific's line, eliminating the need to stop and manually handle switches there, thus reducing train delays. BNSF trains operate over UP for 74 miles from Klamath Falls to Chemult where the junction between the two railroads already is signalized and remotely controlled.
Woodburn-Stayton Line	Silverton	Stayton	21.0	Willamette Valley Railway	Union Pacific	2	Short line Willamette Valley Railway leases this 31-mile line, but has not operated the 21 miles from Silverton to Stayton since January of 2012. There is some unrepaired flood damage and there are bridge issues and some concern about tie condition. This segment is at risk of eventual abandonment, although there are customers along the disused track that would like to have service.
Weston Branch	Spofford	Weston	19.0	Palouse River & Coulee City	Union Pacific	5	Short line Palouse River & Coulee City Railroad operates this line which begins in Walla Walla, WA and passes through Milton-Freewater en route to Weston. In 2012, PCC's parent said they were considering abandoning this line from Spofford, 2 miles south of the state line, to Weston. The line is laid with light rail and has poor tie condition as well.
Joseph Branch	Elgin	Joseph	63.0	Wallowa Union Railroad Authority	Wallowa & Union Counties	5	This line has no freight traffic but does host sporadic seasonal tourist trains and a rail pedal car operation. However, these activities do not generate revenue sufficient to sustain the long-term maintenance needs of the railroad, so the line is slowly deteriorating.
Oregon Eastern Division	MP 20.2	MP 26.2	6.0	Wyoming Colorado	Wyoming Colorado	5	Replace 75-lb. rail with heavier rail to increase carrying capacity of entire line to GVW of 286,000.
Oregon Trunk Subdivision	Moody	Gateway	89.0	Burlington Northern Santa Fe	Burlington Northern Santa Fe	4	Vertical clearance in 5 tunnels between the Columbia River and Madras preclude passage of double-stack containers.

Line Segment	Start	End	Miles	Operator	Owner	ODOT Region	Description of Need/Freight Mobility Issue with the Facility
Fort Hill Line	Willamina	Fort Hill	5.30	Portland & Western	Hampton Railway	2	The Hampton Railway is operated by PNWR under a haulage agreement, but there has been no active customers on the line since 2013; thus, it is at risk of abandonment. Hampton Railway is a subsidiary of Hampton Lumber Co.
Railcars Fleet Modification	N/A	N/A	N/A	Northwest Container Services	Northwest Container Services	1	Increase loading capacity of 23 five-platform double-stack intermodal cars from 115,300 lbs. per well to 120,500 lbs. per well by reducing their length from 312 feet to approximately 270 feet each.
Brooklyn Subdivision	North end Brooklyn Yard	North end Brooklyn Yard		Union Pacific	Union Pacific		Trains entering and exiting Brooklyn Intermodal Terminal have to navigate a series of hand throw switches at north end of the yard.
Rogue Valley Terminal (RVT) Railroad	White City	White City	9.5	Rogue Valley Terminal Railroad	Rogue Valley Terminal Railroad	3	Although RVT handles 286,000 lb. shipments, a significant portion of the railroad's trackage is comprised of small rail generally considered to be inadequate for safely carrying 286,000 lbs. on this first/last mile rail delivery facility.
Union Station Track 6	Fremont Bridge	Steele Bridge	1.0	Burlington Northern Santa Fe/Union Pacific	Burlington Northern Santa Fe/Union Pacific	1	Add Track 6 to increase rail car storage capacity at Union Station. Move freight from Track 4 to Track 5 and Track 6.

EXECUTIVE ORDER NO. 17-21

ACCELERATING ZERO EMISSION VEHICLE ADOPTION IN OREGON TO REDUCE GREENHOUSE GAS EMISSIONS AND ADDRESS CLIMATE CHANGE

WHEREAS, climate change presents a significant threat to our livelihoods, economic security, environment, health, and well-being.

WHEREAS, there has been an increase in extreme weather events, including more frequent and intense heat waves and wildfires. According to the Oregon Climate Change Research Institute and other regional studies, the best available science indicates Oregon is at risk of serious impacts to its natural resources due to climate change.

- Water resources are being affected by decreased winter snowpack, changes to seasonal runoff patterns, decreased precipitation in Eastern Oregon, and increased intensity and occurrence of flooding.
- Agricultural resources are being affected by increases in temperatures.
- Ocean acidification is increasing and there are changes in ocean currents.
- Significant parts of the Oregon coastal region, stretching 363 miles, will be impacted by an expected rise in sea level up to 1 to 4 feet by 2100, incurring billions of dollars of damages and losses to roadways and structures.
- Climate change impacts threaten the State's agricultural, fishing, timber, recreation, and tourism industries, thereby threatening the livelihood of the State's residents and an important source of Gross State Product for the state.

WHEREAS, climate-related pollution from transportation and other emissions is projected to create $1.1 billion in health costs for Oregon families to bear by 2040, including asthma, heart disease, stroke, and cancer; and internal combustion engines burning fossil-based fuels are the largest contributor of greenhouse gas emissions in Oregon, with the transportation sector accounting for 37 percent of greenhouse gas emissions and light-duty vehicles alone accounting for 25 percent of greenhouse gas emissions, all while the state's transportation sector related greenhouse gas emissions continue to grow.

WHEREAS, Oregon is committed to meeting the international Paris Agreement targets to reduce greenhouse gas emissions by 26 to 28 percent below 2005 levels by 2025.

WHEREAS, Oregon has adopted goals to reduce greenhouse gas emissions to 10 percent below 1990 levels by 2020 and at least 75 percent below 1990 levels by 2050 as described in ORS 468A.20.

WHEREAS, greater transition of internal combustion engines to zero emission vehicles, like electric cars, buses, and trucks, play a key role in helping Oregon achieve its climate change goals, improving the health of Oregon communities, and encouraging clean energy job development.

WHEREAS, zero emission vehicles provide multiple benefits to Oregonians, including operating quietly and cleanly; allowing home refueling; lowering operating, maintenance, and fuel costs; and reducing pollutants such as carbon dioxide and black carbon emitted through diesel combustion.

WHEREAS, emissions associated with the combustion of fossil fuels have a negative health impact for Oregonians and, in particular, communities located close to major highways, and the use of zero emission vehicles can have immediate positive impacts on local air quality and public health.

WHEREAS, the median Oregon household spends four to five percent of its income on transportation fuel costs, and Oregon businesses and residents could benefit from the lower costs of zero emission vehicle operation and maintenance and the diversification of our transportation fuels, including electricity, which can help offset price volatility and political instability associated with petroleum fuels.

WHEREAS, the development of a robust clean energy economy includes the sales of electric vehicles, chargers, and other equipment as well as the installation and maintenance of charging equipment that will encourage clean energy job development at a local level.

WHEREAS, Oregon is a member of the following organizations and coalitions that have zero emission vehicle goals and commitments:

- The International Zero Emission Vehicle Alliance has committed that all new light-duty vehicle sales will have an electric powertrain as soon as possible and no later than 2050.

- The Pacific Coast Collaborative established and supports the West Coast Electric Fleets initiative to expand the use of electric vehicles in fleets and the West Coast Green Highway to provide resources for zero emission vehicles on Interstate-5.

- The Zero Emission Vehicle Multi-State Memorandum of Understanding has an Action Plan Goal of a minimum of 25 percent of new light-duty state fleet purchases and leases for applicable uses, to the extent available, will be zero emission vehicles by 2025.

NOW, THEREFORE, IT IS HEREBY DIRECTED AND ORDERED:

1. **Definition.** For purposes of this Executive Order, "state agency" shall be defined as any agency within the Executive Department as defined in ORS 174.112, other than the Oregon Secretary of State, Oregon State Treasury, Oregon Department of Justice, and Oregon Bureau of Labor and Industries.

2. **Statement of Policy and Establishing Statewide Goal.** It is the policy of the State of Oregon to establish an aggressive timeline to achieve a ***statewide goal of 50,000 or more registered and operating electric vehicles by 2020.*** This short-term goal will ensure the state is on track to meet ambitious long-term goals described above. There are currently approximately 16,000 electric vehicles registered in Oregon and establishing this new state goal will focus state agencies and partners in transitioning public and private fleets to electric vehicles to achieve multiple climate change goals and commitments. Strategies outlined in this executive order will close cost gaps, infrastructure gaps, and information gaps to help accelerate the transition toward electric vehicles.

3. **Oregon State Agencies Leading by Example with Increased Use of Electric Vehicles.**

   A. State Electric Vehicle Chargers to Support the State Goal. The Department of Administrative Services (DAS) and the Oregon Department of Energy (ODOE) are directed to develop a plan and estimated budget through 2025 to install electric vehicle chargers for the operation of state agency owned electric vehicles, public charging at

state facilities, and state employee charging. The number and placement of electric vehicle chargers will be designed to provide sufficient charging infrastructure necessary for the state to achieve the fleet conversion goals of the Pacific Coast Collaborative West Coast Electric Fleet initiative described above.

B. Electric Vehicle Policy for State Parking Lots to Support the State Goal. DAS is directed to add electric vehicle charging as a priority criteria for parking lot waitlists, add electric vehicle charging capacity for employee and public visitor parking lots, develop contracts for the procurement and installation of charging infrastructure, and incorporate electric vehicle charging as a tenant improvement for state-leased buildings.

C. Long-term Return on Investment of Electric Vehicles to Support the State Goal. DAS, in cooperation with ODOE, is directed to develop a tool to calculate the long-term return on investment and life-cycle costs of electric vehicles using costs and savings including but not limited to vehicles purchase, fuel, and maintenance. This tool will inform state agencies of potential cost savings for greater state agency fleet conversion toward zero emission vehicles to achieve the state goal established in Section 2. In addition, DAS is directed to develop a "Low-Emission Vehicle First" policy, to encourage state employees to first use electric vehicles or other low-emission vehicles in the state fleet.

D. Bulk Electric Vehicle Purchases to Support the State Goal. DAS and ODOE are directed to improve the use of the West Coast Electric Fleets initiative for electric vehicle bulk procurement to reduce costs for electric vehicle purchases.

E. Enabling Electric Vehicle Purchases and Infrastructure to Support the State Goal. DAS, in cooperation with all state agencies, is directed to inform and support legislative changes that would enable increased charging infrastructure and state agency electric vehicle purchases.

4. Increasing Oregonians' Access to Electric Vehicles.

A. Electric Vehicle Rebate Programs Designed to Achieve the State Goal. The Oregon Department of Environmental Quality (DEQ) is directed to

conduct rulemaking for the electric vehicle rebate programs, established in HB 2017 (2017), to encourage Oregonians to purchase or lease electric vehicles such that these rebate programs are designed to achieve the state goal established in Section 2. As part of the rulemaking, DEQ is directed to develop strategies to help ensure Oregonians are informed about the opportunities to reduce the costs of electric vehicle purchases and leases through the Electric Vehicle Rebate program, in addition to robust outreach to low-income communities and organizations through the Charge Ahead Rebate program.

B. Clean Fuels Program Designed to Achieve the State Goal. DEQ is directed to conduct rulemaking for the Clean Fuels Program to support greater electric vehicle adoption, in cooperation with the Oregon Public Utility Commission (PUC), such that the program is designed to support innovative solutions in the evolving electric vehicle market and achieve the state goal established in Section 2. DEQ is directed to develop a method to aggregate and monetize all eligible electric vehicle credits in the Clean Fuels Program to assist in achieving the state goal.

C. Zero Emission Vehicle Regulation Designed to Achieve State Goal. Today, DEQ's zero emission vehicle regulation requires car manufacturers to sell six to eight percent electric vehicles for new light-duty sales by 2025. DEQ is directed to work with the Environmental Quality Commission to maintain consistency with California's zero emission vehicle regulation, including efforts to ramp up regulatory requirements. DEQ is directed to participate in federal assessments of vehicle emissions standards and work with the Department of Justice to take appropriate steps to retain California's exemption for vehicle standards that are more protective of air quality under the federal Clean Air Act Section 209.

D. Consumer Engagement in Transportation Electrification Plans to Achieve the State Goal. PUC, with input from interested stakeholders, is directed to implement the transportation electrification program, established in SB 1547 (2015), to support consumer engagement in the investor-owned utilities' transportation electrification plans such that the transportation electrification program is designed to achieve the state goal established in Section 2. Wherever possible, the PUC is directed to

encourage programs that support greater electric vehicle adoption in moderate- and low-income communities.

5. **Increasing Oregonians' Access to Electric Vehicle Charging Infrastructure.**

   A. Leveraging Volkswagen Mitigation Fund to Support the State Goal. DEQ, in cooperation with Oregon Department of Transportation (ODOT), ODOE, and Oregon Health Authority Public Health Division, is directed to engage interested stakeholders and receive public comments to inform development of a plan to leverage up to 15 percent of the Volkswagen Mitigation Fund to support vehicle electrification. This plan will use part of Oregon's share of the Volkswagen Diesel Settlement (Appendix D), consistent with the limitations on the use of such funds, to develop and maintain electric vehicle charging stations with a focus on connecting rural communities, low-income communities, and Oregonians living in multi-family homes, while complementing the Electric Vehicle Rebate Program and Charge Ahead Rebate Program that were established in HB 2017 (2017).

   B. Leveraging Volkswagen Zero Emission Vehicle Fund to Support the State Goal. ODOT, in cooperation with ODOE, DEQ, PUC, and local governments, is directed to facilitate the application process for fund deployment of the Volkswagen "Electrify America" investments and projects under the Zero Emission Vehicle Fund, which are developed in accordance with the Volkswagen Diesel Settlement (Appendix C). In addition, these agencies will develop proposals for future 30-month investment periods for the Volkswagen "Electrify America" Zero Emission Vehicle Investment Plans to achieve the state goal established in Section 2.

   C. Charging Infrastructure in Transportation Electrification Plans to Achieve the State Goal. PUC, with input from interested stakeholders, is directed to implement the transportation electrification program, established in SB 1547 (2015), to support electric vehicle charging in the investor-owned utilities' transportation electrification plans such that the transportation electrification program is designed to achieve the state goal established in Section 2. Wherever possible, the PUC is directed to

encourage programs that support greater electric vehicle adoption in moderate- and low-income communities.

D. Electric Vehicle Ready Building Construction to Achieve the State Goal. The appropriate advisory board(s) and the Department of Business and Consumer Services Building Codes Divisions (BCD) are directed to conduct code amendment of the state building code to require that parking structures for all newly constructed residential and commercial buildings are ready to support the installation of at least a level 2 EV charger by October 1, 2022. BCD may establish limited specific exemptions related to types of parking lots, such as temporary parking lots.

6. Providing Partners with Information on Electric Vehicle Use and Functionality.

A. Assisting School Districts to Support the State Goal. ODOE, working with ODOT, PUC, DEQ, and the Department of Education, is directed to develop tools and provide information to assist school districts in making decisions about zero emission vehicle bus options when replacing school buses.

B. Assisting Transit Agencies to Support the State Goal. ODOT, working with ODOE, PUC, and DEQ, is directed to develop tools, information, and best practices to assist transit agencies when making decisions about zero emission vehicle bus technology adoption in transit fleets for their transit districts. In addition, ODOT, working with ODOE, DEQ, and Oregon Health Authority Public Health Division, is directed to engage with transit agencies and interested stakeholders to assess how zero emission vehicle technologies can help to reduce lifecycle emissions, improve public health, and save costs in the heavy-duty sector, including through the accelerated transition to zero-emission buses.

C. Assisting Consumer Owned Utilities to Support the State EV Goal. ODOE is directed to engage with consumer and public-owned utilities to enable increased electric vehicle adoption in their service territories and provide technical assistance on strategies to accommodate increased

loads on their electric systems in order to achieve the state goal established in Section 2.

D. Assisting Investor Owned Utilities to Support the State EV Goal. PUC, in collaboration with utilities and stakeholders, is directed to oversee development of strategies to encourage continuous improvement of the investor-owned utilities' transportation electrification plans, established pursuant to SB 1547 (2015), to achieve the state goal established in Section 2.

7. **Celebrating Achievements by Recognizing Businesses and Organizations that Lead Oregon in Electric Vehicle Adoption.**

A. Establishing Governor's Awards for Automobile Dealerships. ODOE is directed to design and establish "Governor's Awards" for automobile dealerships to encourage sales of electric vehicles, such as highest annual electric vehicle sales and highest percentage per capita of electric vehicle sales in a year.

B. Establishing Governor's Awards for Businesses or Organizations. ODOE is directed to design and establish "Governor's Awards" that recognize businesses and organizations which support increased electric vehicle adoption, such as through installing charging infrastructure and converting fleets to electric vehicles.

8. **Implementation.** The implementation of this Executive Order shall be coordinated through a Zero Emission Vehicle Working Group, which will also identify any structural barriers or barriers to information sharing that may slow the progress of any directive in this Executive Order. The Zero Emission Vehicle Working Group will review directives in this Executive Order, seek input from interested stakeholders, and recommend opportunities to provide equitable access to clean energy by removing barriers to electric vehicles and electric vehicle chargers to the Governor and state agencies. The Zero-Emission Vehicle Agency Working Group shall include the following agencies: DAS, ODOE, OPUC, ODOT, and DEQ. ODOE will lead a collaborative effort through this interagency working group to develop goals, metrics, and other indicators of progress and will establish a website to share information about the directives in this Executive Order with the public. Agencies shall implement each directive in

this Executive Order using their existing internal processes and established rulemaking procedures, including recommendations from any boards. This Executive Order is intended to be consistent with obligations under federal and state law and shall be interpreted as to not violate any requirement of federal or state law.

9. The Governor encourages the Secretary of State, the State Treasurer, the Attorney General, and the Commissioner of the Bureau of Labor and Industries to adopt policies and practices to accelerate zero emission vehicle adoption consistent with measures in this Executive Order. DAS and ODOE are directed to assist the above-mentioned officials and entities of state government in accomplishing these objectives as they may request.

Done at Portland, Oregon, this 6th day of November, 2017.

OREGON FUEL ACTION PLAN

AUTHORITY

GOVERNOR'S AUTHORITY

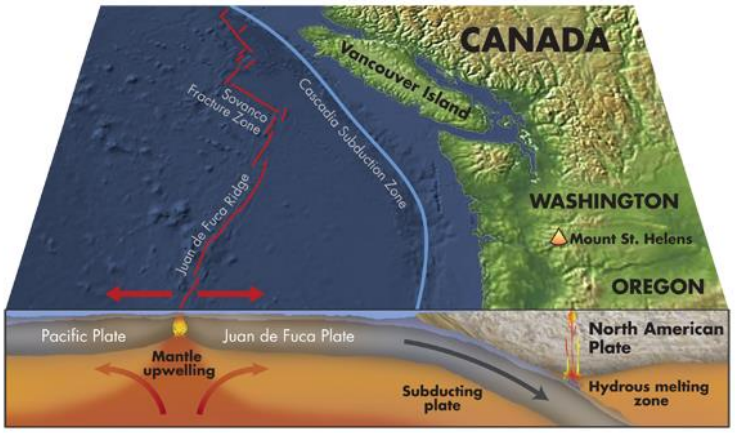
Oregon Revised Statute (ORS) 401 – grants the Governor of Oregon broad authority to protect the public by declaring a State of Emergency regardless of the cause. An emergency declaration gives the governor authority to control emergency operations in the affected area and to:

- Suspend provisions of any order or rule of any state agency
- Use and employ state personnel, equipment, and facilities
- Direct supplemental services and equipment

In the event the Governor is not available to perform the emergency powers described in ORS 401, the authority is next delegated to the Secretary of State, and then to the State Treasurer.

ORS 401.188 – additional powers granted to the governor during a declared emergency are outlined in the "Management of Resources." The governor may issue, amend, and enforce rules and orders to "Control, restrict, and regulate the use, sale or distribution of food, ***fuel***, clothing, and other commodities, materials, goods and services."

OREGON DEPARTMENT OF ENERGY AUTHORITY

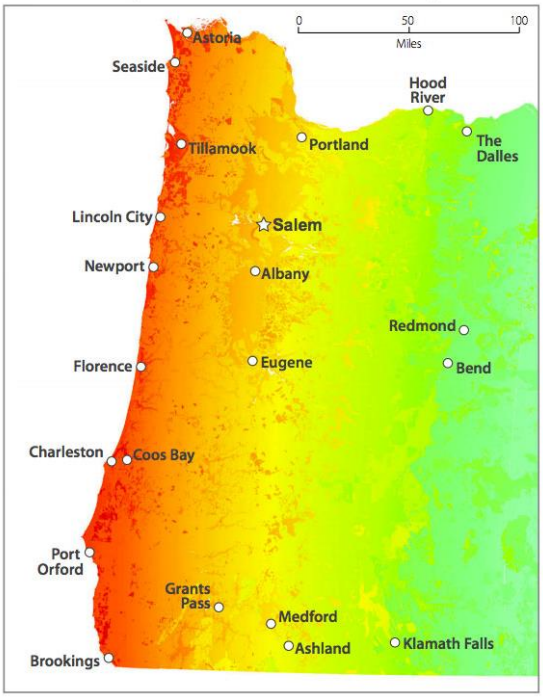


ORS 176.750-820 – authorizes the Oregon Department of Energy (ODOE) to develop and maintain a statewide contingency plan in response to petroleum shortages that impact Oregon. This includes providing adequate fuel supplies to maintain emergency services, transportation, and the operation of the economy to ensure the health, safety, and welfare of the residents of the State of Oregon while an emergency exists.

Emergency Support Functions (ESF) – There are 18 critical lifelines and services that, if disrupted, could threaten the health and safety of Oregonians. These critical lifelines and services are called Emergency Support Functions or ESFs. Each ESF sector has a designated lead state agency and federal agency. ODOE, along with the Oregon Public Utility Commission (PUC) is the designated Primary State Agency for ESF 12: Energy. ODOE is the lead for the petroleum sector. PUC is the lead for the electricity and natural gas sectors. ODOE works closely with the lead federal agency for ESF 12, the U.S. Department of Energy

(USDOE) to ensure the federal plans integrate and align with state strategies in preparation for responding to and recovering from fuel disruptions with potential impacts to Oregon.

PLANNING BASIS: WORST CASE SCENARIO



The Pacific Northwest region's most likely catastrophic event is the 9.0 Cascadia Subduction Zone (CSZ) earthquake and tsunami. Expected impacts include ground shaking for 4 – 6 minutes causing massive critical infrastructure damage along with a tsunami reaching some parts of the Oregon coast within 15 minutes of the quake.

The Federal Emergency Management Agency (FEMA) anticipates up to 25,000 fatalities, tens of thousands of people in need of shelter, and $30+ billion in economic losses.

Oregon counties in the high impact areas along the coast include: Clatsop, Tillamook, Lincoln, Lane, Douglas, Coos, and Curry counties. Mid-range impacted areas include the Portland metropolitan area with Washington, Multnomah, and Clackamas counties. Additional counties west of the Cascades in the mid-range impact areas include: Columbia, Yamhill, Polk, Marion, Benton, Linn, Jackson, and Josephine counties.

ShakeMap for SIMULATED M9 Cascadia earthquake

This event would devastate the region's petroleum supply and distribution system. Oregon can expect to lose most of the normal incoming supply of fuel. The Oregon Department of Geology and Mineral Industries (DOGAMI) 2013 Seismic Study found that the region's refineries and petroleum distribution terminals are expected to sustain moderate to significant damage. The facilities will have tank farm failures, marine dock failures, pipeline system breaks, hazardous material spills, fires, and structural damages onsite. Restoring the region's petroleum infrastructure would likely take months if not longer. In addition, the Olympic Pipeline that transports the majority of gasoline, diesel, and jet fuel to Oregon is projected to suffer as many as 250 breaks and 82 leaks.

ODOE has no regulatory authority to require its private sector partners to make seismic upgrades to their fuel tank farms, pipeline systems, marine docks, or other facilities. However, ODOE is responsible for ensuring the state can respond to a catastrophic event whenever it may happen and is prepared to address the impacts to the fuel infrastructure in its current state with all of its vulnerabilities.

The Oregon Fuel Action Plan was developed to address this need. It is designed to bring bulk fuel supplies into the state from outside the region to support the state's ongoing emergency response and recovery efforts until the regional infrastructure can be restored.

PLAN STRUCTURE

ODOE developed and maintains the Oregon Fuel Action Plan, which:

- Identifies ODOE's decision-making structure and authority to implement Oregon's Fuel Action Plan to provide adequate fuel supplies to emergency and essential service providers in Oregon in the event of a severe/long-term fuel disruption and shortage in the region.

- Identifies timelines for initiating and completing ODOE's nine priority missions called "Actions" to protect public health and safety and restore critical lifeline services during emergencies impacting the region's petroleum supply and distribution system.

- Provides mission analysis for completing each of the nine Actions. This includes identifying: key objectives and tasks; facts and assumptions; constraints and limitations; and gaps/information needed to complete the mission.

- Provides procedures for ODOE Agency Operations Center (AOC) activation and response positions to complete each mission. Each response position procedure includes key objectives, a checklist of tasks, guidance to accomplish objectives and tasks, and reference materials as appropriate.

- Identifies approved priority users and provides a structure and guidelines to request, justify, and receive emergency fuel to support mission critical functions to save lives, protect public health and safety, and restore critical lifelines and services.

- Aligns and integrates with federal, state, and county emergency response plans. This includes:

    - Federal Response Plan
    - Federal ESF 12: Energy Annex
    - State of Oregon Emergency Operations Plan
    - Cascadia Playbook
    - State ESF 12: Energy Annex
    - County emergency response plans
    - Tribal emergency response plans

- Identifies strategies to address all levels of fuel shortages and disruptions impacting Oregon.

PLAN ASSUMPTIONS

The Oregon Fuel Action Plan assumes that all state, local, and tribal organizations with emergency authorities and responsibilities to save lives, protect public health and safety, and restore critical lifeline

services have developed or are in the process of developing agency emergency response plans and strategies for responding to a catastrophic earthquake and tsunami. This includes:

- **ESF Primary State Agencies** – Designated ESF Primary State Agencies in Oregon have emergency response plans identifying all mission critical functions for its sector of responsibility. This includes a general understanding of the amount of fuel needed to perform identified missions.

  ESF 1: Transportation – Assess fuel needs to restore access and repair highways, roads, bridges, rail lines, and tunnels to support the transportation of goods and services and to perform other mission critical functions. *ESF Primary State Agency: ODOT.*

  ESF 2: Communications – Assess fuel needs to repair damaged communications systems and to perform other mission critical functions. *ESF Primary State Agencies: OPUC and Oregon Emergency Management (OEM).*

  ESF 3: Public Works – Assess fuel needs for debris removal from critical highways and for restoration of damaged public systems including: 1) highways, 2) water, sanitary sewage, and storm water systems, and 3) dams, levees, and other water control structures. *ESF Primary State Agency: ODOT.*

  ESF 4: Firefighting – Assess fuel needs for fire suppression, mobilizing Urban Search and Rescue Teams, and to perform other mission critical functions. *ESF Primary State Agency: Oregon State Fire Marshall (OSFM).*

  ESF 5: Information and Planning – Assess fuel needs to conduct a rapid needs assessment of the impacted areas and to perform other mission critical functions. *ESF Primary State Agency: OEM.*

  ESF 6: Mass Care – Assess fuel needs to identify and establish viable shelters and mass care facilities in the impacted areas and to perform other mission critical functions. *ESF Primary State Agency: Oregon Department of Human Services (DHS).*

  ESF 7: Resource Support – Assess fuel needs to deliver emergency relief supplies to impacted areas and to perform other mission critical functions. *ESF Primary State Agency: Oregon Department of Administrative Services.*

  ESF 8: Health and Medical – Assess fuel needs to mobilize professional/reserve medical personnel and supplies to impacted areas to triage and stabilize the wounded in impacted areas, perform casualty clearing/staging, and other mission critical functions. *ESF Primary State Agency: Oregon Heath Authority (OHA).*

  ESF 9: Search and Rescue – Assess fuel needs to deploy teams into impacted areas, transport injured individuals recovered from the scene, and to perform other mission critical functions. *ESF Primary State Agency: OSFM and OEM.*

  ESF 10: Hazardous Materials – Assess fuel needs to identify and deploy teams to contain oil and other hazardous materials spills from impacted areas and to perform other mission critical functions. *ESF Primary State Agencies: OSFM and Oregon Department of Environmental Quality.*

  ESF 11: Food and Water – Assess fuel needs to deliver food and water to shelters and isolated communities and to perform other mission critical functions. *ESF Primary State Agencies: Oregon Department of Agriculture and DHS.*

ESF 12: Energy – Assess fuel needs to assess and restore the petroleum, natural gas, and electricity supply and distribution systems and to perform other mission critical functions. *ESF Primary State Agencies: ODOE and OPUC.*

Note: ODOE is responsible for the petroleum sector. OPUC is responsible for the electricity and natural gas sectors.

ESF 13: Military Support – Assess fuel needs for the Oregon National Guard's air and ground response in support of civilian authorities. This includes the mission critical functions of all ESF Primary State Agencies and Oregon counties as appropriate. *ESF Primary State Agency: Oregon Military Department.*

ESF 14: Public Information – Assess fuel needs for the Public Information Sector to communicate emergency information to the news media and the public as appropriate. *ESF Primary State Agency: OEM.*

ESF 15: Volunteers & Donations – Assess fuel needs for the Red Cross and other non-profit agencies to provide shelter, roadway assistance, donations management, establish blood bank capabilities in impacted areas and to perform other mission critical functions. *ESF Primary State Agency: OEM.*

ESF 16: Law Enforcement – Assess fuel needs to protect life and property, provide traffic and crowd control, provide security for responders and critical facilities, and to perform other mission critical functions. *ESF Primary State Agency: Oregon State Police.*

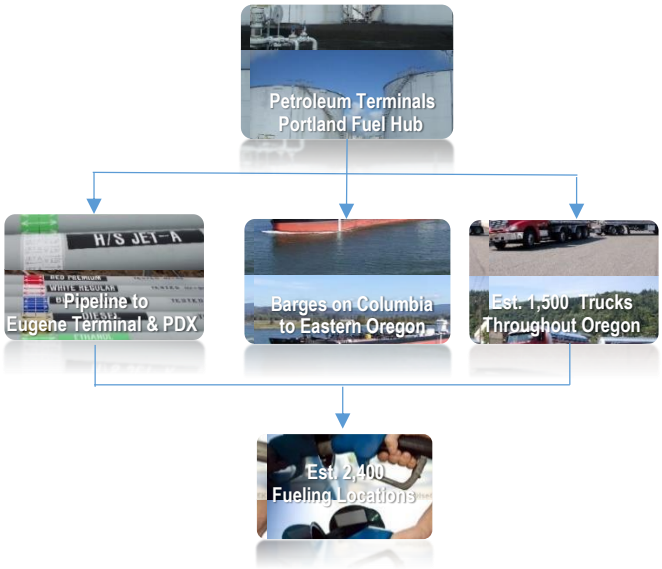
ESF 17: Animal Protection – Assess fuel needs to provide veterinary medical care, animal sheltering, animal carcass disposal and to perform other mission critical functions. *ESF Primary State Agency: OHA.*

ESF 18: Business and Industry – Assess fuel needs for the Business and Industry Sector as appropriate. *ESF Primary State Agency: OEM.*

- **County Emergency Management Agencies** – County emergency management agencies have emergency response plans identifying mission critical functions for the county and a general approximation of the fuel needed to perform identified missions. This includes the cities, special districts, and regional governments within county borders. County plans should have a fuel annex or section in their plans that identifies:
  - Priority tier 1 roads the county will restore to support fuel deliveries and other disaster relief commodities.
  - Fuel Points of Distribution (FPOD) to receive emergency bulk fuel supplies.
  - Methods to deliver the fuel from the designated FPODs to critical facilities and to the emergency responders in the field.
- **Federally-Recognized Tribes** – Tribes have emergency response plans identifying the mission critical functions of the tribe. This includes a general approximation of the amount of fuel needed to perform identified missions.

OREGON PETROLEUM INFRASTRUCTURE

Oregon does not have refining capabilities and imports 100 percent of the refined petroleum products used in the state. That is an estimated three billion gallons of fuel each year or roughly 250 million gallons each month.



Gasoline & Diesel Supply and Distribution System

More than 90 percent of the refined petroleum product used in Oregon come from four refineries located in the Puget Sound area of Washington State. Product is transported from the refineries in Washington to Oregon via the 400 mile Olympic Pipeline (est. 90 percent) and barges (est. 10 percent) entering the state at the Port of Portland where seven petroleum distribution terminals are located in what is called the Portland Fuel Hub.

Oregon receives the remaining less than 10 percent of the state's refined petroleum products from refineries in Salt Lake City, Utah and the California Bay Area. From Salt Lake City, the refineries transport product via Tesoro's Salt Lake Products Pipeline System to a distribution terminal in Pasco, Washington. From the Pasco facility, fuel is trucked into Oregon to service eastern Oregon communities. California Bay Area refineries supply minimal quantities of fuel to a Chico, California terminal and then product is trucked into Oregon to supply southern Oregon communities.

Portland Distribution Terminals (Fuel Hub) – From the Portland Fuel Hub, product is distributed throughout Oregon by:

- Two Pipelines – Kinder Morgan's pipelines link petroleum terminals in the Portland Fuel Hub with the petroleum distribution terminal in Eugene, Oregon and provide jet fuel to the Portland International Airport.
- Barges – Product is loaded onto barges from the BP, Chevron, and Phillips 66 marine docks and delivered up the Columbia River to Pasco to service eastern Oregon communities.

- Tanker Trucks – an estimated 1,500 tanker trucks deliver fuel throughout the state to about 2,400 fueling locations.

Jet Fuel and Aviation Gas Supply & Distribution System

Oregon imports about 15 million gallons of jet fuel each month (about 180 million gallons of jet fuel annually) from the refineries in Washington State. An estimated 90 percent of the jet fuel is transported via the Olympic Pipeline to the petroleum distribution terminals located at the Port of Portland Fuel Hub. The remaining estimated 10 percent of the jet fuel is transported by ship or barge directly to the Port of Portland.

From the Fuel Hub, the Kinder Morgan Pipeline transports the bulk of the jet fuel to the Portland International Airport. Jet fuel is delivered by truck to other airports and air fields in the state from the Fuel Hub.

Oregon also imports up to 170,000 gallons of aviation gasoline (AVGAS) each month (just over two million gallons annually) from Canada and Texas. AVGAS is transported by rail to the Chevron and Kinder Morgan terminals in the Fuel Hub then trucked to airports and airfields throughout Oregon.

Constraints and Limitations

The petroleum industry exercises a "just in time" business strategy. Refineries and distribution terminals maintain adequate supplies to meet expected demands under normal conditions. Because of this, a significant increase in demand regardless of the cause will likely result in a fuel disruption or shortage.

Crude Supply in Alaska – At any given time, there is less than one week of crude oil available at the Alaska Terminal that supplies Washington's four refineries.

Refineries in Washington – Refineries located in the Puget Sound area of Washington State also have about a one week supply of product on hand. These refineries have been operating above 90 percent capacity for decades. The refineries have no plans to increase capacity and cannot accommodate a dramatic demand increase.

Portland Petroleum Distribution Terminals – The seven terminals located in the Fuel Hub in Portland are on a six-day refueling cycle. At any given time, the Fuel Hub has only a one week supply of refined gasoline and diesel reserves on hand.

Retail Service Stations – Depending on the storage capacity and refueling cycles, retail service stations throughout the state have about a two to three day supply on site.

PETROLEUM SECTOR INTERDEPENDENCIES

The rapid recovery of the region's petroleum supply and distribution system is heavily dependent on other critical lifeline services. The fuel sector is reliant on other ESFs to gain situational awareness; conduct damage assessment; obtain and transport fuel to priority users; and support recovery operations in the aftermath of a Cascadia earthquake. These interdependencies include:

ESF 1: Transportation – Viable roads, highways, bridges, and waterways are essential to supporting fuel deliveries to priority users.

ESF 2: Communications – Viable communications are essential to ODOE's ability to: 1) assess impacts to the petroleum supply and distribution system; 2) work with USDOE and petroleum industry partners to obtain fuel from outside the region and transport it into Oregon; 3) facilitate emergency fuel requests and deliveries to priority users; 4) provide fuel sector situational awareness to key federal, state, and local emergency response agencies and other critical stakeholders; and 5) provide emergency information and instructions regarding critical fuel conservation measures to the news media and public.

ESF 12: Energy (Electricity) – Operators at the petroleum terminals need electricity to conduct damage assessments to the facilities, tanks, equipment, and systems. Power is essential to getting the fuel out of the storage tanks into delivery trucks. Electricity is also needed at designated fuel distribution points and emergency fueling locations for responders to fuel up their response vehicles. Electric power is also required for pipeline operation.

ABOUT FUEL ALLOCATION

Because there are no refineries in the state, Oregon is extremely vulnerable to fuel disruptions and shortages. The purpose of fuel allocation is to help alleviate shortages and hardships for priority users who save lives and restore critical infrastructure during severe and long-term fuel disruptions. Criteria for allocating fuel include:

1. Governor's Emergency Declaration.
2. Emergency and essential service providers unable to obtain fuel at any price.
3. Market forces, voluntary fuel conservation, and/or mandatory fuel conservation measures fail to provide for adequate and equitable distribution of fuel.

Set-Aside Volume: Non-Catastrophic Events *(Viable Fuel Infrastructure)* - If fuel allocation becomes necessary, ODOE would administer the state's Fuel Allocation Program. The first step is to designate the Set-Aside Volume. The Set-Aside Volume is the amount of fuel ODOE will request from the state's petroleum industry partners (oil companies) to designate solely to support Oregon's response and recovery efforts.

The Set-Aside Volume Percentage will be no larger than what is expected to be required to meet emergency supply needs based on the amount of fuel already in the state in storage and the amount estimated to enter the state from the prime suppliers each month.

Set-Aside Percentages Monthly Fuel volume from Oregon Supplies	
Motor Gasoline	up to 5 percent
Middle distillate (diesel & heating oil)	up to 4 percent
Jet Fuel	up to 5 percent
Aviation Gasoline	up to 5 percent

The Fuel Allocation Program is designed to: 1) interfere minimally with the market, 2) make no attempt to reduce or inhibit the market price of fuels, and 3) ensure all fuel delivered through the program is purchased at the market price, and whenever possible, through the usual supplier. ***Note:*** *Refer to Appendix H for details.*

Set-Aside Volume: Cascadia Subduction Zone Earthquake *(Fuel Infrastructure Devastated)* – Experts anticipate severe damage to the region's petroleum supply and distribution system from a catastrophic earthquake. This would likely shut down the operations of the region's refineries, pipelines, and petroleum distribution terminals for months. ODOE would work with the oil companies, USDOE, FEMA, and the military to identify and deliver an alternate fuel supply from outside of the region to support the state's emergency response and recovery efforts. No set-aside volume would be implemented. ODOE would initially allocate **ALL** of the fuel brought into Oregon to the state's emergency and essential service providers to save lives, protect public health and safety, and to restore critical infrastructure and lifeline services.

FUEL ALLOCATION STRUCTURE

Allocating fuel is a huge undertaking. Oregon has nearly 120 state agencies with varying degrees of emergency response duties and capabilities. The state has 36 counties with more than 240 cities. Each jurisdiction has its own emergency and essential service providers. ODOE would easily be overwhelmed if we were to receive fuel requests from all of these entities individually.

As a result, ODOE streamlined its process and designed a structure for fuel allocation. Those who qualify for emergency fuel fall under three categories. Our priority users include:

- 18 ESF Primary State Agencies
- 36 County Emergency Management Agencies
- 9 Federally-Recognized Tribes

All fuel requests will be filtered through one of these pre-approved priority users.

MAINTAINING OREGON FUEL ACTION PLAN READINESS

ODOE will work with industry, federal, state, local, and tribal emergency response organizations to ensure a collaborative and seamless response to a long-term or severe fuel shortage or disruption with potential impacts to the State of Oregon.

Training – Training is essential to maintain program readiness to protect public health and safety in the event of a Cascadia Subduction Zone earthquake and tsunami or other disaster scenario impacting Oregon's fuel supply and distribution system. ODOE will work with industry, federal, state, and local emergency response organizations to coordinate, implement, and participate in workshops, drills, tabletops, and exercises as needed to ensure program readiness.

Plan Review and Update - ODOE will review and update the Oregon Fuel Action Plan annually or as needed. Revisions will include lessons learned from drills and exercises. ODOE will coordinate reviews and revisions with industry, federal, state, local, and tribal emergency response organizations.

Public Outreach – ODOE will also work to improve public awareness of and confidence in the Oregon Fuel Action Plan by providing information on ODOE's web page, giving presentations about the program, and producing materials to be distributed to the news media and made available at libraries, schools, hospitals, and other locations as appropriate.

FOR MORE INFORMATION

For more information about the Oregon Fuel Action Plan, contact the Oregon Department of Energy's Nuclear Safety & Energy Emergency Preparedness Division at 503-378-4040 or the agency's Energy Emergency Preparedness Manager at 503-932-4428.

Oregon Fuel Action Plan: Nine Priority Actions

Action 1	Action 2	Action 3	Action 4	Action 5	Action 6	Action 7	Action 8	Action 9
Notification Activation and Authorities	**Public Information**	**Damage Assessment**	**Assess Fuel Needs & Determine Priorities**	**Outside Assistance: Fuel Supply**	**Fuel Conservation Measures**	**Temporary Waivers**	**Fuel Allocation**	**Recovery**

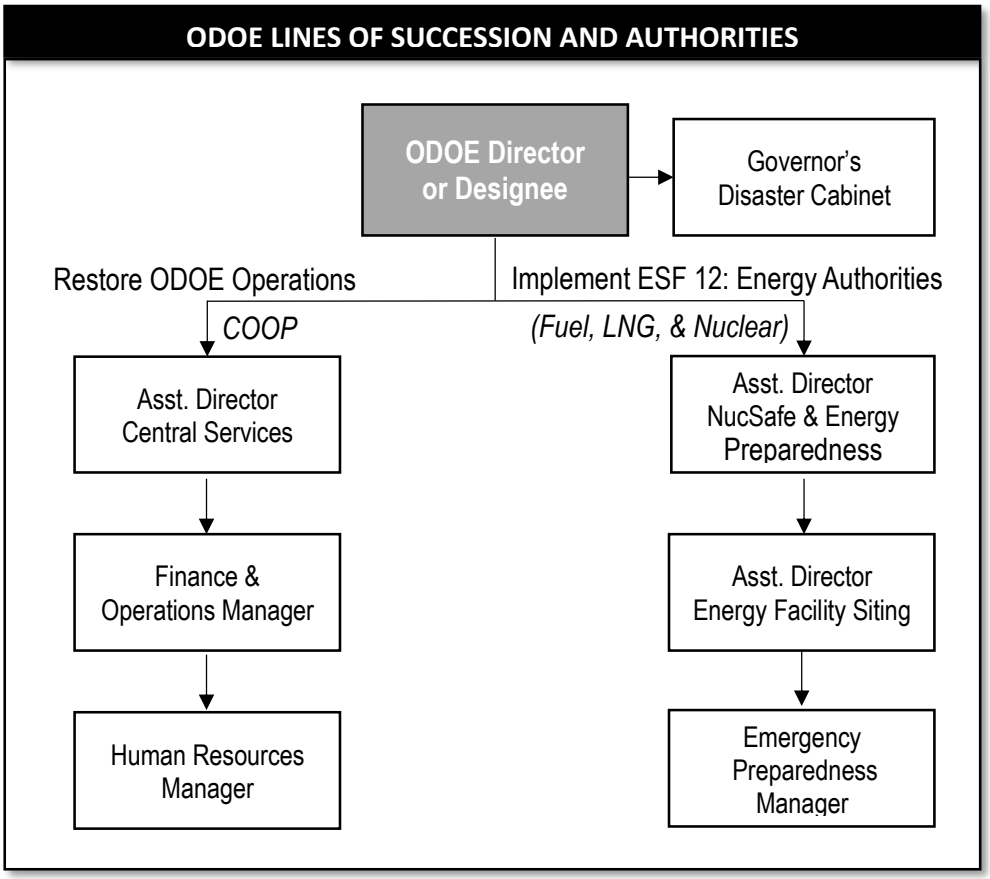
ACTION 1

Notification, Activation, and Authorities

0 – 12 HOURS TO INITIATE - ESTIMATED COMPLETION 96 HOURS	
Mission Analysis	
Objectives/Tasks • Assess availability of ODOE staff. • Determine lines of succession and authorities. • Assess ODOE facility conditions. • Activate the ODOE Agency Operations Center (AOC) if possible, or relocate to state-designated alternative location. • Make initial notifications.	**Facts/Assumptions** • Significant ground shaking (5 + minutes). • Significant damage to region's communications systems. • ODOE response structure disrupted due to personnel injuries and loss of life. • ODOE facility integrity breached disrupting operations. Implement Continuity of Operations Plan (COOP).
Constraints/Limitations ➢ ODOE facility not seismically sound – building may not be habitable in the aftermath of a significant earthquake. ➢ Notifications may be limited to amateur radio, satellite phone, texting and social media with most communications systems down (phone lines, internet, emails, etc.).	**Gaps/Requests for Information** *Prior to Event:* ➢ Develop lines of succession and authorities. ➢ Designate alternate facility - ODOE (COOP). ➢ Identify viable communications for making initial notifications (texting, social media tools, satellite phones, etc.) ➢ Identify ODOE or other volunteer Amateur Radio Emergency Services (ARES) operators to support agency communications. *After an Event:* • Identify ODOE personnel able to respond.
ODOE Response Positions: ➢ ODOE Assistant Director, Nuclear Safety and Energy Emergency Preparedness Division ➢ ODOE Emergency Preparedness Manager ➢ ODOE Duty Officer(s) ➢ AOC Manager ➢ AOC Facilities Specialist ➢ Other Responders as Appropriate **Procedures**: Procedures for ODOE AOC activation and response positions are included in Appendix J of this Plan. Each response position procedure includes key objectives, checklist of tasks, guidance to accomplish objectives and tasks, and reference materials as appropriate.	
Note: ODOE NSEEP Division staff have pre-approved access to and can respond from the following facilities: 1. Oregon State Emergency Coordination Center (ECC) at the Anderson Readiness Center. 2. Washington State Emergency Operations Center (EOC) at Camp Murray.	

Task 1: Assess the availability of ODOE staff.

Note: *In the event of a CSZ earthquake, significant ground shaking (5+ minutes) is considered the initial notification.*



a. ODOE Duty Officer notifies the Assistant Director of NSEEP Division, the Emergency Preparedness Manager, and NSEEP Division staff.

b. The Assistant Director of NSEEP Division or Emergency Preparedness Manager will notify the ODOE Director and Executive Management Team.

c. ODOE's Executive Management Team notifies respective division staff.

Task 2: Determine and activate ODOE lines of succession and authorities.

a. The ODOE Director or authorized designee will implement the agency lines of succession as follows:

Note: *The line of succession is subject to change at the discretion of the ODOE Director or designee.*

b. Exercise authorities and implement the Oregon Fuel Action Plan in response to a state declared emergency resulting in a severe or long-term petroleum shortage with potential impacts to the health and safety of Oregonians. ODOE authorities include:

- ORS 176.750-785 - Energy Resources Emergency Powers authorizes ODOE to develop and maintain a statewide contingency plan in response to petroleum shortages or disruptions that impact the state. This includes the state's Fuel Allocation Program.

- ORS 469.080 - gives the ODOE Director subpoena power to obtain information from producers, suppliers and consumers of energy resources in Oregon on the status of their operations, damage assessments, fuel supply availability, estimated repair times, and overall recovery efforts.

- ORS 469.090 – authorizes the ODOE Director to keep confidential if requested by the provider any information that is proprietary in nature.

Task 3: Assess ODOE facility conditions.

a. ODOE's Assistant Director of the Central Services Division will work with the building owner/manager and others as appropriate to assess the severity of the damages to the building.

b. Upon completion of the damage assessment, determine the status of the facility's condition and make a recommendation to ODOE's Executive Management Team. Assessment and recommendations include:

- ODOE personnel are safe to re-enter the building.

- Only essential ODOE personnel may re-enter the building. ODOE's Executive Management Team identifies essential personnel to perform critical functions as appropriate. This is dependent on the nature of the facility damage, event conditions, and other pertinent factors as appropriate.

- ODOE facility is closed until further notice and personnel are not to re-enter the building. Instruct ODOE staff to standby for further instructions.

c. If ODOE facility is not structurally sound, ODOE's Assistant Director of the Central Services Division will initiate the agency's COOP as appropriate.

Task 4: Begin ODOE AOC Activation *(ODOE or COOP facility)***.**

a. The Assistant Director of the NSEEP Division, Emergency Preparedness Manager, or authorized designee will activate the ODOE AOC to monitor impacts to Oregon's petroleum supply and distribution system. NSEEP Division Responders include:

- Assistant Director of NSEEP Division
- Emergency Preparedness Manager
- ODOE Duty Officer

b. Upon activation, the following responders will report to the ODOE AOC or to the COOP location as directed depending on event conditions. This includes:

- ODOE Director
- Petroleum Event Manager
- Fuel Supply Assessor
- Petroleum Industry Liaison
- County Liaisons
- State Agency Liaison *(reports to the OR ECC upon activation)*
- Federal Agency Liaison
- Public Information Officer (PIO)
- Social Media Liaison
- AOC Manager
- AOC Facilities Specialist
- *Other response positions as appropriate*

Appendix I: ODOE AOC Response Structure Chart

Note: *Multiple positions can be filled by one individual with approval by the Assistant Director of NSEEP or the Emergency Preparedness Manager.*

c. Upon Activation of the OR ECC, ODOE will send the State Agency Liaison to the OR ECC to serve as the Primary State Agency representative for ESF 12: Energy *(specific to the petroleum sector)*.

Note: *For large scale events requiring a joint federal-state response, a Joint Field Office (JFO) may be established. ODOE will respond to the Oregon ECC or the JFO as appropriate.*

Task 5: Make initial notifications.

a. The ODOE Director or authorized designee will notify the governor of the emergency situation resulting in a severe or long-term fuel disruption with potential impacts to the health and safety of Oregonians. This includes:

- Advising the Governor that an executive order *(Appendix F: Fuel Executive Order)* may need to be issued authorizing ODOE to implement the strategies in the Oregon Fuel Action Plan in response to the fuel emergency.

b. The ODOE Director or authorized designee will notify the legislative branches of the emergency situation resulting in a severe or long-term fuel disruption with potential impacts to the health and safety of Oregonians as appropriate. This includes:

- Senate Leadership
- House Leadership

c. Notify the Oregon Emergency Response System (OERS) to inform OERS about ODOE AOC activation status.

d. Notify the Oregon Military Department (OMD) and request OMD contact Department of Defense's (DOD) Defense Logistics Agency (DLA) to activate the Federal Emergency Management Agency's (FEMA) fuel purchasing contract authorizing DLA to purchase bulk fuel to support Oregon's emergency response and recovery activities.

   Note: FEMA contracts with the Department of Defense (DOD) for fuel support during presidential declared disasters to meet civilian and government fuel needs. DOD's Defense Logistics Agency has the capability to purchase bulk fuel and trucks to deliver the fuel to FEMA designated locations. The bulk fuel can be further re-deployed to the impacted communities as directed by FEMA in coordination with state authorities as needed. This includes delivering bulk fuel to existing tanks as well as refuel fleet vehicles and first responder vehicles such as ambulances and fire trucks. In response to Hurricane Sandy, the Defense Logistics Agency purchased 12 million gallons of gasoline and 12 million gallons of diesel fuel. The agency has 260 fuel trucks on contract for fuel distribution.

e. Notify USDOE, the Federal ESF 12: Energy Primary Agency. Notifications include:

   - USDOE Headquarters Duty Officer about the emergency in Oregon and to request information and situation awareness on the impacts to the region's petroleum supply and distribution system.

   - USDOE Region X Field Office in Richland, WA to request USDOE presence and support in Oregon in response to the emergency.

f. Notify the U.S. Coast Guard (USCG) at Sector Columbia River to request initial information on waterway and fuel terminal conditions.

g. Notify the Washington Emergency Management Agency (WA EMD) regarding ODOE AOC activation status and to share initial emergency information between Oregon and Washington regarding impacts to the region's petroleum supply and distribution system.

ACTION 2

Public Information

8 - 24 HOURS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS	
ODOE Mission Analysis	
Objectives/Tasks • Develop and disseminate Oregon fuel sector information to federal, state, local, tribal, and industry emergency response partners. • Participate in the Oregon Joint Information Center news briefings to provide fuel sector information to the news media and the public. • Monitor national, regional, and local news media and social media outlets to identify and address misinformation, rumors, and concerns. • Coordinate with USDOE and the State of Washington to ensure consistent fuel messaging prior to an Oregon Fuel Sector Information release to the Public	**Facts/Assumptions** • Significant damage to the region's communications Infrastructure: - No landlines. - Limited internet or wireless services. • Limited power to charge cell phones or other communication devices. • Communications companies' response structure disrupted due to personnel Injuries and loss of life resulting in significant delays in restoring communication systems.
Constraints/Limitations • Fuel and viable transportation routes required for restoring communications towers and systems. ➢ Power required to sustain communications systems needed to get information out to the news media and public.	**Gaps/Requests for Information** *Prior to Event* ➢ Identify and test all primary and backup communication methods to provide fuel sector information to stakeholders. ➢ Identify and train ODOE employees interested in getting certified to operate Amateur Radio during emergencies. *After an Event* ➢ Use backup communication methods (satellite phones, texting, amateur radio, social media) to provide fuel sector information to all stakeholders until normal communications channels are restored.
ODOE Response Positions: ➢ Petroleum Event Manager ➢ PIO ➢ Deputy PIO ➢ Social Media Liaison ➢ News Center Manager ➢ Telephone Information Manager ➢ Phone Team Operators ➢ Other Response Positions as Appropriate	

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.
Note: Boilerplate news releases, fuel conservation tips, news media information packet, and other fuel sector information exist on file in the procedures of the ODOE PIO Team for use and can be modified as appropriate to address different event situations and conditions.

Task 1: Develop and widely disseminate news releases, situation reports, or other messages on Oregon fuel sector information to provide situation awareness to a broad audience. This includes
:

- Governor
- Legislative leadership
- Federal, state, and local emergency response partners
- Federally-Recognized Tribes
- Petroleum industry partners
- News media
- Public
- Other stakeholders as appropriate

Information to be developed for dissemination includes:

- Oregon's fuel supply outlook
- Event impacts to the region's petroleum infrastructure
- ODOE's actions and decisions in response to the fuel shortage/disruption
- Fuel Conservation Measures recommended for the public
- Fuel allocation for emergency services, essential services, and public
- Warnings against price gouging, topping off tanks or hoarding of fuel
- Tips on conserving fuel
- Links to petroleum industry, federal, state, and local websites with information on the region's energy infrastructure
- Other information as appropriate

Task 2: Participate in the Oregon Joint Information Center (JIC) briefings and news conferences to provide fuel sector information.

a. Develop key messages, rehearse walk-through, and participate in JIC briefings and news conferences.

b. Compile news media kits. These include, but are not limited to brochures, factsheets, and other pre-printed materials that provide general information about Oregon's petroleum supply and distribution system under normal conditions. The kits also include news releases with event conditions, supply disruption status, recommendations for voluntary and emergency conservation measures, information on state decisions and actions in response to the fuel event, and industry actions taken to restore the petroleum infrastructure.

Task 3: Monitor national, regional, and local news media and social media outlets to identify and address misinformation, rumors, and concerns involving Oregon's fuel outlook. This includes, but is not limited to:

a. Requesting Virtual Operations Support Teams (VOST) support from OEM to:

- Monitor trends and rumors involving the region's fuel supply and distribution system as well as other fuel sector information.
- Monitor social media for information involving public concerns and other fuel sector information.
- Gain situational awareness in the impacted communities.
- Reinforce official sources for fuel sector information.

b. Monitoring fuel via VOST at the following sites:

- t: https://twitter.com/OregonVOST
- f: https://www.facebook.com/OregonVOST
- i: https://instagram.com/oregonvost
- w: http://oregonvost.com/about/

Note: VOST provides communication support through internet connected social media devises (Twitter, Facebook, and other messaging devises).

Task 4: Coordinate fuel sector information and messages with USDOE and Washington State's public information officers as appropriate to ensure consistent messages are released to the public, news media, and social media outlets.

Task 5: Establish and maintain Emergency Fuel Outlook Page on the ODOE website when internet and wireless access becomes available**.**

Task 6: Implement Public Information Campaign to reduce fuel consumption and to encourage motorists to practice responsible driving and vehicle maintenance to save on fuel.

Note: *See also voluntary and mandatory fuel conservation measures in Action 6.*

Task 7: Establish and operate the ODOE Telephone Information Center when communications systems are restored**.** When activated, the Telephone Information Center call-in number is 1-800-906-9701. Telephone Information Center Operators are trained to:

a. Receive and address public questions and concerns regarding Oregon's fuel situation and what ODOE is doing in response to the shortage/disruption in supply.

b. Provide information on Oregon's fuel outlook, ODOE's actions and decisions in response to the fuel shortage/disruption, Fuel Conservation Measures recommended for the public, and fuel allocation, as well as warnings against price gouging, topping off tanks or hoarding of fuel, and other information as appropriate.

c. Receive and address media inquiries, clarify misinformation and rumors, and reiterate state actions and decisions in response to the fuel supply shortage/disruption.

d. Direct the public and media to the Emergency Fuel Outlook page on ODOE's Website for more information.

ACTION 3

Damage Assessment

8 – 24 HOURS TO INITIATE - ESTIMATED COMPLETION 21 DAYS

ODOE Mission Analysis

Objectives/Tasks

- Assess state, regional, and national impacts to the petroleum supply and distribution system.
- Assess estimated timelines for repairs.
- Provide petroleum sector situation awareness and status updates.

Facts/Assumptions

Significant damage to the region's:

- Communications systems.
- Transportation infrastructure.
- Power infrastructure.
- Petroleum response structure disrupted due to personnel injuries and loss of life.

Constraints/Limitations

Refinery, Terminal, and Pipeline Interdependencies:

- Viable roads and bridges to provide access to facilities and pipeline systems.
- ➢ Power to conduct engineering assessments on facilities, equipment, and systems.
- ➢ Communication to report the status of facility conditions and to request assistance.
- ➢ An overwhelming number of requests for aerial assessments requiring coordination.

Gaps/Requests for Information

Prior to Event

- ➢ Identify potential assistance needed by the Portland and Eugene terminals and pipeline operators to gain access to facilities, assess damages, and mitigate problems to restore operations. This includes, but is not limited to:
  - Viable roads
  - Generators
  - Communications
  - Security
  - Water
  - Access to state/federal staging area

After the Event

- ➢ Identify actual state assistance needed by the Portland and Eugene terminals & pipeline operators to restore Oregon's petroleum infrastructure.

ODOE Response Positions:

- ➢ Petroleum Event Manager
- ➢ Fuel Supply Assessor
- ➢ Petroleum Industry Liaison
- ➢ Federal Agency Liaison
- ➢ State Agency ESF Liaison
- ➢ Other Response Positions as Appropriate

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.

Notes: Petroleum and Eugene Terminals - Once operators have access to their facilities, adequate power, and communications, an estimated 72 hours is required to complete damage assessments to facilities, equipment and systems.

Olympic Pipeline Company – Pipeline operators also estimate 72 hours to assess damages before repairs are made. Prior to restarting the line, pipeline personnel must walk the entire 400 mile line to ensure pipeline integrity. The portion of the pipeline that impacts Oregon runs 299 miles from Blaine, Washington to the Portland Fuel Hub.

Task 1: Establish and maintain communications and work with the Portland & Eugene petroleum distribution terminals to:

a. Support terminals as appropriate to ensure safe conditions onsite.

b. Identify, request, and facilitate the delivery of state and/or federal assistance needed by petroleum terminal operators to conduct damage assessments. This includes, but is not limited to:

ESF 1: Transportation – Work with the Oregon Department of Transportation (ODOT) to:

- Identify lifeline roadways, bridges, and tunnels to the terminals.
- Provide transportation of company responders to the terminals.

ESF 2: Communications – Work with the Oregon Public Utility Commission (OPUC) and Oregon Emergency Management (OEM) to:

- Establish communications between ODOE and the terminals.
- Coordinate the provision of temporary communications capabilities to the terminals.

ESF 3: Public Works – Work with ODOT to:

- Assist the terminals to stabilize hazardous infrastructure and systems to prevent additional injuries and/or damages.
- Develop strategies for the provision of potable water to the terminals.

ESF 5: Information and Planning – Work with OEM to:

- Provide oil companies access to federal-state staging areas to deliver personnel, equipment, and resources from outside our region to support the restoration of the terminals and the petroleum infrastructure.

ESF 10: Hazardous Materials – Work with the Oregon State Fire Marshall's Office (OSFM) and the Oregon Department of Environmental Quality (DEQ) to:

- Assist terminals to contain oil spills and hazardous material spills onsite.

ESF 12: Energy – Work with PUC to:

- Ensure utility companies make power restoration a priority to the Portland Fuel Hub and Eugene Terminal to ensure timely damage assessment at the terminals.
- Ensure generators are provided to the terminals to support initial damage assessment activities until power can be restored to the Portland Fuel Hub and Eugene terminal.

ESF 13: Military Support – Work with the Oregon Military Department (OMD) to:

- Secure aerial surveillance to assess impacts to the region's petroleum supply and distribution system. This includes the refineries, pipelines, and fuel terminals in Portland and Eugene, and the Willamette and Columbia River shipping channels.
- Obtain and deliver generators to the terminals.
- Build temporary roads to provide operators access to the terminals.

Note: ODOE will develop pre-scripted missions under Annex E of this plan for the fuel sector. The pre-scripted missions will identify the type and level of support the agency will require from federal and military agencies to accomplish the actions and objectives of the Oregon Fuel Action Plan.

ESF 16: Law Enforcement – Work with Oregon State Police (OSP) to:

- Provide security at the Portland Fuel Hub and the Eugene terminal.

c. Receive and review with petroleum terminal managers' damage assessment findings. This includes, but is not limited to:

- Fuel Supply (unleaded, diesel, jet fuel, and aviation gas)
- Tank Farms
- Pipeline Systems
- Containment Areas
- Marine Docks
- Loading Racks
- Other as appropriate

Note: In the aftermath of a Cascadia Subduction Zone earthquake, ODOE will likely rely on USDOE to gather initial damage assessment data on Oregon and the region's petroleum supply and distribution system. USDOE will have communications capabilities and access to the petroleum industry at the corporate level.

d. Confirm with petroleum terminal managers the estimated timeline for repairs to the damages to the terminals, equipment, systems, and operations.

Note: Seismic vulnerability studies by the Oregon Department of Geology and Mineral Industries (DOGAMI) and the U.S. Department of Homeland Security (DHS) show that the Portland Fuel Hub would be devastated from earthquake impacts and may likely be shut down for more than three months if not longer as a result of a Cascadia Subduction Zone earthquake.

e. Provide damage assessment findings, estimated timeline for repairs, and status updates on petroleum terminal response activities in Command and General Staff Briefings, Governor's Disaster Cabinet Briefings, OR ECC briefings, situation reports, news releases, news conferences, and other forums as appropriate.

Task 2: Establish and maintain communications and work with pipeline companies to:

a. Receive and review with pipeline operators damage assessments to pipelines for line breaks, product leaks, and destruction to the pressure stations' equipment and systems located throughout the pipeline.

- Olympic Pipeline Company – connects refineries in the Puget Sound area of Washington State to the Portland Fuel Hub.
- Kinder Morgan Pipeline – connects the Portland Fuel Hub to the Portland International Airport and to the Eugene terminal.

b. Confirm with pipeline operators the estimated timeline for repairs to the damaged pipeline equipment and systems.

Note: DOGAMI and FEMA seismic vulnerability studies show that the Pacific Northwest liquid fuel pipelines may likely be shut down more than three months if not longer as a result of a Cascadia Subduction Zone earthquake.

c. Confirm with pipeline operators the estimated timeline for pipeline inspectors to walk the entire line prior to restarting.

d. Provide damage assessment findings, estimated timeline for repairs, and status updates on pipeline response activities in Command and General Staff Briefings, Governor's Disaster Cabinet Briefings, OR ECC briefings, situation reports, news releases, news conferences, and other forums as appropriate.

Task 3: Establish Communications and work with refineries located in the Puget Sound area to:

a. Receive and review with refinery operators damage assessments to the refinery facilities and impacts to the region's fuel supply.

b. Confirm with refinery operators the estimated timeline for repairs to the damaged facilities, equipment, and systems.

Note: FEMA seismic vulnerability studies show that the refineries in Washington may likely sustain moderate to significant damage and remain shut down for more than three months if not longer as a result of a Cascadia Subduction Zone earthquake.

c. Provide damage assessment findings, estimated timeline for repairs, and status updates on refinery response activities in Command and General Staff Briefings, Governor's Disaster Cabinet Briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate.

Task 4: Establish and maintain communications with the oil companies (corporate offices), USDOE and Washington Department of Commerce (WDOC) State Energy Office to:

a. Receive and review with industry, USDOE, and WDOC the regional and national energy sector impacts as a result of the CSZ earthquake.

b. Receive and review with industry, USDOE, and WDOC the regional and national fuel availability to support Oregon and Washington emergency response efforts.

c. Begin collaborating with USDOE and WDOC to obtain bulk fuel supplies and to coordinate the logistics for fuel delivery into Oregon and Washington from outside of the region to support emergency response efforts.

Note: USDOE, FEMA, and other federal agencies and military would convene a National Fuel Task Force, which includes the petroleum industry to coordinate obtaining bulk fuel supplies and coordinating logistics to deliver fuel to the impacted states. *See Action 5 for more details.*

d. Provide information on available fuel supplies and strategies to obtain fuel from outside of the region into Oregon and Washington in Command and General Staff Briefings, Governor Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate.

Task 5: Establish and maintain communications and work with USCG to:

a. Receive and review with USCG damage assessments to marine docks, bridges, and other structures obstructing fuel deliveries along the Willamette and Columbia Rivers.

Note: According to DHS earthquake studies it will take at least three weeks to assess damages along the Willamette and Columbia Rivers and months to reopen the river system and shipping channels as a result of jetty failures, dike system failures, collapsed bridges and structures, and vessels running aground.

b. Confirm with USCG the estimated timeline for repairs to marine docks, bridges and other structures as well as river debris removal to clear the Willamette and Columbia Rivers to support fuel transports by barge or tanker vessels.

c. Provide damage assessment findings, estimated timelines for repairs and debris removal, and status updates in Command and General Staff Briefings, Governor's Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate.

Task 6: Establish and maintain communications and work with DHS Infrastructure Security to:

a. Notify Oregon's Department of Homeland Security (DHS) Protective Security Advisor to request bulk fuel supplies on the Special Event and Domestic Incident Tracker to initiate the process for securing bulk fuel supplies to Oregon from outside of the region.

Note: Once Oregon's request is in the DHS queue, ODOE will need to follow up by completing a FEMA resource request form to complete the resource request process.

b. Confirm the federal Incident Support Base (ISB) for the event.

Note: Pre-designated federal Incident Support Bases for a Cascadia Subduction Zone earthquake include: 1) Redmond Airport, 2) Klamath Falls Airport, and 3) Boise, Idaho. Refer to Appendix B.

c. Receive and review with the Protective Security Advisor damage assessments to other critical infrastructure with the potential to impede access and delivery of bulk fuel supplies to Oregon.

Note: Oregon has its own designated Protective Security Advisor from DHS to assist the state with identifying and resolving critical infrastructure security concerns during emergencies. Oregon's Protective Security Advisor will respond to the Oregon ECC, JFO, or other alternate state response location as appropriate.

d. Confirm with the Protective Security Advisor the estimated timeline needed to resolve critical infrastructure concerns with the potential to impede access and delivery of bulk fuel supplies to Oregon.

e. Provide critical infrastructure concerns with the potential to impede access and delivery of bulk fuel supplies to Oregon and possible resolutions in the Command and General Staff Briefings, Governor's Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate.

Task 7: Establish and maintain communications and work with ODOT to:

a. Receive and review with ODOT damage assessments to the state's priority lifeline routes to support fuel deliveries and other disaster relief commodities.

b. Receive and review damage assessments to the rail system to support fuel deliveries and other disaster relief commodities.

c. Confirm with ODOT the estimated timeline for repairs to the state's priority lifeline routes and rail systems to support fuel deliveries and other disaster relief supplies by road and by rail.

Task 8: Establish and maintain communications and work with Oregon Department of Aviation (Aviation) to:

a. Receive and review with Aviation damage assessments to the airports and air fields in the state to support fuel deliveries and other disaster relief commodities.

b. Confirm with Aviation the estimated timeline for repairs to the airports and air fields to support fuel deliveries and other disaster relief supplies by road and by rail.

Task 9: Establish and maintain communications and work with Oregon Emergency Management (OEM) to:

a. Receive and review with OEM damage assessments to the pre-designated State Staging Areas (SSA) and Forward Staging Areas (FSA) to support fuel deliveries and other disaster relief commodities.

Note: Refer to Appendix B.

b. Confirm with OEM the approved SSAs and FSAs to support fuel deliveries and other disaster relief supplies closer to the impacted areas.

ACTION 4

Assess Fuel Needs and Determine Priorities

24 - 76 HOURS TO INITIATE - ESTIMATED COMPLETION 21 DAYS

ODOE Mission Analysis

Objectives/Tasks

- Assess fuel supply availability in Oregon to support initial mission critical functions.
- Work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to assess fuel needs to conduct mission critical functions.
- Prioritize statewide fuel needs.

Facts/Assumptions

Significant damage to region's:

- Communications systems.
- Transportation infrastructure.
- Power infrastructure.
- State, county, and tribal response structures disrupted due to personnel injuries and loss of life.

Constraints/Limitations

- ➢ Timely and comprehensive assessments are contingent on the quality and level of fuel assessments completed by each lead state agency, county, and tribal government prior to a Cascadia Subduction Zone earthquake and tsunami.
- ➢ Viable road access to/from pre-identified fuel stockpiles and power to access fuel supply at fuel sites within the counties and communities.
- ➢ Communications capabilities required to convey fuel needs and priorities to ODOE.

Gaps/Requests for Information

Prior to Event

ODOE will work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to identify:

- Available in-state fuel supplies and storage capacity within each ESF sector, county, and tribal land.
- ➢ Personnel, equipment, and resources requiring fuel to perform mission critical functions for each sector, community, and tribe. This includes having a general understanding of fuel required and systems interdependencies.

After an Event

- ➢ Secure Governor emergency declaration to authorize state, local, and tribal emergency response organizations to use available in-state fuel (gasoline, diesel, jet fuel, and aviation gas) supplies to perform initial mission critical functions.
- ➢ Prioritize statewide fuel needs.

ODOE Response Positions:

- ➢ ODOE Director
- ➢ Petroleum Event Manager
- ➢ Fuel Allocation Coordinator
- ➢ State Agency ESF Liaison
- ➢ County Liaison Manager
- ➢ County Liaison(s): Regions 1 – 5 *(as needed)*
- ➢ Tribal Liaison
- ➢ Other Response Positions as Appropriate

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.

Task 1: Review ODOE's fuel database of above and underground fuel storage tanks in the state by county and city.

Note: The database lists owner/operator names, type of fuel site (motor pool, public works yard, card lock, airport, or other) physical address, latitude and longitude locations, number of tanks on site, tank size, fuel type and backup power capabilities (generator or generator connection installed on site). ODOE compiled the fuel information from DEQ, OSFM, and ODA fuel databases and then modified the data to support fuel allocation strategies.

Task 2: Work with state, county, and tribal emergency response organizations to assess existing fuel supply availability in Oregon to support initial life safety and other mission critical functions. This includes determining the duration the supplies are expected to last.

Note*:** Planning basis approximates ***3 weeks before bulk fuel supplies can be delivered to local communities after a catastrophic earthquake.

a. ESF Primary State Agencies:

- Work with OMD, Oregon Department of Aviation (Aviation), and Oregon Department of Forestry (ODF) to assess viable supplies of jet fuel and aviation gasoline at airports and air fields in the state. Determine how long the fuel supply will last until it runs out.

  Note: Refer to Annex E in OMD's Air Coordination Plan for baseline data.

- Work with the Oregon Department of Administrative Services (DAS) to assess viable supplies of unleaded gasoline and diesel fuel at state motor pools and state agency fleets.

- Work with ODOT to assess viable supplies of unleaded gasoline and diesel at ODOT District Fleet fueling locations.

- Work with the Oregon Department of Corrections (ODOC) to assess viable supplies of unleaded gasoline and diesel fuel at state prisons and penitentiaries.

- Work with OEM to assess viable supplies of unleaded gasoline and diesel fuel with private industry partners including mega grocery chains with fueling capabilities and mass transit companies to assess viable supplies of diesel to support state mission critical functions.

- Work with other state agencies as needed.

b. County Emergency Management Agencies

- Work with county emergency management agencies to assess viable supplies of unleaded gasoline and diesel fuel to support initial local mission critical functions.

c. Federally- Recognized Tribes

- Work with tribal emergency response personnel to assess viable supplies of unleaded gasoline and diesel fuel to support initial tribal mission critical functions.

Task 3: Work with the Oregon Department of Justice (ODOJ) and OEM to ensure a Governor's emergency declaration provides state, county, and tribal emergency responders' authority to purchase and use existing fuel supplies at market price to support initial mission critical functions.

a. Instruct ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to use existing in-state fuel supplies to conduct initial life-saving functions until bulk fuel supplies can be secured and delivered from outside of the region.

Task 4: Assess Statewide Fuel Needs - Work with ESF Primary State Agencies to assess fuel needs to support mission critical functions for each sector to save lives and restore critical lifelines and services.

18 ESF SECTORS AND STATE PRIMARY AGENCIES

a. ESF 1: Transportation - Work with ODOT to assess fuel needs to restore access and repair highways, roads, bridges, rail lines, and tunnels to support the transportation of goods and services and to perform other mission critical functions.

b. ESF 2: Communications – Work with the OPUC and OEM to assess fuel needs to repair damaged communications systems and to perform other mission critical functions.

c. ESF 3: Public Works – Work with ODOT to assess fuel needs for debris removal to establish viable routes to the impacted areas and to perform other mission critical functions.

d. ESF 4: Firefighting – Work with OSFM to assess fuel needs for fire suppression, mobilizing Urban Search and Rescue Teams, and to perform other mission critical functions.

e. ESF 5: Information and Planning – Work with OEM to assess fuel needs to conduct a rapid needs assessment of the impacted areas and to perform other mission critical functions.

f. ESF 6: Mass Care – Work with the Oregon Department of Human Services (DHS) to assess fuel needs to identify viable shelters and mass care facilities and establish operations of these facilities in the impacted areas and to perform other mission critical functions.

g. ESF 7: Resource Support – Work with DAS to assess fuel needs to deliver emergency relief supplies to impacted areas and to perform other mission critical functions.

h. ESF 8: Health and Medical – Work with Oregon Heath Authority (OHA) to assess fuel needs to mobilize professional/reserve medical personnel and supplies to impacted areas to triage and stabilize the wounded in impacted areas, perform casualty clearing/staging, and other mission critical functions.

i. ESF 9: Search and Rescue – Work with OSFM to assess fuel needs to deploy teams into impacted areas, transport injured individuals recovered from the scene, and to perform other mission critical functions.

j. ESF 10: Hazardous Materials – Work with OSFM and DEQ to assess fuel needs to identify and deploy teams to contain oil and other hazardous materials spills from impacted areas and to perform other mission critical functions.

k. ESF 11: Food and Water – Work with ODA and DHS to assess fuel needs to deliver food and water to shelters and isolated communities and to perform other mission critical functions.

l. ESF 12: Energy – Work with OPUC to assess fuel needs to assess and restore the natural gas and electricity supply and distribution systems and to perform other mission critical functions.

   Note: ODOE is lead for the petroleum sector. OPUC is lead for the electricity and natural gas sectors.

m. ESF 13: Military Support – Work with OMD to assess fuel needs for the Oregon National Guard's air and ground response in support of civilian authorities. This includes the mission critical functions of all ESF Primary State Agencies and Oregon counties as appropriate.

n. ESF 14: Public Information – Work with OEM to assess fuel needs for the Public Information Sector as appropriate.

o. ESF 15: Volunteers & Donations – Work with OEM to assess fuel needs for the Red Cross and other non-profit agencies to provide shelter, roadway assistance, donation management, establishing blood bank capabilities in impacted areas and to perform other mission critical functions.

p. ESF 16: Law Enforcement – Work with OSP to assess fuel needs to protect life and property, provide traffic and crowd control, provide security for responders and critical facilities, and to perform other mission critical functions.

q. ESF 17: Animal Protection – Work with DHS to assess fuel needs to provide veterinary medical care, animal sheltering, animal carcass disposal and to perform other mission critical functions.

r. ESF 18: Business and Industry – Work with OEM to assess fuel needs for the Business and Industry Sector as appropriate.

Note: ODOE's State Agency Liaison will work with ESF Primary State Agencies to ensure fuel assessments are complete. ODOE will work with and rely on the expertise and assessments of each ESF Primary State Agency to determine fuel needs for their respective sector(s).

Task 5: Assess County Fuel Needs - Work with county emergency management agencies to assess local fuel needs to support mission critical functions to save lives and restore critical lifelines and services.

a. Region 1: Clackamas, Hood River, Multnomah, and Washington

b. Region 2: Benton, Clatsop, Columbia, Lane, Lincoln, Linn, Marion, Polk, Tillamook and Yamhill

c. Region 3: Coos, Curry, Douglass, Jackson, and Josephine Counties

d. Region 4: Crook, Deschutes, Gilliam, Jefferson, Klamath, Lake, Sherman, Wasco, and Wheeler

e. Region 5: Baker, Grant, Harney, Malheur, Morrow, Umatilla, Union, and Wallowa

Note: ODOE AOC will assign a County Liaison to assist each region's counties to ensure fuel assessments are complete. ODOE will work with and rely on the expertise and assessments of each county emergency management agency to determine fuel needs for their respective jurisdictions.

Task 6: Work with county emergency management agencies to integrate the use of biofuels to support mission critical functions or to sustain regions not directly affected by earthquake and tsunami impacts.

Note: ODOE recognizes that biofuels cannot replace conventional fuel. The goal of integrating biofuels into the state's emergency response and recovery efforts is to allow eastern Oregon and other parts of the state that are not directly impacted by quake impacts to sustain community functions with ethanol or biodiesel until the region's petroleum supply and distribution system is restored.

a. Work with Sequential Biodiesel to allocate biodiesel to support mission critical functions for counties in Region 2: Benton, Clatsop, Columbia, Lane, Lincoln, Linn, Marion, Polk, Tillamook and Yamhill.

b. Work with Pacific Ethanol to allocate ethanol to support mission critical functions for counties in Region 5: Baker, Grant, Harney, Malheur, Morrow, Umatilla, Union, and Wallowa.

Note: Counties must have access to flex cars to be fueled by ethanol.

Task 7: Work with the Federally-Recognized Tribes to assess tribal fuel needs to support mission critical functions to save lives and restore critical lifelines and services. This includes:

- Burns Paiute Tribe
- Confederated Tribes of the Coos, Lower Umpqua and Siuslaw
- Confederated Tribes of the Grand Ronde
- Confederated Tribes of the Siletz
- Confederated Tribes of the Umatilla Indian Reservation

- Confederated Tribes of the Warm Springs Reservation
- Coquille Indian Tribe
- Cow Creek Band of Umpqua Tribe of Indians
- Klamath Tribes

Task 8: Work with the Governor's Disaster Cabinet to prioritize fuel needs in preparation for fuel allocations.

a. As fuel assessments are completed by ESF Primary State Agencies, county emergency management agencies, and the federally-recognized tribes, establish a fuels priority list in preparation for fuel allocations.

Note: Initial bulk fuel supplies delivered into Oregon by federal and military agencies may not meet all of the state's fuel needs to emergency response activities. Establishing priorities for fuel allocation becomes a responsibility of the Governor's Disaster Cabinet. ODOE's Director is a member of the Governor's Disaster Cabinet.

Task 8: Provide Action 4 status reports in Command and General Staff Briefings, Governor Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes:

- Current in-state fuel availability and outlook
- State, county, and tribal fuel needs assessment status
- Status of the Governor's Disaster Task Force in establishing statewide fuel priorities

ACTION 5

Outside Assistance: Fuel Supply

12 - 24 HOURS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS

ODOE Mission Analysis

Objectives/Tasks

Request the activation and represent Oregon on the nationally convened Fuel Task Force to:

- Coordinate the request, delivery, and estimated time of arrival of bulk fuel supplies into Oregon from outside of the region with federal, military, and industry partners to support state's response and recovery effort.
- Verify the pre-designated federal Incident Support Base (ISB) in Oregon for receiving bulk fuel supplies.
- Verify State Staging Areas (SSA) and Forward Staging Areas (FSA) in Oregon in preparation for moving bulk fuel supplies from the federal ISB closer to the impacted areas.

Facts/Assumptions

Aging petroleum infrastructure in the Pacific Northwest not designed to withstand catastrophic seismic impacts resulting in significant damage:

- Refineries located in Washington inoperable.
- 299 mile Olympic Pipeline, Kinder Morgan Pipeline to the Eugene terminal and Portland International Airport inoperable.
- Petroleum terminals in the Portland Fuel Hub inoperable (includes marine docks).
- Transportation infrastructure unable to support product movement.
- Significant fuel supply loss from the Portland Fuel Hub located on liquefiable soils.

Constraints/Limitations

- Anti-trust laws and proprietary business practices under normal conditions prevent oil companies from collaborating without facilitation from government agencies. A national forum like the Fuel Task Force allows oil companies to coordinate their response to a catastrophic event to restore the region's fuel infrastructure and provide bulk fuel supplies to impacted states.
- "Just-in-Time" strategy for fuel deliveries limit the amount of reserves on hand at all U.S. refineries and terminals.
- ➢ U.S. refineries operating at near capacity limit the capability to meet sudden increase in demand.
- ➢ No easily accessible alternate source of refined product in Oregon.

Gaps/Requests for Information

Prior to Event

- ➢ Conduct fuel workshops, tabletop drills and full scale functional exercises to improve coordination and integration of federal, military, state, and industry emergency response and procedures to ensure a seamless, collaborative response to fuel emergencies in Oregon.
- ➢ Improve overall understanding of the roles, responsibilities, and capabilities of industry, federal agencies, and military branches providing bulk fuel supplies to Oregon.
- ➢ Improve overall understanding of options and logistics required for transporting, storing, and dispensing of fuel by air, water, rail and roads from the federal ISB to the SSAs, FSAs, and county FPODs.

After an Event

- ➢ Represent Oregon on the national Fuel Task Force to secure bulk fuel supplies from outside of the region into Oregon to support the state's response and recovery effort.

ODOE Response Positions:

- Petroleum Event Manager
- Fuel Allocation Coordinator
- Fuel Supply Assessor
- State Agency ESF Liaison
- Federal Agency Liaison
- Petroleum Industry Liaison
- Other ODOE Response Positions as Appropriate

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.

NOTES

Federal and state seismic vulnerability studies show the petroleum infrastructure in the Pacific Northwest will be ***inoperable for at least three months*** if not longer:

Task 1: Work with the Protective Security Advisor to assess the status of ODOE's initial bulk fuel supply request via DHS's Special Event and Domestic Incident Tracker. This includes:

a. Complete and submit a federal resource request form for bulk fuel supplies to FEMA.

b. Provide a copy of the resource request to USDOE ESF 12 Liaison and the DHS Protective Security Advisor.

Note: ODOE's initial request for bulk fuel supplies was verbally communicated to the Protective Security Advisor in Action 3 of this plan. A federal resource request form must then be completed and submitted for record keeping to ensure timely federal reimbursements.

Task 2: Coordinate with the USDOE ESF 12 Liaison at the Oregon ECC or JFO to request the activation of a national Fuel Task Force.

Note: USDOE may activate a national Fuel Task Force without prompting from ODOE or the Washington Department of Commerce. Fuel Task Force members include: USDOE, FEMA, DOD, Maritime Administration, USNORTHCOM, petroleum industry partners, impacted states, and other as appropriate.

For events not requiring the activation of a national Fuel Task Force, ODOE will work with USDOE and petroleum industry partners to accomplish the tasks identified in Action 5 as appropriate.

Task 3: Upon activation, coordinate with the Fuel Task Force to secure bulk fuel supplies from outside of the region into Oregon to support the state's emergency response and recovery activities. This includes:

a. Inform the Fuel Task Force about the status of ODOE's initial bulk fuel supplies request to Oregon's Protective Security Advisor via DHS's Special Event and Domestic Incident Tracter to ensure continuity and timely follow through and delivery of Oregon's bulk fuel supply request.

b. Identify and secure source of bulk fuel supplies to support Oregon's emergency response and recovery effort.

c. Assess and determine viable transportation modes and responsible military, federal agency(s), and/or company(s) to support bulk fuel deliveries to Oregon to the authorized federal Incident Support Base.

- Air – Identify type of aircraft(s), availability, and capacity.
- Waterway - Identify viable marine docks and vessels (tankers/ships/barges) availability, and capacity.
- Rail – Determine availability and capacity.
- Pipeline – Viable alternate or temporary pipelines and capacity.
- Land – Viable transportation routes.

d. Coordinate all logistics and resources (personnel, equipment, and systems) needed to transport bulk fuel supplies to Oregon to the confirmed federal Incident Support Base or other authorized location.

Task 4: Coordinate with the Fuel Task Force to prepare and deliver bulk fuel supplies from the federal Incident Support Base to authorized State Staging Areas and Forward Staging Areas closer to the impacted areas. This includes:

a. Assessing and determining viable transportation modes and responsible military, federal agency(s), and/or company(s) to support fuel deliveries.

- Air – Identify type of aircraft(s), availability, and capacity.
- Waterway - Identify viable marine docks and vessels (tankers/ships/barges) availability, and capacity.
- Rail – Determine availability and capacity.
- Pipeline – Viable alternate or temporary pipelines and capacity.
- Land – Viable transportation routes.

b. Coordinate with OEM to verify authorized State Staging Areas and Forward Staging Areas for transporting bulk fuel supplies closer to the impacted areas.

c. Coordinate with the county emergency management agencies to verify pre-designated FPODs within their respective communities for receiving bulk fuel supplies from the federal and state staging areas.

Task 5: Coordinate with the Fuel Task Force to identify maritime response operations, assets and capabilities to support bulk fuel and other disaster relief supply deliveries to Oregon. This includes:

a. Waterway and port facility restoration on the Columbia River and along the Oregon Coastline.

b. Availability of maritime vessels to support deliveries of bulk fuel and other disaster relief supplies to viable and/or temporary ports on the Columbia River and along the Oregon Coastline.

c. Lifting the Jones Act to allow foreign ships to deliver bulk fuel supplies to viable and/or temporary ports along the Oregon Coastline.

Note: During Superstorm Sandy, the Maritime Administration lifted the Jones Act to allow 11 foreign vessels to deliver 115 million gallons of fuel from the U.S. Gulf Coast to the ports of New York and New Jersey.

Task 6: Coordinate with the Fuel Task Force to identify, obtain, and coordinate the implementation of all necessary federal environmental, transportation, and other waivers to ensure timely delivery of fuel and other disaster relief commodities into Oregon. This includes:

c. Working with Oregon state agencies to ensure all state equivalent waivers are identified, obtained and implemented to prevent delays in the delivery of emergency supplies and services in the state.

Note: See Action 7 and Appendix G for more details on Oregon waivers required to ensure timely fuel deliveries.

Task 7: Coordinate with the Fuel Task Force to develop regional fuel priorities for Oregon and Washington if needed.

a. Compare prioritized fuel list from the Governor's Disaster Cabinet with the regional priorities recommended by the Fuel Task Force to ensure consistency.

b. If discrepancies are found, resolve the differences with members of the Governor's Disaster Cabinet prior to implementing fuel allocations.

Task 8: Coordinate damage assessment and estimate repair and restoration timelines to the region's fuel supply and distribution system.

Task 9: Provide Action 5 status reports in Command and General Staff Briefings, Governor's Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes:

- Fuel Task Force priorities, actions, and decisions.
- Details about the status of bulk fuel supply deliveries into Oregon from all viable transportation modes.
- Status of federal and state fuel waivers to ensure timely deliveries.
- Regional fuel priorities.

ACTION 6

Fuel Conservation Measures

24 - 48 HOURS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS	
ODOE Mission Analysis	
Objectives/Tasks Reduce Fuel Consumption: • Recommend voluntary fuel conservation measures for Oregonians. • Require mandatory fuel conservation measures for government agencies and all political subdivisions.	**Facts/Assumptions** • Significant fuel supply loss from the Portland Fuel Hub. • Significant reduction in demand for fuel due to widespread damage to highways, roads and bridges.
Constraints/Limitations • Mandatory fuel conservation measures require Governor Emergency Declaration. • No enforcement capability to require mandatory fuel conservation measures for the public.	**Gaps/Requests for Information** *Prior to Event* ➢ ODOE will develop performance measures to evaluate the success of fuel conservation measures to reduce demand on fuel. *After an Event* ➢ ODOE will assess the success of the fuel conservation measures to reduce demand on fuel.
ODOE Response Positions: ➢ Petroleum Event Manager ➢ PIO ➢ Fuel Allocation Coordinator ➢ Fuel Supply Assessor ➢ Odd/Even Fuel Administrator ➢ State Agency ESF Liaison ➢ County Liaison Manager ➢ Tribal Liaison ➢ Other Response Positions as Appropriate **Procedures**: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.	
Note: In general and unless otherwise instructed, fuel conservation measures will remain in effect throughout the duration of the emergency and recovery phases of an event. The goal of fuel conservation measures is two-fold. First, it allows for the gradual drawdown of the limited supplies on hand. Second, it reduces panic, prevents fuel hoarding, and prevents price gouging at the gasoline pumps. In addition, fuel conservation measures reassure Oregon citizens that the state is taking the necessary steps to mitigate the impending or actual supply shortage situation.	

Task 1: Recommend voluntary fuel conservation measures to reduce driving during fuel shortages and disruptions.

a. Implement public information campaign to encourage commuters to practice responsible

driving and vehicle maintenance to save on fuel. This includes the following fuel saving tips:

- Slow down and watch speed.
- Consolidate trips.
- Accelerate and brake smoothly.
- Reduce idling.
- Check tire pressure.
- Travel light.
- Minimize use of heater and air conditioning.
- Close windows at high speeds.
- Choose the right oil.
- Be kind to your vehicle.
- Other fuel saving tips as appropriate.

b. GAS PRICE REPORTER WEBSITE/TOLL FREE NUMBER – Request the Oregon Department of Justice (ODOJ) establish and manage the "Gas Price Reporter Website" and a 1-800 number to enable Oregonians to report evidence suggesting unlawful conduct in gasoline pricing at www.doj.state.or.us. The Attorney General investigates and prosecutes individuals and companies that unlawfully fix the price of gasoline in Oregon.

c. RIDE SHARE PROGRAM **-** Initiate emergency rideshare program to save fuel by improving the attractiveness of car and vanpools.

d. MASS TRANSIT PROGRAM - Assist local agencies in expanding new transit service, reducing transit fare and instituting or expanding free transit fare zones.

e. BICYCLE PROGRAM **-** Encourage commuters who live within bicycling distance of their places of employment to use their bicycles. For this program to be successful, local governments and employers may need to provide more bicycle racks or secured parking areas for employees. Temporary bicycle lanes may be created to encourage cycling and to accommodate increases in the number of cyclists.

f. FLEXIBLE WORK HOURS - Encourage the use of flexible work hours for both short and long-term demand reduction, improvement in fuel efficiency, and reduction in traffic congestion.

g. THERMOSTAT SETTINGS **-** Set thermostats higher in the summer and lower in the winter to reduce the amount of fuel used for heating or air conditioning.

Task 2: Recommend mandatory fuel conservation measures for All Levels of Government and Political Subdivisions in Oregon. This includes, but is not limited to:

a. ELIMINATE NON-ESSENTIAL DRIVING - Reduce or eliminate all non-essential government and commercial vehicle use.

b. STRICTLY ENFORCING SPEED LIMITS - Intensified speed limit enforcement by eliminating the use of warnings.

c. INTENSIFY FLEXIBLE WORK HOUR PROGRAMS - Programs include, but are not limited to the following:

- Staggered work hours
- Flextime
- Four-day work week
- Parking facility limitations

d. MANDATORY VEHICLE TIRE PRESSURE INSPECTION

Note: Implementing mandatory fuel conservation measures requires a Governor's Emergency Declaration.

Task 8: Provide Action 6 status reports in Command and General Staff Briefings, Governor's Disaster Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes:

- Voluntary fuel conservation measures considered or issued for the public.
- Mandatory fuel conservation measures considered or issued to all levels of government and political subdivisions.
- Impacts of voluntary and mandatory fuel conservation measures issued, if any.

ACTION 7

Temporary Waivers

24 – 48 HOURS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS	
ODOE Mission Analysis	
Objectives/Tasks Ensure access and timely movement of fuel to support emergency activities • Obtain Governor's Emergency Declaration. • Obtain Governor's executive order giving ODOE authority to implement the Oregon Fuel Action Plan. • Obtain all fuel waivers needed to ensure timely fuel deliveries in Oregon.	**Facts/Assumptions** • Significant fuel supply loss from the Portland Fuel Hub. • Significant damage to region's petroleum infrastructure. • Atypical supply and distribution systems will be created to support Oregon's response and recovery activities. • Bulk fuel supplies will be transported into Oregon from greater distances.
Constraints/Limitations • Waivers require Governor's Emergency Declaration. • Waivers may require presidential approval. ➢ Waivers may require coordination with multiple Oregon state agencies, federal agencies, the military, and other states in the region. ➢ Waivers are temporary and require review for extensions.	**Gaps/Requests for Information** *Prior to Event* ➢ Draft executive order for the governor to sign giving ODOE authority to implement the Oregon Fuel Action Plan. ➢ Draft a menu and boilerplate waivers of all potential waivers needed to ensure fuel deliveries within and into Oregon without delays during an emergency *After an Event* • Obtain and disseminate copies of emergency declarations, executive orders, and waivers.
ODOE AOC Response Positions: ➢ ODOE Director ➢ Petroleum Event Manager ➢ Fuel Supply Assessor ➢ Fuel Allocation Coordinator ➢ State Agency ESF Liaison ➢ Federal Agency Liaison ➢ Petroleum Industry Liaison ➢ Other Response Positions as Appropriate **Procedures**: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.	
***Note*:** ODOE will work directly with the Oregon Department of Justice to obtain and issue all necessary waivers to support timely fuel deliveries and the transportation of other disaster relief supplies on Oregon highways, roads, and bridges.	

Task 1: Obtain Governor's Emergency Declaration.

a. Obtain from OEM a copy of the Governor's Emergency Declaration as a result of a catastrophic event under ORS 401.

b. For emergencies impacting the fuel sector ONLY, ODOE's Director may advise the Governor to declare an ENERGY emergency declaration under ORS 176.785.

c. Provide a copy of the Governor's Emergency or Energy Declaration to 1) petroleum industry partners, 2) federal agencies as appropriate, 3) western states, 4) ESF Primary State Agencies, 5) county emergency management agencies, 6) federally-recognized tribes, and 7) other stakeholders as appropriate.

Task 2: Obtain temporary waivers (Emergency Declaration Required).

a. Work with the appropriate federal and/or state agencies to complete waiver request forms to obtain all necessary waivers to ensure timely deliveries of fuel to support emergency and recovery activities in Oregon.

Note: The oil industry operates under various regulations to ensure safe operations, environmental quality, and fair market competition. These same regulations could also impede the rapid restoration of the petroleum supply and distribution system in the aftermath of an emergency resulting in a long-term or severe fuel shortage. Lifting environmental and safety requirements temporarily after a catastrophic event could ensure timely deliveries of fuel and other disaster relief supplies into impacted communities.

- Biofuel Blending – Oregon requires a minimum amount of biofuels to be blended into all gasoline and/or diesel sold within the state. This requirement could impede fuel supplies from states without biofuel blending requirements from entering the disaster area.

- Clean Fuel Supply - Producers and importers of fossil-based transportation fuels are required to comply with the Oregon Clean Fuel Standards to reduce the overall carbon content of fuel used in Oregon. This requirement could impede fuel supplies coming from states with lesser standards from entering the disaster area.

- Dealer License – Oregon requires a carrier to pay a fee and obtain a Distributor's License to transport motor fuel within the state. Temporarily waiving this fee and license requirement may help speed fuel into the disaster area.

- Diesel Fuel Penalty - The federal government imposes 24.4 cents per gallon tax on diesel fuel sold for on road use. Meanwhile dyed diesel fuel used for farming purposes and home heating are not subject to the tax. If the dyed diesel fuel was used for on road purposes, the federal government would require that use to be reported and the tax paid accordingly. Temporarily waiving this penalty would allow use of available supplies of dyed diesel fuel for emergency use.

- Driver Qualification, Load, and Inspection – Federal and state laws set standards for a driver's physical fitness, level of fatigue, fluency in English, cargo and cargo inspection,

and vehicle maintenance and repairs. Temporarily waiving these requirements may be necessary to increase the pool of available drivers.

- Hazmat Specifications – Federal and state laws set strict specifications on the types of vehicles that can carry gasoline, which includes shipping papers and placarding. Temporarily waiving these specifications may be necessary if there is a shortage of available fuel carrying vehicles.

- Hours of Service – Federal and state laws set standards on how many hours a truck driver can be on duty and drive in a given day and week. Temporarily waiving these standards may be necessary to get needed fuel delivered.

- Importer/Exporter License - State law requires fuel importers and exporters to pay a fee and obtain a license from the state to move fuel across state lines. Without these licenses, the fuel merchant cannot legally buy gasoline from one state and move it to another. Temporarily waiving this fee and license requirement may be necessary to bring fuel from nearby states into the disaster area.

- International Registration/International Fuel Tax Agreement - The International Registration Plan (IRP) is an agreement among states of the U.S, the District of Columbia, and the provinces of Canada providing for payment of commercial motor carrier registration fees. To operate in multiple states or provinces, motor carriers must register in their base jurisdiction (state or province). The International Fuel Tax Agreement (IFTA) is an agreement among states to report fuel taxes by interstate motor carriers. Temporarily waiving this requirement may be necessary to bring fuel from Canada or nearby states into the disaster area.

- Jones Act - The Merchant Marine Act (Jones Act) prohibits foreign-built, foreign-owned, or foreign-flagged vessels from carrying goods and commodities between U.S. ports. To get adequate fuel supplies into the disaster area without delays, foreign vessels may need to be used to deliver fuel between U.S. ports.

- Oxygenated Fuel Emergency – State law requires the use of oxygenated fuels during winter months in certain designated areas that are not meeting carbon monoxide (CO) ambient air quality standards. Temporarily waiving this requirement may be needed to use fuel in the disaster area that would otherwise not be permitted.

- Reid Vapor Pressure (RVP) – RVP is a common measure of the volatility of gasoline. Many states allow a variance, up to 1 lb. RVP from current standards for gasoline blended with ethanol. This requirement could impede fuel supplies from other states without RVP requirements from entering into the disaster area.

- Ultra Low Sulfur Diesel – Federal and state law require a cleaner fuel with a maximum 15 parts per million sulfur specification for vehicles and equipment. Temporarily waiving this requirement may be necessary if fuel that doesn't meet these requirements is otherwise available.

- Vapor Recovery and Fuel Transfer, Loading and Storage Waivers – Federal and state law require fuel terminal loading and unloading systems and tank trucks that transport fuels to use specified vapor recovery equipment and comply with other vapor control requirements. Vapor recovery requirements vary from state to state. Some states also establish vapor control requirements to various fuel transfer, loading and storage operations. Temporarily waiving this requirement may be necessary to deliver some fuel into the disaster area.

- Vessel Movement Control – The U.S. Coast Guard has authority to control vessel traffic through the enactment of safety and security zones. Delivery of fuel by water may necessitate implementing such zones.

- Weight Limits - All states set weight restrictions on the maximum weights allowable for trucks that travel on roadways. Temporarily modifying these restrictions may be necessary for emergency delivery of fuel.

Note: Refer to Appendix G for more details about specific fuel waivers and the federal and state agencies responsible for lifting the waivers.

b. Provide a copy of the waiver(s) obtained to 1) petroleum industry partners, 2) federal agencies as appropriate, 3) western states, 4) ESF Primary State Agencies, 5) county emergency management agencies, 6) federally-recognized tribes, and 7) Other stakeholders as appropriate.

Task 3: Work with lead federal and state agencies to monitor waivers issued and evaluate the need for an extension of the temporary waivers as appropriate.

a. Work with the appropriate lead federal and/or state agencies to complete the approval process for extending all necessary waivers to ensure continued timely deliveries of fuel to support emergency and recovery activities in Oregon.

Note: Fuel waivers are usually effective for a period of 20-30 calendar days from the date of the emergency declaration and require extensions if the emergency situation persists.

Task 4: Work with lead federal and state agencies to terminate temporary waivers lifted in response to the emergency and reinstate all federal and state requirements as appropriate.

Task 5: Provide Action 7 status reports in JFO Command and General Staff Briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes:

- Temporary waivers issued
- Temporary waivers extended
- Temporary waivers deactivated

ACTION 8

Fuel Allocation

72 HOURS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS	
ODOE Mission Analysis	
Objectives/Tasks • Implement and Manage Oregon's Fuel Allocation Program. • Receive, review, and approve/deny emergency fuel requests from pre-approved priority fuel users. This includes: ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes. • Allocate fuel to pre-approved priority fuel users as needed. • Identify and implement pre-scripted missions involving fuel requiring federal and military assistance. • Implement Odd/Even Fuel Allocation as appropriate.	**Facts/Assumptions** Significate damage to: • Region's communications systems. • Region's power infrastructure. • Region's transportation infrastructure (highways, roads, bridges, waterway systems, and rail). • Portland Fuel Hub (terminal facilities, pipeline systems, tank farms, and marine docks). • Eugene terminal. • Region's pipeline systems: - 230 mile Olympic Pipeline. - Kinder Morgan Pipeline to the Eugene terminal and to the Portland International Airport.
Constraints/Limitations • Criteria for initiating fuel allocation: - Governor's Emergency Declaration. - State, county, and tribal emergency responders unable to get fuel at any price. - Anticipated long-term/severe supply shortage or disruption. • Obtaining necessary federal and state regulatory waivers to support timely deliveries of fuel and other disaster relief supplies. • Fuel deliveries largely dependent on factors beyond ODOE's control: - Significant loss of normal incoming fuel supply post-quake. - Securing bulk fuel supplies from outside of the region to Oregon takes time (est. 1 – 3 weeks). - Viable telecommunications to coordinate the allocation of fuel to priority users. - Viable transportation modes to deliver bulk fuel supplies from the federal ISB to SSAs, FSAs, and FPODs in the impacted areas. - Limited power or backup power capabilities to dispense fuel.	**Gaps/Requests for Information** *Prior to Event* ➢ ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes responsible for identifying: ➢ Mission critical functions for each agency and sector/area of responsibility and the fuel needed to perform identified missions. ➢ Priority life line routes to receive fuel. ➢ Pre-designated FPODs to receive fuel. ➢ Strategies to move fuel from the FPODs to critical facilities in the community and to emergency responders in the field. ➢ Identify and confirm pre-designated federal ISBs, SSAs, and FSAs in Oregon. *After an Event* ➢ Assess fuel needs, review fuel requests, and facilitate fuel deliveries to pre-approved priority fuel users to pre-designated FPODs as appropriate. ➢ Implement pre-scripted missions seeking federal and military assistance to deliver fuel. ➢ Implement Odd/Even Fuel Allocation for the public as appropriate.

ODOE AOC Response Positions:

- ODOE Director
- Petroleum Event Manager
- Fuel Allocation Coordinator
- Fuel Supply Assessor
- Federal Agency Liaison
- Petroleum Industry Liaison
- State Agency ESF Liaison
- County Liaison Manager
- County Liaison(s): Regions 1 – 5 *(as needed)*
- Tribal Liaison
- Other Response Positions as Appropriate

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.

ABOUT THE FUEL ALLOCATION PROGRAM

IMPLEMENTATION CRITERIA

- Governor's Emergency Declaration.
- Emergency and essential service providers unable to obtain fuel at any price.
- Market forces, voluntary fuel conservation, and/or mandatory fuel conservation measures fail to provide for adequate and equitable distribution of fuel.

GOAL

- Interfere minimally with the market.
- Make no attempt to reduce or inhibit the market price of fuels.
- Ensure all fuel delivered through the program will be purchased at the market price, and whenever possible, through the usual supplier.

STRUCTURE

Ensure adequate fuel supplies to save lives, protect public health and safety, and to restore critical lifelines and services. Those who qualify for emergency fuel supplies fall under three categories:

- 18 ESF Primary State Agencies
- 36 county emergency management agencies
- 9 federally-recognized tribes

All emergency fuel requests will be filtered through one of these pre-approved priority fuel users.

ASSUMPTIONS

- ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes completed identifying mission critical functions and fuel required to complete missions prior to a catastrophic event.
- County priority lifeline routes identified that connect to ODOT's state priority lifeline routes.
- Counties pre-designated FPODs along priority lifeline routes within their communities to receive emergency bulk fuel supplies.
- Bulk fuel supplies requested by ODOE have arrived at the designated federal Incident Support Base awaiting fuel allocation direction from ODOE to pre-designated fueling locations for use by pre-approved priority fuel users.

ODOE's fuel allocation structure is a GUIDELINE. Severe or long-term fuel disruptions and shortages are largely dependent on event conditions, the availability of fuel, and the state's priorities.

FUEL REIMBURSEMENTS

ODOE will not provide funding or administer the disbursement of funds to priority users for fuel allocation. Payment for fuel is the responsibility of the recipients.

Federal Reimbursements – An Oregon State Declared Emergency will trigger financial assistance through FEMA's Public Assistance Cost Share Program under the Stafford Act of 1988. Under the federal cost share program, FEMA is responsible for covering 75 percent while state, county, and tribes are responsible for covering 25 percent of the costs. FEMA Guidance defines eligibility and cost recovery procedures for compliance.

Task 1: Implement and manage Oregon Fuel Allocation Program and Process Fuel Requests.

a. Receive and review Fuel Request Forms from ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes.

Note: State agencies, counties, and tribes are to use the Fuel Request Form in Appendix A to apply for emergency fuel. Incomplete forms will be returned to the requesting organization.

b. Validate authenticity of each application to ensure fuel requests are submitted by an approved ESF Primary State Agency, county emergency management agency or federally-recognized tribe.

c. Compare requests with established fuel priorities and cross check requests with other applications to eliminate duplicate requests.

Note: The Governor's Disaster Cabinet may establish statewide fuel priorities that could impact which fuel requests from state agencies, counties, and tribes are approved. Refer to Action 4 for more information about establishing statewide fuel priorities.

d. Process Fuel Request Form as appropriate.

- ☐ Approve Emergency Fuel Request.
- ☐ Approve with Conditions – ODOE will work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to meet identified conditions to complete the fuel requests for approval as appropriate. Upon meeting identified conditions for fuel request approval, ODOE will facilitate fuel orders and deliveries for approved requests.
- ☐ Approve Pending Additional Information – ODOE will work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to obtain additional information to complete the fuel requests for approval as appropriate. Upon obtaining the additional information for fuel request approval, ODOE will facilitate fuel orders and deliveries for approved requests.

- Deny Emergency Fuel Request *(provide reason)*

  - Request met through mutual aid
  - Duplicate request
  - Request fails to meet mission critical priorities *(can be appealed)*
  - Unavailability of fuel *(request remains active for reconsideration when fuel becomes available)*
  - Unable to get fuel to requested location *(request remains active for reconsideration when a viable fueling location is identified)*

- Appeals Process – ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes can appeal a fuel request denial by completing the Appeals section of the Fuel Request Form. This involves providing a justification for "how" the fuel request does meet mission critical priorities. The appeal will be submitted to the Governor's Disaster Cabinet for consideration. After re-evaluating the fuel request, the Governor's Disaster Cabinet can:

  - Approve the appeal for requesting emergency fuel
  - Approve the appeal with conditions
  - Approve the appeal pending additional information
  - Deny the appeal for requesting emergency fuel

- ODOE will assist ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes in completing the Fuel Request Form, appeals process, and monitor fuel requests through to completion.

Task 2: **INITIAL RESPONSE - Process approved Fuel Request Forms and facilitate orders and deliveries to ESF Primary State Agencies, county emergency management agencies and federally-recognized tribes as appropriate.**

a. Review and confirm with approved state agency, county, or tribe on the pre-designated locations to receive emergency bulk fuel supplies from Appendixes B and D. If the pre-designated locations are not viable post-quake, ODOE will work with state, county, and tribes to designate alternate locations to stage, deliver, and receive bulk fuel supplies.

   Note: ODOE maintains a Statewide Fuel Database on all above and understand fuel storage tanks. ODOE's Statewide Fuel Database is a compilation of fuel data from DEQ, OSFM, and ODA that was modified to meet specific fuel allocation program needs and eliminates duplications and streamlines the information from the three existing databases.

b. Coordinate initial movement of fuel by air with other state ESF Primary State Agencies moving other disaster relief commodities into the impacted areas. This includes, but is not limited to:

   - ESF 1: Transportation – ODOT/Aviation
   - ESF 6: Mass Care – DHS
   - ESF 7: Resource Support – DAS
   - ESF 8: Health & Medical – OHA

- ESF 11: Food & Water – DHS
- ESF 13: Military Support – OMD

Note: Coordination is critical during the initial response phase due to the limited number of initial viable locations within the impacted areas that can receive fuel and other disaster relief supplies.

c. Coordinate with federal and state ESF 7: Logistics Management and Resource Support teams to determine viable air transportation modes to deliver bulk fuel supplies to confirmed designated fuel locations. This includes identifying:

- Type of aircraft(s), availability, and capacity
- Responsible military branch(s), federal agency(s) and/or petroleum industry company(s) transporting bulk fuel supplies
- Delivery Type
  - Single Delivery: Specify estimated time of arrival
  - Multiple Deliveries: Specify delivery schedule

Note: The lead Federal ESF 7 agencies include: DHS, FEMA, and the General Services Administration (GSA) to provide a centralized management for the role of the National Logistics Coordinator and management of resource support requirements to support impacted states. Oregon's ESF Primary Agency for ESF 7 is DAS supported by OMD, OEM, and other state agencies.

d. Work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to document and track all bulk fuel supply orders and deliveries to State Staging Areas, Forward Staging Areas and Fuel Points of Distribution throughout the duration of the emergency. This includes:

- Monitoring delivery schedules, date and time of deliveries, and the type and amount of fuel delivered.
- Identifying the responsible military branch(s), federal agency(s) and/or petroleum industry company(s) delivering the bulk fuel supplies.
- Modifying fuel deliveries as appropriate.

Task 3: SUSTAINED RESPONSE **Process approved Fuel Request Forms and facilitate orders and deliveries to state agencies, counties, and tribes as other transportation modes become available.**

Note: While delivering disaster relief supplies by air initially is essential, restoring overland transportation, rail, and waterway routes is critical to achieve a sustained response.

a. **STATE PRIORITY LIFELINE ROUTES** – Work with ODOT to assess the viability of the state pre-designated priority lifeline routes and estimate timeline for repairs for Oregon (Appendix C).

- Upon ODOTs approval of state's priority lifeline routes for use, coordinate with ODOT and PUC to send out fuel trucks with road, utility, and communications crews to repair and restore:

  - Designated state priority lifeline routes
  - Powerlines and substations along state priority lifeline routes
  - Communications towers and systems along state priority lifeline routes.

- Coordinate with ODOT and PUC to identify and confirm public/private partners to do this work and designate start points (State Staging Areas, ODOT district yards, or other location) for fuel trucks and work crews to congregate prior to deployment.

  Note: Coordinate with federal and state ESF 7: Logistics Management and Resource Support teams as appropriate.

b. **COUNTY PRIORITY LIFELINE ROUTES** – Work with county emergency management agencies to confirm the viability of county pre-designated priority lifeline routes (Appendix D) linking to the state's priority lifeline routes. This includes:

- Estimating the timeline for repairs and operation to support fuel deliveries as well as other disaster relief supplies.

- Coordinate with the counties to request resource support from state and federal ESF 7 logistic and resource support teams to ensure county pre-designated priority lifeline routes are restored to support fuel deliveries and other disaster relief supplies to their FPODs and CPODs.

- Review and confirm pre-designated FPODs to receive emergency bulk fuel supplies from Appendix D. If the pre-designated FPODs are not viable post-quake, work with ODOE to designate alternate FPODs.

  Note: More FPODs may become viable to receive bulk fuel supplies as more county priority lifeline routes are restored.

c. **RAIL** – Work with ODOT's Rail Division to determine the timeline for restoring rail lines and consider the viability of using rail cars to store and deliver fuel closer to the impacted areas to support emergency response activities. If this option is determined viable:

- Coordinate with ODOT, state and federal ESF 7: Logistics Management and Resource Support teams, and well as the rail industry to determine:

  - Number of available railcars
  - Rail yards that might serve as staging areas
  - Security and access control
  - Other logistics as appropriate

Note: The U.S. DHS Study titled "Columbia River Basin Petroleum and Refined-Products Supplies: Disruptions and Mitigations under CSZ Earthquake Scenario" states that rail might

be the fastest way to bring fuel into the affected area. The study notes that this solution is limited to the availability of tanker railcars and viability of the track.

d. **WATERWAY** – Work with DEQ and USCG Sector Columbia River to determine the timeline for restoring waterway routes and consider the viability of using barges trapped upriver from Portland on the Columbia River upriver to store, deliver, and offload fuel to support emergency response activities.

- Coordinate with DEQ, USCG, U.S. Army Corp of Engineers, state and federal ESF 7: Logistics Management and Resource Support teams, as well as the barge companies to determine:

  - Number of available barges and fuel storage capacity
  - Viable marine docks
  - Security and access control
  - Other logistics as appropriate

Note: The U.S. DHS Study estimates it would take about two weeks to assess conditions on the lower Columbia and Willamette Rivers and clear the waterway for shallow-draft vessels.

BARGE COMPANIES ON THE COLUMBIA RIVER		
Tidewater	8 Barges	264,000 Barrels (Combined Capacity)
Olympic Tug & Barge Element of Harley Marine	1 Barge *(Portland)*	14,000 Barrel Capacity
1 Barrel = 42 gallons		

e. Work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to document and track all bulk fuel supply orders and deliveries to SSAs, FSAs, and FPODs throughout the duration of the emergency. This includes:

- Monitoring delivery schedules, date and time of deliveries, and the type and amount of fuel delivered.
- Identifying the responsible military branch(s), federal agency(s) and/or petroleum industry company(s) delivering the bulk fuel supplies.
- Modifying fuel deliveries as appropriate.

Task 4: Coordinate and assess the need for requesting maritime assets to support fuel deliveries and other disaster relief supplies to the Oregon coast to support emergency response activities. This includes:

a. Working with lead state agencies, coastal counties, and federally-recognized tribes along the coast to identify resource needs to support emergency response activities along the Oregon Coast. This includes, but is not limited to:

- Providing shelter and housing
- Delivering bulk fuel supplies and establishing temporary fueling locations

- Providing emergency power
- Delivering food, water, medicine, and medical supplies
- Transporting personnel, vehicles, equipment, and other disaster relief assistance

b. Coordinate with federal and state ESF 7: Logistics Management and Resource Support teams to request maritime assistance to the communities along the Oregon Coast based on identified need. This includes:

- Completing the appropriate federal resource request forms to request maritime assets.
- Identifying destinations (locations) and estimated time of arrival of maritime assets approved to respond to the Oregon Coast.
- Identifying the Maritime Administration's expectations of state and county responsibilities in anticipation and preparation of the arrival of maritime assets.

c. Work with ESF Primary State Agencies, county emergency management agencies, and federally-recognized tribes to document and track all maritime requests, orders and deliveries to approved destinations along the Oregon Coast throughout the duration of the emergency. This includes:

- Monitoring date and time of arrivals and deliveries and the type of assistance provided.
- Identifying the number and type of maritime assets that responded.

Task 6: Identify and implement pre-scripted missions as appropriate from Appendix E for requesting federal and military support to accomplish Action 8 fuel allocation objectives and tasks.

Task 7: Implement fuel allocation for Oregon citizens.

a. Implement the Odd/Even Fuel Allocation Program for the public to alleviate potentially long lines at retail service stations. This measure is designed to:

- Help space purchases of gasoline and aid in its equitable distribution.
- Provide a psychological benefit by reducing uncertainty regarding fuel availability.
- Encourage the conservation of fuel by causing trips to be better planned.
- Minimize waiting lines (may also reduce consumption by saving fuel that is used while idling).

Under this plan, gasoline may be purchased or sold only in accordance with the following procedures.

ODD/EVEN FUEL ALLOCATION MEASURE *Compliance rests with service station personnel*		
ODD Days of the Month	**EVEN Days of the Month**	**SUNDAYS, HOLIDAYS, & 31ST of Any Month**
Vehicles with license plates: • Ending w/odd numbers	Vehicles with license plates: • Ending w/even numbers	**Everyone** can purchase fuel on

• Ending w/letters A-M	• Ending w/letters N-Z	Sundays, legal holidays, or the 31st of any month.
***EXEMPTIONS*:** The following vehicles are exempted from the odd/even gasoline purchase plan, but will wait their turn in line at any gasoline station: Common carriers, including taxis, rental vehicles, commercially licensed vehicles, or private vehicles used for designated commercial purposes.		

b. Implement Fuel Limit Purchase Requirement for the public in conjunction with the Odd/Even Fuel Allocation Measure, depending on the severity of the fuel shortage situation. Under this plan, gasoline may be purchased or sold only in accordance with the following procedures.

FUEL LIMIT PERCHASE REQUIREMENT *Compliance rests with service station personnel*	
MIMIMUM **Fuel Purchase Requirement**	**MAXIMUM** **Fuel Purchase Requirement**
Minimize gasoline lines by discouraging the making of frequent but small gasoline purchases by consumers. This measure also discourages tank topping.	Ensures some gasoline will be available to motorists located or traveling through the state. Limiting the amount of gasoline purchased by motorists in one visit will help prevent supplies from running out prematurely at a particular retailer.
***NOTE*:** ODOE will set the minimum and maximum purchase quantity as appropriate. Retailers may lower the set amount at their discretion due to market forces.	

c. Implement the Limited Hours of Operation measure if the fuel shortage situation continues to worsen. Under this plan, gasoline may be purchased or sold only in accordance with the following procedures.

LIMITED HOURS OF OPERATION *Compliance rests with service station personnel*		
PERCENTAGE **of Hours Rule**	**DESIGNATED** **Days Rule**	**SUNDAY CLOSINGS ,** **W/PERCENTAGE Rule**
Order retail gasoline and diesel outlets to reduce hours of weekly operation by a fixed percentage of normal operating hours	Order retail gasoline and diesel outlets to close for business on specified days of the week. Pre-designated emergency fueling locations for priority users are exempt.	Order retail gasoline and diesel outlets to not operate on Sundays of any week and to reduce hours of normal operation on other weekdays.
***NOTE*:** If any of the three rules are ordered, stations will post the hours of operation visibly upon the premises for all motorists to see.		

d. Implement additional fuel allocation measures as appropriate.

Task 8: Provide Action 8 status reports in JFO Command and General Staff Briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes:

- Availability of fuel in-state to support initial life-saving functions.

- Availability of bulk fuel supplies from outside of the region to be brought into Oregon to support the state's emergency response and recovery activities.

- Status of fuel allocations, processing of requests, facilitating and delivering of bulk fuel supplies to approved state, county, and tribal emergency responders.

- Viability of transportation routes to support fuel deliveries including air, overland, rail and waterway routes.

- Odd/Even Fuel Allocation Program for the public.

ACTION 9

Recovery

14-30 DAYS TO INITIATE - ESTIMATED COMPLETION 180+ DAYS	
ODOE Mission Analysis	
Objectives/Tasks • Assess need and allocate fuel to support state, county, and tribal recovery activities. • Serve on Coordinating Team - State Recovery Function (SRF) 6: Infrastructure Systems. • Participate on the Governor's Recovery Cabinet. • Terminate Oregon Fuel Action Plan as state, county, and tribal emergency responders are able to purchase fuel at normal fueling outlets. • Ensure ongoing Oregon Fuel Action Plan readiness.	**Facts/Assumptions** • Critical lifelines and services largely restored to the region as repairs are made to the state's: ➢ Communications systems. ➢ Transportation infrastructure. ➢ Power infrastructure. ➢ Petroleum Infrastructure. • State, county, and tribal emergency responders are mostly able to purchase fuel from "normal" fueling outlets.
Constraints/Limitations • Transition from Response Phase to the Recovery Phase presents new decision-making structure, which can create confusion. This includes: ➢ Going from 18 ESFs to 7 State Recovery Functions (SRF). ➢ Designated "Coordinating Agency" to lead SRFs. ➢ Coordinating Agency may not have actual authority/expertise over SRF and must rely on the 18 ESF Primary State Agencies for decision-making and implementation of SRF activities. ➢ Creates additional layer requiring coordination.	**Gaps/Requests for Information** *Prior to Event* ➢ Primary State RSF Agencies, county emergency management agencies, and federally-recognized tribes identify critical recovery functions and fuel needs for these activities. *After an Event* ➢ Assess timeline and industry's capability to restore the region's petroleum supply and distribution system back to pre-emergency conditions or to a "new normal." ➢ Coordinate with Primary State RSF Agencies, counties, and tribes to verify fuel needs to support recovery activities. ➢ Continue fuel allocations to support recovery activities as appropriate.
ODOE AOC Response Positions: ➢ Petroleum Event Manager ➢ Fuel Allocation Coordinator ➢ Fuel Supply Assessor ➢ Petroleum Industry Liaison ➢ Federal Agency Liaison ➢ State Agency Liaison ➢ County Liaison Manager ➢ Tribal Liaison ➢ PIO ➢ Other Response Positions as Appropriate	

Procedures: Procedures for ODOE AOC response positions are included in Appendix J of this plan. Each response position procedure includes key objectives, checklist of tasks, guidance on how to accomplish objectives and tasks, and reference materials as appropriate.
***Note*:** Recovering the state's fuel supply and distribution system to pre-emergency conditions or to the approved new normal infrastructure for the region will take months to years. Upon deactivation of the ODOE AOC, State ECC, and/or JFO, ODOE's Energy Emergency Preparedness Manager will lead ongoing fuel recovery activities for the agency as appropriate.

Task 1: Assess need and allocate fuel to support local, tribal and State Recovery Functions (SFRs).

a. Work with the Coordinating Agency(s) to assess fuel needs to support seven State Recovery Functions. This includes:

SRF 1: Community Planning and Capacity Building	
Coordinating Agency	Oregon Department of Land Conservation and Development (DLCD)
Primary Agencies	DLCD and OEM
Federal Coordinating Agency	FEMA
Related ESFs	ESF 5 – Information and Planning ESF 7 – Resource Support ESF 14 – Public Information ESF 15 – Volunteers and Donations

SRF 2: Economic Recovery	
Coordinating Agency	Business Oregon
Primary Agencies	Business Oregon Oregon Department of Consumer and Business Services (DCBS)
Federal Coordinating Agency	Department of Commerce
Related ESFs	ESF 18 – Business and Industry

SRF 3: Health Services	
Coordinating Agency	OHA
Primary Agencies	OHA
Federal Coordinating Agency	Department of Health and Human Services
Related ESFs	ESF 8 – Health and Medical ESF 17 – Agriculture and Animal Protection

SRF 4: Social Services	
Coordinating Agency	DHS
Primary Agencies	DHS
Federal Coordinating Agency	Department of Health and Human Services
Related ESFs	ESF 6 – Mass Care ESF 11 – Food and Water

SRF 5: Disaster Housing	
Coordinating Agency	Oregon Housing and Community Services (OHCS)

Primary Agencies	OHCS
Federal Coordinating Agency	Department of Housing and Urban Development
Related ESFs	ESF 6 – Mass Care

SRF 6: Infrastructure Systems	
Coordinating Team	DAS, ODOE, ODOT, & OPUC
Primary Agencies	DAS, ODOE, ODOT, & OPUC
Federal Coordinating Agency	U.S. Army Corps of Engineers
Related ESFs	ESF 1 – Transportation ESF 2 – Communications ESF 3 – Public Works ESF 12 – Energy

SRF 7: Natural and Cultural Resources	
Coordinating Agency	DEQ
Primary Agencies	Oregon Department of Fish and Wildlife ODA ODF Oregon Parks and Recreation Department Oregon Water Resources Department
Federal Coordinating Agency	Department of the Interior
Related ESFs	ESF 3 – Public Works ESF 10 – Hazardous Materials ESF 12 – Energy ESF 17 – Agriculture and Animal Protection

b. Work with the OEM Local Disaster Recovery Manager, SRF agencies, county emergency management agencies, and federally-recognized tribes to assess fuel needs to support state, county, and tribal recovery activities.

Note: Assessing fuel needs of state, county, and tribal emergency responders is ongoing and will overlap and continue from the emergency response phase into the recovery phase.

c. Facilitate the allocation of fuel to support SRFs, county, and tribal recovery activities as needed.

Note: Allocating fuel to state, county, and tribal emergency responders is ongoing and will overlap and continue from the emergency response phase into the recovery phase.

Task 2: Serve on the Coordinating Team for SRF 6: Infrastructure Systems.

a. Coordinate with SRF Coordinating Agencies to prioritize fuel requests and allocations to support state, county, and tribal recovery activities as appropriate

.

b. Advise SRF Coordinating Agencies on alternate fuel supplies, delivery systems, and refueling locations in support of recovery efforts as appropriate.

c. Provide status updates to the SRF Coordinating Agencies on the petroleum industry's recovery efforts to ensure timely restoration of fuel supply levels, infrastructure, and delivery systems back to pre-emergency conditions.

d. Provide status updates to the SRF Coordinating Agencies on voluntary and mandatory fuel conservation measures and other strategies implemented by ODOE to reduce fuel consumption during the Recovery Phase.

Task 3: Participate on the Governor's Recovery Cabinet as needed.

a. Identify priorities and provide technical expertise on the region's petroleum supply and distribution system recovery activities.

***Note*:** ODOE Director or authorized designee is a member of the Governor's Recovery Cabinet

Task 4: Provide Action 9 status reports in Governor's Recovery Cabinet briefings, OR ECC briefings, Situation Reports, news releases, news conferences, and other forums as appropriate. This includes, but is not limited to:

- ODOE fuel priorities, actions, and decisions during the Recovery Phase.
- Petroleum industry recovery priorities and activities, status of repairs, and proposed infrastructure changes and modifications.
- SRF, county, and tribal fuel needs, priority delivery routes, FPODs for recovery activities.
- Temporary waivers, fuel conservation measures and other institutional controls implemented for the Recovery Phase.

Task 5: Terminate fuel recovery activities as appropriate.

a. Terminate Fuel Allocation Program when state, county, and tribal emergency responders are able to obtain fuel at retail service stations and other refueling outlets. This includes terminating:

- Fuel Set-Aside Volume if implemented.
- Fuel deliveries to the federal ISB, SSAs, FSAs, FPODs, and other temporary emergency fueling locations.
- Odd/Even Fuel Allocation for Oregonians as appropriate.

b. Work with lead federal and state agencies to terminate temporary waivers lifted in response to the emergency and reinstate all federal and state requirements as appropriate.

Note: Refer to Action 7 and Appendix G for details.

c. Terminate voluntary fuel conservation measures for the public and mandatory fuel conservation measures for all levels of government and political subdivisions.

Note: Refer to Actions 6 for details.

d. Terminate the Public Information Campaign providing tips to motorists on conserving fuel.

Note: Refer to Action 2 for details.

e. Work with ODOJ to terminate the Gas Price Reporter Website and a 1-800 number for Oregonians to report evidence suggesting unlawful conduct in gasoline pricing.

Note: Refer to Action 6 for details.

f. Deactivate ODOE AOC.

Task 6: Ensure Oregon Fuel Action Plan Program Readiness.

a. Plan Review and Update **–** Review and update the Oregon Fuel Action Plan following each activation, drill/exercise, or at least annually to include lessons learned and improvements identified from responding to actual events, drills, and exercises.

b. Training – Coordinate, implement, and participate in regional, statewide, and local drills and exercises involving ESF 12: Energy specific to the petroleum sector.

c. Maintain Regional/National/International Fuel Outlook – Serve as the Oregon State Liaison to the Western States, USDOE, and the National Association of State Energy Officials on the petroleum sector. This includes participating on:

- Quarterly conference calls to address energy issues of concern and interest
- Annual energy sector meetings, conferences, workshops, or seminars
- Online training and presentations on the energy sector
- Western States Regional Energy Exercise
- Other activities as appropriate

d. Public Information and Outreach – Conduct public information program for Oregonians to increase awareness of and confidence in the Oregon Fuel Action Plan.

APPENDIX A
Fuel Request Form

Appendix A includes a Fuel Request Form for Oregon's emergency and essential services providers. This includes the 18 ESF Primary State Agencies, 36 county emergency management agencies, and the 9 federally-recognized tribes. All fuel requests will be filtered through one of these pre-approved priority fuel users.

To prepare state, county, and tribal emergency response organizations to request emergency bulk fuel supplies and to complete Fuel Request Forms when needed, ODOE worked with the states' priority fuel users to complete the necessary work prior to an emergency event. This includes:

- Mission Critical Functions - Identifying mission critical functions requiring fuel for each of the state's 18 ESF sectors, 36 counties, and 9 federally-recognized tribes.

- ODOE Fuel Database – Even with the activation and support of a National Fuel Task Force to secure and deliver bulk fuel supplies to Oregon, time is needed to bring fuel from outside of the region to support Oregon's response and recovery activities. State, county, and tribal organizations should know the location and amount of fuel available within their jurisdictions to support initial life-saving functions and begin restoring critical lifeline services. Without roads to deliver supply, the fuel within each

jurisdiction will be used to support the initial response until an alternate supply can be brought in from outside of the region to sustain response activities.

ODOE developed a Fuel Database to support fuel delivery strategies in Oregon following a CSZ event. The ODOE Fuel Database provides information about in-state fuel stockpiles to be used by emergency and essential service providers at the state, county, and tribal levels to conduct initial life safety missions until ODOE can bring in bulk fuel supplies to the state from outside of the region. The ODOE Fuel Database was provided to the state's 36 county emergency management agencies. ODOE will update this database every few years or as resources allow.

Note: ODOE collected fuel data from DEQ, OSFM and ODA to develop the ODOE Fuel Database. These three agencies collect data from the state's suppliers annually for the different requirements and laws governing their organization's authorities and responsibilities. DEQ's data is specific to the underground fuel storage tanks, OSFM's data is specific to aboveground fuel storage tanks. ODA's data was a combination of both aboveground and underground fuel storage tanks in Oregon and was used to cross reference DEQ and OSFM's data. ODOE eliminated all duplicate and nonessential data to support fuel allocation strategies and added additional information to support fuel delivery strategies.

- County Data Request - To ensure timely delivery of bulk fuel supplies to the impacted areas after a catastrophic earthquake and tsunami, ODOE requested the following data from county emergency management agencies.

  - 24/7 Primary and Backup Communications Contact Information and Capabilities

  - Preliminary County Lifeline Routes – Pre-designate priority lifeline routes within the county to be restored to support fuel deliveries into the local communities. County priority lifeline routes should connect to ODOT's priority lifeline routes for the state.

  - Preliminary Fuel Points of Distribution – Pre-designate Fuel Points of Distribution (FPOD) along county designated priority lifeline routes to receive the emergency fuel supply within each ESF sector, county, and tribal reservation.

    Note: Federal, state, and local emergency responders may share the same FPODs. Make sure a method is in place to: 1) identify specific agencies, 2) document fuel use, and 3) record payment for reimbursement purposes.

- County Authority - Identify county authority to commandeer fuel from county stockpiles to perform life safety functions following a catastrophic earthquake and tsunami.

  Note: Authority varies by county. ODOE will work with ODOJ to clarify county authority. Some counties in a state declared emergency, already have the authority to acquire the necessary resource to conduct emergency response activities. For example:

  Marion County Code 2.35.070 Acquisition of Resources - The board of county commissioners is authorized to extend government authority to nongovernmental resources (i.e., personnel, equipment) which may support regular government forces during an emergency and may enter into agreements

with other public and private agencies for use of resources. When real or personal property is taken under power granted by this section, the owner of the property shall be entitled to reasonable compensation. Marion County Code is available at the following link: http://www.codepublishing.com/OR/MarionCounty/html/MarionCounty02/MarionCounty0235.html

Long-Term Fuel Planning Goals

ODOE is responsible for getting bulk fuel supplies to the counties. It's the responsibility of the county in coordination with their respective cities' to develop a plan or method to deliver the fuel to community's critical facilities and emergency responders in the field.

- County Fuel Distribution Plans – ODOE will work with county emergency management agencies as appropriate to develop a county fuel distribution plan identifying strategies for delivering fuel to the community's critical facilities and emergency responders in the field.

- Federally-Recognized Tribes Fuel Distribution Plans – ODOE will work with the tribes as appropriate to develop a fuel distribution plans identifying strategies for delivering fuel to the tribe's critical facilities and emergency responders on tribal land to save lives and restore critical lifelines and services.

  Note: If a tribe decides not to receive fuel directly on tribal lands, the tribe can work with its host county to ensure the county fuel distribution plan identifies strategies for delivering fuel to tribal responders and critical facilities on tribal lands. The federally-recognized tribes can also go directly to FEMA to request emergency fuel supplies and to coordinate fuel deliveries onto tribal lands.

Fuel Request Form

All sections must be completed to ensure timely processing of fuel requests

Additional Comments:

APPENDIX B

Federal Incident Support Bases and State Staging Areas

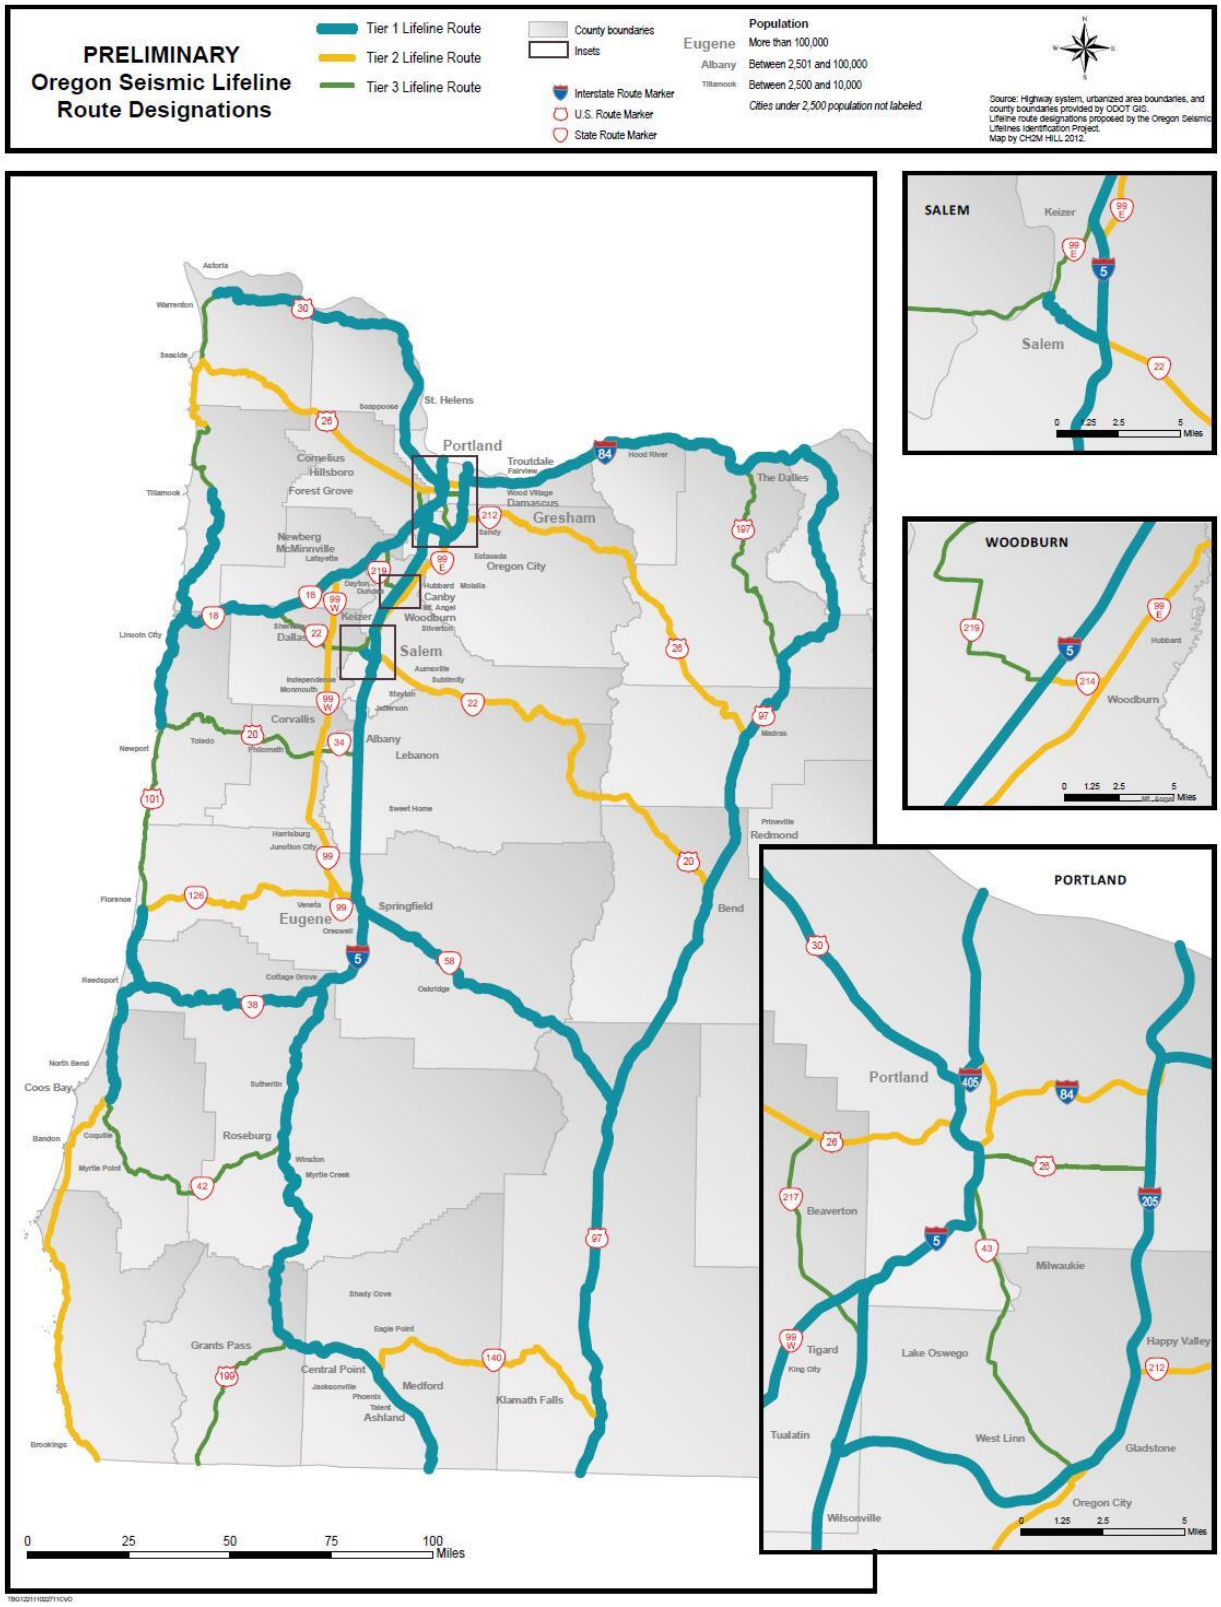
Appendix B identifies proposed federal Incident Support Bases (ISBs) in response to a catastrophic even in Oregon. Federal ISBs are temporary locations outside of the impacted area for receiving and staging resources (supplies, equipment, and teams) that may be provided to state and local governments during incidents involving large numbers of commodities or response teams.

Proposed Forward Staging Areas (FSA) are also identified. FSAs are "mini" ISBs where commodities and resources would essentially flow from the federal ISBs outside of the impacted area to FSAs within or closer to the impacted areas.

The state of Oregon has also identified proposed State Staging Areas (SSAs) to support the state's response and recovery activities in the aftermath of a catastrophic event. SSAs are locations established where resources can be placed while awaiting a tactical assignment.

Bulk fuel supplies requested by ODOE will be delivered to federal staging areas prior to deployment to state designated locations to support ODOE's fuel allocation program into the impacted areas.

All federal and state staging areas will need to be vetted and validated prior to finalization.



Incident Support Bases (ISB), Forward Staging Areas (FSA) and State Staging Areas (SSA)

APPENDIX D

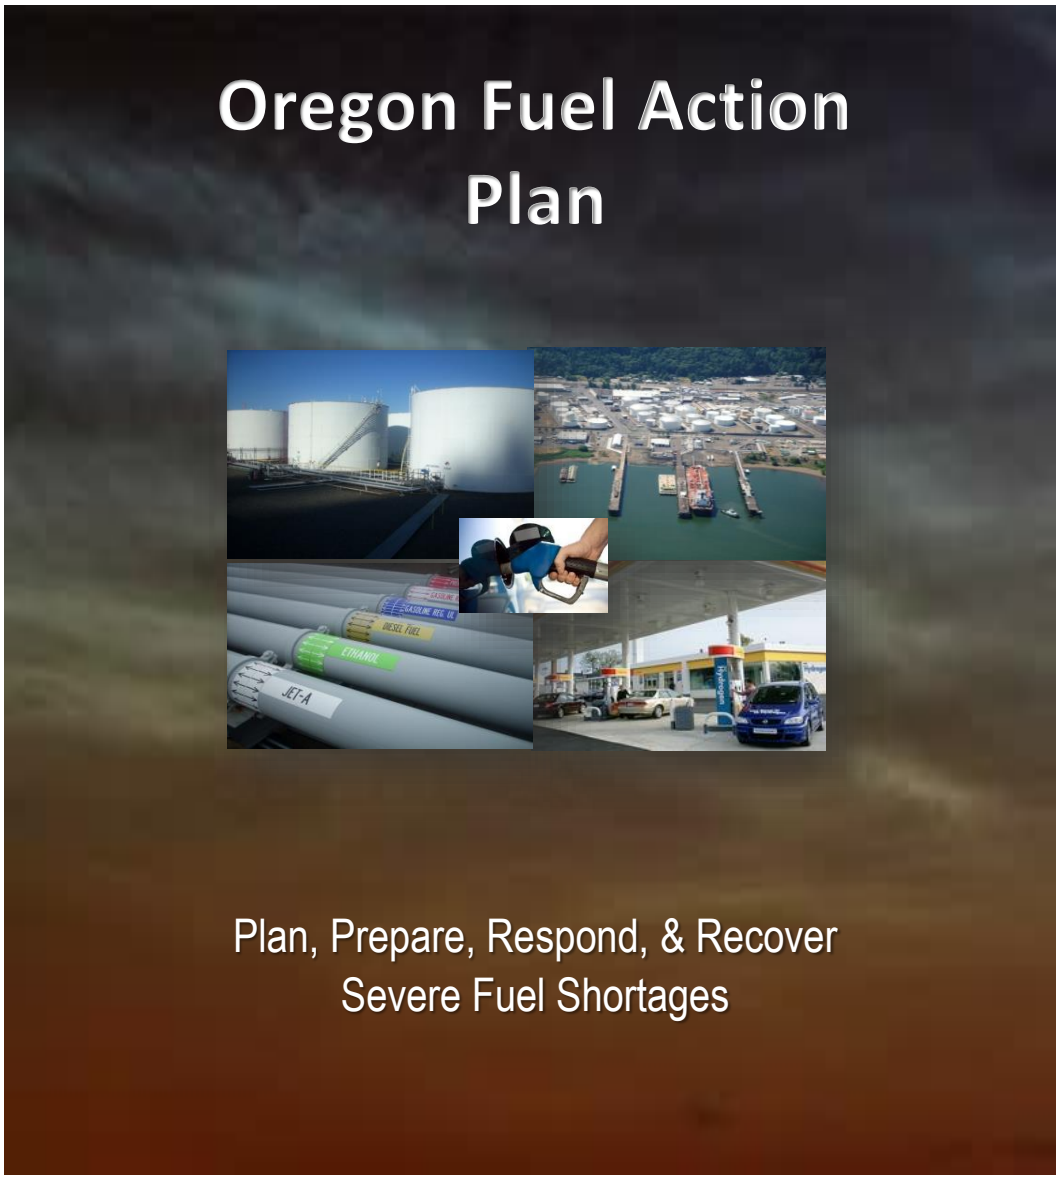
County Lifeline Routes and FPODs

Appendix D provides information on the priority lifeline routes and pre-designated Fuel Points of Distribution (FPODs) for each of Oregon's 36 counties. County designated priority lifeline routes should connect with state priority lifeline routes to support deliveries of fuel and other disaster relief commodities like food, water, and medical supplies.

WORK IN PROGRESS

ODOE is working with all counties to designate priority lifeline routes and FPODs to support fuel deliveries to the communities prior to an emergency as county resources allow. As the counties complete this work, ODOE will include the information in future revisions of the Oregon Fuel Action Plan.

Appendix D provides Marion County as an example.



APPENDIX E
ESF 12 Fuel Pre-Drafted Mission Assignments

APPENDIX E – WORK IN PROGRESS

ODOE is developing Pre-Drafted Mission Assignments for ESF 12 specific to the fuel sector. The Pre-Drafted Mission Assignments will identify and describe the type and level of support the agency will require from federal and military agencies to accomplish the missions and objectives identified in the Oregon Fuel Action Plan.

APPENDIX F
Fuel Executive Order

OREGON DEPARTMENT OF ENERGY

Appendix F is the Fuel Executive Order to be signed by the Governor authorizing ODOE to implement the strategies in the Oregon Fuel Action Plan when a severe and/or long term fuel shortage or disruption exists. The purpose is to maintain emergency services, productivity and work to ensure the health, safety, and welfare of the residents of the State of Oregon while the emergency exists.

EXECUTIVE ORDER NO. ## - ##

PROCLAMATION OF A STATE OF EMERGENCY DUE TO CASCADIA SUBDUCTION ZONE EARTHQUAKE AND RESULTING THREAT TO FUEL RESOURCES IN THE STATE OF OREGON

Pursuant to ORS 401.165(1), I find that a state of emergency now exists in Oregon after the recent earthquake along the Cascadia Subduction Zone. Because this earthquake constitutes a "natural event or circumstance" that now "threatens widespread loss of life, injury to person or property, human suffering or financial loss," the present circumstances qualify as an emergency as defined under ORS chapter 401. Under this chapter, my authority as Governor is to "reduce the vulnerability of the State…resulting from emergencies" like that which we are now facing here in Oregon. ORS 401.032.

Furthermore, the recent earthquake's destruction specifically constitutes an "energy emergency" that has presented a serious threat to our fuel resources that are critical to support Oregon's "essential services and transportation." ORS 176.809(2). [Because of the significant damage caused by the earthquake at _____.] Therefore, because the supply and distribution of Oregon's fuel resources are specifically threatened, the "health, safety and welfare of the people of Oregon" is now at risk with regard to the state's fuel resources. ORS 176.785.

As Governor, pursuant to ORS 401.168, I have "complete authority over all executive agencies of state government and the right to exercise…all police powers vested in the state by the Oregon Constitution," and my authority includes suspending provisions of "any order or rule of any state agency" if I determine that compliance with the rule would impact the "mitigation of the effects of the emergency." Thus, I now exercise my power during the present emergency to delegate authority to the Oregon Department of Energy (ODOE) to address the present threat to the fuel supply in the State of Oregon. ORS 401.035, 176.785. I trust that the ODOE will be able to help maintain emergency services, productivity, and work to ensure the health, safety, and welfare of the residents of the State of Oregon while the emergency exists.

IT IS HEREBY DIRECTED AND ORDERED:

1. The ODOE shall coordinate and implement the Oregon Fuel Action Plan in response to the emergency that now impacts the State of Oregon in order to address the current issues surrounding the supply and distribution of fuel resources. ORS 401.168, 401.236.

2. The ODOE is authorized to allocate and control all fuel stockpiles throughout the State of Oregon consistent with the Oregon Fuel Action Plan. ORS 401.168, 401.188.

3. The determination of an emergency is statewide and will continue until I proclaim that the state of emergency no longer exists, or when the threat of an emergency has passed. ORS 401.204(1).

Done at _____, Oregon, this ____ day of _____, _____.

SECRETARY OF STATE

APPENDIX G

Fuel Waivers

ODOE has identified waivers that may be lifted temporarily during state declared emergencies to ensure adequate fuel supplies are delivered without delays to support the state's emergency response and recovery activities. Appendix G lists the potential fuel waivers and provides a description of both the federal and state regulations that would need to be waived to ensure timely fuel deliveries and the deliveries of other disaster relief supplies into the impacted areas of the state.

ODOE will work with lead federal and state agencies as appropriate to develop boilerplate waivers to be included in Appendix G of the Oregon Fuel Action Plan to ensure the timely execution of fuel waivers if and when needed to save lives, protect public health and safety, and to restore critical lifelines and services in Oregon.

FUEL WAIVERS

The oil industry operates under various regulations to ensure safe operations, environmental quality, and fair market competition. These same regulations could also impede the rapid restoration of the petroleum supply and distribution system in the aftermath of an emergency resulting in a long-term or severe fuel shortage.

As the lead agency over ESF 12 responsible for the petroleum sector, ODOE will work with the appropriate federal and state agencies to temporarily waive safety, environmental, and fair market regulations as appropriate. The goal is to ensure the rapid recovery of the petroleum infrastructure in the Pacific Northwest region and provide adequate fuel supplies to the state's emergency and essential services providers to save lives and restore the state's critical lifeline services to citizens.

The following is a list of potential waivers ODOE will consider requesting during an incident. ODOE will coordinate all waivers with the U.S. Department of Energy as the lead federal agency over ESF 12.

ULSD WAIVER

Issue: Ultra Low Sulfur Diesel is a cleaner fuel with a maximum 15 parts per million sulfur specification required by EPA for vehicles and equipment. During an emergency, lifting this requirement would allow distributors to get available fuel into the affected area regardless of the sulfur content.

Waiver Needed: 40 CFR 80.510 and 80.520 set standards for Ultra Low Sulfur Diesel. ORS 646.922(1) restricts the sale or offer for sale of diesel fuel unless the diesel fuel contains at least 5 percent biodiesel by volume or other renewable diesel with at least 5 percent renewable component by volume by retail dealers, nonretail dealers, or wholesale dealers.

ODOE Action: Work with the Environmental Protection Agency (EPA) and the Oregon Department of Environmental Quality (DEQ) to ensure this waiver is obtained to ensure any available fuel can be used in the affected area during a declared emergency if appropriate. This waiver would allow the use of high sulfur heating oil in model year 2006 and older vehicles, generators, and home heating oil during an emergency.

VAPOR RECOVERY AND FUEL TRANSFER, LOADING AND STORAGE WAIVERS

Issue: Fuel terminal loading and unloading systems and tank trucks that transport fuels are required to use specified vapor recovery equipment and comply with other vapor control requirements. Vapor recovery requirements differ from state to state. All state vapor recovery requirements are submitted to EPA for review and approval. During an emergency, lifting the vapor recovery requirement would allow fuel to get from bulk gasoline terminals to local fueling outlets without vapor recovery requirements by whatever transport means possible.

Waiver Needed: 40 CFR Part 60 Subpart XX and Part 63 Subparts R, Y, and BBBBBB set the standards for loading at bulk gasoline terminals, pipeline breakout stations, and marine tank vessel loading operations. ORS 468A.025 establishes areas of the state and prescribes the degree of air pollution or air contamination that may be permitted for such areas. OAR 340-232-0080 through 340-232-0150 establish volatile organic compounds control requirements applicable to various fuel transfer, loading and storage operations. OAR 340-244-0232 establishes the limitations and management practice for hazardous air pollutants and volatile organic compounds emitted from the loading of gasoline storage tanks and gasoline

dispensing facilities, and OAR 340-244-0239 requires each owner to maintain their equipment and records accordingly. These rules apply differently based on the location of the facilities or activities in the state. ORS 468A.045 prohibits certain activities to be carried out without a permit including that no person shall increase in volume or strength discharges or emissions from any air contamination source for which a permit is required…in excess of...emission specified under an existing permit.

ODOE Action: Work with EPA and DEQ to obtain Vapor Recovery and Fuel Transfer, Loading, and Storage Waivers, as necessary, during a declared emergency if appropriate to ensure fuel can be transported from refineries to bulk gasoline terminals to local fueling outlets if compliant transport means are not available or feasible.

CLEAN FUEL SUPPLY WAIVER

Issue: Producers and importers of fossil-based transportation fuels are required to comply with the Oregon Clean Fuel Standards to reduce the overall carbon content of fuel used in Oregon. During an emergency, clean fuels may not be available in sufficient quantity to comply with the standards. The standards do not impose any direct limit on the type of fuel that may be provided for use at any time and so providing any necessary fuels during an emergency would not itself be a violation of the standards. But application of the standard would create an economic disincentive to fuel suppliers if they are unable to comply due to an emergency that reduces the supply of clean fuels.

Waiver Needed: OAR 340-253-2000(1)(a) authorizes DEQ to grant an emergency deferral of the standards if there is a shortage of clean fuels available due to a natural disaster.

ODOE Action: Work with DEQ to obtain an Emergency Deferral of the Clean Fuels Standards.

OXYGENATED FUEL EMERGENCY WAIVER

Issue: DEQ rules require the use of oxygenated fuels during winter months in certain designated areas that are not meeting carbon monoxide (CO) ambient air quality standards. Although no areas are currently designated and required to use such fuels, the requirements remain in effect as a contingency plan option in the event that any such areas slip back into noncompliance with CO standards. Given that newer car engines are very effective at controlling such emissions, this is not anticipated to occur.

Waiver Needed: In the event that any area again becomes subject to the requirement to use oxygenated fuels in winter months, OAR 340-258-0270 authorizes DEQ to grant a waiver of such requirements in an emergency that is outside of the control of fuel suppliers.

ODOE Action: Work with DEQ to obtain an Oxygenated Fuel Emergency Waiver, if necessary, during a declared emergency.

DRIVER QUALIFICATION, LOAD, AND INSPECTION WAIVER

Background: The U.S. Department of Transportation's (USDOT) Pipeline & Hazardous Materials Safety Administration (PHMSA) sets general standards for vehicle labeling, record keeping, operator qualifications, and other requirements for transporting commodities across the country. PHMSA also requires transporters to follow all applicable state requirements.

Issue: PHMSA has certain rules requiring a driver's physical fitness, level of fatigue, fluency in English, thorough inspection of cargo, ensuring lighting and cargo standards, and vehicle maintenance and repairs are met. During an emergency, lifting the driver qualification, load, and inspection waiver would allow fuel supplies to be delivered into the disaster area fewer delays.

Waiver Needed: 49 CFR Parts 391-3 and 396 set driver standards, load standards, and inspection standards. ORS 818.400(b) requires any vehicle or combination of vehicles to stop and submit to any enforcement of commercial vehicle, weight, size, load, conformation, or equipment regulation when directed by proper authority.

ODOE Action: Work with PHMSA and the Oregon Department of Transportation (ODOT) to obtain a Driver Qualification, Load, and Inspection Waiver during a declared emergency if appropriate to ensure fuel and other relief supplies are delivered into the disaster area with fewer delays.

HOURS OF SERVICE WAIVER

Issue: PHMSA sets standards on how many hours a truck driver can be on duty and drive in a given day and week. There are also certain rest time requirements between on duty periods. Some states have hours of service requirements that are more stringent than PHMSA's. These requirements may hinder the effort to get as many relief commodities into the disaster area as possible with fewer delays.

Waiver Needed: 49 CFR Part 395 sets hours of service regulations. ORS 825.252 limits the hours that drivers or operators of motor vehicles may remain on duty, as well as the required number of hours released from duty, in order to protect and safeguard the health and safety of all employees, passengers, and the public. ORS 825.254 limits the movement of vehicles on particular days of the week and limits the movement of vehicles subject to regulation under the same section.

ODOE Action: Work with PHMSA and ODOT to obtain federal and state Hours of Service Waivers during a declared emergency if appropriate to ensure timely deliveries of emergency relief supplies and fuel into the disaster area with fewer delays.

WEIGHT LIMITS WAIVER

Issue: All states set weight restrictions on the maximum weights allowable for trucks that travel on roadways. Weight restrictions vary from state to state. Most states require fuel tankers to be filled at levels below their capacity.

Waiver Needed: ORS 818.010 establishes maximum allowable weight limitations for trucks. ORS 825.450(1) requires that ODOT shall issue a receipt stating the combined weight of each vehicle…or combination of vehicles.

ODOE Action: Work with ODOT to obtain a Weight Limits Waiver and set temporary limits for trucks carrying emergency relief supplies to ensure timely deliveries of fuel into the disaster area with fewer delays.

HAZMAT SPECIFICATIONS WAIVER

Issue: PHMSA sets strict specifications on the types of vehicles that can carry gasoline. There are also requirements related to shipping papers and placarding. To get adequate fuel supplies into the disaster

area with fewer delays, vehicles that are designed to carry gasoline and diesel fuel, even if they do not meet the strict hazmat specifications may need to be used to deliver fuel.

Waiver Needed: 49 CFR Parts 173.242 and 172 Subparts C, D, F, and I govern vehicle specifications and other shipping standards for tank trucks. ORS 825.258 applies the rules for the transportation of hazardous waste, material and PCB to anyone who transports, or causes to be transported, any hazardous material. ORS 825.260 allows for the impoundment of vehicles unlawfully transporting hazardous wastes or substances.

ODOE Action: Work with PHMSA and ODOT to obtain a Hazmat Specifications Waivers during a declared emergency if appropriate to ensure adequate fuel supplies are delivered into the disaster area.

JONES ACT WAIVER

Issue: The Merchant Marine Act (Jones Act) prohibits foreign-built, foreign-owned, or foreign-flagged vessels from carrying goods and commodities between U.S. ports. To get adequate fuel supplies into the disaster area, foreign vessels may need to be used to deliver fuel between U.S. ports. This waiver can be granted automatically on request of the Secretary of the Department of Defense (DOD) or the Secretary of the Department of Homeland Security (DHS) if considered necessary in the interest of national defense.

Waiver Needed: 46 USC 551 codifies the restriction on non-U.S. flagged vessels delivering disaster relief supplies including fuel between U.S. ports.

ODOE Action: Work with USDOE to obtain a Jones Act Waiver through DOD and/or DHS during a declared emergency if appropriate to ensure that non-U.S. flagged vessels are allowed to deliver adequate fuel supplies into U.S. ports near the disaster area.

DIESEL FUEL PENALTY WAIVER

Issue: The Internal Revenue Service (IRS) imposes 24.4 cents per gallon tax on diesel fuel sold for on road use. Meanwhile dyed diesel fuel used for farming purposes and home heating are not subject to the tax. If the dyed diesel fuel was used for on road purposes, the IRS would require that use to be reported and the tax paid accordingly. During an emergency, lifting the Diesel Fuel Penalty requirement would allow as much transportation fuel into the market as possible to make up for the supply shortages.

Waiver Needed: Publication 510 governs the Internal Revenue Code for excise taxes. ORS 465.104 requires that the seller of a petroleum product withdrawn from a bulk facility shall collect from the person who orders the withdrawal a fee. In addition, any person who imports petroleum products in a cargo tank or a barge for delivery into a storage tank in the state shall pay a petroleum products delivery fee to the Department of Revenue for each delivery. ORS 465.106 requires that the State Fire Marshall establish the amount of the fee as necessary for the state's oil, hazardous material and hazardous substance emergency response program. ORS 465.111 requires that the Oregon Department of Revenue (ODOR) collects these fees.

ODOE Action: Work with USDOE and ODOR to obtain a Diesel Fuel Penalty Waiver during a declared emergency if appropriate to ensure as much transportation fuel into the market by removing the tax requirement that may impede bringing dyed fuel into the transportation mix.

VESSEL MOVEMENT CONTROL WAIVER

Issue: The U.S. Coast Guard has authority to control vessel traffic through the enactment of safety and security zones. Delivery of fuel by water may necessitate implementing such zones.

Waiver Needed: Captain of the Port Order waiver under the Ports and Waterways Safety Act (33USC1221 et seq.).

ODOE Action: Work with USDOE to obtain a Vessel Movement Control Waiver through the USCG and DHS to provide exclusive access to ports in the disaster area to those bringing fuel and other relief supplies.

RVP WAIVER

Issue: Reid Vapor Pressure (RVP) is a common measure of the volatility of gasoline. Many states allow a variance, up to 1 lb. RVP from current standards for gasoline blended with ethanol. This requirement could impede fuel supplies from other states without RVP requirements from entering into the disaster area.

Waiver Needed: ORS 646.913(3)(d) requires that the Oregon Department of Agriculture (ODA) adopt standards that require that gasoline blended with ethanol…complies with or is produced from a gasoline base stock that complies with current standards.

ODOE Action: Work with ODA and DEQ to obtain a RVP Waiver during a declared emergency if appropriate to ensure as much transportation fuel into the disaster area to make up for shortages.

BIOFUEL BLENDING WAIVER

Issue: Many states require a minimum amount of biofuels to be blended into all gasoline and/or diesel sold within the state. This requirement could impede fuel supplies from other states without biofuel blending requirements from entering into the disaster area.

Waiver Needed: ORS 646.913(1) prohibits the sale of gasoline unless the gasoline contains 10 percent ethanol by volume, and ORS 646.922 limits the sale of diesel fuel based on the biodiesel content by volume.

ODOE Action: Work with DEQ to obtain a Biofuel Blending Waiver during a declared emergency if appropriate to ensure fuel supplies that do not contain the specified volume of biofuels can be delivered and sold in Oregon.

DEALER LICENSE WAIVER

Issue: Many states require a carrier to pay a fee and obtain a Distributor's License to transport motor fuel within the state. During an emergency, this requirement could impede carriers without a Distributor's License from delivering fuel supplies into the disaster area.

Waiver Needed: ORS 319.030 requires that no dealer shall sell, use or distribute any motor vehicle fuel until the dealer has secured a dealer's license as described in ORS 319.040 under the application for and issuance of dealer's license.

ODOE Action: Work with ODOT to obtain a Distributor License Waiver during a declared emergency if appropriate to ensure that fees and license requirements are lifted to allow all drivers and trucks available within the state and/or those from across state lines to deliver fuel into the disaster area.

IMPORTER/EXPORTER LICENSE WAIVER

Issue: State revenue departments require fuel importers and exporters to pay a fee and obtain a license from the state to move fuel across state lines. Without these licenses, the fuel merchant cannot legally buy gasoline from one state and move it to another. During an emergency, this requirement could impede fuel importers and exporters from delivering fuel supplies into the disaster area.

Waiver Needed: ORS 319.275 states that a person shall not accept or receive motor vehicle or aircraft fuel in this state from a person who imports motor vehicle or aircraft fuel who does not hold a valid motor vehicle fuel dealer license in this state…the purchaser or receiver shall be liable for all taxes, interest and penalties contained in ORS 319.010 to 319.430.

ODOE Action: Work with Oregon Department of Revenue (ODOR) to obtain an Importer/Exporter License Waiver during a declared emergency if appropriate to ensure that fees and license requirements are lifted to allow merchants to deliver fuel across state lines without being properly licensed and registered.

IRP/IFTA WAIVER

Issue: The International Registration Plan (IRP) is an agreement among states of the U.S, the District of Columbia, and the provinces of Canada providing for payment of commercial motor carrier registration fees. To operate in multiple states or provinces, motor carriers must register in their base jurisdiction (state or province). The International Fuel Tax Agreement (IFTA) is an agreement among states to report fuel taxes by interstate motor carriers. During an emergency, this requirement could impede fuel deliveries into the disaster area.

Waiver Needed: ORS 825.555 permits the ODOT to enter into international fuel tax agreements with jurisdictions outside of the state to provide for the cooperation and assistance among member jurisdictions in the administration and collection of taxes, such as the IFTA. Section 6 gives ODOT authority to adopt rules establishing an annual fee under IFTA. ORS 826.007 allows ODOT to enter into agreements with…representatives of any jurisdiction that issues out-of-state registration to provide for proportional registration of vehicles and for the apportionment of registration fees and other fixed fees and taxes on vehicles proportionally registered in this state and the other jurisdiction. Fees, in regard to the IRP, are designated under ORS 826.019, which allows the ODOT to collect a fee from each applicant for proportional registration under Chapter 826.

ODOE Action: Work with ODOT and USDOE to obtain an IRP/IFTA Waiver during a declared emergency if appropriate to ensure that fees and fuel tax reporting requirements are lifted to allow fuel deliveries into the disaster area from the Canadian provinces.

APPENDIX H
Response to Non-Catastrophic Events

Response to Non-Catastrophic Events *(Viable Fuel Infrastructure)*

The response strategies in the Oregon Fuel Action Plan are designed to be implemented for a variety of fuel shortage situations, not only catastrophic earthquake events. In any given year, Oregon experiences a variety of fuel supply disruptions. Many are minor and limited in scope and resolved quickly by the petroleum industry. However, if these disruptions extend over wide areas and last more than several hours they could potentially impact public health and safety.

As a result, the Oregon Department of Energy will implement the Oregon Fuel Action Plan as appropriate to monitor events, provide situational awareness, and respond to fuel shortage situations as the event conditions require.

Threats to the Petroleum Infrastructure

- *Severe Weather Conditions* – Winter storms, drought (fires), floods, wind storms, and freezing rain could stress the fuel supply and distribution system as sudden or unexpected surges in demand cannot be met by actual or expected supply levels. Delays in fuel deliveries could also occur due to road closures or heavy traffic.

- *Special Events* – Major sporting events, festivals, and other events that draws hundreds of thousands of visitors to Oregon could also stress the fuel supply and distribution system.

- *Energy Infrastructure Events* – Unanticipated refinery, terminal, and pipeline shutdowns, extended power outages, and equipment and system failures could result in the reduction of supply and disrupt fuel distribution.

- *National Security Events* – Acts of terrorism, cyber attacks, and sabotage could result in the physical destruction of the petroleum infrastructure, increasing demand for fuels, and also

reducing the fuel supplies available to the United States and the Pacific Northwest.

- *Political Factors* – Oil embargos, war, and the mobilization of defense resources could create a sudden surge in demand. These events could also reduce the fuel supplies available to the United States and the Pacific Northwest.

- *Market Related Events* – A sharp, sudden escalation in the price of fuel could result from a curtailment of supplies and stocks.

Fuel Set-Aside Plan

ODOE is in the process of updating the state's Fuel Set-Aside Plan. The National Association of State Energy Officials (NASEO) is currently developing a template plan to provide guidance and assistance to the states as they update or revise their fuel curtailment plans. ODOE will await the completion of NASEO's guidance prior to finalizing Oregon's Fuel Set-Aside Plan.

EXAMPLE – LIMITED Activation of Oregon Fuel Action Plan

Solar Eclipse

ESF 12: Fuel Sector Planning

BACKGROUND

The August 21, 2017 eclipse wil be the first total solar eclipse in the continental U.S. in 38 years. A partial eclipse can be seen anywhere in the United States. However, the path of totality, where the moon will completely block the sun, will stretch across 12 states including Oregon. The solar eclipse is expected to attract viewers from around the globe. The Oregon Coast is the first easily-accessible place in the United States where the eclipse will be visible. Central and eastern Oregon are considered by subject matter experts as the best sites in the nation to view totality due to the dry weather, clear skies, and low levels of light pollution.

LOCATION

- The 60-mile wide eclipse path of totality will impact a 337.8 mile distance across the state of Oregon, and continue eastward along a path across the United States.
- The path of totality will cross 16 Oregon counties: Baker, Benton, Clackmas, Crook, Deschutes, Grant, Jefferson, Lincoln, Linn, Malheur, Marion, Polk, Tillamook, Wasco, Wheeler, and Yamhill.
- The eclipse is expected to last from 9:00 am to 11:45 am. Totality will occur for approximately 2 minutes at about 10:15 am.

STATE PLANNING ASSUMPTIONS

As a planning tool, Oregon Emergency Management assumed a statewide visitor population of approximately one million people into Oregon to observe the event. This is in addition to Oregon's estimated four million residents, representing a short-term surge of 25 percent in state population. This increased population will likely concentrate along the path of totality from the coast to the border with Idaho, with increases in lodging, transportation, and other effects to be felt statewide.

The population assumptions were extrapolated from figures provided by local communities and industry groups reporting that lodging at hotels and campsites along the path of totality as well as those near major highway connections are at or above capacity. It is further assumed that these visitors will primarily travel by personal vehicles.

POTENTIAL IMPACTS

- Increases in traffic, causing congestion
- Strain on public safety services
- Shortages in fuel

FUEL MESSAGES

- All fuel messages, in general, result in a surge or run on fuel. Messages advising motorists NOT to top off tanks or hoard fuel warns people that there might be a shortage on fuel or a distribution problem. Messages telling people to prepare and fuel up for a solar eclipse or other event also lets people know there might be a supply or distribution problem. Fuel messages tend to create concern, which is what we're trying to prevent.

- The petroleum industry's "just-in-time" business strategy does not accommodate fueling behaviors that are out of the "norm." This includes topping off tanks and hoarding of fuel. These actions put undue stress on an already tight supply system.

- The petroleum industry is extremely resilient and addresses supply and distribution problems routinely without government intervention. Companies are taking the necessary steps to prepare for the solar eclipse.

- ODOE will not allocate fuel for this scheduled short-term event. The purpose of fuel allocation is to help alleviate shortages and hardships for priority users who save lives and restore critical infrastructure during severe and long-term fuel disruptions. Criteria for allocating fuel include:

  1. Governor's Emergency Declaration.
  2. Emergency and essential service providers unable to obtain fuel at any price.

  However, ODOE will work with industry to monitor and resolve potential supply and distribution issues before, during, and after the solar eclipse.

- Messages preparing out-of-state visitors to have a fuel plan, which includes fueling up prior to entering into Oregon's path of totality could be helpful to lessen the strain on in-state supply, though these messages could also prompt Oregonians to be concerned about fuel supplies and top off themselves.

- All public safety agencies along the path of totality *(law enforcement, fire service, EMS, park rangers, etc.)* should fuel up in preparation for the solar eclipse to protect public health and welfare. This is consistent with what public safety agencies routinely do to prepare for holidays and special events.

OREGON DEPARTMENT OF ENERGY (ODOE) ACTIONS

Preparing for the Event

- Work with petroleum industry partners to increase awareness of the solar eclipse and potential impacts on fuel. This allows the companies' time to apply industry planning strategies for special events to meet anticipated increases in demand. Strategies include:

  - Increase Supply – A planned event allows industry time to gradually maximize supply volumes beyond summer stocks to meet anticipated demands.

- Modify Delivery Schedule – Increase the schedule for fuel deliveries from once every four days to delivering fuel every day and a half.

- Prepare Distribution System – Marketers and jobbers operate at 40 percent capacity routinely. To meet anticipated increases in demand, marketers and jobbers have the ability to ramp up to 100 percent capacity to make more frequent fuel deliveries into communities along the path of totality.

Note: BP, Chevron, Kinder Morgan, Phillips 66, Shell, and the Western State's Petroleum Association provided ODOE with the information on industry strategies for special event planning.

- Coordinate with the Oregon Department of Justice (ODOJ) to activate the agency's "Price Gouging" website to allow citizens to report suspected case of inflated fuel prices. ODOJ will investigate reported cases as appropriate.

Response for the Event

- **Activate "Control Cell"** – Designated ODOE responders will monitor the fuel outlook before, during, and after the Solar Eclipse on August 21, 2017. The tentative schedule includes:

  - Wednesday, August 16 - Sunday, August 20 – From ODOE's office in Salem, monitor the fuel supply and distribution system as visitors are traveling into Oregon communities along the path of totality.

  - Monday, August 21 - Tuesday, August 22 – Respond to Oregon State Emergency Coordination Center (ECC) to monitor and respond to potential fuel supply and distribution concerns.

  - Wednesday, August 23 and following days – From ODOE's office in Salem, monitor the fuel supply and distribution system as visitors are traveling from Oregon communities.

1. Track Fuel Outlook ✓ Work with industry to monitor potential fuel supply, scheduling, and distribution problems. ✓ Work with 16 counties to monitor potential fuel shortages along the path of totality. ✓ Report ESF 12 fuel priorities, actions and decisions at Oregon ECC briefings, and in daily Situation Reports and Incident Action Plans.
2. Participate in the Oregon ECC Joint Information System to Provide Fuel Sector Information ✓ Fuel outlook ✓ ODOE actions in response to the solar eclipse ✓ Industry strategies to meet increases in fuel demand ✓ ODOJ's Price Gouging Website ✓ Oregon's fuel supply and distribution system
3. Activate Price Gouging Website ✓ Request ODOJ activate the agency's Price Gouging Website to allow citizens to report suspected cases of inflated fuel prices.

4. Secure Hours of Service Waiver

- ✓ Request ODOT temporarily lift the Hours of Service requirement for fuel haulers delivering supply to communities in the path of totality as a result of severe traffic congestion.

- Wednesday, August 23 – Continue monitoring the fuel situation from ODOE's office in Salem if necessary.

ODOE AUTHORITY

ORS 176.750-785 – authorizes ODOE to develop and maintain a statewide contingency plan in response to petroleum shortages that impact Oregon. This includes providing adequate fuel supplies to maintain emergency services, transportation, and the operation of the economy to ensure the health, safety, and welfare of the residents of the State of Oregon while an emergency exists.

APPENDIX I

Primary and Backup Communications Phone Directory

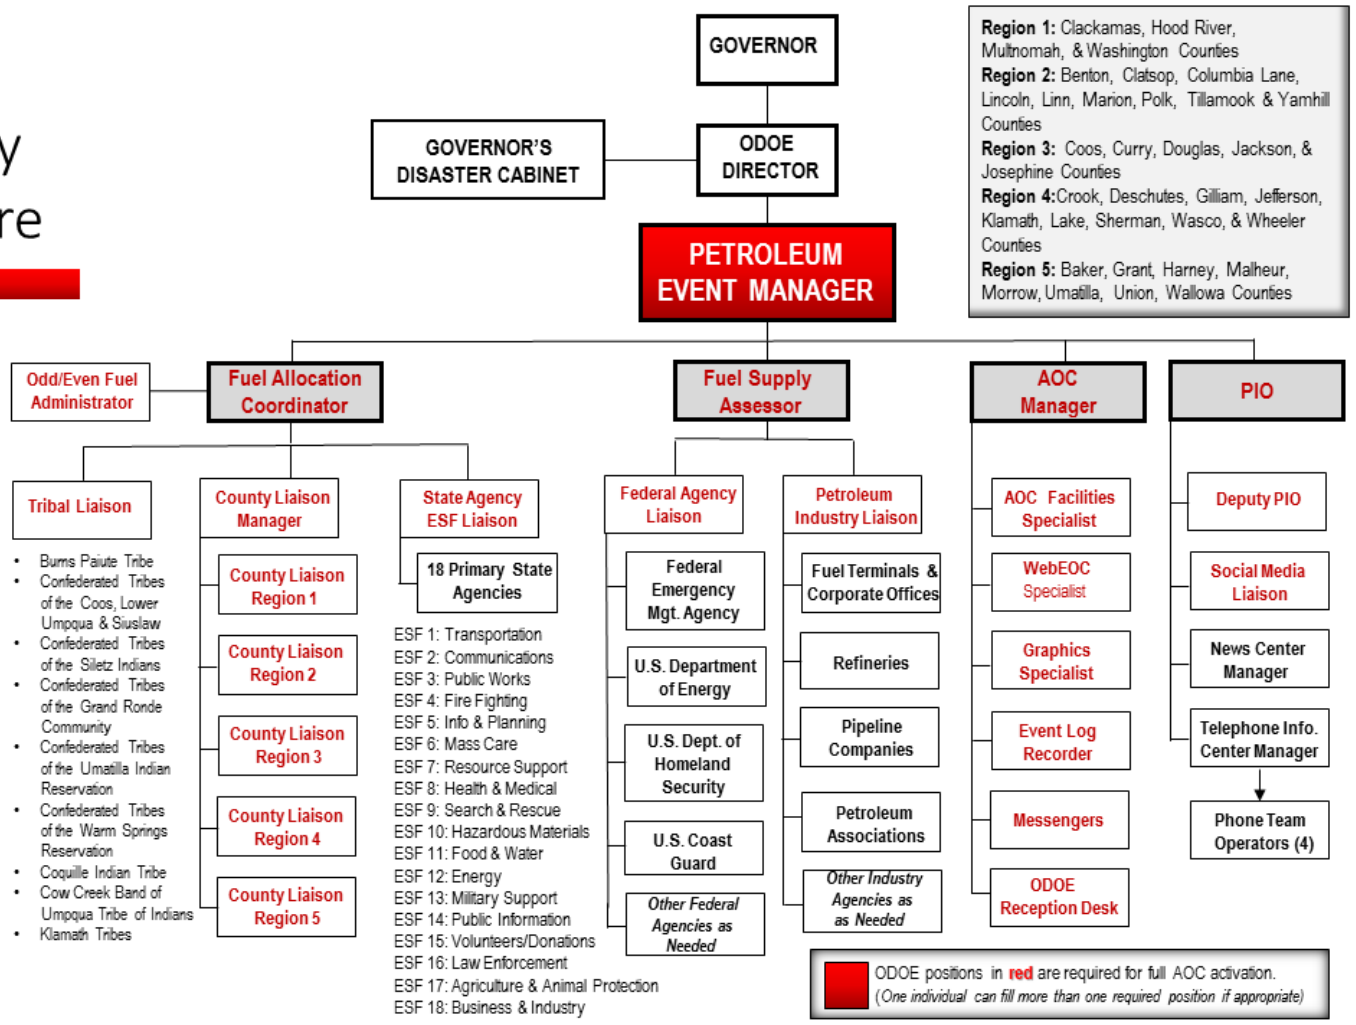
ODOE's ability to implement the Oregon Fuel Action Plan and strategies to provide adequate fuel supplies to the state's emergency and essential services providers is heavily dependent on the agency's ability to communicate with industry, federal, state, county, and tribal emergency response partners. ODOE's Primary and Backup Communications Phone Directory identifies 24/7 primary and backup communications contact information for each agency, organization, and jurisdiction that has a role in securing, delivering, and/or receiving emergency fuel supplies. The goal is to save lives, protect public health and safety, and to restore critical lifelines and services in Oregon after an emergency.

INTERNAL AGENCY DISTRIBUTION ONLY

APPENDIX J

ODOE Emergency Response Procedures

Procedures for ODOE agency operations for the Oregon Fuel Action Plan are included in this appendix. This includes:



- ODOE Duty Officer Procedures
- ODOE AOC Emergency Response Organizational Chart
- ODOE AOC Activation Procedures
- ODOE AOC Response Position Procedures. Each response position procedure includes key objectives, checklists of tasks, guidance to accomplish objectives and tasks, and applicable reference materials.

Appendix J

ODOE Emergency Response Structure

- 24/7 Response Capabilities
- ODOE Agency Operations Center activation requires staff from all agency divisions to support shift changes

Executive Summary

Overview

Washington sits astride a great international trade route that links our state to the world's economy. The investments that have been made to maintain and strengthen this asset pay substantial dividends in terms of supply-chain efficiencies, shipping rates and access to emerging markets. In concert with the state's transportation system, our ports provide:

- Family wage jobs, especially in industrial and agricultural sectors.
- Transport of commercial goods at substantially reduced cost.
- Cost-effective access to global markets.

The purpose of the *2017 Marine Cargo Forecast* is to assess the expected flow of waterborne cargo through Washington's port system and to evaluate the distribution of cargo through the state's transportation network, including waterways, rail lines, roads, and pipelines. The study includes forecasts of trade by commodity and cargo type from 2015 through 2035.

These forecasts are unconstrained, which means they assume that the infrastructure needed to move the cargo will be in place in time to meet the demand. However, they do provide a qualitative assessment of these factors because meeting demand will inevitably require upgrades and investment, particularly in rail capacity.

The Washington Public Ports Association (WPPA) has been involved in similar forecasting efforts since 1975, on approximately a five year basis. These reports are used as planning tools within the port community and related industries. They also alert state and local policymakers, as well as the public, to potential opportunities and constraints. The Freight Mobility Strategic Investment Board is a co-sponsor of the project.

Economic opportunities on the Pacific Rim

The first section of the report assesses the prospects for the world economy with an emphasis on the state's principal trading partners in Asia. The state's dependence on Asia is difficult to overstate. Consider the following:

- 97 percent of containers imported through Washington ports come from Asia.
- 90 percent of containers exported through the state go to Asia.

This report analyzes each region or country to identify factors impacting those areas in the short term. That information is used to make long-term projections, and to inform cargo forecasts up to the year 2035. While economic recovery from the Great Recession has been slow, the Pacific Rim continues to grow faster than most of the world.

China is especially critical to Washington, as it is to other West Coast states. For most commodities, its importance has surpassed all other Asian countries. China's economy is expected to continue growing and will soon be second only to the United States.

Washington's chief domestic trading partners, Alaska and Hawaii, are also included in the macroeconomic overview section of the report. Alaska's economy is driven by the petroleum industry and the federal government. Hawaii's is led by the tourism industry, but has a more diversified economy than Alaska. Both states are projected to grow slowly during the forecast period.

Trade opportunities in the Evergreen State

Washington ports handle a diversified range of cargoes, and the future should bring growth opportunities to the various cargo groups. Highlights of the forecast include the following:

Containers face stiff competition. International container traffic peaked in 2007 then fell sharply during the Great Recession. Volumes have since recovered some of the lost ground, but competing ports in British Columbia have gained market share at our expense. International container volumes are projected to grow, but the rate of growth will depend on the ability of local ports to compete with other regions. Growth in domestic containers (i.e. Alaska and Hawaii) is likely to be slow.

Fully assembled autos are projected to grow steadily. Auto imports dropped sharply during the great recession, and volumes have still not fully recovered. From their current level of 500,000 units, imports are projected to grow by an additional 100,000 to 250,000 units by 2035. Exports of automobiles were negligible until 2008. Since then, they have been as high as 160,000, and are projected to grow to between 320,000 and 420,000 in 2035.

Log exports are likely to level off. In the last decade log exports have grown to levels not seen in years. This sudden jump in exports has ended, but volumes remain substantially higher than they were a decade ago. Future growth is projected to be slow under the reference and high forecasts, and flat under the low. Imports of logs dropped by 75% from their peak in 2005, and are projected to remain essentially flat.

Breakbulk cargo volumes are likely to grow slowly. Metal, forest products and other breakbulk cargo will grow slowly due to containerization and structural changes in the industries that produce these cargoes. Much of the expansion will occur as ports diversify.

Grain shipments are projected to continue growing. Grain shipments saw strong growth over the past 15 years, and this growth is projected to continue. The deepening of the Columbia River Channel led to major investments in export terminals on the river, and they are well-positioned to serve the increasing demand from Asia.

Dry bulk trends will continue. Alumina has greatly decreased in importance to the region, but other commodities have increased. On the export side, potash and soda ash accounted for most of the growth, while exports of other commodities such as petroleum coke moved in steady volumes. On the import side, key commodities include building materials, fertilizer, and chemicals. Slow growth is projected for most of these commodities.

Liquid bulk will shift source. Crude by rail has replaced a share of crude from Alaska, and will likely continue to be an important source. Crude is also received by pipeline from Canada. As crude oil production decreases in Alaska, northwest refineries will replace Alaskan crude oil with a combination of rail, pipeline, and foreign waterborne sources. In addition, shipments of crude oil from the northwest will increase if proposed new shipping terminals are constructed.

Transportation: moving goods to market over road, rail and water

An efficient transportation system that integrates road, rail, and water, and air transportation is essential to meeting our state's present and future trade opportunities. This report focuses in depth on the waterborne transportation system, as well as the road and rail systems that serve the waterborne transportation system. Air transportation is not examined in this report, as there is a limited volume of waterborne cargo that moves to or from Washington marine terminals by air.

Road

Road, highway, and on-terminal truck transport is critical to Washington's ports. Heavy, midsize, and light trucks play important roles in cargo movement and goods distribution. Trucks overall comprise a relatively small portion of total road and highway traffic in the urban regions of the state. While truck traffic is expected to grow between now and 2035, auto traffic will increase even faster. In light of this competition for limited road capacity, the challenge will be to protect the functionality and reliability of the road system for truck transport. Road capacity development will be critical for continued economic growth.

Rail

Trade prosperity in our state is directly linked to the level of rail capacity serving our ports, and the amount of cargo moving to our ports by rail is forecast to increase. If several proposed new marine terminals are constructed the associated growth in rail traffic could be tremendous, but even without those projects port-related rail volumes will grow. In order to meet future demand, it is likely that additional capacity will be needed in various locations.

The state rail system consists of the mainline system and a number of short-line operations. The mainline system is the primary inland transportation component for large-volume import and export cargo moving through our ports. The short-line network consists of many small local railroads, many of which evolved as the state's rail network experienced system-wide contractions, and low-density feeder lines were abandoned by mainline operators.

Washington's mainline rail system is comprised of two competing railroads: the Burlington Northern Santa Fe (BNSF) and the Union Pacific (UP). Both operators have invested significantly in improvements and upgrades to their mainline systems, including new locomotives, new traffic control systems and substantial mainline rail bed improvements.

In general, the key mainlines are able to accommodate existing levels of traffic, and improvements made over the past decade have increased capacity. In particular, a number of projects described in previous Marine Cargo Forecasts were either constructed or are under construction, which has helped to eliminate many of the key capacity constraints. The mainline railroads have demonstrated that they are very good at adding capacity in a relatively short timeframe, if they are able to anticipate the need. State and local governments can facilitate the investments these railroads make by helping with permitting and other local issues.

Waterways

In addition to road and rail transportation, our state's waterways are critically important to international and domestic trade. The Columbia-Snake River navigation system allows Washington-grown agricultural products to move from farm to market, and creates price competition between modes of transportation. Puget Sound and the Washington Coast are vital to domestic barge trade as well as international trade.

LUBA No. 2020-009
Page 5503

The Columbia River deepening project has greatly benefitted shippers who use Washington and Oregon ports along the Lower Columbia by creating transportation cost savings. The recent investments in expanded capacity at grain terminals along the river are proof of the importance of this project.

From harbors in Puget Sound to dams on the Snake River, our waterways are integral to Washington's economy. Future challenges related to channel deepening, maintenance dredging and potential dam breaching must be addressed to preserve the viability of the system.

Challenges on the horizon

Washington's public ports provide economic security, opportunity and diversity to our local communities, to the state as a whole, and to the surrounding region. If we invest wisely in transportation and port infrastructure, trade will continue to flow through the state and deliver tremendous opportunity in the next two decades and beyond.

Every ship that calls in Washington provides greater choices and better prices for consumers, but it also creates opportunities for all Washingtonians: farmers who must move their crops to markets overseas; manufacturers who rely on inbound shipments for parts and materials; and countless innovators who ship their high-demand products cheaply and efficiently around the world.

Our ability to cultivate new opportunities will depend on the investments made today and tomorrow. Much of the cargo received at Washington ports is discretionary, and can move through alternative gateways; in order to preserve the shipping options available local producers, we must compete aggressively to preserve and expand access to trade routes.

Competition is especially fierce from ports in Southern California and British Columbia, as well as ports on the East and Gulf Coast. Southern California is especially attractive to shippers due to its large population base, and British Columbia has been able to offer a low-cost alternative to ports in the Pacific Northwest.

The key to maintaining and expanding our place in the global economy is to continue investing in our transportation infrastructure – beginning with an efficient, cost-effective rail system. Our state's participation in trade brings with it thousands of jobs and greater collective wealth, but it also requires investment. If we make wise choices now, our state stands to benefit from the growth on the horizon for Washington's port transportation system.

Chapter 1
Overview

Purpose

The purpose of the *2017 Marine Cargo Forecast* is to assess the expected flow of waterborne cargo through Washington's port system and to evaluate the distribution of cargo through the state's transportation network, including waterways, rail lines, roads, and pipelines. The study includes forecasts of trade by commodity and cargo type from 2015 through 2035.

These forecasts are unconstrained, which means they assume that the infrastructure needed to move the cargo will be in place in time to meet the demand. However, they do provide a qualitative assessment of these factors because meeting demand will inevitably require upgrades and investment, particularly in rail capacity.

The Washington Public Ports Association (WPPA) has been involved in similar forecasting efforts since 1975, an approximately a five year basis. These reports are used as planning tools within the port community and related industries. They also alert state and local policymakers, as well as the public, to potential opportunities and constraints. This year the Freight Mobility Strategic Investment Board is the co-sponsor of the project.

Methodology

The macroeconomic overview of various geographic regions is based on short-term analyses supplied by IHS Markit. These were supplemented with population growth comparisons based on data from the IMF, World Bank, USDA, and OECD. Trends and forecast data for GDP growth were based on information from the USDA.

The commodity forecasts were based on a variety of sources, depending on the handling group and commodities included. The initial basis for all of the projections was trade forecasts produced by IHS Markit, which served as the "reference" cases for most commodities. Low case and high case forecasts were then developed using additional sources.

These forecasts are **unconstrained**, which means they assume that the infrastructure needed to handle the projected volumes will be available when needed. The **high case** for each handling type includes cargo volumes related to projects that are currently in the permitting process, such as the Millennium Bulk Terminal in Longview, the Northwest Innovation Works methanol plant in Kalama, and the Vancouver Energy terminal in Vancouver, among others.

The Pacific Northwest was divided into four regions, and cargo projections were developed for each. These regions include:

- PSRC – this region includes marine terminals in King, Pierce, Snohomish, and Kitsap County, the counties included in the Puget Sound Regional Council, or PSRC.
- Puget Sound / Other Washington – this includes all ports and marine terminals on Puget Sound that are not in the PSRC region, as well as those on the Washington coast and in the Strait of Juan de Fuca.
- Lower Columbia Washington – this includes all marine terminals on the Washington side of the Columbia River, from Vancouver to the mouth of the river.

- Lower Columbia Oregon – this includes all marine terminals on the Oregon side of the Columbia River, from Portland to the mouth of the river, including those on the Willamette River.

Organization

Chapter 2 provides background on the economy in key trading regions for the Pacific Northwest.

Chapter 3 provides forecasts for waterborne cargo moving through deep-draft marine terminals.

Chapter 4 includes a description of inland navigation on the Columbia-Snake River system, and provides forecast of waterborne cargo movements on the system.

Chapter 5 provides analysis of the inland transportation modes used by marine cargo.

Chapter 6 provides an analysis of the capacity of the mainline rail system in Washington, and includes the results of the detailed rail traffic simulation model created for this analysis.

Chapter 7 provides an overview of port access issues, as well as details on the participating ports.

Acronyms and Abbreviations

Africa: World region that includes all countries in Africa.

ATCS: A system of railroad equipment designed to ensure safety by monitoring locomotive and train locations.

BNSF: BNSF Railway.

Breakbulk: Cargo that must be loaded individually, and not in containers nor in bulk.

CAGR: Compound annual growth rate.

Capesize: Vessels which are too large to pass through the Panama Canal or Suez Canal, and therefore travel around the Cape of Good Hope or Cape Horn.

CBR: Crude by rail.

China: World region that includes mainline China, Hong Kong, and Macao.

Coastwise traffic: Domestic waterborne traffic carried over the ocean, (e.g. Alaska to Puget Sound, or Columbia River to California).

DBEDT: Hawaii Department of Business, Economic Development & Tourism.

DDGS: Distiller's dried grains with solubles.

DPU: Distributed power unit (DPU) is a locomotive capable of remote-control operation in conjunction with locomotive units at the train's head end. DPUs are placed in the middle or at the rear of heavy trains (such as coal, grain, and soda ash).

Dry bulk: Free–flowing solids (such as grain) that are poured into the hold of a vessel.

Eastern Europe: World region that includes Albania, Armenia, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Estonia, Georgia, Hungary, Kosovo, Latvia, Lithuania, Macedonia, Moldova, Montenegro, Poland, Romania, Russian Federation, Serbia, Slovak Republic, Slovenia, Ukraine, and former Soviet republics.

Eurozone: The geographic and economic region that consists of all the European Union countries that have fully incorporated the euro as their national currency.

FRA: Federal Railroad Administration.

GDP: Gross domestic product (GDP) is the monetary value of all the finished goods and services produced within a country's borders in a specific time period.

GDP per capita: Gross domestic product divided by population.

Grade crossing: Location where a road intersects railroad tracks.

Great Recession: The economic downturn that started with the collapse of the housing market in December 2007, and which officially ended in June 2009.

IANA: Intermodal Association of North America.

IHS Markit: Consulting firm that provides industry and trade forecasts and analysis.

IMF: The International Monetary Fund (IMF) is an organization of 189 countries, working to foster global monetary cooperation, secure financial stability, facilitate international trade, promote high employment and sustainable economic growth, and reduce poverty around the world.

Internal traffic: Vessel movements (origin and destination) which take place solely on inland waterways. An inland waterway is one that is geographically located within the boundaries of the contiguous 48 states or within the boundaries of the State of Alaska. Puget Sound is one such inland waterway, as is the Columbia/Snake River system.

Indian Sub-Continent: World region that includes Afghanistan, Bangladesh, Bhutan, India, Maldives, Nepal, Pakistan, and Sri Lanka.

Latin America / Caribbean: World region that includes Mexico, all countries in Central America, all countries in South America, and all countries in the Caribbean.

Liquid Bulk: Free-flowing liquid cargoes that are poured into holds of tankers. Examples include crude oil, petroleum products, certain chemicals, and liquefied natural gas.

Lower Columbia Oregon: Port region on the Columbia River in Oregon, from Portland to Astoria. It includes the Ports of Portland, St. Helens, and Astoria.

Lower Columbia Washington: Port region on the Columbia River in Washington, from Vancouver to the mouth of the river. It includes the Ports of Vancouver, Kalama, and Longview.

Main line rail: Track that is used for through trains or is the principal artery of the system from which branch lines, yards, sidings and spurs are connected. It is also referred to as "mainline" rail.

Metric ton: 2204.6 pounds.

Middle East: World region that includes Bahrain, Iraq, Iran, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Syria, Turkey, United Arab Emirates, and Yemen.

MRL: Montana Rail Link.

Oceania: World region that includes Australia and New Zealand, as well as Pacific island nations not included in Southeast Asia or the Indian Sub-Continent.

OECD: Organization for Economic Co-operation and Development.

Other Northeast Asia: World region that includes Japan, South Korea, North Korea, Taiwan, and Mongolia.

Other Puget Sound / Washington Coast: Port region which includes all Washington deep-draft ports not included in Lower Columbia Washington or PSRC regions.

PADD: Petroleum Administration for Defense Districts (PADDs) are five regions of the United States which are used to analyze the movement of crude oil and petroleum products throughout the nation.

PNW: Pacific Northwest (PNW) is the region that includes Washington and Oregon. Idaho is also included in some usage.

PSRC: Port region encompassing the same counties as the Puget Sound Regional Council region (King, Pierce, Snohomish, and Kitsap Counties). It includes the Ports of Tacoma, Seattle, and Everett.

RTC: Rail Traffic Controller (RTC) is a computer program that simulates the movement of trains through rail networks.

Shortline railroad: A small or mid-sized railroad company that operates over a relatively short distance relative to larger, national railroad networks. These typically fall under the FRA Class II and Class III designations.

Southeast Asia: World region that includes Brunei, Burma, Cambodia, East Timor, Indonesia, Laos, Malaysia, Papua New Guinea, Philippines, Singapore, Thailand, and Vietnam.

Subdivision: Most railroads identify each main line segment between crew change points as one subdivision.

TEU: Twenty-foot equivalent unit.

UP: Union Pacific Railroad.

USDA: U.S. Department of Agriculture.

Western Europe: World region that includes Andorra, Austria, Belgium, Channel Islands, Denmark, Faeroe Islands, Finland, France, Germany, Greece, Greenland, Iceland, Ireland, Isle of Man, Italy, Liechtenstein, Luxembourg, Malta, Monaco, Netherlands, Norway, Portugal, San Marino, Spain, Sweden, Switzerland, and the United Kingdom.

World Bank: The International Bank for Reconstruction and Development (World Bank) is an international financial institution that offers loans to middle-income developing countries.

Chapter 2
International Macroeconomic Overview

Introduction

The following chapter serves as a background discussion of the key trading partner regions for Pacific Northwest ports. The chapter begins with overviews of the trends in waterborne trade between Pacific Northwest ports and both international and domestic regions. This is followed by detailed discussions of each of the trading regions, which include summaries of the major key demographic and economic projections for the regions.

For this discussion, "Pacific Northwest" (or "PNW") includes all ports in Washington, as well as Oregon ports located on the Columbia River.

Several sources were used to produce the macroeconomic overview. IHS Markit provided short-term analyses of the economies of various geographic regions. These were supplemented with population growth comparisons based on data from the IMF, World Bank, USDA, and OECD. Of these sources, only the OECD and World Bank project population beyond 2030. GDP growth comparisons were based on information from the USDA, which produces forecasts for the most comprehensive list of countries; however, these run only through the year 2030.

Key Observations

- Long-term world GDP growth of 3.0%.
- Most of Pacific Northwest waterborne trade is with Asia.
- Asia accounts for majority of container trade.
- China has become the biggest partner.
- China's per capita income is projected to grow quickly, while population stabilizes.
- Other Northeast Asia is a key market.
- Southeast Asia is smaller, but growing in importance.
- Latin America is a non-containerized partner, with a growing population.
- Africa is growing, but waterborne trade with Pacific Northwest is limited.
- Alaska is dependent on the declining production of crude oil, the largest sector of Alaska's economy. Growth prospects are not strong, unless the proposed gas pipeline is built.
- Hawaii GDP grew at approximately 2.0% per year over the past 15 years (higher than average U.S. growth of 1.6% per year), and long-term forecast growth is similar. Economy is based on tourism and government, particularly military.

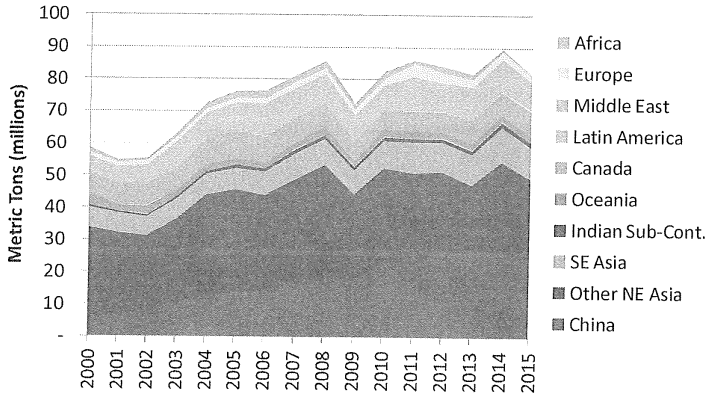
Trading Regions

International Trading Partner Regions

Since 2000, two-thirds or more of the waterborne tonnage moving through Pacific Northwest ports has been related to trade with Asia. During this period, the most important change is that China has nearly overtaken the rest of Northeast Asia as the largest trading region for Pacific Northwest ports.

Table 2-1: Countries Included by Trade Region

Africa	**Middle East**	**Other Northeast Asia**	**Southeast Asia**
All of Africa	Bahrain	Japan	Brunei
	Iraq	South Korea	Burma
Canada	Iran	North Korea	Cambodia
Canada	Israel	Taiwan	East Timor
	Jordan	Mongolia	Indonesia
China	Kuwait		Laos
China	Lebanon	**Indian Sub-Continent**	Malaysia
Hong Kong	Oman	Afghanistan	Papua New Guinea
Macao	Qatar	Bangladesh	Philippines
	Saudi Arabia	Bhutan	Singapore
Europe	Syria	India	Thailand
All of Western and Eastern	Turkey	Maldives	Vietnam
Europe, including Russia	United Arab Emirates	Nepal	
	Yemen	Pakistan	
Latin America & Caribbean		Sri Lanka	
Mexico	**Oceania**		
All of Central America	Australia		
All of South America	New Zealand		
All of Caribbean	Pacific island nations		
	(excl Southeast Asia and		
	Indian Sub-Continent)		



The share of trade moving between the Pacific Northwest and China grew from less than 10% in 2000 to more than 29% in 2015, while the share moving to and from other Northeast Asia dropped from more than 48% to 31%. During this period PNW-China trade grew from 5.5 million metric tons to 24.1 million metric tons, while PNW-Other Northeast Asia trade fell from 28.3 million metric tons to 25.6 million metric tons (see Figure 2-1).

Southeast Asia's share of Pacific Northwest waterborne trade grew slowly over the last 15 years, increasing from 10.8% in 2000 to 11.7% in 2015, but the total tonnage carried in this trade grew from 6.3 million metric tons to 9.5 million metric tons.

Canada and Latin America account for most of the remaining trade. Between 2000 and 2015, Canada's share of waterborne tonnage fell from 10.3% to 9.2%, while Latin America's grew from 6.9% to 8.2%. Despite the decline in market share, PNW-Canada waterborne tonnage grew from 6.0 million metric tons in 2000 to 7.5 million metric tons in 2015, while the PNW-Latin America trade grew from 4.0 million metric tons in 2000 to 6.7 million metric tons in 2015.

No other region accounted for more than 3% of Pacific Northwest tonnage in 2015. Total Pacific Northwest waterborne trade grew for the Middle East (from 1.4 million metric tons to 2.4 million metric tons), Europe (from 1.2 million metric tons to 2.0 million metric tons), and the Indian Sub-Continent (from 0.7 million metric tons to 1.6 million metric tons). Total Pacific Northwest waterborne trade fell for Oceania (from 3.9 million metric tons to 2.3 million metric tons) and for Africa (from 1.3 million metric tons to 0.2 million metric tons).

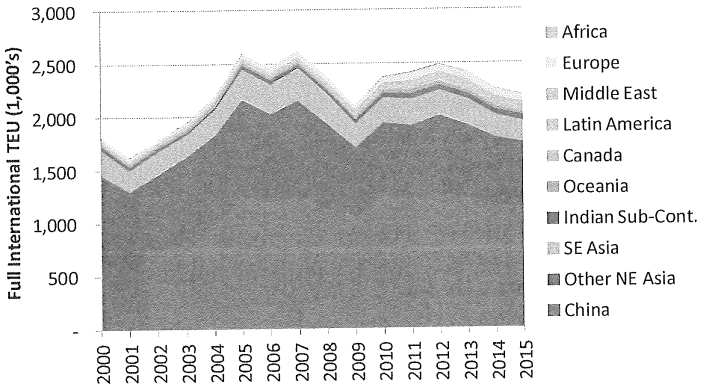
Figure 2-1: PNW Waterborne Trading Partners – Total Trade

Source: BST Associates using WISERTrade data

For containerized trade, eastern Asia (i.e. China, Other Northeast Asia, and Southeast Asia) represents the key trading area for Pacific Northwest ports. From 2000 through 2015, eastern Asia accounted for between 88.6% and 94.2% of Pacific Northwest containerized trade[1].

During this period China became the largest container market for the Pacific Northwest, as measured in full international TEU. China's share of PNW container trade grew from 34.5% in 2000 to 51.6% in 2015, while Other Northeast Asia's share fell from 45.5% to 27.9% and Southeast Asia's share fell from 13.3% to 9.2%.

The total volume of full containers moving between China and the Pacific Northwest grew from 628,000 TEU in 2000 to as much as 1.27 million TEU in 2012, but declined to 1.13 million TEU in 2015. Container volume between the PNW and Other Northeast Asia grew from 828,000 in 2000 to a peak of 912,000 in 2005, but declined to 612,000 in 2015. Container volume between the PNW and Southeast Asia grew from 242,000 in 2000 to a peak of 280,000 in 2005, but dropped to 201,000 in 2015 (see Figure 2-2).



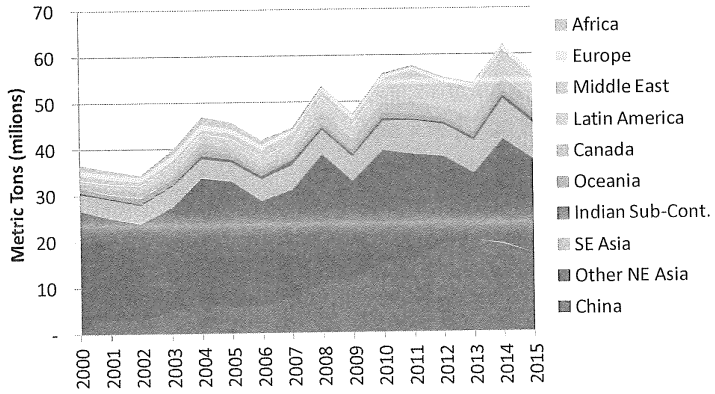
The remaining world regions currently account for a limited share of Pacific Northwest container trade, but container volumes with many of these regions grew between 2000 and 2015. For example:

- Trade with the Indian Sub-Continent grew from 33,000 TEU to 55,000 TEU
- Oceania grew from 25,000 TEU to 30,000 TEU
- Latin America grew from 23,000 TEU to 52,000 TEU,
- Middle East grew from 11,000 TEU to 38,000 TEU, and
- Europe grew from 27,000 TEU to 67,000 TEU.

[1] Container volume is measured in twenty-foot equivalent units, or "TEU".

LUBA No. 2020-009
Page 5513

Figure 2-2: Pacific Northwest International Containerized Trade



Source: BST Associates using PIERS data

Eastern Asia (i.e. China, Other Northeast Asia, and Southeast Asia) also accounts for most of the non-containerized cargo moving through Pacific Northwest ports. From 2000 through 2015, eastern Asia's share of Pacific Northwest non-containerized cargo averaged 81.0%.

Latin America and Canada are the largest non-Asian trading partners (for non-containerized trade). Latin America's share grew from 1.7% in 2000 to 6.6% in 2015, and reached as high 9.3% in 2013. Canada's share grew from 3.2% in 2000 to 5.4% in 2015, reaching as high as 6.3% in 2013.

Total non-containerized tonnage grew for each trading partner region, with the exceptions of Other Northeast Asia and Africa. Non-containerized trade with China jumped from 1.1 million metric tons in 2000 to more than 19.0 million metric tons from 2012 through 2014, before falling to 16.9 million metric tons in 2015 (due primarily to a short-term drop in grain exports in 2015). Non-containerized trade with Southeast Asia grew from 3.8 million metric tons in 2000 to 7.9 million metric tons in 2015. In contrast, non-containerized trade between the PNW and Other Northeast Asia dropped from 25.6 million metric tons in 2000 to 20.3 million metric tons in 2015 (see Figure 2-3).

Figure 2-3: Pacific Northwest International Non-Containerized Trade

Source: BST Associates using WISERTrade data

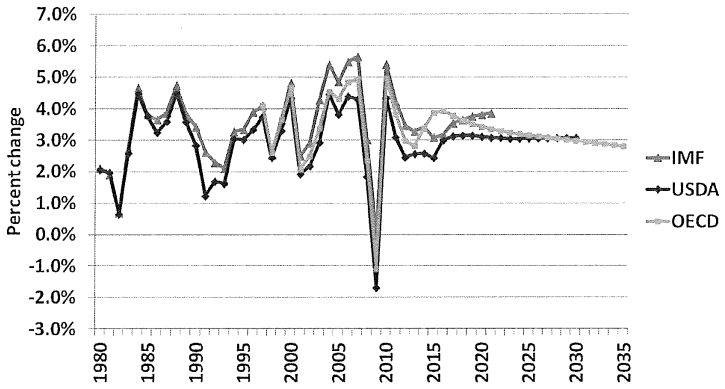
Table 2-2 summarizes the shifting market shares for Pacific Northwest waterborne trade, by world region.

Table 2-2: Summary of Pacific Northwest Trade Share by World Region

	Containerized (% of TEU)		Non-Containerized (% of Metric Tons)		Total (% of Metric Tons)	
Region	2000	2015	2000	2015	2000	2015
China	34.5%	51.6%	2.9%	30.2%	9.4%	29.4%
Other Northeast Asia	45.5%	27.9%	69.8%	36.1%	48.2%	31.2%
Southeast Asia	13.3%	9.2%	10.5%	14.0%	10.8%	11.7%
Indian Sub-Cont.	1.8%	2.5%	0.9%	1.4%	1.2%	1.9%
Oceania	1.4%	1.3%	2.4%	2.1%	6.6%	2.8%
Canada	0.0%	0.1%	3.2%	5.4%	10.3%	9.2%
Latin America	1.2%	2.4%	1.7%	6.6%	6.9%	8.2%
Middle East	0.6%	1.7%	2.9%	2.2%	2.4%	3.0%
Europe	1.5%	3.0%	2.5%	1.7%	2.0%	2.5%
Africa	0.2%	0.3%	3.2%	0.2%	2.2%	0.2%

Source: BST Associates using WISERTrade data

World Economic Trends



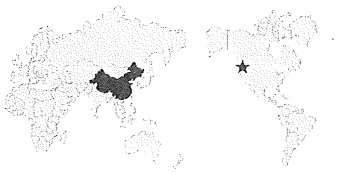
World gross domestic product (GDP) grew at average annual rate of 3.5% per year from 1980 through 2015, according to data from the International Monetary Fund (IMF). During the 1980's, annual GDP growth averaged 3.2%, an average that was weighed down by very slow growth from 1980 through 1982. The year 1982 was especially bad for the world economy, with GDP growth of less than 0.7%. In contrast, annual growth did not drop below 3.6% from 1984 through 1989, and reached as high as 4.7% in both 1984 and 1988.

During the 1990's annual growth in GDP averaged 3.1%. Overall, the decade witnessed steadier growth than the 1980's, with minimum annual growth of 2.1% and maximum of 4.1%.

For most of the 2000's, world GDP growth was substantially higher than during the previous decades, due in large part to growth in China. GDP growth averaged 4.3% from 2000 through 2008, and only dropped below 3.0% in 2001 and 2002. In contrast, GDP growth in both 2006 and 2007 was higher than 5.5%. In 2009 the world economy fell into the deepest recession in decades, and world GDP growth actually fell into negative territory. However, world GDP growth returned in 2010, and has been 3.0% or higher in each year since.

Over the short term (i.e. 2016 through 2021), the IMF is projecting that world GDP growth will average 3.6% per year. In the longer run, both the USDA and OECD project that world GDP growth will average approximately 3.0% per year (see Figure 2-4).

Figure 2-4: GDP Growth - World



Source: IMF, USDA, OECD

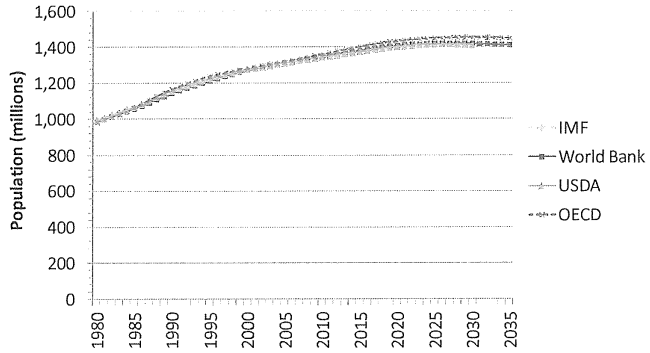
Regional Growth

The following sections describe key economic factors for each of the world regions, including data on population growth, GDP growth, and other factors. GDP figures are presented in 2010 dollars, as developed by the USDA. [2]

China

China has developed into the most important market for Pacific Northwest waterborne trade over the past several decades, and is likely to grow in importance. A huge population base with rising per-capita income represents a key opportunity for the Pacific Northwest.

Chinese economic growth has been slowing from the high levels seen during the past two decades. GDP was projected to be 6.5% in 2016, which, while low by recent Chinese standards, is substantially higher than world average. According to IHS Markit, this moderation means China will be less of a growth engine for Asia and the rest of the world in the coming years. This will be particularly true for commodity and energy-intensive sectors because more of China's growth will come from services than from industry and construction.



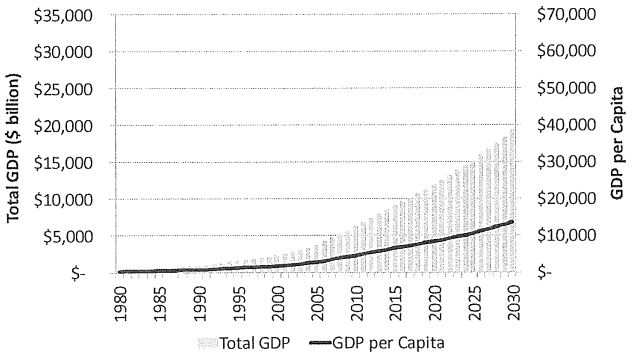
According to IHS Markit, future risk in China is tied to the government's response to changing economic conditions. Until the market-driven correction of the Chinese stock market in mid-2015, it appeared that Chinese policy embraced structural reforms at a modest pace. However, the government's response to the stock market correction raised questions about the Chinese leadership's comfort level with true market outcomes in the economy, and it is unclear how this will play out over time.

China's population reached one billion people in 1980, and has continued to grow since then. It took just seven years for China to add another 100 million people, and six years to add the next 100 million. Since reaching 1.2 billion in 1993, however, China's population growth has slowed. It took ten years (until 2003) to add the next 100 million people, and the population is not projected to reach 1.4 billion until 2016 or 2017.

Multiple sources project that 1.4 billion represents the peak of China's population, and that by the late 2020's the population will actually start to decline slowly (see Figure 2-5).

[2] USDA developed these figures using data from World Bank World Development Indicators, International Financial Statistics of the IMF, IHS Markit, and Oxford Economic Forecasting, as well as estimated and projected values developed by the USDA Economic Research Service, all converted to a 2010 base year.

Figure 2-5: Population Growth - China



Source: IMF, World Bank, USDA, OECD

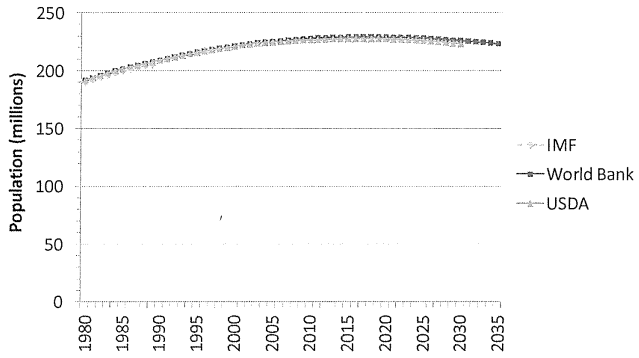
Total GDP for China doubled approximately every five years, between 1980 and 2010. Over the entire 30 year period, China's GDP jumped from $396 billion to $6.297 trillion (measured in 2010 US dollars). On a per capita basis, GDP grew from $398 per person to $4,684 per person.

GDP growth in China, which had been averaging between close to 10% per year, began to slow after 2010. From 2015 through 2030 it is projected to average approximately 5.0% per year, which is substantially higher than the world average (see Figure 2-6).

Figure 2-6: GDP Growth - China

Source: USDA

Because GDP is forecast to grow faster than population, however, per capita GDP should continue to rise. Between 2010 and 2015 per capita GDP in China grew from $4,684 to $6,603; it is projected to reach $8,478 by 2020, $10,733 by 2025, and $13,696 by 2030 (as measured in 2010 dollars). This increased buying power makes China a growing opportunity for trade with the Pacific Northwest.



Other Northeast Asia

Northeast Asia (excluding China) was the largest waterborne trading region for Pacific Northwest ports in 2015, as it has been for decades. Although total trade volume between the PNW and Other Northeast Asia (i.e. Japan, South Korea, North Korea, Taiwan, and Mongolia) is likely to be surpassed by that between the PNW and China, the region will continue to be a critical trading partner.

A major reason for trade volume with China overtaking that of Other Northeast Asia is that the population of Other Northeast Asia has apparently peaked, and is projected to begin a slow decline. As illustrated in Figure 2-7, the population of the region has peaked at approximately 229 million, and is projected to begin declining slowly; between 2025 and 2035 it is projected to drop by approximately 0.5% per year. The population of Other Northeast Asia is currently approximately one-sixth of that of China, down from approximately one-fifth in 1980.

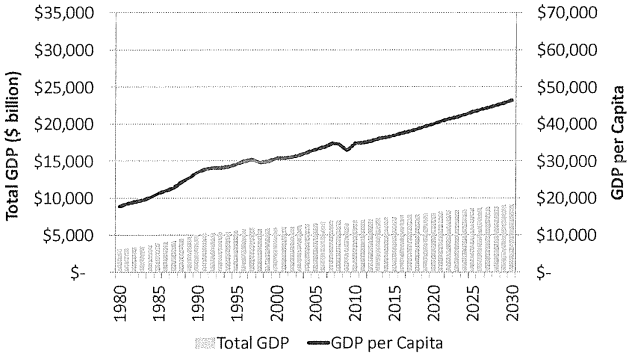


Figure 2-7: Population Growth – Other NE Asia

Source: IMF, USDA, OECD

GDP growth in Other Northeast Asia averaged 5.0% per year during the 1980's, but dropped to just 1.8% per year during the 1990's and to 1.4% during the 2000's. The regional economy slowed even more between 2010 and 2015, dropping to an average of 1.2% per year (see Figure 2-8).

Figure 2-8: GDP Growth – Other Northeast Asia

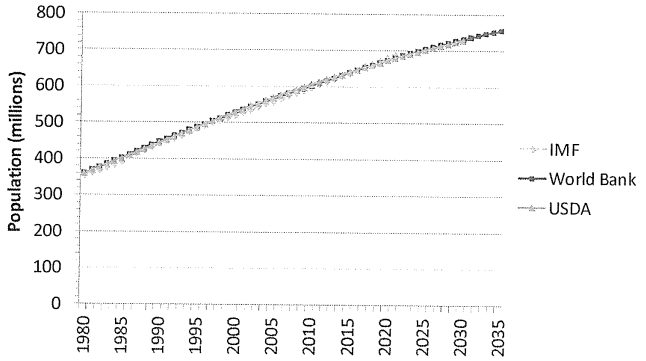
Source: USDA

Total regional GDP grew by approximately $2.0 trillion between 1980 and 1990 (from $3.1 trillion to $5.1 trillion), but by only $1.0 trillion between 1990 and 2000, and by less than $1.0 trillion between 2000 and 2010. Regional GDP growth is projected to continue averaging approximately $1.0 billion per year from 2010 through 2020, as well as from 2020 through 2030.

GDP per capita grew from $17,900 in 1980 to $36,900 in 2015, and is projected to grow to $46,500 by 2030.

In 1980 Japan accounted for more than 90% of regional GDP, followed by South Korea (5%) and Taiwan (2%). In 2015, Japan's share of regional GDP dropped to approximately 76%, while Korea's grew to 17% and Taiwan 7%. By 2030 Japan is projected to account for 71% of regional GDP, Korea 21%, and Taiwan 7%.

Southeast Asia



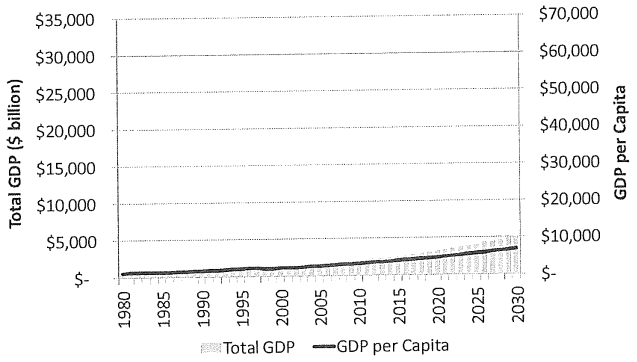
According to IHS Markit, ineffectual macroeconomic policies and political scandals in Southeast Asia[3] are negatively impacting regional economies. Several currencies fell to post-Asian-crisis lows in 2015, while external demand floundered. The mounting threat is that without adequate stimulus or reform, domestic demand in the region will suffer, further weighing on growth.

Despite the current problems, Southeast Asia has the potential to become a more important trading partner for the Pacific Northwest. It is currently the third-largest market for Washington ports, and projected population growth and GDP per capita mean that there will be more people with more money to spend on imported goods.

The population of Southeast Asia grew by 75% between 1980 and 2015, from approximately 358 million in 1980 to 640 million in 2015 (see Figure 2-9). This growth in population (281 million) was higher than the total population of Other Northeast Asia (excluding China). Despite an expected slowdown in the growth rate, the population of Southeast Asia is projected to reach 757 million by 2035. This increase of 117 million people is roughly equivalent to one-third of the current U.S. population.

Figure 2-9: Population Growth – Southeast Asia

Source: IMF, USDA, OECD



Total GDP for Southeast Asia is substantially lower than that of Other Northeast Asia, but is growing at a much faster rate. In 1980, the GDP of Southeast Asia was $439 billion, which was only 14% of Other Northeast Asia's GDP. By 2015, GDP in Southeast Asia had increased to nearly $2.6 trillion, which was equivalent to 34% Other Northeast Asia's GDP. By 2030 Southeast Asia is projected to reach approximately $5.1 trillion, or nearly 56% that of Other Northeast Asia.

GDP growth has outpaced population growth in Southeast Asia, which means that GDP per capita has also increased. Between 1980 and 2015, per capita GDP jumped from $1,214 to $2,986; by 2030 it is projected to reach $6,951 (see Figure 2-10). The increasing per capita GDP makes Southeast Asia an increasingly important trading region for the Pacific Northwest. As discussed above, Southeast Asia saw its share of Pacific Northwest waterborne trade grow from 10.8% in

[3] Southeast Asia includes: Brunei, Burma, Cambodia, East Timor, Indonesia, Laos, Malaysia, Papua New Guinea, Philippines, Singapore, Thailand, and Vietnam

2000 to 11.7% in 2015, while waterborne tonnage grew from 6.3 million metric tons to 9.5 million metric tons.

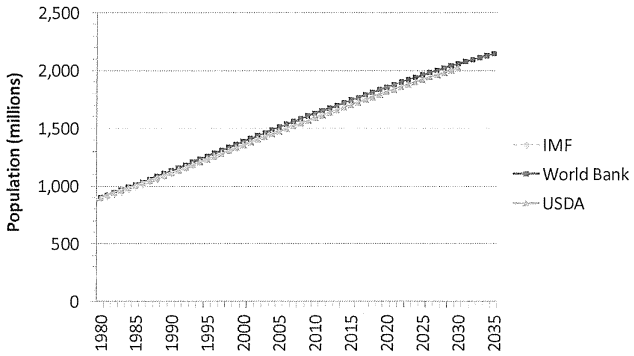
Figure 2-10: GDP Growth – Southeast Asia

Source: USDA

Indonesia has long been the largest economy of the region, and consistently accounted for approximately 38% of regional GDP between 1980 and 2015. The Philippines had the second largest economy in 1980, but has dropped to fifth. Thailand is now the second largest, followed by Malaysia and Singapore. Combined, these top five economies account for nearly 87% of regional output. By 2030 this share is projected to drop only slightly, to 84%.

Indian Sub-Continent

The Indian Sub-Continent accounts for a limited share of Pacific Northwest waterborne trade, but this share grew from 1.2% in 2000 to 1.9% in 2015. Total tonnage also grew during this period, increasing from 0.7 million metric tons to nearly 1.6 million metric tons. With a population that continues to grow by 100 million people every four to five years, the region represents an opportunity for increased trade with the Pacific Northwest.



IHS Markit is not optimistic about the short-term prospects for economic growth in the Indian Sub-Continent region. India, which had been a brighter spot in Asia, appears to not have the ability to meaningfully lift growth. In the long run, however, population growth and increasing per-capita GDP may lead to additional demand for imported commodities.

The population of the Indian Sub-Continent surpassed the combined population of China and Other Northeast Asia around the year 2010, and that gap is projected to grow over the next several decades.

The population of the Indian Sub-Continent grew from approximately 900 million in 1980 to 1.1 billion in 1990, climbed past 1.3 billion in 2000, and reached 1.6 billion in 2010. By 2015 in was greater than 1.7 million. Although the rate of growth is projected to slow slightly, the addition of 100 million people every four to five years will result in a population greater than 2.1 billion by 2035 (see Figure 2-11).

Indian has by far the largest share of the sub-continent's population. India's 1.3 billion people accounted for 75% of the total in 2015. By 2035, India's projected population of 1.6 billion will still account for nearly 75% of the total.

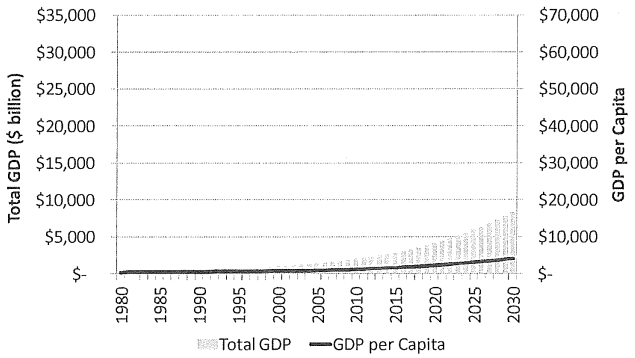


Figure 2-11: Population Growth – Indian Sub Continent

Source: IMF, USDA, OECD

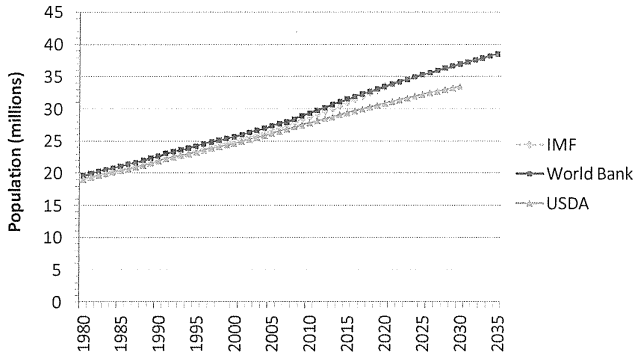
From 1980 through 2000, the total GDP for the Indian Sub-Continent was approximately 85% the size of Southeast Asia's. Beginning in 2000, however, the Indian Sub-Continents began to grow more quickly, and by 2009 the region's output was larger than that of Southeast Asia; by 2015 this margin had grown to more than 11%. This trend is projected to continue, with the region's economy projected to be 64% larger than that of Southeast Asia by 2030 (see Figure 2-11).

Figure 2-12: GDP Growth – Indian Sub-Continent

Source: USDA

Despite the growth in total GDP, the fast expansion of the Indian Sub-Continent's population means that per capita GDP will lag behind that of its neighbors. Per capita GDP was only one-third that of Southeast Asia's from 1980 through 2000. By 2015 it reached 42% of Southeast Asia's, and by 2030 is projected to reach 59%, or $4,137 per person.

India's economy is projected to grow faster than that of the rest of the sub-continent. In 2015, India accounted for 83% of regional GDP, and is projected to account for 87% in 2030. Per capita GDP in India was $1,889 in 2015, compared to a regional average of $1,673. In 2030 India is projected to have per capita GDP of $4,976, compared to a regional average of $4,137.



Oceania

Oceania accounts for approximately 10% of Pacific Northwest waterborne tonnage, a share that remained relatively stable between 2000 and 2015.

Oceania has the smallest population of the regions included in this analysis: the 31 million in Oceania in 2015 is equivalent to just 2.2% of China's population and 1.8% of the Indian Sub-Continent's population. As illustrated in Figure 2-13, Oceania is projected to add approximately 8 million people between 2015 and 2035.

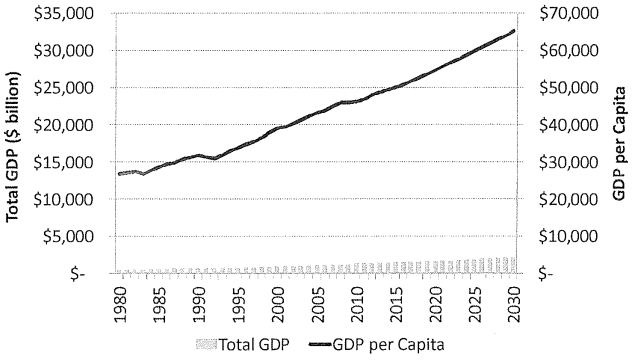


Figure 2-13: Population Growth – Oceania

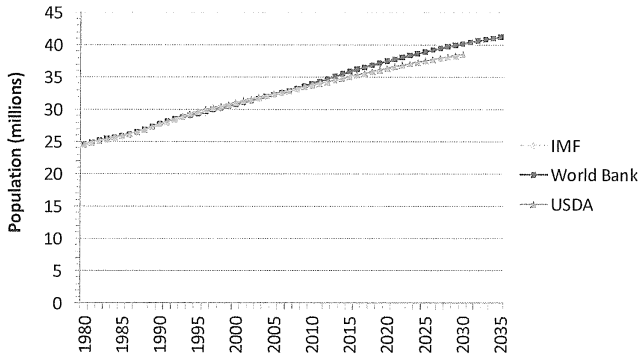
Source: IMF, USDA, OECD

GDP per capita in Oceania is nearly the same as in the United States, while the population is approximately 9% as large. With similar growth rates, per capita GDP in Oceania is projected to remain roughly equivalent to that of the U.S. through 2030 (see Figure 2-14).

Figure 2-14: GDP Growth – Oceania

Source: USDA

Canada



For Pacific Northwest ports, Canada is the largest waterborne trading region outside of Asia. Canada's share of PNW waterborne trade dropped from 10.3% in 2000 to 9.2% in 2015, but total tonnage grew from 6.0 million metric tons to 7.5 million metric tons over the same period.

Canada's population has been approximately 11% the size of the U.S. population for a number of decades, and this is projected to continue through 2035. The population of Canada grew by approximately 11 million between 1980 and 2015, rising from 24.5 million to 35.6 million. During the same period the population of the United States grew from 229.5 million to 323.8 million.

As illustrated in Figure 2-15, over the next 20 years the population of Canada is projected to grow by another 5.6 million, to 43.6 million.

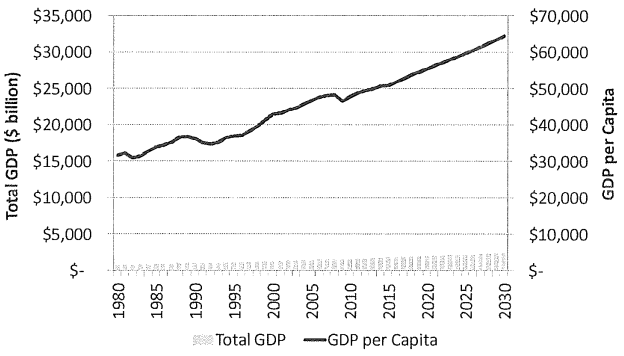


Figure 2-15: Population Growth – Canada

Source: IMF, USDA, OECD

In 2015, GDP per capita in Canada ($51,000) was nearly the same as that in the United States ($51,800). This similarity is projected continue from 2015 through 2030, with Canada's 2030 GDP per capita of $64,500 only slightly lower than the U.S. average of $67,100 (see Figure 2-16).

Figure 2-16: GDP Growth – Canada

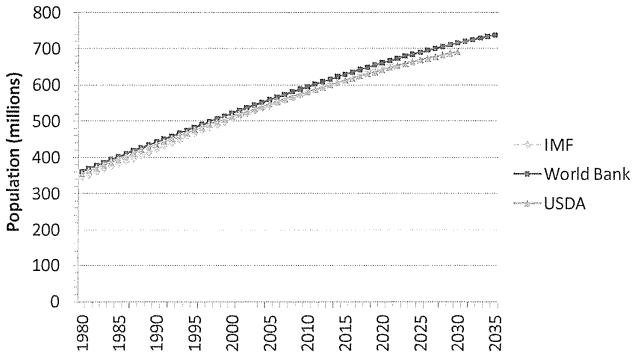
Source: USDA

Latin America/Caribbean

Latin America accounted for 8.2% of Pacific Northwest waterborne tonnage in 2000, up from 6.9% in 2000. With income growing faster than population the region could grow in importance for the Pacific Northwest, but political and economic problems will need to be solved for the region to meet its potential.

According to analysis from IHS Markit, political and economic problems in Brazil are dragging down regional growth, and the outlook for Brazil is not very encouraging. The end of the supercycle of high commodity prices and cheap credit has raised the importance of ongoing structural economic problems in the region. Argentina, Brazil, and Venezuela have been hit especially hard.

Despite these problems, IHS is relatively positive about the long-term prospects for Latin America. The macroeconomic fundamental conditions have improved substantially. For example, fiscal policies are being implemented to reduce fiscal deficits and public debt, and flexible exchange-rate regimes have translated into relative exchange-rate stability. Most of the countries enjoy positive trade balances and some of them even post current-account surpluses. Latin American economies are well positioned to continue on the path of moderate growth, provided the rest of the world does not fall again into recession.



The outlook for Mexico's economy is one of cautious optimism, due to its linkages with the U.S. economy. Acceleration of economic growth in the United States will continue to lift the speed of Mexican economic growth.

The region encompassing Latin American and the Caribbean saw its population grow by 75% between 1990 and 2015. Over this period the population grew from 353 million to 619 million, an increase of more than 266 million.

Despite the rate of growth starting to slow, the population is expected to add another 118 million people between 2015 and 2035 (see Figure 2-17).

With approximately 205 million people, Brazil has the region's largest population, accounting for approximately one-third of the regional total. Mexico's population of 127 million is the next largest, with approximately one-fifth of the total. More than half of the regional population is in Brazil or Mexico.

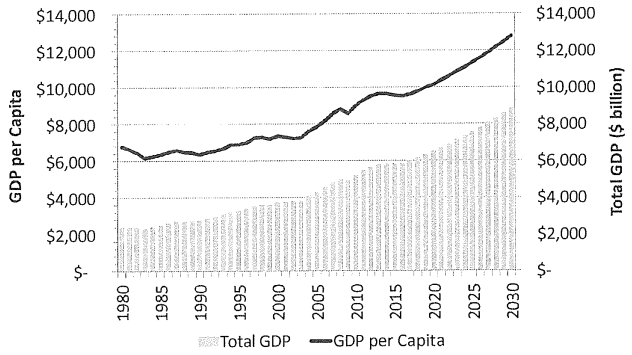


Figure 2-17: Population Growth – Latin America/ Caribbean

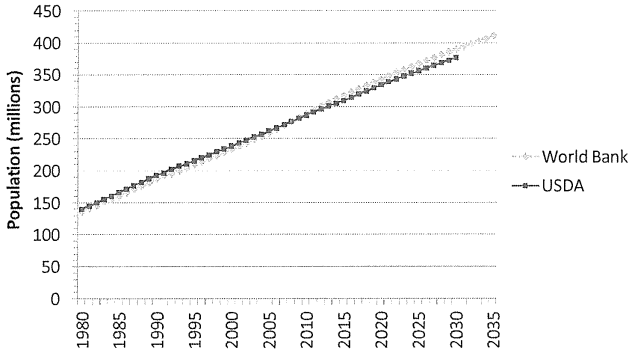
Source: IMF, USDA, OECD

Regional GDP is projected to grow faster than population over the long run, which will lead to increasing per capita GDP (see Figure 2-18).

Figure 2-18: GDP Growth – Latin America/Caribbean

Source: USDA

Middle East



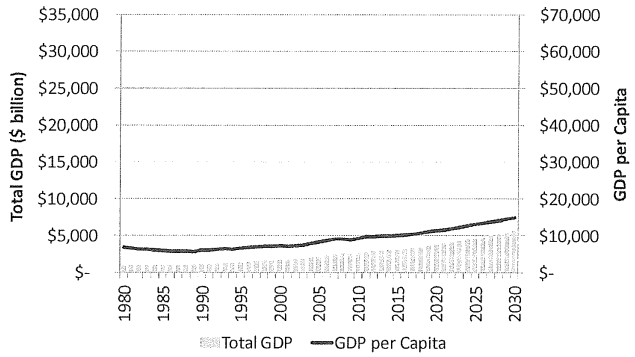
The Middle East is a relatively small waterborne trading partner for Pacific Northwest ports, accounting for approximately 3.0% of waterborne tonnage in 2015.

According to IHS Markit, low oil prices will limit economic growth in the Middle East[4]. Oil prices were projected to grow from approximately $30 per barrel in 2015 to $49 per barrel in 2017, but there is further downside risk to the outlook. Prices for other commodities have also fallen (including metals, minerals, and agricultural products), and projected global growth of 3% could lead to soft world demand for oil. Political instability is also a major concern, with conflicts in Syria, Yemen, and Libya, and threats from the Islamic State across the Middle East.

The population of the Middle East grew steadily between 1980 and 2015, adding an average of 25 million people every five years, to a total of approximately 315 million in 2015. The population is projected to continue growing at approximately the same pace and to reach approximately 410 million in 2035 (see Figure 2-19).

Iran and Turkey are the largest countries in the region, each with a population of approximately 80 million in 2015. These two countries accounted for more than half of the regional population in 2015, and are projected to continue to account for approximately half through 2035.

Figure 2-19: Population Growth – Middle East



Source: IMF, USDA, OECD

Total GDP of the Middle East grew from approximately $1.0 trillion 1980 to $3.2 trillion in 2015, and is expected to grow to $5.7 trillion in 2030. GDP per capita grew much more slowly than total GDP. While total GDP grew by 330% between 1980 and 2015, GDP per capita only grew by 150% (see Figure 2-20).

[4] Middle East includes: Bahrain, Iraq, Iran, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Syria, Turkey, United Arab Emirates, and Yemen.

Figure 2-20: GDP Growth – Middle East

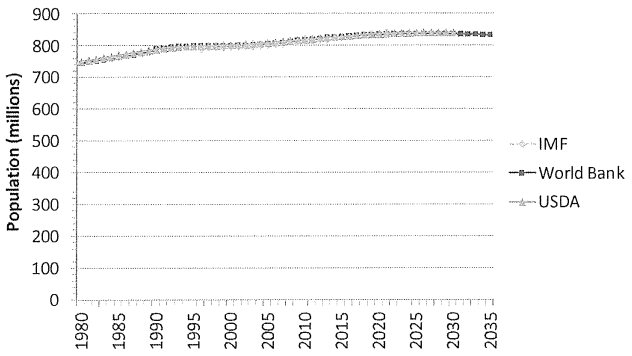
Source: USDA

Europe

Europe is a relatively small trading region for Pacific Northwest ports, accounting for 2.5% of waterborne trade in 2015. However, this represented an increase over the 2.0% share in 2000, and total waterborne tonnage grew from nearly 1.2 million metric tons in 2000 to 2.0 million metric tons in 2015. Because GDP per capita is also relatively high in Europe, especially Western Europe, the region presents some potential for trade growth with the Pacific Northwest.

According to IHS Markit, global growth concerns and financial market weakness are currently hampering Eurozone economic activity. This is in spite of several positive factors, including low oil and commodity prices, a competitive euro, increased European Central Bank (ECB) stimulus, and more growth-oriented fiscal policies in a number of countries. Economic growth for the region has averaged 2% or less for several years, and growth of 1.7% to 1.8% was projected for 2016 and 2017.

The impact on Pacific Northwest waterborne trade due to Britain exiting the European Union is likely to be quite limited. As illustrated above, Europe in total accounts for less than 3% of total Pacific Northwest waterborne tonnage, and approximately 3% of waterborne traffic.



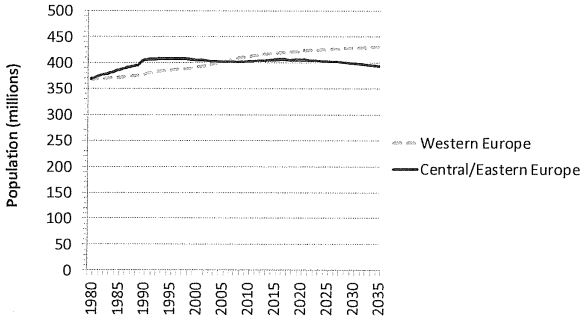
Central European economies are doing better than the Eurozone, and prospects are good for continued strong growth.

As illustrated in Figure 2-21, Europe's population has essentially reached its peak, and will eventually experience a slow decline.

The region's population grew at less than 0.5% per year between 1980 and 2015, while growing from approximately 746 million to 827 million. The population is projected to grow by a total of 1.4% between 2015 and 2027 (i.e. an additional 12 million people), but then start to decline.

Europe's projected population in 2035 is approximately 832 million, an increase of less than six million from 2015, and a decrease of more than six million from its peak in 2027.

Figure 2-21: Population Growth – Europe



Source: IMF, USDA, OECD

Population growth trends are much different in Western Europe than in Central/Eastern Europe. As illustrated in Figure 2-22, the population of Central/Eastern Europe has been falling since approximately 1995, and is expected to continue to decline. After topping out at 408 million in

1993-1995, the region's population dropped to 402 million in 2007, but recovered to 406 million in 2015. By 2035, however, the population is projected to drop to 393 million.

In contrast, the population of Western Europe grew from 368 million in 1980 to 418 million in 2015, and is projected to reach 430 million by 2035. The population of Western Europe surpassed that of Central/Eastern Europe in 2006, and continues to grow larger.

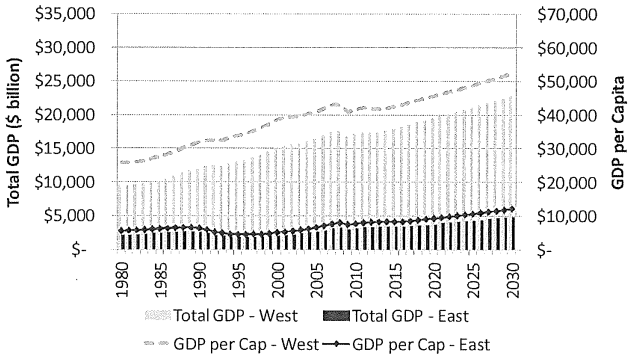


Figure 2-22: Population Growth – Europe Sub-Regions

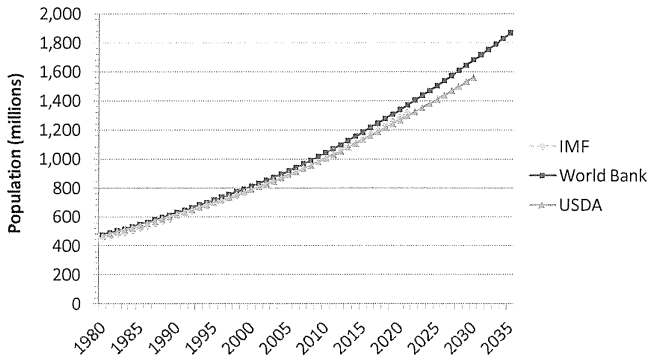
Source: World Bank

In 2015 the economy of Western Europe was more than 6.25 times larger than that of Central/Eastern Europe, as measured by total GDP. By 2030 this ratio is expected to decrease but still be large, with the GDP of Western Europe 4.65 times larger than that of Central/Eastern Europe (see Figure 2-23).

Figure 2-23: GDP Growth – Europe

Source: USDA

Africa



Africa is a very small market for waterborne trade with Pacific Northwest ports, and this is not likely to change substantially over the next 20 years. Africa accounted for just 0.2% of total Pacific Northwest waterborne tonnage in 2015, down from 2.2% in 2000. Total tonnage grew from 1.3 million metric tons in 2000 to 3.2 million metric tons in 2006, but dropped to only 0.2 million metric tons in 2015.

According to IHS Markit, political instability and regional conflicts in North Africa jeopardize the regional growth outlook. In Sub-Saharan Africa, low prices for commodities produced in the region have hampered growth. In recent years China has been especially involved in Africa, and has made substantial investments in infrastructure. The slowing of China's economy will decrease the demand for commodities, however, and may also limit how much China invests in the region. Across the region, exports of primary commodities account for more than 90% of total exports.

Africa is the only world region where population growth is not projected to slow over time. Between 1980 and 1985 the population of Africa grew by approximately 71 million people. Between 2010 and 2015 the five-year growth was nearly twice as high, with 135 million people added to the population, and from 2030 to 2035 the population is forecast to jump by 248 million (see Figure 2-24).

By 2035 the population of Africa may reach nearly 1.9 billion people, making it larger than any region except the Indian Sub-Continent. The increase in population in Africa is also projected to be much greater than in other regions. Africa's 20-year projected population increase is 716 million, compared with 420 million for the Indian Sub-Continent, 118 million for Latin America, and only 44 million for China.

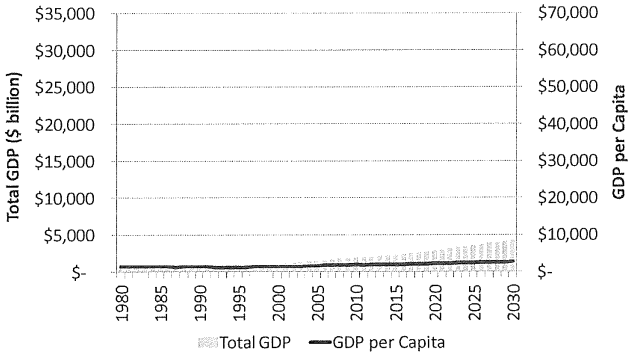


Figure 2-24: Population Growth – Africa

Source: IMF, USDA, OECD

The fast-growing population will limit how fast per-capita GDP grows. Over the long run (i.e. 2015 through 2030), GDP is only projected to grow from $2,000 per capita to $2,800 per capita (see Figure 2-25).

Figure 2-25: GDP Growth – Africa

Source: USDA

Summary of International Trends

The United States has been the world's largest economy for many decades, and is likely to continue to be so. The biggest changes have occurred in the rankings of the next largest economies.

In 2000, the second, third and fourth largest economies were Japan, Germany and France, while China was the fifth largest. By 2015 China had surpassed Japan as the second-largest economy, followed by Japan, Germany and France. India was not in the top 10 in 2000 but ranked as the world's seventh-largest economy in 2015, despite its relatively low per capita GDP (see Table 2-3).

By 2030, India is projected to have the third-largest economy, following the United States and China. Japan is projected to be the fourth-largest, followed by Germany, the United Kingdom, and France.

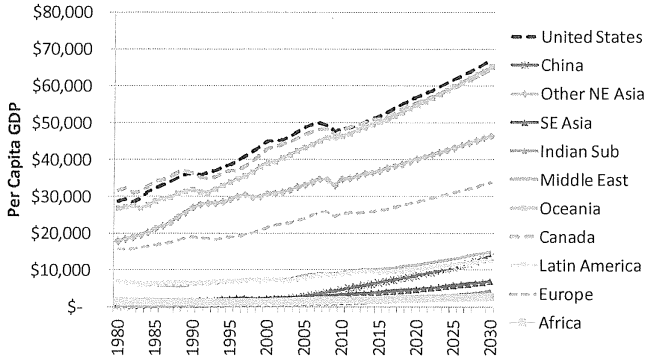

Table 2-3: Country GDP Rank: Top Ten in Real U.S. Dollar Terms

2000	2015	2030
United States	United States	United States
Japan	China	China
Germany	Japan	India
France	Germany	Japan
China	France	Germany
Italy	United Kingdom	United Kingdom
United Kingdom	India	France
Brazil	Brazil	Brazil
Canada	Italy	Canada
Spain	Canada	Italy

Source: USDA

Despite having what is now the world's second-largest economy, China's GDP per-capita is still relatively low. GDP per capita in China is lower than all regions except Africa, the Indian Sub-Continent, and Southeast Asia. It is rising fast, however, and by 2030 is projected to also be higher than that of Latin America and nearly as high as that of the Middle East (see Figure 2-26 and Table 2-4).

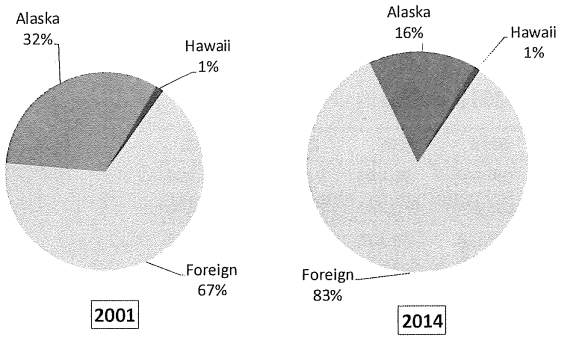
Figure 2-26: Per Capita GDP Growth by Region

Source: IMF, USDA, OECD

Table 2-4: Summary of GDP per Capita (in 2010 dollars)

Region	2000	2005	2010	2015	2020	2025	2030
China	$1,870	$2,860	$4,680	$6,600	$8,480	$10,730	$13,700
Other Northeast Asia	$30,760	$33,090	$34,770	$36,920	$40,170	$43,250	$46,490
Southeast Asia	$2,310	$2,720	$3,310	$3,990	$4,820	$5,830	$6,950
Indian Sub-Continent	$780	$980	$1,310	$1,670	$2,280	$3,120	$4,140
Middle East	$7,390	$8,390	$9,360	$10,150	$11,420	$13,100	$14,970
Oceania	$39,070	$43,300	$46,370	$50,150	$54,850	$59,900	$65,250
Western Europe	$38,500	$40,950	$41,630	$42,550	$45,670	$48,850	$52,370
Eastern Europe	$5,050	$6,600	$7,710	$8,230	$9,290	$10,610	$12,130
Latin America /Carib.	$7,360	$7,870	$9,020	$9,550	$10,170	$11,350	$12,800
Africa	$1,470	$1,690	$1,930	$2,030	$2,270	$2,540	$2,790
Canada	$42,980	$46,790	$47,810	$50,980	$55,510	$59,660	$64,470

Source: USDA



Alaska and Hawaii

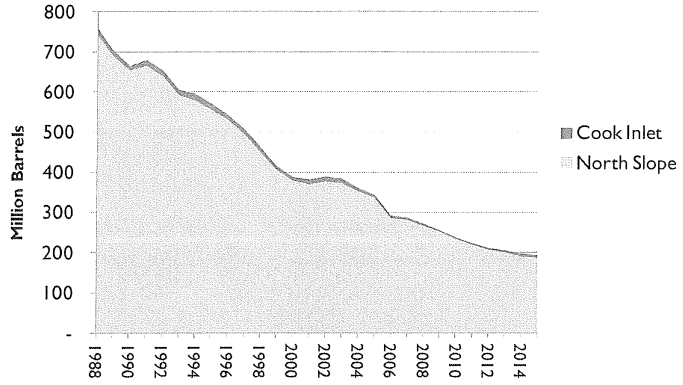
A substantial portion of Pacific Northwest waterborne cargo moves to and from domestic locations, primarily Alaska and Hawaii. In 2001, domestic trade accounted for approximately one-third of Pacific Northwest waterborne cargo; by 2014 (most recent year for which data is available) this share had dropped to approximately one-sixth (see Figure 2-27).

As measured in tonnage, Alaska accounted for most of the domestic trade. Crude oil accounted for most of this tonnage, and as crude oil production has dropped in Alaska, so has Alaska's share of Pacific Northwest waterborne trade declined. Alaska accounted for 32% of this trade in 2001, but only 16% in 2014.

Hawaii has consistently accounted for approximately 1% of Pacific Northwest waterborne trade.

Figure 2-27: Relative Size of PNW Foreign and Domestic Trade

Source: U.S. Army Corps of Engineers data



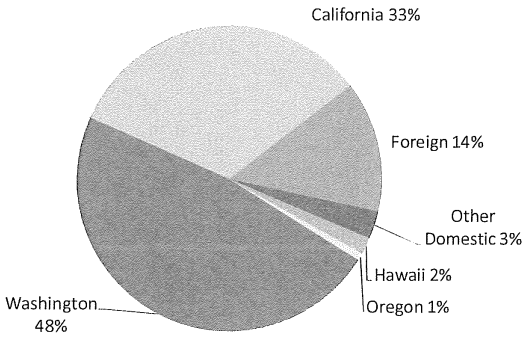
The following sections describe the economy of Alaska and Hawaii, and discuss the implications for waterborne trade with the Pacific Northwest.

Alaska

The economy of Alaska consists of three relatively equal parts: oil production, government (largely funded by oil revenues), and everything else (tourism, fisheries, other sectors). The decline in oil production and oil prices has significantly impacted the Alaskan economy. Future trade volumes are expected to decline and then stabilize.

As shown in Figure 2-28, production of oil in Alaska has been in decline since the peak year of 1988. Statewide production in that year totaled nearly 760 million barrels; by 2001 it had dropped to half of that volume (i.e. 382 million barrels), and by 2015 it had fallen in half again (i.e. to 193 million barrels). Alaskan oil production will continue to decline, unless large new oil discoveries are made.

Figure 2-28: Alaska Historic Oil Production



Source: Alaska Division of Oil and Gas

Approximately 97% of Alaska's oil is produced on the North Slope, with a small volume also produced in Cook Inlet. All of the North Slope oil is transported on the Trans-Alaska Pipeline. The pipeline requires a minimum amount of oil to continue functioning, and as North Slope production continues to decline, the risk of reaching this minimum increasing. Although there is some uncertainty around the minimum volume that is technically possible for the line to transport, this limit could be reached by 2026, according to the U.S. Energy Information Administration.

With declining production of crude oil (the largest sector of Alaska's economy), growth prospects are not strong. One mega-project that has been discussed and planned for decades is a new pipeline that would transport natural gas from the North Slope. The financial feasibility of this line is uncertain, however, and the prospects of it being constructed have been declining due to lower gas prices and to increasing domestic and world competition. In addition, the State of Alaska is one of the primary owners of the project, but low oil prices have created major budget problems for the State.

Washington is Alaska's primary waterborne trading partner. As shown in Figure 2-29, Washington accounted for nearly half of all waterborne cargo tonnage moving to and from Alaska from 2001 through 2014. California accounted for one-third, followed by foreign trade (14%), Hawaii (2%) and Oregon (1%). All other trading partners accounted for a total of 3% of Alaska waterborne trade.

Figure 2-29: Alaska Waterborne Trading Partners

Source: U.S. Army Corps of Engineers, 2001 through 2014

The largest share of waterborne tonnage shipped from Alaska is crude oil. Crude oil accounts for a large share of the tonnage shipped from Alaska to Washington, as well as most of the tonnage shipped from Alaska to California.

Oregon receives fertilizer from Alaska, as well as building products.

Fish is the other key product type shipped from Alaska to domestic destinations, and most of this fish moves through ports on Puget Sound. Fish is also shipped directly to foreign customers.

Coal is also shipped from Alaska to foreign destinations. Coal volumes vary widely from year to year, depending on foreign exchange rates, overseas demand, and other factors.

Waterborne cargo moving to Alaska includes essentially everything needed to live there, including food, consumer goods, building materials, and petroleum products. Most of these goods are shipped from Puget Sound.

Hawaii

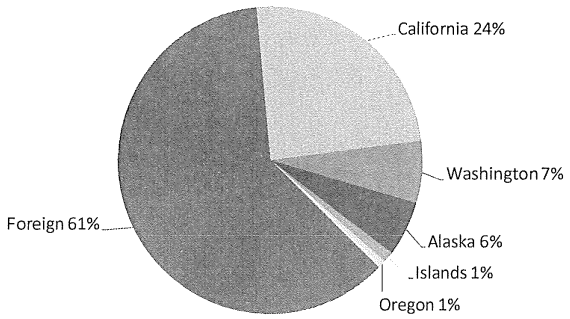
Hawaii's gross domestic product grew from $53.4 billion in 2000 to $70.5 billion in 2014 (in real 2009 dollars) or at approximately 2.0% per year. This was higher than average U.S. GDP growth rate of 1.6% per year (from 2000 through 2015). The Hawaii Department of Business, Economic Development & Tourism (DBEDT) expects that real GDP will grow at approximately 2.3% per year through 2019.[5]

The two leading drivers of the Hawaiian economy are tourism (accounting for approximately 16.7% of Hawaii's GDP in 2014) and government (accounting for approximately 21.6% of Hawaii's GDP in 2015 [6]).

- In 2015, Hawaii had 8.6 million visitors, who stayed a total of 78 million days (9 days per visitor on average). Spending by visitors averaged approximately $1,800 per trip. DBEDT projects that visitation could increase by 1.9% per year through 2019, and at 0.9% per year through 2030.

[5] Source: Hawaii DBEDT Quarterly Statistical and Economic Report, Q2 2016

[6] Source: Bloomberg Government Study, Impact of Defense Spending: A State-by-State Analysis, 2011



- The military is a key part of the economy of Hawaii; this includes the economic impact of active military and their families, as well as defense contracting, base operations, and capital expenditures. The largest military presence is centered in and near Joint Base Pearl Harbor–Hickam, where the Pacific operations of both the Navy and Air Force Pacific are headquartered. In 2014 there were 115,360 Hawaii residents associated with the active duty military, including 51,045 service members and 64,315 family members.[7]

Hawaii's population (1.43 million residents in 2015) grew at an average rate of 1.1% per year between 2000 and 2015. DBEDT estimates that the population could reach 1.66 million by 2035.[8]

The number of people employed in Hawaii grew at an average rate of 1.2% per year from 2000 through 2014. This rate was significantly higher than the U.S. average employment growth rate of 0.8% per year. DBEDT projects that the number of employed persons could pass 1 million in 2035. The unemployment rate in Hawaii has remained below 5.0% since 2013, down from a peak of 7.2% in 2009.

Hawaii's waterborne trade was relatively stable between 2001 and 2014, averaging approximately 13.2 million metric tons per year. This included 11.6 million metric tons of inbound cargo and 1.5 million metric tons of outbound cargo. As illustrated in Figure 2-30, the majority of Hawaii's off-island trade is with foreign countries (dominated by imports of crude petroleum, petroleum products, sand and gravel, and scrap metal et al.). California accounts for the next largest share (24%); this is primarily consumer products. Washington is the next largest trading partner (7%); this tonnage consists of consumer products and building products. Alaska (primarily crude oil) accounts for 6%, while and Oregon and non-Hawaiian Islands account for 1% each.[9]

Chapter 3
Marine Cargo Forecast

Introduction

This chapter provides the forecasts for waterborne cargo moving through deep draft marine terminals in Washington, as well as portions of Oregon. The forecasts include cargo moving through all public and private marine terminals in the region. These forecasts are also divided into four port sub-regions:

- Lower Columbia Washington,
- Lower Columbia Oregon,
- PSRC[10], and
- Other Puget Sound / Washington Coast.

The forecasts are organized by cargo handling type, including:

- Containers,
- Breakbulk,
- Neobulk,
- Dry bulk, and
- Liquid bulk.

Key Observations

- Containers
  - Ports in British Columba have been taking market share..
  - Direct East Coast service and Southern California ports also compete with PNW ports.
  - Transloading is increasing.
  - Ships are getting bigger, which impacts other parts of the transportation system.
- Breakbulk / Neobulk
  - Exports are projected to grow faster than imports.
  - Log Exports - demand spiked for a few years, due to China suddenly buying. China will continue to grow (more slowly), while Japan will decrease.
  - Log Imports - little change is projected under any scenario. Essentially all log imports are from Canada.
  - Auto Imports - under the reference case the PNW only reaches the peak volume of 2006-2007 in the outer years. Under the high forecast the historical peak is reached approximately halfway through the forecast period.
  - Auto exports are projected to grow strongly.

[10] PSRC is the Puget Sound Regional Council counties: King, Snohomish, Pierce, and Kitsap. It includes the Ports of Seattle, Tacoma, and Everett, as well as private facilities located in the region.

- Grain and oilseeds
  - The last fifteen years have seen strong growth; this is projected to continue under reference case, with even higher growth rates under the high forecast.
  - Significant export capacity has been added on the Columbia River, and the deepening of the navigation channel has attracted new grain export volumes.
- Other Dry Bulks
  - Imports - alumina has significantly decreased in importance. Most imports are now construction-related (i.e. gypsum, limestone, cement), in addition to fertilizers and chemicals. Future growth is tied closely to construction spending.
  - Exports - soda ash and potash account for most tonnage, all which currently moves through terminals on the Columbia River. Petroleum coke is steady, and is tied to refinery production. Other commodities include scrap metal and ores.
- Liquid Bulks
  - Crude oil accounts for the majority of tonnage. Waterborne volume is projected to be flat or to decrease slightly, unless crude-by-rail terminals are built.

Methodology

The forecasts were based on a variety of sources, depending on the handling group and commodities included. The initial basis for all of the projections was trade forecasts produced by IHS Markit. The IHS forecasts served as the "reference" cases for most commodities. Low case and high case forecasts were then developed using additional sources.

These forecasts are **unconstrained**, which means they assume that the infrastructure needed to handle the projected volumes will be available when needed. This includes capacity at marine terminals as well as on the rail system and other related infrastructure.

The **high case** for each handling type includes cargo volumes related to projects that are currently in the permitting process, such as the Millennium Bulk Terminal in Longview, the Northwest Innovation Works methanol plant in Kalama, and the Vancouver Energy terminal in Vancouver, among others. The **reference case** and **low case** growth projections do not include these volumes.

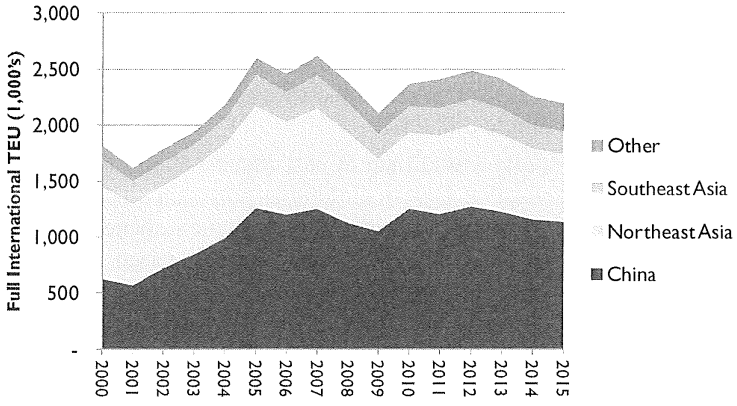
The Pacific Northwest was divided into four regions, and cargo projections were developed for each. These regions include:

- PSRC – this region includes marine terminals in King, Pierce, Snohomish, and Kitsap County, the counties included in the Puget Sound Regional Council, or PSRC.
- Puget Sound / Other Washington – this includes all ports and marine terminals on Puget Sound that are not in the PSRC region, as well as those on the Washington coast and in the Strait of Juan de Fuca.
- Lower Columbia Washington – this includes all marine terminals on the Washington side of the Columbia River, from Vancouver to the mouth of the river.
- Lower Columbia Oregon – this includes all marine terminals on the Oregon side of the Columbia River, from Portland to the mouth of the river, including those on the Willamette River.

Containers

The Pacific Northwest container trade is centered in Seattle and Tacoma. The Port of Seattle and Port of Tacoma recently merged their container operations under the Northwest Seaport Alliance (NWSA). The container terminals in Seattle are now referred to as the North Harbor, and the facilities in Tacoma are referred to as the South Harbor. In this document, forecasts for these facilities are included in the PSRC region.

Portland has also historically been a smaller player in the container trade, but lost most of its container service in 2015. Portland is working to secure a new container line. In addition, several other ports (such as Everett) handle relatively small numbers of containers



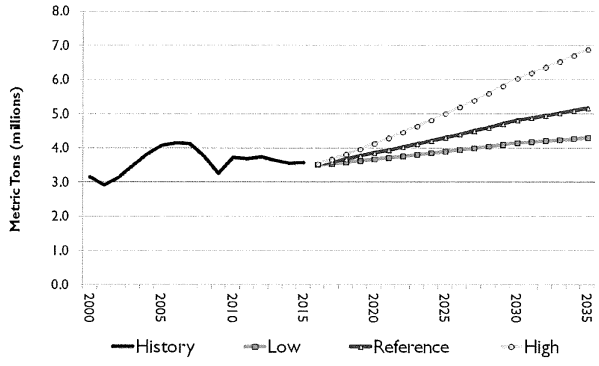
Container Trends and Forecast

Pacific Northwest container traffic increased sharply between 2001 and 2005, growing from 2.9 million TEU to nearly 4.1 million TEU (including full and empty imports, exports, and domestic containers). After remaining at the 4.1 million TEU level through 2006, volumes dropped sharply during the recession, falling to less than 3.3 million TEU in 2009. Although container volumes recovered somewhat in 2010, annual volumes were approximately 3.7 million TEU or less from 2010 through 2015.

International container traffic that moves through ports in the U.S. Pacific Northwest has long been dominated by trade with Asia. China, Other Northeast Asia, and Southeast Asia accounted for 93% of all full international containers in 2000 and 89% of full international containers in 2015 (see Figure 3-1).

The biggest change that occurred over this period was the increasing importance of China. The share of Pacific Northwest container trade accounted for by China grew from 34% in 2000 to 52% in 2015, while volume grew from approximately 630,000 TEU to 1.13 million TEU (full international containers). In contrast, Northeast Asia's share of container trade fell from to 45% to 28%, and volume dropped from 830,000 TEU to 610,000 TEU (full international containers). Southeast Asia's share also fell, from 13% to 9%, while volume dropped from 240,000 TEU to 201,000 (full international containers). All other regions accounted for 11% of international container traffic in 2015, which was an increase from the 7% share in 2000.

Figure 3-1: PNW International Container Trade Partners



Between 2000 and 2015, container volume grew at an annual rate of 0.9%. The forecast growth rates range from 0.9% (low) to 3.3% (high). The reference growth rate is 1.9% per year (see Figure 3-2).

One key factor that will impact future growth is competition from British Columbia ports (as discussed below). The U.S. Pacific Northwest has lost a large portion of its intermodal traffic to ports in British Columbia over the past decade, and, if this trend continues, container traffic growth will tend toward the low rate.

On the other hand, the share of container traffic that is transloaded from ocean containers into domestic containers and trailers is increasing. While this trend is occurring at ports in the U.S. Pacific Northwest, customs regulations essentially prevent the transloading of U.S.-bound cargo that moves through ports in British Columbia.

Finally, slow economic growth is projected for both Alaska and Hawaii, which will limit growth in Pacific Northwest domestic container trade.

Figure 3-2: Pacific Northwest Container Forecast (Million TEU)

Source: BST Associates, IHS Markit

Import container traffic grew at an average annual rate of 2.3% between 2000 and 2015. The reference growth rate for 2015 through 2035 is slightly lower, at 2.1%. The low growth rate is projected to average 1.2% per year and the high rate 4.3% per year (see Table 3-1).

Export container traffic growth was slow between 2000 and 2015, averaging just 0.1% per year. Future growth is expected to be stronger, ranging between 1.4% per year (low) and 3.0% (high). The reference growth rate is 2.2% per year.

Combined, international container trade averaged 1.1% growth per year between 2000 and 2015. Future growth in international container trade is projected to range between 1.3% per year (low) and 3.7% (high), with a reference growth rate of 2.2%.

These projected growth rates are substantially lower than in past Marine Cargo Forecasts. The main reason for these lower rates is the success that British Columbia ports have had in capturing U.S.-bound intermodal traffic. The Fairview Terminal in Prince Rupert, which opened in 2007, has been able to offer shippers faster ocean transit times and lower rail rates for cargo moving to the U.S. Midwest. Also, cargo moving through ports in British Columbia is not subject to the Harbor Maintenance Tax while cargo moving the U.S. ports is subject to the tax, providing shippers with additional savings. This combination of factors has allowed British Columbia to capture a substantial share of cargo that would have moved through the U.S. Pacific Northwest.

Domestic container traffic includes cargo shipped to and from Alaska and Hawaii. Most cargo shipped by water to Alaska originates at ports on Puget Sound, primarily Seattle and Tacoma. The Pacific Northwest is also one of three main sources of cargo for Hawaii (along with Southern California and Northern California. Seattle and Tacoma are the center of the Pacific Northwest - Hawaii trade, but some of this traffic also moves through the Columbia River.

As described above, growth in domestic container traffic is projected to be relatively slow, due to slow economic growth in both Alaska and Hawaii. From 2000 through 2015, domestic container cargo grew at 0.1% per year, on average. Future growth is projected to range between -0.5% and 1.7%, with a reference growth rate of 0.6%.

The overwhelming majority of Pacific Northwest container traffic will continue to move through ports in the PSRC region, primarily Seattle and Tacoma. Most of the container traffic that had moved through Portland shifted to Seattle and Tacoma; if Portland is able to attract a new carrier some of this traffic could shift back to Portland, otherwise it will continue to move through Seattle and Tacoma. In addition, limited volumes of container traffic will likely continue to move through other ports in the Pacific Northwest.

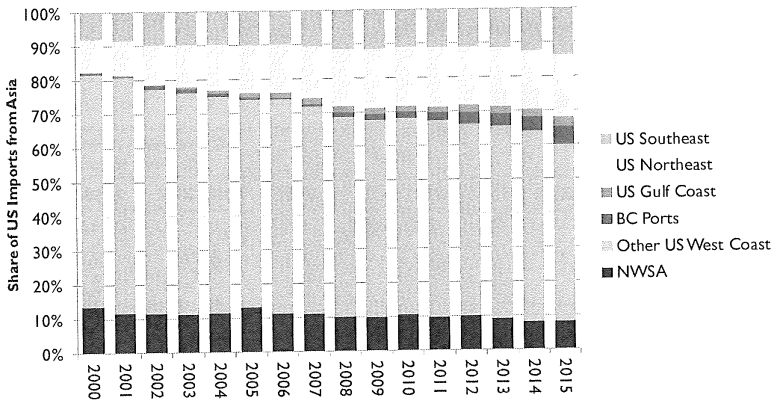
Key Issues for Container Traffic



As described above, nearly all of the international container traffic that moves through the Pacific Northwest is moving from or to Asia. Ports in the Pacific Northwest face competition from several other port regions for cargo moving to and from inland points. West Coast ports handle the majority of containerized cargo that moves from Asia to the United States, but the U.S. West Coast market share has declined steadily since 2000, as ports on the East Coast, Gulf Coast, and British Columbia have attracted Asian cargo bound for inland U.S. destinations.

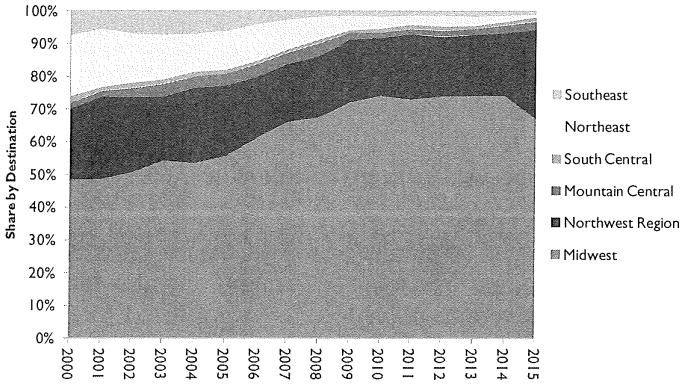
Between 2000 and 2015, the share of U.S.-Asia containerized imports that moved through U.S. West Coast ports declined from 82% to 60%. The share of Asian imports moving through the Northwest Seaport Alliance ports dropped from 14% in 2000 to 8% in 2015. The rest of the U.S. West Coast also saw a declining market share for Asian imports; from 2000 through 2015, U.S. West Coast market share declined from 68% in 2000 to 52% (see Figure 3-3).

As discussed above, ports in British Columbia (i.e. Prince Rupert and Vancouver) have taken a significant portion of the Asian import traffic bound for the U.S. In 2000, ports in British Columbia handled essentially no U.S.-bound container traffic, but by 2015 their share had grown to 5%.

The share of Asian import traffic moving through ports in the Northeast grew from 10% in 2000 to 18% in 2015, and the share moving through ports in the Southeast grew from 8% to 14% over the same period. Gulf Coast ports also gained market share, growing from 0% to 3%.

Figure 3-3: Share of Import Containers from Asia (Million TEU)

Source: PIERS data



The Midwest has become increasingly important as a destination for containers imported through the Pacific Northwest, while other regions have become less important. The main reason for this shift is that importers have increasingly chosen to serve East Coast markets using all-water shipping routes via the Panama Canal, rather than shipping through West Coast ports.

Figure 3-4 illustrates trends in the shipment by rail of containers imported through the Pacific Northwest. Shipments to the Midwest accounted for 67% of these movements in 2015, up from 47% in 2000. At the same time, the share moving to the Northeast dropped from more than 18% in 2000 to 1% in 2015.

The share of import ocean containers shipped by rail from the Pacific Northwest to other Pacific Northwest destinations jumped in 2015, due to the loss of container service in Portland. Much of the container traffic that had moved through Portland shifted to Puget Sound ports, and a substantial share of these import containers were shipped by rail to Portland.

All other destinations (combined) accounted for 4% to 5% of import container traffic from 2009 through 2015, compared with 14% in 2000.

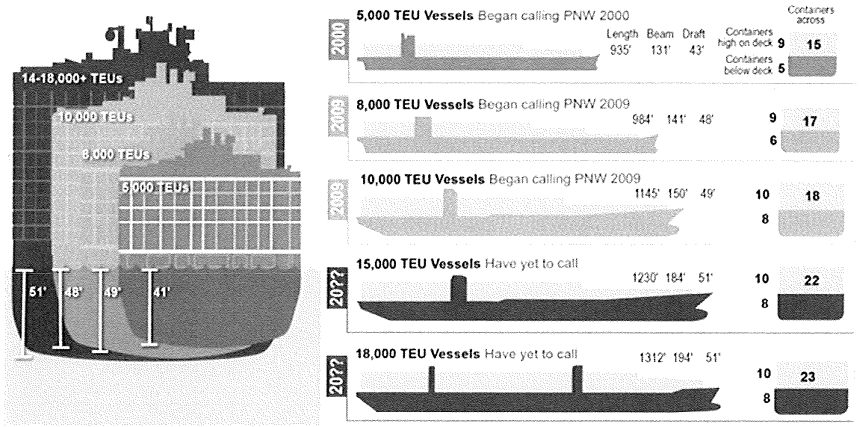


Figure 3-4: Pacific Northwest Originating Intermodal Traffic (Ocean Containers) by Destination

Source: Intermodal Association of North America (IANA) data

The size of container ships calling at container terminals in the Pacific Northwest has been increasing rapidly and is expected to continue to increase in the future. As shown in Figure 3-5, 5,000 TEU vessels began calling Pacific Northwest ports in 2000, followed by 8,000 TEU and 10,000 TEU vessels in 2009. The Benjamin Franklin, CMA-CGM's 18,000 TEU vessel, called at Terminal 18 on February 29, 2016. This vessel is 1,310 feet long and has a beam of 177 feet.

Figure 3-5: Evolution of Container Ships

Source: Mercator International[11]

The increasing size of container ships is a key factor that is negatively impacting Portland's ability to attract a new container carrier. As shown in Figure 3-5, the 8,000 to 10,000 TEU vessels that began calling the Pacific Northwest in 2009 have drafts of 48 feet or more when fully loaded. The Columbia River navigation channel, however, is maintained to a depth of 43 feet. Other types of ships (such as bulk carriers that move grain) have not seen such an increase in size, and are generally not limited by the 43-foot channel.

[11] Mercator International, *Seaport Alliance Strategic Business Plan*, May 16, 2015

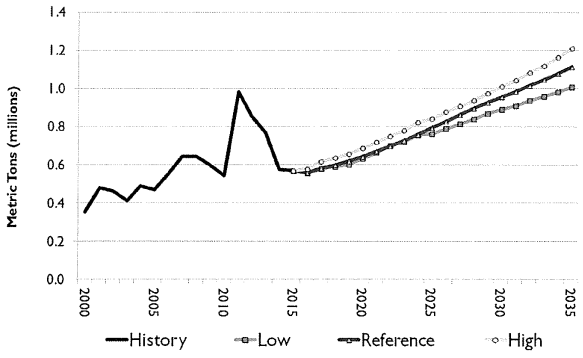
The adoption of larger vessels has led to a reduction in the number of ports at which a ship calls on each voyage, which means that more containers are handled during each vessel call. This has increased the pressure on ports to improve terminal capacity and throughput. In order to accommodate the larger vessels, significant investments will be required in port infrastructure, including:

- Longer berths,
- Larger container cranes,
- Increased water depth in channels and alongside berths (51 feet or more), and
- Additional on-dock rail to quickly move cargo off dock.

The consolidation of shipping lines into fewer and larger alliances gives the carriers significant leverage in negotiating with ports, due to the amount of cargo they control. It also limits any individual carrier's reliance on any particular port or terminal.

Breakbulk/Neobulk Cargo

Pacific Northwest breakbulk and neobulk cargo includes forest products, machinery, metal products, and autos.



Breakbulk Exports

Breakbulk exports consist primarily of forest products, including lumber, pulp and paper. These grew from approximately 350,000 metric tons in 2000 to 600,000 metric tons in 2010, or at an average rate of 3.2% per year. In 2011 there was a surge of exports, consisting of forest products and machinery/equipment. The surge subsided in 2014, when breakbulk exports fell back to 600,000 metric tons (see Figure 3-6).

Pacific Northwest breakbulk export volumes are expected to increase from 2015 to 2035 as follows:

- Low case: reaching 1.0 million metric tons (2.9% per year growth),
- Reference case: reaching 1.1 million metric tons (3.4% per year growth),
- High case: reaching 1.2 million metric tons (3.9% per year growth).

Figure 3-6: Pacific Northwest Breakbulk Exports (1,000 Metric Tons)

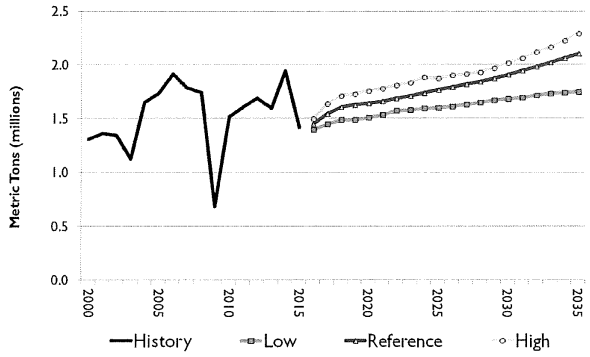
Source: BST Associates, IHS Markit

Breakbulk Imports

Breakbulk imports are dominated by iron and steel, such as coil, bars, pipe, rail and other products. Most of these products are used by local/regional firms as inputs to manufacturing and construction. A small portion is also shipped by rail to the Midwest and beyond. The Lower Columbia River (on both sides of the river) and Central Puget Sound have extensive industry clusters of construction and manufacturing firms that use imported steel.

In addition to steel, other breakbulk imports include forest products and machinery/equipment.

A strong U.S. dollar is expected to accelerate imports in the next few years. However, growth in imports of iron and steel will be tempered to some degree by import duties.



Breakbulk imports increased at an average annual rate of 0.5% between 2000 and 2015, growing from 1.3 million metric tons to 1.4 million metric tons. Volumes peaked in 2005 but then collapsed in 2009 as a result of the Great Recession. However, volumes rebounded in 2010, peaking

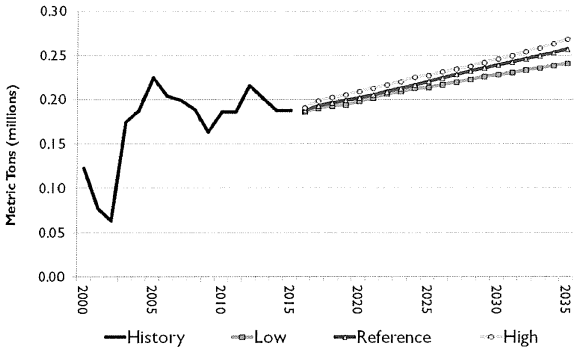
in 2014 at nearly 1.9 million metric tons before declining to 1.4 million metric tons in 2015 (see Figure 3-7).

Pacific Northwest breakbulk import volumes are projected to increase to the following levels between 2015 and 2035:

- Low case: reaching 1.8 million metric tons (1.1% per year growth),
- Reference case: reaching 2.1 million metric tons (2.0% per year growth),
- High case: reaching 2.3 million metric tons (2.4% per year growth).

Figure 3-7: Pacific Northwest Breakbulk Imports (1,000 Metric Tons)

Source: BST Associates, IHS Markit



Domestic Coastwise Traffic

Coastwise breakbulk traffic consists mainly of shipments of forest products (lumber and other building products) to California, Alaska and Hawaii. Coastwise traffic increased from 120,000 metric tons in 2000 to 190,000 metric tons in 2015 (see Figure 3-8).

Volumes of coastwise breakbulk shipments are projected to increase to the following levels between 2015 and 2035:

- Low case: reaching 240,000 metric tons (1.3% per year growth),
- Reference case: reaching 260,000 metric tons (1.7% per year growth),
- High case: reaching 270,000 metric tons (1.9% per year growth).

Figure 3-8: Pacific Northwest Breakbulk Coastwise Shipments (1,000 Metric Tons)

Source: BST Associates, IHS Markit

Summary

As shown in Table 3-2, total breakbulk cargoes (including exports, imports and coastwise shipments) are projected to grow as follows from 2015 through 2035:

- Low case: reaching 3.0 million metric tons (1.6% per year growth),
- Reference case: reaching 3.5 million metric tons (2.4% per year growth),
- High case: reaching 3.8 million metric tons (2.8% per year growth).

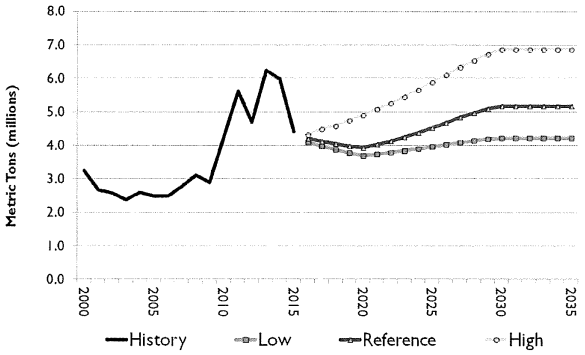
Logs

Log Exports



From 2000 to 2009, log exports remained relatively stable, ranging from 2.5 million metric tons to 3.0 million metric tons per year. There was rapid growth from 2010 to 2013/14, when log exports increased to 6.0 million tons, largely due to increased exports to China. However, exports fell in 2015 to 4.4 million tons (see Figure 3-9).

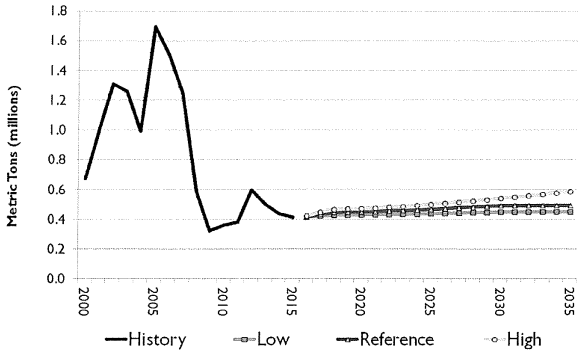
The forecast low and reference cases assume that Chinese demand continues to grow, but at a slower pace than in recent years; the high case assumes that demand from China increases. All growth scenarios assume that Japanese demand declines due to increasing domestic timber harvests in Japan.

Pacific Northwest log export volumes are projected to increase from 2015 to 2035 as follows:

- Low case: reaching 4.2 million metric tons (-0.2% per year growth),
- Reference case: reaching 5.2 million metric tons (0.8% per year growth),
- Low case: reaching 6.9 million metric tons (2.2% per year growth).

Figure 3-9: Pacific Northwest Log Exports (1,000 Metric Tons)

Source: BST Associates, IHS Markit



Log Imports

Some Pacific Northwest mills source logs from Canada, depending upon availability and price. Waterborne imports of logs grew steadily from 700,000 metric tons in 2000 to 1.7 million metric tons in 2005 as domestic sources dwindled. After 2005, import volumes began to decline, and ranged from 300,000 metric tons to 600,000 metric tons between 2008 and 2015 (see Figure 3-10)

Pacific Northwest log import volumes are expected to increase from 400,000 metric tons in 2015 to the following levels in 2035:

- Low case: 450,000 metric tons (0.5% per year growth),
- Reference case: 500,000 metric tons (0.9% per year growth),
- High case: 600,000 metric tons (1.8% per year growth).

Figure 3-10: Pacific Northwest Log Imports (1,000 Metric Tons)

Source: BST Associates, IHS Markit

Domestic Coastwise Traffic

Coastwise traffic is domestic waterborne traffic carried over the ocean, (e.g. Alaska to Puget Sound, or Columbia River to California). Coastwise log traffic steadily declined from approximately 400,000 metric tons per year from 2001 through 2004 to less than 50,000 metric tons in 2013, and to approximately 3,000 metric tons in 2014. Coastwise log traffic is not projected to grow significantly during the forecast period.

Internal traffic is vessel movements (origin and destination) which take place solely on inland waterways. An inland waterway is one that is geographically located within the boundaries of the contiguous 48 states or within the boundaries of the State of Alaska. Puget Sound is one such inland waterway, as is the Columbia/Snake River system. There is a substantial volume of internal movements of logs on Puget Sound, such as log shipments from the Olympic Peninsula to La Conner for distribution to local mills. However, this cargo forecast focuses on coastwise and international traffic and, as a result, internal shipments and receipts are not included.

Summary

Total log traffic grew from 4.2 million metric tons in 2000 to 4.8 million metric tons in 2015, or at an average annual rate of 1.0%. As shown in table 3-3, log traffic is projected to increase to the following levels in 2035:

- Low case: 4.7 million metric tons (-0.1% per year growth),
- Reference case: 5.7 million metric tons (0.8% per year growth),
- High case: 7.5 million metric tons (2.2% per year growth).

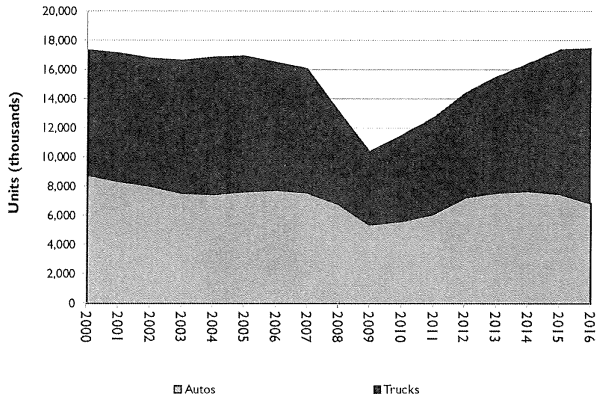
Automobiles



Pacific Northwest ports have long been major players in the automobile import trade, and in recent years have also begun to serve the export trade. The following sections provide an analysis of U.S. auto sales and production, as well as forecasts of Pacific Northwest auto imports and exports.

Imports

Sales of autos in the U.S. averaged 16 to 17 million units from 2000 to 2007, until the Great Recession drove sales to a low of 10.4 million units in 2009 (a drop of nearly 40%). Restructuring of the auto industry and gradual recovery of the economy led to a rebound in sales. Auto sales reached 16.5 million units in 2014, and exceeded 17 million units in both 2015 and 2016 (see Figure 3-11).

The type of vehicle sold in the U.S. has changed dramatically since 2000. In 2000, the market was evenly split between autos and trucks. Driven largely by low fuel prices, sales of trucks (including SUV's) surged during 2016, and now represent 61% of passenger vehicle sales in the U.S.

Figure 3-11: U.S. Auto Sales Trends
(1,000 Units)

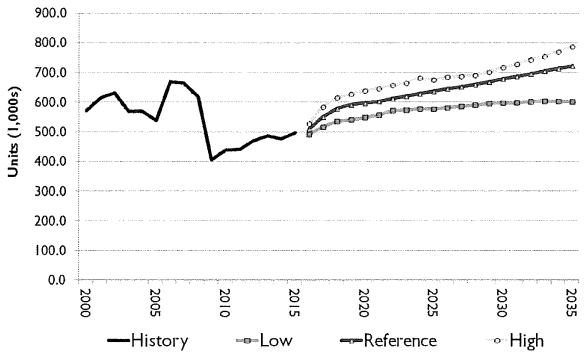
Source: U.S Bureau of Economic Analysis

In the U.S., the market share of foreign vehicles grew from approximately 17% in 2000 to a peak of 26% in 2009; for the past five years imports have leveled off at 21% to 22% of U.S. sales. A growing share of these vehicles is manufactured in Mexico, which has now surpassed Japan as the second largest exporter to the U.S. Canada remains the largest exporter to the U.S., with export volumes that have remained relatively stable.

IHS expects that the U.S. auto market is reaching maturity, with sales momentum slowed due to rising interest rates, as well as to the impact of legislated content (safety and environmental requirements) on prices. In addition, increased urbanization is reducing the need for vehicles. Other trends include electrification and hybrids, automated driving and shared mobility services.

Global light vehicle production is expected to grow at the following annual rates between 2015 and 2021:

- Chinese production – 4.0 % per year between 2015 and 2021,
- South Asian production – 6.4 % per year between 2015 and 2021,



- EU production – 1.6 % per year between 2015 and 2021, and
- North American production – 1.1 % per year between 2015 and 2021.

Auto imports moving through Pacific Northwest ports ranged from 550,000 units to 650,000 units between 2000 and 2008. During the Great Recession, import volumes declined to 400,000 units in 2009, but grew back to approximately 500,000 units in 2015 (see Figure 3-12)

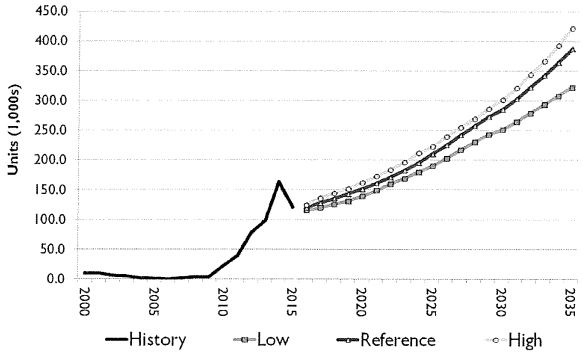
Between 2015 and 2035, Pacific Northwest auto import volumes are expected to increase from 500,000 units to:

- Low case: 601,000 units (1.0% per year growth),
- Reference case: 723,000 units (1.9% per year growth),
- High case: 756,000 units (2.3% per year growth).

Figure 3-12: Pacific Northwest Auto Imports (1,000 Units)

Source: BST Associates, IHS Markit

Exports



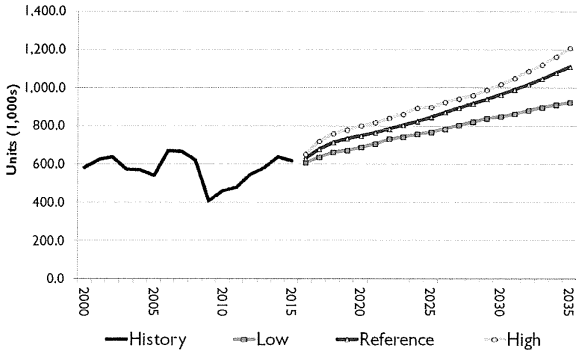
Exports of U.S. autos across all ports and border crossings increased rapidly between 2000 and 2015, growing at an annual rate of 11.4%. Emerging markets in China, India, Brazil, Eastern Europe and South Africa drove much of this growth.

Between 2000 and 2015, auto exports moving via Pacific Northwest ports increased at an annual rate of 23.0%, due mainly to shipments from Grays Harbor and Portland to China (see Figure 3-13).

Between 2015 and 2035, Pacific Northwest auto export volumes are expected to increase from 121,000 units to:

- Low case: 322,000 units (5.0% per year growth),
- Reference case: 387,000 units (6.0% per year growth),
- High case: 422,000 units (6.5% per year growth).

Figure 3-13: Pacific Northwest Auto Exports (1,000 Units)



Source: BST Associates, IHS Markit

Summary

Pacific Northwest auto import and export volumes are expected to increase from 616,000 units in 2015 to the following volumes in 2035 as follows:

- Low case: 923,000 units (2.0% per year growth),
- Reference case: 1.1 million units (3.0% per year growth),
- High case: 1.2 million units (3.4% per year growth) (see Figure 3-14 and Table 3-4).

Summary of Breakbulk and Neobulk Cargoes by Region

Breakbulk and neobulk volumes are summarized by region in Table 3-5. The differential rates of growth are caused by the differences in product mix and direction of trade.

The Lower Columbia Oregon region has lost breakbulk cargo to Lower Columbia Washington and to Northern California; between 2000 and 2015 the region's volume dropped from 1.24 million metric tons 1.05 million metric tons. This drop was partially offset by increased log exports from Astoria, and by coastwise shipments from Rainier, Oregon to Hawaii. Between 2015 and 2035, projected growth in breakbulk and neobulk cargo for the Lower Columbia Oregon region is:

- Low case: 1.4 million metric tons (1.3% per year growth),
- Reference case: 1.6 million metric tons (2.2% per year growth),
- High case: 1.9 million metric tons (3.0% per year growth).

The shift of breakbulk cargo from Lower Columbia Oregon contributed to growth in Lower Columbia Washington, where breakbulk/neobulk volumes rose from 2.5 million metric tons in 2000 to 3.9 million metric tons in 2015. Between 2015 and 2035, projected growth in breakbulk/neobulk volume in the Lower Columbia Washington is:

- Low case: 4.2 million metric tons (0.4% per year growth),
- Reference case: 5.1 million metric tons (1.3% per year growth),
- High case: 6.3 million metric tons (2.4% per year growth).

In the PSRC region, breakbulk/neobulk volumes saw little change over the past 15 years, with 1.57 million metric tons in 2000 and 1.60 million metric tons in 2015. Between 2015 and 2035, projected growth in breakbulk/neobulk volume in the PSRC region is:

- Low case: 2.1 million metric tons (1.3% per year growth),
- Reference case: 2.4 million metric tons (2.0% per year growth),
- High case: 2.8 million metric tons (2.8% per year growth).

Breakbulk/neobulk volumes moving through the Other Puget Sound / Washington Coast region were also essentially flat, with 1.45 million metric tons in 2000 and 1.42 million metric tons in 2015. Between 2015 and 2035, projected growth in breakbulk/neobulk volume in the Other Puget Sound / Washington Coast region is:

- Low case: 1.7 million metric tons (0.7% per year growth),
- Reference case: 2.0 million metric tons (1.6% per year growth),
- High case: 2.4 million metric tons (2.7% per year growth).

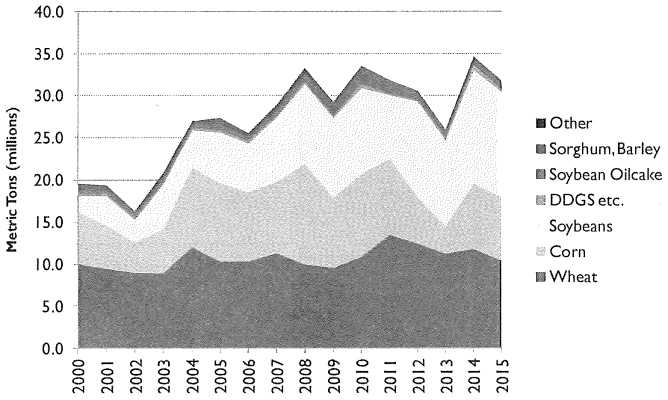
Grain and Oilseeds



Overview

Grain terminals handle a variety of grains, oilseeds, and related products. These include wheat, corn, barley, soybeans, grain sorghum, and some animal feeds such as beet pulp pellets and DDGS[12].

Exports of grain and oilseeds through Pacific Northwest ports grew from less than 20 million metric tons in 2000 to nearly 35 million metric tons in 2015. Volumes fluctuate from year to year, depending on annual harvest and other factors, but the long-term trend has been one of strong growth (see Figure 3-15)

Wheat, corn, and soybeans account for most of the grain and oilseed volume. Wheat volumes in 2015 were essentially the same as in 2000 (approximately 10.0 million metric tons), but ranged from a low of 9.0 million metric tons to a high of 13.4 million metric tons. Over the same period corn exports grew from 6.2 million to 7.6 million metric tons, and ranged from 3.2 million to 12.0 million metric tons. Soybeans grew from 1.8 million to 12.5 million metric tons, with growth occurring in most years. In fact, between 2010 and 2015 soybean exports dropped to less than 10.0 million metric tons in only one year (i.e. 7.6 million metric tons in 2011).

Figure 3-15: Pacific Northwest Grain and Oilseed Trends)

Source: BST Associates, WISERTrade

Wheat is primarily used for human consumption, as opposed to the coarse grains (corn, barley, sorghum), which are primarily used as animal feed. Demand for human food is less affected by changes in personal income than demand for animal feed, but currency exchange rates do have a strong impact on wheat sales. Competition for wheat exports is intense, particularly with Canada and Australia, among other countries.

In the Pacific Northwest, nearly all wheat and barley exports are handled through ports on the Columbia River. Much of the wheat exported through the Pacific Northwest is grown in the Great Plains, but the ports also handle substantial volumes of wheat grown in Eastern Washington,

[12] DDGS is distiller's dried grains with solubles, the nutrient rich co-product of ethanol production used as a feed ingredient.

Oregon, Idaho, Montana, and Utah. Export sales are critical to farmers in the Pacific Northwest, where 85% to 90% of Washington wheat and 90% of Oregon wheat is sold for export.

Competition is intense in the world coarse grain market, and Washington exporters vie for sales against Brazil, Argentina, and others. Washington ports also face competition from other U.S. port regions, specifically ports on the Gulf of Mexico.

Soybeans are used both for animal feed and for human consumption. The export markets are large and growing, particularly in China. As with other crops, there is strong international competition (mainly from Brazil and Argentina).

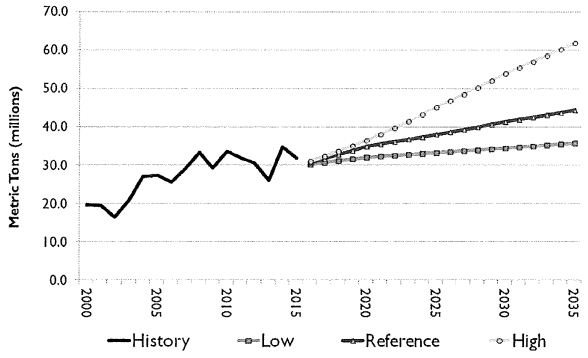
Completion of the Columbia River navigation channel deepening project has encouraged significant investments in capacity expansions at grain terminals on the river. These investments have increased annual export capacity from approximately 21 million metric tons to more than 37 million metric tons. These capacity improvements allowed the total volume of grain to jump to a new record of 25 million metric tons in 2014. Terminal improvement projects included:

- Portland - annual throughput capacity of the Columbia Grain Terminal was increased by 2 million metric tons (from approximately 5 million metric tons to 7 million metric tons).
- Vancouver - throughput capacity of the United Grain Terminal also increased by 2 million metric tons (from 4 to 6 million metric tons).
- In Kalama, both export terminals completed projects that increased combined annual capacity from approximately 10 million metric tons to more than 14 million metric tons.
- In Longview, a new terminal was constructed, with annual throughput capacity of 8 million metric tons.

One potential competitive threat to Pacific Northwest ports is future use of larger vessels at U.S. Gulf ports and at South American ports. New locks at the Panama Canal can handle vessels with maximum draft of 60 feet, and the Corps of Engineers is studying the potential to deepen the Mississippi River channel to 50 feet upstream to Baton Rouge. Depending on the origin of the grain (i.e. how far it is grown from the river system) the increased efficiency of the larger vessels could attract a larger share of the grain exports.

Another competitive threat is grain loaded into containers. Although the volume of this type of movement is still small relative to bulk shipments, it does provide shippers with additional options. Grain can be loaded into containers near the farming areas if empty containers are available, or it can be shipped by rail to the vicinity of container ports (such as Los Angeles / Long Beach), where empty containers are available for transloading.

Shifts in trade and consumption patterns have created opportunities for additional growth in grain and oilseed exports for Pacific Northwest ports. For example, the rising number of middle class households in China is expected to increase the demand for exports from the PNW. Changes in Canada's system for sales and distribution of grain have also led to increasing volumes of Canadian grain exported through Columbia River ports.



Changes in domestic consumption of corn may also create opportunity for increased exports. An estimated 40% of U.S. corn production is now used to make ethanol production, but demand for ethanol could decrease due to increasing U.S. production of oil, freeing more of the crop for export.

Forecast

Pacific Northwest grain exports grew at an average annual rate of 3.3% between 2000 and 2015. Future growth is projected to range from a low of 0.6% per year to a high of 3.4% per year, with a reference rate of 1.7% (see Figure 3-16)

Corn exports are forecast to grow strongly over the next twenty years, especially if less corn is used domestically in ethanol production. Wheat and soybean exports are also projected to continue growing.

Figure 3-16: Pacific Northwest Grain and Oilseed Forecast (1,000 Metric Tons)

Source: BST Associates, IHS Markit

Regional Forecast

Most of the growth over the past 15 years occurred in the Lower Columbia River Washington region, where volumes doubled. Total tonnage grew from 9.8 million to 19.9 million metric tons, or at an average annual rate of 4.9%, and the region accounted for nearly two-thirds of Pacific Northwest exports. As discussed above, significant new capacity was added to grain terminals in the region, and this investment appears to be paying off. Future growth is projected to range between 0.4% and 3.1% per year, with a reference rate of 2.3% (see Table 3-6).

Lower Columbia Oregon saw a drop in grain exports between 2000 and 2015, although 2015 was an outlier year. Future growth is projected to range between 1.2% and 3.9% per year, with a reference growth rate of 3.9%.

Between 2000 and 2015, grain exports through the PSRC region increased from 5.3 million to 7.0 million metric tons, or at an average annual rate of 1.9%. However, during that period the volume reached nearly 12 million metric tons in some years. Future growth is projected to range between 0.8% and 3.8% per year, with a reference growth rate of 2.0% per year.

Other Puget Sound / Washington Coast ports handled almost no grain exports in 2000, but handled 1.6 million metric tons in 2015. This jump is attributable to the construction of the new AGP export terminal in Aberdeen. Future growth is projected to range between -0.1% and 3.2% per year, with a reference rate of 0.7%.

Dry Bulk Cargoes (Excluding Grain)

Overview

This section examines dry bulk cargo, excluding grains, oilseeds, and related products.

Imports

Alumina once accounted for most dry bulk import tonnage in the Pacific Northwest. For decades the region was home to ten aluminum smelters, but this number has now dropped to only two, and the closure of most of the smelters has significantly reduced imports of alumina. Dry bulk imports are now dominated by construction-related commodities, such as gypsum, limestone, and cement. Fertilizers and chemicals account for most of the remaining import tonnage.

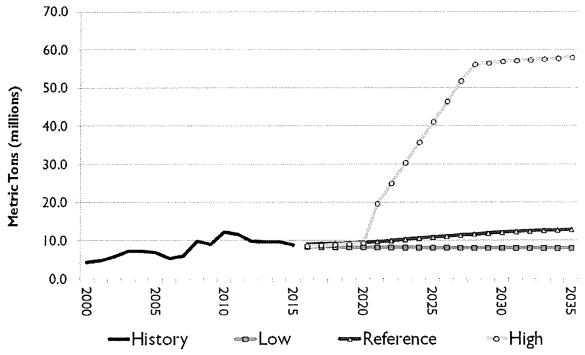
Import tonnage of dry bulks fell from approximately 8.0 million metric tons in 2000 to 7.0 million metric tons in 2015, or a decline of 0.9% per year. Most of this decline occurred between 2007 and 2009, when import tonnage dropped to less than 4.4 million metric tons during the recession. After several years of slow growth imports have recovered strongly.

Future growth rates for import dry bulks are tied closely to projections of construction spending. The reference growth rate averages 1.8% per year from 2015 through 2035, the high growth rate averages 2.1%, and the low rate averages 0.7%. It should be noted that there will likely be one or more economic recessions over the forecast period, and during the oscillations of the economic cycle import volumes may deviate from these growth rates in any given year. Over the long run, however, these growth rates represent the projected annual average growth (see Figure 3-17)

Figure 3-17: Pacific Northwest Other Dry Bulk Imports Forecast (1,000 Metric Tons)

Source: BST Associates, IHS Markit

Exports



Dry bulk export commodities include minerals, scrap metal, petroleum coke, and hay pellets. Two minerals, potash and soda ash, account for more than two-thirds of dry bulk export tonnage. Soda ash mined in Wyoming has been exported through Portland for decades, while exports of potash (primarily from Saskatchewan) began in the mid-2000's. Other minerals, such as bentonite clay and sulfur, account for less than 4% of export dry bulk tonnage. Copper concentrates from Montana are exported via the Port of Vancouver.

Most of the remaining export dry bulk tonnage consists of petroleum coke and scrap metal. Petroleum coke is produced in steady volumes by the petroleum refineries on northern Puget Sound, and accounts for approximately 14% of export dry bulk tonnage. Scrap metal also accounts for 14% of export tonnage. Wood chips accounted for 14% of export tonnage in 2000, but dropped to just 2% of tonnage in 2015.

Between 2000 and 2015, dry bulk exports volumes grew at an annual rate of 5.0%. Much of this growth was due to the start-up of potash exports, which did not exist in 2000. Soda ash volumes also grew also over that time. From 2015 through 2035, the reference growth rate is projected to average 1.9% per year (see Figure 3-18)

The high case forecast growth rate is 10.2% per year; based on the assumption that coal will begin to be exported through the U.S. Pacific Northwest. The high case assumes that the Millennium Bulk Terminal in Longview is constructed and operates at maximum volume (i.e. 44 million metric tons per year.)

Figure 3-18: Pacific Northwest Other Dry Bulk Exports Forecast (1,000 Metric Tons)

Source: BST Associates, IHS Markit

Regional Forecast

More than half of dry bulk import tonnage moves through ports in the PSRC region. The region is home to a number of plants that manufacture construction materials, including cement plants, wallboard plants, and concrete batch plants. Key commodities include gypsum, limestone, sand and gravel, and scrap metal. Dry bulk imports moving through ports in the PSRC region are projected to grow from 3.9 million metric tons in 2015 to 6.3 million metric tons under the reference forecast, and to range between 5.0 million metric tons and 6.6 million metric tons. The rate of growth over twenty years is 2.5% per year under the reference forecast, 1.2% under the low forecast, and 2.7% under the high forecast (see Table 3-7).

Lower Columbia Oregon ports handle approximately one-quarter of import dry bulks. Growth was slow between 2000 and 2015, averaging 0.1% per year. From 2015 through 2035 the reference growth rate is 0.3%, with a low rate of -0.7% and a high rate of 0.7%. As with the PSRC region, the primary commodities are construction-related, including gypsum, limestone, and cement. Fertilizer accounts for most of the remaining tonnage.

Dry bulks import volumes are relatively limited in both the Lower Columbia Washington and Other Puget Sound / Washington Coast region, and the volumes of imports dropped in both regions

between 2000 and 2015. For the Lower Columbia Washington ports the main source of the decline was alumina, which dropped sharply as smelters closed. Fertilizer and chemicals account for most of the tonnage now, and both saw increasing volumes between 2000 and 2015. For Other Puget Sound / Washington Coast ports, the main source of the declining tonnage was limestone and aggregates. Future growth for Lower Columbia Washington is projected to range between 1.1% and 2.6% per year, with a reference growth rate of 2.2%. Growth in Other Puget Sound / Washington Coast is projected to range between -0.2% and 0.7% per year, with a reference growth rate of 0.2%.

For the entire region, dry bulk imports are projected to grow at an average annual rate of 1.8% under the reference case, 0.7% under the low case and 2.1% under the high case.

Most dry bulk exports move through the Lower Columbia region, especially the Lower Columbia Oregon. Combined, the Lower Columbia Oregon and Lower Columbia Washington regions accounted for 85% of dry bulk exports in 2015, and tonnage more than doubled between 2000 and 2015. Portland accounts for the largest share of these movements, due to the high volumes of potash and soda ash exports.

Export tonnage increased by an average of 5.8% per year in the Lower Columbia Oregon between 2000 and 2015. Future growth is projected to range between -0.3% and 2.3%, with a reference growth rate of 1.8% per year. In the Lower Columbia Washington region the projected low and reference growth rates are similar to those for Oregon. The high rate, however, is much higher, due to the inclusion of Millennium Bulk Terminal coal exports (see Table 3-8).

The PSRC region saw declining dry bulk exports between 2000 and 2015, due almost entirely to a fall in wood chip exports. Volumes dropped by an average of -2.9% per year between 2000 and 2015. With wood chips gone and not expected to return, the different commodity mix results in projected growth rates ranging between 0.2% and 5.0% per year, with a reference growth rate of 3.2% per year.

LUBA No. 2020-009
Page 5566

Other dry bulk exports doubled in volume through ports in the Other Puget Sound / Washington Coast region between 2000 and 2015, although the total volume handled is much smaller than through the Columbia River. Growth averaged 4.9% per year between 2000 and 2015, but is forecasted to slow between 2015 and 2035. Future growth is projected to range between -0.1% and 1.9%, with a reference growth rate of 1.4%.

For the region as a whole, the reference growth rate for dry bulk exports is 1.9% per year, the low rate is -0.2% and the high growth rate is 10.6%. The large jump between the reference and high growth rates is due to the inclusion of Millennium Bulk Terminal coal in the high forecast.

Liquid Bulks

Waterborne liquid bulk traffic in the Pacific Northwest is dominated by crude oil and refined petroleum products. A variety of other liquid commodities (e.g. animal fats, vegetable oils, chemicals, and fertilizers) are also handled, but in much smaller volumes.

Crude Oil

Five refineries on Puget Sound receive crude oil by water: two at Cherry Point near Ferndale, two at March Point near Anacortes, and a smaller facility in Tacoma. Puget Sound refineries have the capacity to process approximately 631,700 barrels of crude oil per day; incremental improvements to these facilities increased production capacity by an average of 0.6% per year between 1995 and 2015.[13] However, the amount of crude oil actually processed has remained relatively constant at approximately 560,000 barrels per day.[14] (See Table 3-9).

Table 3-9: Puget Sound Refinery Capacity (barrels per day)

Area	1995	2015	CAGR 1995-2015
Tacoma	44,300	40,700	-0.4%
Anacortes	236,500	265,000	0.6%
Ferndale	284,000	326,000	0.7%
Total	564,800	631,700	0.6%

Source: U.S. Energy Information Administration

As shown in Table 3-10, Washington refineries receive crude oil via seven different combinations of sources and modes of transportation.

Table 3-10: Puget Sound Crude Oil Sources and Routes

Source and Type of Crude	#	Route	Estimated Loading in 2015
Alaska (Alaska North Slope or (ANS))[10]	1	by tanker to the refineries	250,000 bbls/day or 45%, down from 90% in 2003 and expected to continue to decline.
Canadian crude from Alberta (heavy, medium and light)	2	by Trans Mountain Mainline Pipeline to Abbotsford, BC and then by Kinder Morgan's Puget Sound pipeline system to the refineries	140,000 bbls per day or 25% from 2011 to 2015, up from 10% in 2003
	3	by Trans Mountain Mainline Pipeline to the Westridge Terminal in Burnaby BC and then by barge to the refineries	
	4	by rail to refineries in Puget Sound	
Inland U.S., mostly Bakken (mainly light shale crude)	5	by rail to refineries in Puget Sound	140,000 bbls per day or 25%, up from 2% in 2011
	6	by rail to marine transload terminals and then by barge to Puget Sound	
Overseas imports from Latin America, the Middle East, and other global sources (a mix of heavy, medium and light)	7	by tanker to the refineries	30,000 bbls per day or 5%, down from 19% in 2011

[14] Source: Ian Goodman & Brigid Rowan, Technical Appendix to Expert Testimony on the Need for the Vancouver Energy Distribution Terminal: Market Analysis, May 13, 2016

Washington refineries have historically relied primarily on crude oil from Alaska, but as illustrated in Figure 3-19, crude oil receipts from Alaska peaked in 2003 and 2004, and have steadily declined since then. Forecasts by the Alaska State Department of Revenue and the U.S. Energy Information Administration (EIA) both project continued declines in crude oil production in Alaska. This continued decline in Alaskan crude oil is causing refineries to seek new sources and routes.

Figure 3-19: Pacific Northwest Crude Oil Receipts by Source: Reference Case (Million Metric Tons)

Source: BST Associates, IHS Markit

Canada is one alternative source of crude oil for the refineries. Canadian crude is received via pipeline, vessel (barge and tanker), and rail. The Trans Mountain Pipeline (owned by Kinder Morgan) connects oil fields in Alberta to the Westridge Terminal in Burnaby, B.C. An extension of this pipeline reaches the Washington refineries at Cherry Point and March Point. The Canadian Government recently granted Kinder Morgan a permit to expand the capacity of the Trans Mountain Pipeline from 300,000 barrels per day to 890,000 barrels per day[15]. Construction is expected to be completed by the end of 2019. However, the capacity of the extension to Washington refineries (approximately 180,000 barrels per day) will not be increased under this plan.

Canadian crude oil can also be shipped by water from the Westridge Terminal to Washington refineries, although the amount available depends on the level of demand for this same crude oil in Asia.

Canadian crude oil is also shipped by rail to Puget Sound refineries. In 2014 and 2015, regional receipts of crude by rail ("CBR") from Canada were an estimated at 3.4 million barrels per year.[16]

Domestic oil from the Lower 48 states is another alternative source of crude oil for the refineries. Most of this crude oil is originates in North Dakota (PADD 2[17]) and Utah (PADD 4), and is shipped to Washington by rail. The first CBR shipments to Washington were received in 2011, when approximately 250 carloads were received. The volume jumped to more than 80,000 carloads in 2015, including some receipts from Canada.

[15] There are 157 conditions that need to be met to construct the pipeline expansion.

[16] CBR volumes are based on data from EIA and the California Energy Commission.

[17] The United States is divided into five Petroleum Administration for Defense Districts, or PADDs

Most of the CBR was shipped directly to refineries in Washington, but a portion was also shipped by rail to a terminal on the Columbia River near Clatskanie, Oregon and then barged to Puget Sound. Shipments through this Oregon terminal peaked in 2014 at 9,151 railcars, and then fell to 1,345 railcars in 2015. This decline was due to completion of rail unloading facilities at four of the five Puget Sound refineries (The Shell refinery near Anacortes is the only refinery without a rail unloading facility. Shell was planning such a facility, but decided not to complete the environmental impact study for the project.)

Use of CBR by Washington refineries depends on the price and availability of oil. Inland U.S. oil is typically pegged to the West Texas Intermediate crude oil price and foreign oil is pegged to the Brent oil index. From 2011 to 2015, as the crude oil production rose in the U.S. (especially North Dakota), the price for domestic oil dropped. The difference in price between North Dakota oil and international oil was as much as $13 to $25 per barrel, driving up demand from the Washington refineries. Since 2015, however, the price differential has dropped significantly.

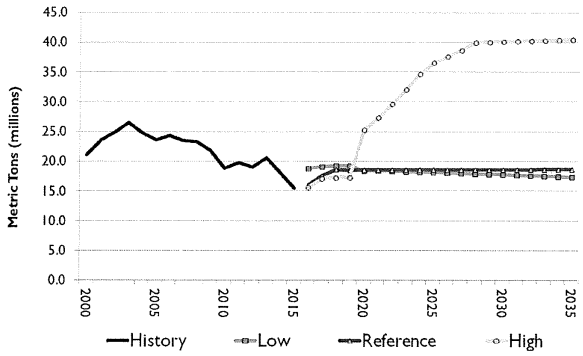
Availability of North Dakota oil will be impacted by pipeline construction. As new lines are completed that connect North Dakota oil fields to the existing pipeline system, more of the oil will be shipped by pipeline. For the most part these pipelines run to the Gulf Coast and East Coast; they do not connect to the West Coast. The shift to pipeline will not end CBR shipments to the Pacific Northwest, but the share of oil transported by rail to the refineries will decline.

The Washington refineries can also receive crude oil by tanker from foreign sources other than Canada. As noted above, these other foreign sources currently account for 5% of the supply, down from 19% in 2011.

Under the reference case, the modal split in 2035 is projected to be:

- Vessel from Alaska: 14%
- Pipeline from Canada: 30%
- Vessel from foreign sources (including Canada): 42%
- Rail: 13%

In addition to the rail unloading facilities at Washington refineries, a number of terminals have been proposed to transfer oil from rail to vessel.[18]. These include:



- Vancouver Energy Terminal (Port of Vancouver) – capacity of 360,000 barrels of crude oil per day, under review.
- Westway Terminal (Port of Grays Harbor) – 23,000 barrels of crude oil per day, under review.
- Global Partners (Port of St Helens at Port Westward) – capacity of 30,000 barrels of crude oil per day.
- Imperium Terminal (Port of Grays Harbor) – capacity of 14,000 barrels of crude oil per day.
- Arc Logistics (Portland) – capacity of 14,000 barrels of crude oil per day.
- NuStar Terminal (Port of Vancouver) – capacity of 41,000 barrels of crude oil per day.

[18] Included at the time of the forecasts.

These proposed rail-to-vessel terminals could supply domestic markets (notably California) as well as foreign markets, since export of U.S. crude oil was legalized in 2016. The high cast forecast includes these terminals, while the reference and low cases do not.

As shown in Figure 3-20, crude oil receipts are expected to remain relatively stable under the low and reference cases, with volumes averaging around 19 million metric tons per year through the end of the forecast period. The loss of Alaskan crude is fully offset by foreign sources arriving by water (barges and tankers). Under the high case scenario, crude oil used by refineries is projected to reach 21 million tons per year while crude oil moving through rail-to-vessel terminals is projected to reach the planned capacity of 25 million tons in 2025, and then to remain at that level through 2035.

Figure 3-20: Pacific Northwest Crude Oil Receipts and Shipments[19] (Million Metric Tons)

Source: BST Associates, IHS Markit

Refined Petroleum Products

Puget Sound refineries supply 90% approximately of the refined petroleum products consumed in Washington and Oregon; the remaining 10% moves by pipeline from other states, primarily Utah and Montana. As shown in Table 3-11, the Seattle and Portland areas generate most of the demand for refined products, and account for 46% and 25%, respectively[20]. Other communities account for the remaining demand.

[19] Includes domestic and foreign sources of crude oil.

[20] U.S. Department of Homeland Security National Protection and Programs Directorate Office of Cyber and Infrastructure Analysis Columbia River Basin Petroleum and Refined-Product Supplies: Disruptions and Mitigations under Cascadia Subduction Zone Earthquake, Scenario, July 2016

Table 3-11: Average Refined Product Demand in Washington and Oregon

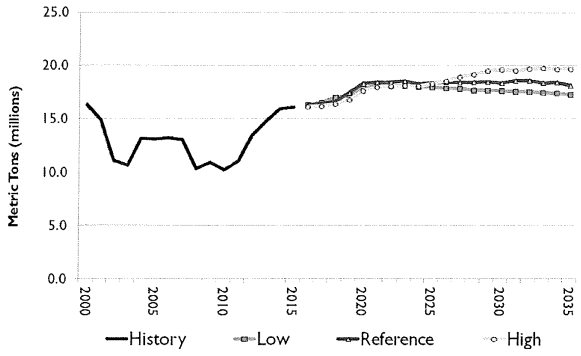
Demand Region	Barrels per Day (1,000's)	Percent of Market
Seattle	216.9	46%
Portland	117.88	25%
Eugene	47.15	10%
Moses Lake	9.43	2%
Kennewick-Richland	42.43	9%
Spokane	37.72	8%
Total	**471.51**	100%

Source: U.S. Department of Homeland Security

Washington and Oregon have a total of four pipelines that carry refined petroleum products. These include:

- Olympic Pipeline,
- Tesoro Pipeline,
- Yellowstone Pipeline, and
- Kinder Morgan Pipeline.

Of these, the Olympic Pipeline is the most important. This line runs from the refineries on Puget Sound as far south as Portland, and has distribution terminals located at Bayview (Mount Vernon), Seattle, Renton, Sea-Tac, Tacoma, Spanaway, Olympia, and Vancouver in Washington, as well as Linnton and Portland in Oregon. This line carries gasoline, diesel fuel and jet fuel, and has annual throughput capacity of approximately 4.6 billion gallons. This pipeline carries a relatively large share of the refined products shipped to the Portland area.



The Tesoro Pipeline runs from refineries near Salt Lake City to Pasco, with an extension from Pasco to Spokane. The Yellowstone Pipeline runs from Billings, Montana to Spokane and Moses Lake. The Kinder Morgan Pipeline runs from Portland to Eugene, and supplies virtually all of the gasoline used in the Willamette Valley.

Some of the petroleum products from the Puget Sound refineries are shipped by water to Alaska, California, and British Columbia, as well as to other domestic and foreign destinations. In 2000, 16.3 million metric tons of refined products was shipped or received by water. Volumes were higher in 2000 and 2001 while the Olympic Pipeline was out of service. After the pipeline was repaired the volume moving by water dropped to approximately 10 to 13 million metric tons for several years, but climbed back to 16 million metric tons again in 2015. The recent increase in volume was due to growth in shipments of refined products to British Columbia and other foreign destinations.

As shown in Figure 3-21, between 2015 and 2035, waterborne shipments and receipts of refined products are projected to grow to:

- Low case: 17.3 million metric tons (0.5% per year growth),
- Reference case: 18.1 million metric tons (0.8% per year growth),
- High case: 19.7 million metric tons (1.4% per year growth).

Figure 3-21: Pacific Northwest Refined Product Shipments & Receipts (Million Metric Tons)

Source: BST Associates, IHS Markit

Other Liquid Bulks

Other liquid bulks include animal fats, vegetable oils, chemicals, fertilizers, and methanol.

Animal fats and vegetable oils

Animal fats and vegetable oils are used as ingredients for animal feed, and as inputs to biodiesel production, among other uses. Shipments and receipts of animal fats and vegetable oils averaged less than 100,000 metric tons between 2000 and 2015, and ranged from a low of 19,600 metric tons in 2015 to a high of 123,000 metric tons in 2008. Projected growth of these products from 2015 through 2035 is:

- Low case: 22,000 metric tons (0.5% per year growth),
- Reference case: 38,000 metric tons (4.4% per year growth),
- High case: 53,000 metric tons (6.9% per year growth).

Chemicals and fertilizers

Chemicals and fertilizers include caustic soda and sodium hydroxide (used in the forest products industry), benzene and toluene (used in the chemical industry), and nitrogenous fertilizers (used in the agricultural industry), among others. Shipments and receipts of chemicals and fertilizers declined between 2000 and 2015, ranging from a low of 414,000 tons in 2012 and a high of 880,000 tons in 2002. Projected growth of these products from 2015 through 2035 is:

- Low case: 426,000 metric tons (-1.9% per year growth),
- Reference case: 850,000 metric tons (2.7% per year growth),
- High case: 1.3 million metric tons (5.5% per year growth).

Methanol

Methanol plants are proposed at the Port of Kalama and the Port of St. Helens. Methanol is a primary input to manufacturing plastics and other products, and demand is strong in Asia. Methanol is currently produced in China using crude oil and coal as feedstocks. The methanol manufactured at the Port of Kalama and Port of St. Helens would use natural gas as a feedstock, which is relatively clean when compared to oil and coal, and is relatively abundant in North America. Each of the

plants would produce approximately 10,000 metric tons of methanol per day (or approximately 3.4 million metric tons per year, per plant). It is assumed that the plants would begin construction in 2018 and production in 2021 (at 1.8 million metric tons) and then ramp up to full production by 2024.

The methanol plants should have minimal impacts on road and rail infrastructure. The primary input, natural gas, is transported via pipeline. The finished product will be piped a short distance from the plant to the dock.

Summary of Liquid Bulks

Table 3-12 summarizes historical trends and projected growth rates for the different liquid bulk commodities.

Table 3-12: Pacific Northwest Waterborne Liquid Bulk Traffic by Category (Million Metric Tons)

Regional Forecast

Regional splits for liquid bulk volumes are presented in Table 3-13.

The Lower Columbia Oregon region experienced a decline in liquid bulks between 2000 and 2015, with volumes dropping from 7.3 million metric tons in 2000 to 3.4 million metric tons in 2015. The volume in 2000 was much higher than in other years, due to the Olympic Pipeline being out of service and a shift from pipeline to vessel. This temporary shift ended after the pipeline was repaired and put back into services. Between 2015 and 2035, liquid bulk volumes in the Lower Columbia Oregon are projected to grow to:

- Low case: 3.0 million metric tons (-0.6% per year growth),

- Reference case: 3.9 million metric tons (0.8% per year growth),
- High case scenario (includes methanol at St Helens, and CBR at Portland and St Helens): reaching 8.0 million metric tons (4.4% per year growth).

Liquid bulk traffic in the Lower Columbia Washington region ranged between 250,000 metric tons and 650,000 metric tons from 2000 through 2015. Between 2015 and 2035, liquid bulk volumes in the Lower Columbia Washington are projected to grow to:

- Low case: 289,000 metric tons (-1.5% per year growth),
- Reference case: 570,000 metric tons (1.9% per year growth),
- High case (includes CBR at Vancouver and methanol at Kalama): 20.0 million metric tons (21.7% per year growth).

The PSRC region's liquid bulk traffic increased from 2.4 million metric tons in 2000 to 3.5 million metric tons in 2015, or at an average annual growth rate of 2.6%. Between 2015 and 2035, liquid bulk volume in the PSRC region is projected to grow to:

- Low case: 4.5 million metric tons (1.3% per year growth),
- Reference case: 4.6 million metric tons (1.5% per year growth),
- High case: 4.9 million metric tons (1.7% per year growth).

Liquid bulk volumes in the Other Puget Sound / Washington Coast region dropped from 28.2 million metric tons in 2000 to 24.9 million metric tons in 2015 due to falling crude oil receipts from Alaska. Between 2015 and 2035, liquid bulk volume in the Other Puget Sound / Washington Coast region is projected to increase to:

- Low case: 27.4 million metric tons (0.5% per year growth),
- Reference case: 28.6 million metric tons (0.7% per year growth),
- High case (includes CBR at Grays Harbor): 35.4 million metric tons (1.8% per year growth).

Chapter 4
Inland Navigation System

Introduction

The Columbia/Snake River System is one of the most important waterway systems in the United States. It begins at the mouth of the Columbia River and extends 465 miles to Lewiston, Idaho, at the confluence of the Snake and Clearwater Rivers. The deep draft portion of the navigation system is 43 feet deep and 600 wide, and runs 105 miles from the mouth of the Columbia River to Portland and Vancouver. Other ports along the deep draft channel include Longview, Kalama, and Woodland in Washington, and Astoria and St. Helens in Oregon.

The inland navigation system extends 360 miles along the Columbia River from Vancouver to Pasco, and along the Snake River from Pasco to Lewiston, Idaho, and along the last several miles of the Clearwater River in Lewiston. The system includes four locks and dams on the Columbia River and four locks and dams on the Snake River. The system is maintained to a minimum depth of 14 feet.

The deep draft and shallow draft channels are both critical portions of the river transportation system. A large volume of the grain and other products exported through the deep draft ports is shipped by barge to the export terminals, while fertilizer and other commodities are imported by ship and then barged upriver.

Key Findings

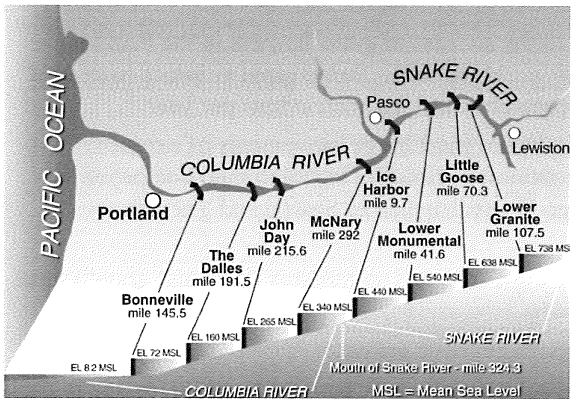
- The inland navigation system is critical to the success of grain farmers in the Pacific Northwest, allowing them to compete on world markets. Barge grain volumes have held steady in recent years, averaging approximately 4 million metric tons per year.
- Loss of container service at Portland eliminated most barge movements of export containers. The cargo carried in these containers primarily included pulp and paper, hay, and lentils. Most this containerized cargo is now trucked to Seattle and Tacoma for export.
- Volumes of forest products (wood chips, logs, etc.) and aggregates (sand and gravel) have been steady, and are projected grow slowly.
- Volumes of municipal solid waste (i.e. garbage) have grown.
- Volumes of petroleum products dropped substantially between 2000 and 2015, due in part to closure of the Port of Wilma oil storage terminal.
- Loss of the inland navigation due to dam breaching would negatively impact roads and rail lines in the region.

Description of the Columbia-Snake River Navigation System

The deep draft portion of the Columbia River was maintained at an authorized depth of 40 feet for decades, beginning in the 1970's. In the late 1980's, several Columbia River ports joined together to request the Congress to direct the Corps of Engineers to study navigation in the river. The initial study began in 1989, and the record of decision authorizing a deepening of the channel to 43 feet was finally signed in 2004. Deepening began in 2006, and was completed in 2010.

Since the deepening was completed, public and private entities have invested more than $1 billion in improvements to marine terminals and other infrastructure in order to maximize the utilization of the improved system.[21]. These improvements have included:

- Construction of the first new grain terminal built in the U.S. in 25 years,
- Expansion of the largest export grain terminal on the West Coast of the U.S.,
- Construction of the first new grain barge on the Columbia River since 2011, and
- Purchase of the largest drydock in the U.S.



Several improvements are being considered for the system, including:

- Methanol plants at the Port of Kalama and the Port of St Helens,
- A crude oil terminal at the Port of Vancouver, and
- A coal terminal in Longview, among others.

There are eight dams and navigational locks in the Columbia and Snake River that facilitate barge traffic movements. The Columbia River locks are located at the Bonneville, The Dalles, John Day and McNary Dams. The Snake River locks are located at Ice Harbor, Lower Monumental, Little Goose and Lower Granite Dams.

Most Washington inland ports are located in the McNary, Lower Granite, and Little Goose pools. Port facilities in Pasco and Walla Walla are located in the McNary pool, port facilities at Clarkston and Wilma are in the Lower Granite pool, and the port facilities at Almota and Central Ferry are located in the Little Goose pool.

Figure 4-1: Map of Columbia-Snake River Navigation System

Source: Pacific Northwest Waterways Association

All upriver locks have upper and lower miter sills (i.e., the chamber wall under water at each end of the lock channel) of 15 feet. The existence of these locks and authorized maintenance of the river pools at a 14-foot depth allows for low cost transportation of local and regionally produced commodities.

The river system has typically been managed to approximately 4 to 5 feet above minimum pool depending on the pool, in order to maintain a minimum 14-foot depth within the channel. However,

[21] Source: Impacts of Channel Deepening on the Columbia River, by ECONorthwest for the Pacific Northwest Waterways Association, June 2015.

the consideration of dam breaching or flow augmentation alternatives to enhance salmon revitalization efforts places these operating systems in jeopardy, because the locks would become "stranded" above lower than minimum required levels.

The barge system has evolved to take maximum advantage of the authorized minimum pool characteristics. "Jumbo" grain barges capable of carrying 3,600 tons of grain have become the mainstay of the wheat export fleet and are the largest vessels on the river system, drawing 13.5 feet. Container and other barges typically have a draft of 10 to 11 feet. Larger tugs typically push four barges and have a draft of 11 to 12 feet.

Access to the inland navigation system is a critical component of the success of the deep draft navigation system, and offers a low cost alternative to rail transportation. In addition to the transportation benefits, the dam system also provides irrigation, power generation, flood control, and recreational facilities.

Cargo Trends

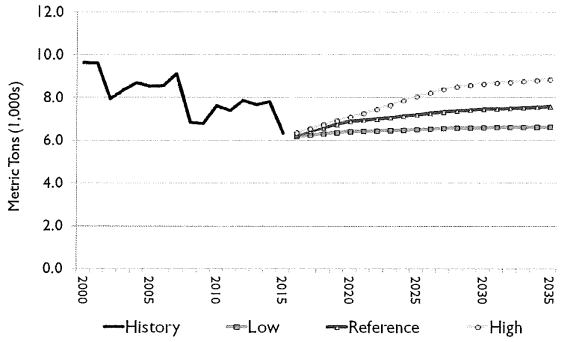
Columbia River Inland Navigation Cargo Trends

Grain moving downstream continues to be the lifeblood of the barging system on the Columbia/Snake River System, accounting for 56%[22] of all commodity tonnage moving on the Columbia River section of the system (as measured at the Bonneville Lock and Dam). Approximately 90% of the wheat grown in Washington and Oregon is exported, and approximately 40% of all wheat shipped from Lower Columbia export terminals arrives by barge. The inland navigation system is a critical asset that allows regional grain shippers to compete in world markets.

Upbound movements of petroleum products are also key, accounting for an average of 20% of cargo movements at Bonneville. Other commodities, such as crude materials (logs and wood chips, among other products), and other products (chemicals and fertilizer, manufactured products and garbage) make up the remainder.

As shown in Figure 4-1 and Table 4-1, overall traffic growth on the Columbia River section of the Columbia/Snake River inland navigation system is projected to grow under all three scenarios. Between 2015 and 2035 the volume is projected to grow to:

- Low case: 6.63 million metric tons (0.2% per year growth),
- Reference case: 7.59 million metric tons (0.9% per year growth),
- High case: 8.84 million metric tons (1.7% per year growth).



While the projected rates of growth are relatively low, they represent steady demand for barge transportation. Millions of tons of cargo is moved by barge, and includes some of the main commodities produced in the inland Northwest.

It should also be noted 2015 tonnage was relatively low (i.e. 3.4 million metric tons), due to low harvest volumes in 2015. Initial reports for 2016 indicate that grain volumes were closer to the recent average of 4.4 million metric tons.

Loss of the barge system would force existing cargo traffic onto the rail and road system. The impact on the road system would likely be substantial as traffic shifted from existing routes to new ones, especially if these new routes were not built for heavy truck traffic. The additional shipping could also cost local farmers a portion of their potential sales.

[22] Average value calculated for the period 2000 to 2015.

Figure 4-2: Columbia River Waterborne Traffic above Bonneville Lock (Million Metric Tons)

Cargo Forecast by Commodity Group

Forecasts for major commodity groups are described in the following section. These forecasts are summarized in Table 4-1.

Food and farm products

The food and farm product category consists almost entirely of grain. Between 2000 and 2015, the volume of grain moving by barge on the river declined as new, high-capacity rail loading facilities came online in Montana and Washington. However, the volume of grain shipped by barge has stabilized in recent years at an average of approximately 4 million metric tons per year.

Wheat is the primary grain crop transported by barge. Harvested volumes can vary widely from year to year, but the long-term trend in the region (i.e. Washington, Oregon, and Idaho) is one of slow growth in wheat production. At the same time that production has increased, the acreage dedicated to wheat production has slowly declined, which shows that yield per acre has trended upward.

The reference case projects that barged volumes of grain will remain at approximately this level over the long run. Under the low case scenario, volumes in 2035 are projected to be 3.8 million metric tons, and under the high growth scenario 2035 volumes are projected to be 5.2 million metric tons.

Other food products (frozen potatoes, onions, peas and lentils) and farm products (hay and animal feeds) generally move in containers on barge, but the decline and subsequent loss of container service in Portland essentially eliminated this type of move. These products are now transported by truck, rail or truck-rail combination directly to the Northwest Seaport Alliance container terminals. As production of peas and lentils increases the volumes may reach the level where shipment via bulk ship (rather than containers) is feasible, which in turn could lead to additional traffic for the barge system. However, this opportunity was not included in this forecast.

Crude materials

Crude materials are primarily composed of wood chips, logs, other forest products and sand and gravel. Between 2000 and 2015, the annual volumes in this category ranged from 1.2 million

metric tons to 1.5 million metric tons. The exception was 2009, when volumes dropped to 700,000 metric tons during the great recession.

By 2035, the volume of crude materials is projected to grow to between 1.4 million metric tons (low case) and 1.6 million metric tons (high case).

Petroleum products

Petroleum products shipped upriver to Pasco and Wilma represents the second largest cargo group transiting Bonneville Locks. These products include gasoline, residual fuel oil, and distillate fuels. Between 2005 and 2015 the volume of petroleum products declined significantly, due partially due to the closure in 2012 of a petroleum terminal at the Port of Wilma.

According to the U.S. Department of Homeland Security,[23] the Kennewick-Richland area has daily demand for approximately 42,430 barrels of refined petroleum products, representing 9% of the Washington and Oregon market. Many of the communities in this area are located along the inland navigation channel and have barge terminals capable of handling petroleum products. Petroleum products are shipped to the area by barge from terminals in Vancouver and Portland, as well as via pipeline (from Salt Lake City), truck, and rail.

Consumption of petroleum products is projected to decline on a per capita basis during the forecast period, resulting in a further decline in barged petroleum products. Volumes in 2035 are projected to range from 994,000 metric tons under the low case to 1.1 million metric tons under the high case, as compared to 1.2 million metric tons in 2015.

The market for petroleum products is extremely competitive, however, and the share shipped by barge could increase relative to that moved by pipeline. In addition, the U.S. Department of Homeland Security evaluated options to provide petroleum products in the event of a catastrophic earthquake affecting oil-related terminals in the Lower Columbia and Puget Sound. One of the options for responding to such an event would be to barge petroleum products down river from Pasco"[24] While neither of these potential changes was included in the forecast, they demonstrate how the barge system increases the robustness of the regional transportation system.

Other Cargoes

Other cargoes declined from 693,000 metric tons in 2000 to 475,000 metric tons in 2015. The mix of commodities in this catchall category has changed over the past fifteen years:

- Chemicals and fertilizers declined from 151,000 metric tons in 2000 to 57,000 metric tons in 2007, but grew back to 137,000 metric tons in 2015.
- Primary manufactured products (mainly pulp and paper products from upriver mills) were barged in containers to Portland, until Portland lost its container business. The volume of primary manufactured products moving by barge fell from 305,000 metric tons in 2000 to none in 2015.
- Equipment and machinery increased from 22,000 metric tons in 2000 to 51,000 in 2015. This includes products manufactured upriver (such as cranes manufactured by Lampson in Pasco) as well as products moving upriver for construction projects (such as power generation equipment and oil equipment, others).

[23] U.S. Department of Homeland Security, July 2016

[24] Ibid, page 21.

- Waste materials barged upriver to landfills increased from 213,000 metric tons in 2000 to 288,000 metric tons in 2015.

The loss of some manufactured products was partially offset by gains in others. Under the low case scenario, other cargoes are projected to decline to 422,000 metric tons by 2035. Under the reference case the volume is projected to grow to 672,000 metric tons, and under the high it is projected to grow to 866,000 metric tons.

As shown in Table 4-1, inland navigation traffic on the Columbia River dropped between 2000 and 2015, but is projected to grow, albeit slowly, from 2015 through 2035. There are several reasons for this:

- As discussed above, 2015 saw a relatively low grain harvest, which impacted the historical growth rate for food and farm products. As noted, however, it appears that grain volumes recovered in 2016, indicating that the volume of grain is not declining.
- The volume of crude materials dropped between 2000 and 2010, but grew slowly between 2010 and 2015. This slow growth is projected to continue.
- The volume of "Other" commodities also dropped between 2000 and 2010, but grew between 2010 and 2015. As with crude materials, this slow growth is projected to continue.
- The one major barge commodity projected to continue declining between 2015 and 2035 is petroleum products.

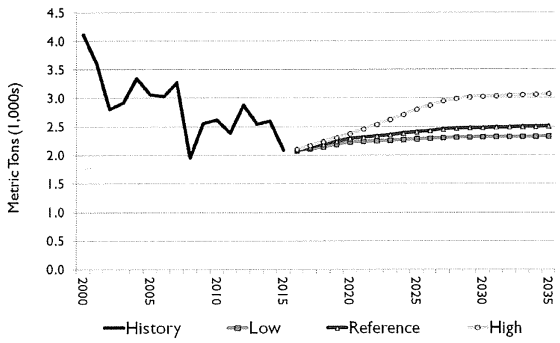
Snake River Cargo Trends

Grain accounts for 72%[25] of all commodity tonnage moving on the Snake River, as measured at the Ice Harbor Lock and Dam. Crude materials (logs and wood chips, among other products), and other products (chemicals and fertilizer, manufactured products and garbage) make up the remainder. Upbound movements of petroleum products ended in 2012.



The volume of cargo moving through the Ice Harbor Locks accounts for approximately 34%[26] of the volume moving through Bonneville Locks. The same factors impacting Columbia River barge volumes also impact Snake River barge volumes, including a shift of some grain from barge to rail, and the loss of container service at Portland.

As discussed above, volumes in 2015 were lower than average, due in large part to a below-average grain harvest. As shown in Figure 4-3 and Table 4-2, barge traffic on the Snake River is projected grow from approximately 1.2 million metric tons in 2015 to:

- Low case: 2.3 million metric tons (0.6% per year growth),
- Reference case: 2.5 million metric tons (0.9% per year growth),
- High case: 3.1 million metric tons (2.0% per year growth).

As is the case for barge traffic on the Columbia River, while the projected rates of growth on the Snake River are relatively low, they represent steady demand for barge transportation. Under the reference case, traffic levels return to the average post-recession level (i.e. 2009 through 2015), and under the high case they grow beyond this level. Under the low case the volume does not return to the post-recession level.

Figure 4-3: Snake River Waterborne traffic above Ice Harbor Lock (Million Metric Tons)

Cargo Forecast by Commodity Group

Food and farm products

The grain volume of 1.8 million metric tons in 2015 was lower than in prior years; volumes averaged approximately 2.3 million metric tons from 2010 through 2015. In 2035, the volume

[25] Average value calculated for the period 2000 to 2015.

[26] Average value calculated for the period 2010 to 2015

LUBA No. 2020-009
Page 5583

under the reference case is projected to remain at approximately 2.3 million metric tons. Volumes are projected to decline to 2.0 million metric tons under the low case, and to grow to 2.7 million metric tons under the high case.

Other food products and farm products (peas, lentils, hay and animal feeds) declined due to the loss of container service in Portland, since these commodities are shipped in containers. These commodities are not likely to return to barge in large volumes unless container service at Portland resumes.

Crude materials

The crude materials category includes wood chips, logs, other forest products, and sand and gravel. From 2000 through 2015, the volume of crude materials moving through the Ice Harbor Locks ranged between 130,000 metric tons and 370,000 metric. In 2015 they totaled 220,000 metric tons.

By 2035, the volume of crude materials is projected to grow to 239,000 metric tons under the low case and 294,000 metric tons under the high case.

Petroleum products

The petroleum distribution facility at the Port of Wilma historically handled most Snake River barge movements of petroleum products (e.g. gasoline, residual fuel oil, and distillate fuels), but that facility closed in 2012. The forecast assumes that shipments of petroleum products do not re-start.

Other Cargoes

The "Other Cargoes" category includes a mix of commodities, such as chemicals, fertilizers, primary manufactured products, equipment, and machinery. Because a large share of this cargo is containerized, loss of container service caused the volume of "Other Cargoes" to drop from 223,000 metric tons in 2000 to 18,000 metric tons in 2015. Changes to specific commodities included:

- Chemicals and fertilizers dropped from 37,000 metric tons in 2000 to 4,700 metric tons in 2008, but increased to 11,000 metric tons in 2015.
- Primary manufactured products (mostly pulp and paper products from upriver mills) disappeared completely in 2015.
- Equipment and machinery increased from 6,300 metric tons in 2000 to 7,200 in 2015. This category includes products manufactured upriver as well as project cargo shipped upriver for construction projects (e.g. power generation equipment and oil field equipment).

Barge volumes in this category account for a limited share of cargo moved on the Snake River, and are not projected to increase substantially by 2035. Under the low case, the volume is projected to decline further, while under the reference and high case scenarios, volumes are projected to grow slowly. Even under the high scenario (i.e. 3.5% average annual growth), the volume barged in 2035 is projected to be less than 17% of the volume moved in 2000.

As shown in Table 4-2, barge traffic on the Snake River dropped between 2000 and 2015, but is projected to grow, albeit slowly, from 2015 through 2035. The main reasons for this are:

- Grain now accounts for nearly 90% of barge tonnage on the Snake River, and grain volumes are projected to grow.
- The 2015 grain harvest was below average, which led to lower grain volumes in 2015.

- Most other commodities in the Food and Farm Products category are containerized, and barge container movements have essentially disappeared.

Table 4-2: Snake River Waterborne Traffic by Category (1,000 Metric Tons)

River Barging As an Integrated System

The Columbia/Snake River inland navigation system is part of a larger integrated and interdependent system. This larger system includes farmers and manufacturers, barge carriers, ocean shipping lines, deep-draft marine terminals, railroads, and trucks. Each of these plays an important role in the functioning of the entire system.

Wheat and barley farmers in the Pacific Northwest have a number of upriver terminals in Idaho, Oregon or Washington through which they can ship their grain. The routing choice depends on the needs of the buyer, the location of the farm field, membership in a famer's co-op, relative inland freight costs, and various other competitive factors.

Some grain is also trucked to these upriver terminals from as far away Montana, the Dakotas and even as far away as Minnesota. Typically, these long-distance moves are a backhaul cargo, with the front haul comprising shipment of forest products and vegetables from Walla Walla, the Tri-Cities or Lewiston to the Midwest.

One example of how the system is interdependent is the impact that loss of container service at Portland had on the barge carriers. Barges were used to move containers down river to Portland, where they were loaded onto container ships for export. Without container service at Portland, these containers are now trucked to Seattle and Tacoma, rather than moving by barge.

Cargo movements by barge on the Columbia and Snake rivers must be analyzed within the context of a total "transportation system" that involves three important elements.

- Combined domestic and import/export barge movements. A typical barge tow includes one towboat pushing four barges, each of which may carry different commodities. Some

of these commodities move in international trade (imports and exports), and some move in domestic trade (shipments that are purely of an intrastate or interstate nature).

- Combined barge activity from Oregon, Washington and Idaho. There are no commodity groups that involve movements of either import/export cargo or domestic cargo solely between upriver Washington ports and deepwater Washington ports on the Lower Columbia River. Rather, every cargo category is characterized by products that:
  - are produced in more than one state,
  - are shipped through upriver ports in more than one state, and
  - move through deepwater ports in both Oregon and Washington.

  For example, wheat is grown in Idaho, Washington and Oregon, is loaded onto barge at upriver terminal in all three states, and is exported through deepwater terminals in both Washington and Oregon.
- Barge terminals in one state serve customers in many states. For example, cargo moving through terminals in Wilma and Clarkston (in Washington) may originate in Washington, Idaho, or other states.

On a single round trip, a towboat may transport barges carrying a variety of cargoes to and from upriver ports in Washington, Oregon and Idaho. With this type of integrated operation, both the frequency of service and the rates charged depend on the combined total of all products moving, whether in international or domestic trade. While grain is the most important commodity moved, no individual commodity by itself determines either the frequency of barge service or the rates charged.

Impacts of Dam Breaching

Proposals to breach the dams on the lower Snake River could have a serious and negative impact on barge transportation on the Columbia River. While the goal of dam breaching is to enhance the survival of various endangered fish species, the impact on the fish is uncertain. What is certain is that dam breaching would negatively impact shippers, with higher transportation costs and lower levels of service.

Transportation System Impacts

The current Snake River barge system is very efficient for moving cargo. The barge system provides shippers with an alternative to shipping by rail, imposes price competition on the railroads, and supplies sufficient capacity to absorb substantial fluctuations in grain shipments, especially during peak export months and years.

The major components of the existing barge transportation system include:

- Barge terminals and river elevators,
- Access roads to the barge terminals and river elevators,
- Navigation channel,
- Barge fleet, and
- Export elevators.

If the Snake River dams were breached, much of the grain (and other commodities) that is now barged on the Snake River could be expected to shift to barge terminals in the McNary pool

(between Pasco and Umatilla). Elimination of barge transportation on the lower Snake River would cause grain to be moved farther by truck, and would result in a less efficient system.

All parts of the regional transportation system would be impacted by dam breaching. The mainline rail system, shortline rail system, and state and county roads would all see an increase in volumes. Without additional investment in the road and rail system this could lead to capacity constraints.

The shortline railroads in the region do not necessarily have the capacity to handle greatly increased volumes. These shortlines typically generate enough revenue to only cover operating costs, and not enough to pay for capacity improvements. In order to transport substantially more grain, they may require grants or other public assistance to help pay for capacity expansion. Without expanded rail capacity, Washington farmers might face higher shipping costs, making Washington grain less competitive on world markets.

Grain elevators served by rail may also require substantial capital improvements if they are to handle the grain that now moves by barge. One of the main issues at rail-served elevators is the capacity of their rail tracks. When many of these elevators were built it was common to include enough track to handle three cars. However, in order to get the best rates from railroads, elevators must now be able to accommodate a minimum of 25 or 26 cars. As with improvements to the shortline system, grant funding or other financial assistance may be needed to pay for these upgrades. In addition, many of the existing rail-served elevators have seen little use in years, and the condition of their equipment is unknown.

The highway system will also face increased costs, due to shifting transportation patterns. Roads that were not designed and constructed to handle large volumes of truck traffic can be expected to face increased maintenance and reconstruction costs. It is unlikely that state and local governments would be able to quickly respond if the dams were breached.

Rate Impacts

Competition between barge and rail prevents either from charging monopoly rates for their service. Breaching the Snake River dams, however, would decrease competition and would likely lead to higher rates.

According to the National Corn Growers Association, "it has been demonstrated numerous times that areas throughout the country that do not have access to barge transportation have higher rail rates." The Tennessee Valley Authority examined the effect of barge transportation on rail rates on the upper Mississippi River, and concluded that "the continued availability of water transport appears to have a significant impact on the pricing behavior of other surface transportation modes - at least when these modes are reasonably close to the river. In particular, there is a large body of economic literature, which suggests that available barge transportation effectively constrains railroad pricing for the transportation of commodities that are appropriately moved by barge. These barge-constrained rail prices have come to be called 'water-compelled' rates."

Since Washington farmers sell into world markets, they have little ability to raise their selling price to recover additional transportation costs.

Page 5587

Chapter 5
Modal Shares and Corridors

Introduction

Waterborne shipments and receipts in Washington are dependent on a comprehensive array of land-side transportation modes. These land-side modes, including truck, rail, and pipeline, as well as barge transportation, move cargo to and from marine terminals.

This chapter describes the modes of transportation used to move each commodity group to and from marine terminals. While this chapter looks at each mode separately, all of the modes function as parts of an integrated system. Air cargo is not included in this analysis, because the volume of marine cargo that is also moved by air is very small.

The land transportation network continues to serve as the lifeline that links industrial plants, farms and forests with cities and ports, and connects products with both local and distant markets. A large percentage of the Washington State economy is inextricably linked, either directly or indirectly, to offshore domestic commerce and international trade. As a result, the efficient performance of the highway, rail and waterways systems are of critical importance for moving freight to and from the ports.

Key Findings

- Waterborne cargo depends on a well-functioning inland transportation system.
- All inland modes are important, including road, rail, pipeline, and inland navigation.
- The inland mode of transportation varies by commodity group.
- Rail baseline volumes are projected to grow steadily, but have the possibility to increase substantially (due mainly to the ultimate fate of proposed coal and crude oil terminals).

Table 5-1: Summary of Transportation Modes

	Waterborne Shipments				Waterborne Receipts			
Commodity	Truck	Rail	Pipeline	Barge	Truck	Rail	Pipeline	Barge
Containers	✓	✓			✓	✓		
Autos		✓			✓	✓		
Logs	✓			✓				
Crude oil		✓				✓	✓	
Other liquid bulk			✓	✓	✓			
Breakbulk	✓	✓			✓	✓		
Grain		✓		✓				
Other dry bulk	✓	✓		✓	✓	✓		✓

Existing Cargo Throughput

As shown in Table 5-2, foreign waterborne traffic (i.e. imports and exports) increased by nearly 50% between 2000 and 2014, (the last year available), growing from 61.6 million metric tons to 90.3 million metric tons. Most of the growth was due to increasing exports, which grew by 24.9 million metric tons; imports grew by 3.8 million metric tons during the same period.

Domestic coastwise traffic dropped by approximately one-third between 2000 and 2014, falling from 41.3 million metric tons to 26.6 million metric tons. (Coastwise traffic includes waterborne movements that enter or leave the internal waters of Puget Sound, as well as movements into and out of the Columbia River system. It mainly includes traffic moving to and from Hawaii, Alaska, and California, but also includes some intra-Northwest moves.) Most of the drop in coastwise traffic was due to declining receipts of crude oil from Alaska. Coastwise receipts fell from 28.9 million metric tons to 16.2 million metric tons, while coastwise shipments dropped from 12.4 million to 10.4 million metric tons

Internal waterborne traffic includes movements of cargo entirely within the internal waters of Puget Sound or the Columbia River system. Only internal shipments (and not receipts) are presented in Table 5-2, in order to avoid double-counting. Internal shipments fell from 20.6 million to 13.3 million metric tons between 2000 and 2014. Declining log and woodchip movements account for a portion of the drop, but the biggest drop was in movements of liquid bulks. It should be noted that both internal and coastwise shipments of liquid bulks were unusually high in 2000 and 2001, due to a temporary shift of petroleum products out of the damaged Olympic Pipeline and onto vessels.

Table 5-2: Waterborne Commerce in Washington (including Lower Columbia Oregon) (Million Metric Tons)

	Foreign			Domestic Coastwise			Internal
Case	Shipping	Receiving	Total	Shipping	Receiving	Total	Shipments
2000	39.3	22.3	61.6	12.4	28.9	41.3	20.6
2001	39.3	19.3	58.6	11.2	29.7	41.0	16.5
2002	37.2	21.9	59.0	8.8	28.0	36.8	15.0
2003	40.7	23.5	64.2	9.3	27.0	36.3	15.0
2004	49.0	26.4	75.4	10.5	26.9	37.3	16.2
2005	49.2	31.1	80.4	10.0	26.4	36.3	15.9
2006	48.7	33.3	82.0	10.4	24.3	34.7	14.7
2007	54.2	31.5	85.7	10.1	24.5	34.6	15.6

2010	60.0	24.3	84.3	8.0	19.1	27.0	11.1
2011	62.0	26.2	88.2	7.6	18.4	26.0	11.8
2012	60.3	27.0	87.3	8.7	17.3	26.0	12.7
2013	56.2	25.7	81.9	9.4	17.8	27.1	13.5
2014	64.2	26.1	90.3	10.4	16.2	26.6	13.3
CAGR 2000-2014	3.6%	1.1%	2.8%	-1.3%	-4.0%	-3.1%	-3.1%

Source: BST Associates, using data from the U.S. Army Corps of Engineers

Domestic traffic primarily includes coastwise trade with Alaska, Hawaii and Southern California, but also includes internal traffic (such as grain barged down the Snake and Columbia Rivers), and local traffic[27] (i.e., traffic within a single harbor).

[27] Please note that local traffic is not included in the remaining sections of this report.

Modal Distribution of Freight

Imports through Washington ports move to their final destination and exports arrive at marine terminals through several modes of transport including rail, truck, barge/raft or direct movement into a plant (or distribution facility) for consumption.

- Rail transport is the preferred mode for large volumes of cargo moving at least 500 miles, such as containers imported from China and destined for Chicago. Rail is also efficient for moving large volumes of heavier cargo on shorter routes, such as petroleum coke movements from Ferndale to Longview, or alumina shipments from Longview to Wenatchee.
- Truck transport is more likely for cargoes moving within the state or region.
- Barge transport is used on the inland navigation system on the Columbia and Snake Rivers, and accounts for a substantial portion of the grain exported via ports on the Lower Columbia River. Barge transport also connects Puget Sound ports with shippers on the Olympic Peninsula and in British Columbia; logs are frequently barged or rafted from one port to another for export or for use in local mills.
- Commodities may be transferred directly from vessel into a plant. For example, imports of limestone, gypsum, salt and other like products often move directly into a manufacturing plant for processing into cement, sheetrock, chemicals or other products.

The following analysis of modal distribution focuses on the first movement of a commodity after offloading from a vessel (for inbound cargo), or on the last mode of transport prior to loading on a vessel (for outbound cargo). For commodities offloaded directly into waterfront plants for manufacturing, it is not feasible to track the final destinations of the manufactured products. For example, imports of gypsum can be traced to a manufacturing plant, but the final destination of the wallboard made from the gypsum cannot be tracked using available databases. This is also true for commodities that are moved through a central distribution facility and later are transported to market.

Modal Split by Handling Group

Containers

Containers have different modal splits, depending on whether they are imports, exports, or domestic moves. In 2015, an estimated 75% of containerized imports moved by rail, either in ocean containers or transloaded into domestic containers. Ocean containers on rail accounted for 49% of imports, transloaded containers accounted for 27%, and local distribution by truck accounted for 24%. Under the reference case and the low case the truck share is projected to grow to 34% by 2035, while under the high case it is projected to grow to 29%. Under all three cases the share of ocean containers loaded directly to rail continues to decrease, while the share of transloaded containers grows.

It is critical to note that only a portion of the import containers shipped by rail are loaded directly onto rail at marine terminals. For the remainder, trucks are used to dray the containers from port terminals to railroad intermodal yards or transload facilities. In Seattle, especially, this means that port container traffic must use city streets to reach container yards.

Export containers are more likely to move by truck than by rail; in 2015 approximately 25% of export containers arrived by rail and 75% by truck. These shares are not projected to change substantially between 2015 and 2035.

Domestic waterborne containers move to and from the port terminals almost entirely by truck.

Combining imports, exports, and domestic moves, approximately 40% of containers move by rail and 60% by truck.

Automobiles

Approximately 20% of the automobiles imported through the Pacific Northwest remain in the region and are distributed by truck. The remaining 80% is shipped inland by rail.

Export automobiles are essentially 100% moved by rail.

Crude Oil

All waterborne inbound crude oil (foreign imports and coastwise receipts) moves directly into refineries for processing. Most of the refineries are also able to receive crude oil by pipeline from Canada, and in the past five years they have also begun to receive oil by rail. Over the next 20 years, waterborne receipts will likely continue to account for most of the crude oil processed by the refineries, although as production in Alaska declines it will be replaced by foreign oil.

Alaska's share of refinery inputs dropped from 90% in 2003 to 45% in 2015, and is projected to decline to just 14% in 2035. The share of refinery inputs received by water from other foreign sources dropped from 19% in 2011 to 5% in 2015, due mainly to advent of crude receipts by rail. However, as new pipelines absorb much of the domestic crude oil that currently moves by rail, foreign waterborne receipts will grow in importance for Washington refineries; by 2035 they are expected to account for 42% of refinery inputs. Receipts by rail are projected to account for 12% to 13% of refinery inputs in 2035. The pipeline from Canada currently accounts for the remaining 30% of refinery inputs, and this is projected to continue through 2035.

Shipments of crude oil by water from Pacific Northwest ports occurred in very limited quantities prior to the Bakken oil boom and the crude by rail revolution. Over the past few years, however, a number of terminals in the Pacific Northwest have been constructed or re-purposed to ship crude oil outbound. These terminals have been used to move U.S.-produced oil to U.S. refineries in California and Washington, but in the future they may be used to export crude oil to foreign destinations.

All of the oil now shipped outbound by water from the Pacific Northwest arrives at the marine terminals by rail, and this will likely still be the case in the future. With a number of new oil shipping terminals now in the permitting phase, the biggest unknown factor is how much more oil will arrive by rail for shipment by water. The largest of these proposed terminals is the Vancouver Energy project in Vancouver, Washington; smaller terminals have been proposed for Grays Harbor and elsewhere. Under the high growth forecast scenario these new terminals could increase rail receipts from 7.4 million metric tons in 2014 to 30.1 million metric tons in 2030.

The uncertainty over these crude oil shipping terminals is one of the two main areas of uncertainty in the 2017 Marine Cargo Forecast (the other is coal).

Other Liquid Bulks

Most of the petroleum products manufactured at Washington refineries moves by pipeline (approximately 47%) or water (approximately 42%). Of the remainder, approximately 10% moves by truck and the remainder by rail. These modal shares are projected to remain relatively stable through 2035.

Most liquid fertilizer is imported, and approximately 13% of this is shipped to inland river or coastal destinations by barge. The remainder moves by truck or rail.

Other liquid bulk products move by truck or rail, or directly into plants.

Logs

Logs are primarily moved by truck, with a small share transported by barge or raft. Trucks account for an estimated 95% of logs, and barge/raft the remaining 5%.

Breakbulk

Breakbulk cargo is moved by truck and rail. Trucks account for an estimated 70% of breakbulk cargo and rail 30%.

Grain

Grain exports move to shipping terminals by rail or by barge. In total, approximately 89% of grain exports moved by rail in 2015, and 11% moved by barge.

All of the grain exported through the PSRC region and the Other Puget Sound/Washington Coast region is moved by rail, while grain exported through the Columbia River moves by rail or barge.

Wheat is the most dependent on barge transportation, and the barge system on the Columbia/Snake River System is critical to the wheat farmers in the Pacific Northwest. Essentially all wheat exports move through terminals on the Lower Columbia River, and none through Puget Sound or coastal ports. As discussed in Chapter 3, barge grain volumes (primarily wheat) on the have averaged approximately 4 million tons (average over the period 2005 to 2015), and are projected to range from 3.8 million to 5.2 million metric tons in 2035.

In 2035, 100% of the grain moving through the PSRC region and the Other Puget Sound/Washington Coast region will continue to move by rail. On the Lower Columbia River, rail currently accounts for 85% of exports and barge 15%; these shares are projected to remain relatively constant through 2035. Because export terminals on the Oregon side of the river mainly handled wheat, the barge share of total exports is higher than on the Washington side of the river. Oregon exports are approximately 61% rail and 39% barge currently, and over time the rail share is projected to grow to approximately 65%. On the Washington Columbia River the inland split is currently 89% rail and 11% barge, which is projected to remain relatively constant.

Dry Bulk Imports

Dry bulk imports are moved inland by rail, barge, and truck, but most moves directly into manufacturing plants. For example:

- Gypsum moves directly into wallboard plants
- Limestone moves directly into cement manufacturing plants

Aluminum ore moves directly into the aluminum smelter in Ferndale (in the Other Puget Sound / Washington Coast region), and by rail to the Wenatchee smelter. However, the Wenatchee smelter may be permanently closing, in which case 100% of aluminum ore would move directly in the plant in Ferndale.

Portland cement moves directly into concrete batch plants, and is also moved to inland batch plants by truck and by rail.

Aggregates and sands also move directly into concrete batch plants, or are shipped to inland destinations by truck or rail.

Scrap steel and steel slag moves directly into steel mills, or is trucked to mills.

Dry bulk fertilizer is transported inland by barge, rail and truck.

Dry Bulk Exports

Dry bulk commodities exported through Pacific Northwest ports move almost entirely by rail. The two largest commodities, in terms of tonnage, are potash and soda ash. Potash is shipped by rail from Saskatchewan to ports on the Columbia River, and soda ash is shipped by rail from Wyoming, also to the Columbia River. Together, these two commodities account for two-thirds of dry bulk exports.

Petroleum coke accounts for approximately 14% dry bulk exports, and moves by rail and by truck. This product is manufactured at oil refineries on northern Puget Sound, and then moved to Anacortes by truck or to Longview by rail. Approximately 70% is moved by rail and 30% by truck.

Scrap also accounted for 14% of dry bulk exports in 2015; it moves by truck, rail and barge.

Other commodities that move in relatively small volumes include bentonite clay (rail) and wood chips (barge).

Overall, rail accounts for approximately 90% of dry bulk exports, while barge and truck each account for 5% or less.

The major question hanging over future dry bulk modal splits is what happens with coal exports. Coal is not currently exported through terminals in Washington or Oregon. Coal is included in the high forecast, however, and this forecast assumes that the Millennium Bulk Terminal in Longview is constructed and operates at full capacity (44 million metric tons per year). All of the coal would move by rail. To provide a sense of the scale of the potential coal exports, total dry bulk exports are currently approximately 7.5 million metric tons per year, while current grain exports are 32 million metric tons.

Chapter 6
Rail System Capacity

Introduction and Background

MainLine Management Inc. (MLM) was retained by BST Associates (BST) to assist in the preparation of the 2017 Marine Cargo Forecast Update and Rail Capacity Study. MLM and BST have previously jointly completed similar studies in 2004, 2009 and 2011.

The following chapter presents a summarized version of the rail capacity analysis. A more detailed version is presented in a separate document as *Appendix A*.

The current analysis differs from previous ones in the use of a rail simulation model. The previous studies used a "static analysis" of each line segment and corridor, rather than a rail simulation model. For the current analysis, a computer model of the mainline rail system in Washington State was created, using the Rail Traffic Controller (RTC) simulation software. RTC is the standard analysis program used by all Class I railroads in North America to analyze rail operations and capacity under various operating protocols, train volumes and infrastructure design. To a large extent, the mainline system in Washington is essentially the BNSF Railway (BNSF) network.

The rail capacity analysis included five scenarios, beginning with current conditions (in 2016), and continuing in five-year increments from 2020 through 2035. For the 2020 through 2030 analyses, MLM added capacity improvements to the simulated rail system as needed, in order to maintain traffic movement. The 2035 results were based on a static analysis, rather than a model simulation. The five cases analyzed were:

1. Base case of current operations and infrastructure (early 2016).
2. Growth case of train volumes at 2020 with infrastructure and capacity improvements as identified.
3. Growth case of train volumes at 2025 with infrastructure and capacity improvements as identified.
4. Growth case of train volumes at 2030 with infrastructure and capacity improvements as identified.
5. Growth case of train volumes at 2035 with infrastructure and capacity improvements as identified.

All train types were modeled, including international cargo, domestic cargo, and passenger trains. International train volumes were based on the Marine Cargo Forecast results, described in previous chapters. Domestic train volumes were based on current conditions and anticipated growth factors. Passenger train volumes were based on existing conditions and planned additions, including new passenger train service from WSDOT the will begin in fall of 2017. Passenger train volumes do not include any additional trains that may be added through Sound Transit 3.

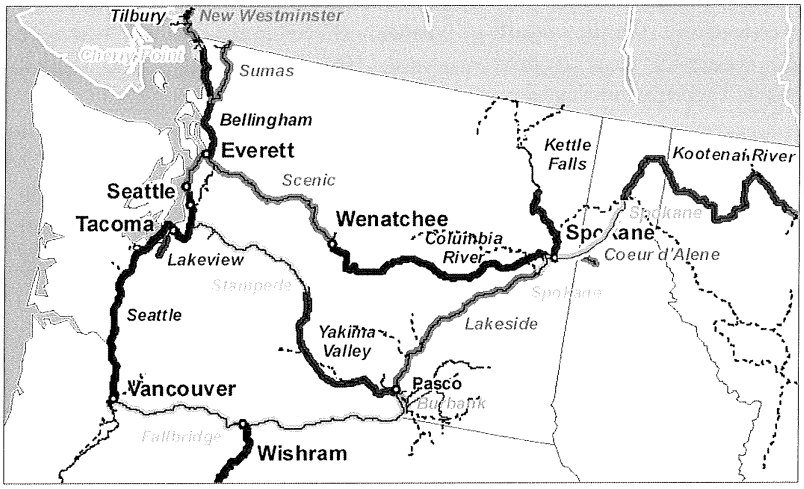
BST Associates developed three growth scenarios (i.e. reference case, low case, and high case) for each cargo type. MLM used the reference growth case for the 2020 simulation, and the high case for the 2025, 2030, and 2035 analyses. The high case was used in the 2025 – 2035 analyses in order to understand the potential impact on rail capacity of large increases in rail traffic. The high

cases also include the rail traffic that would be generated by several planned new marine terminals, including coal export facilities and crude oil transfer facilities.

The following chapter describes the methodologies and findings from each of the cases studied. A more detailed version of the rail capacity analysis is provided in *Appendix A*; this appendix provides a more complete discussion of the analyses performed and the results.

MLM does not represent that the capacity improvements and/or operational adjustments it introduced into the various simulation cases are requirements that BNSF would likely employ as growth in train volumes occurs. MLM introduced infrastructure and operational enhancements in a manner that it believes is reasonable given the significant growth in train volumes that were tested. The modifications were included to satisfy the ability of the model to successfully complete specific simulations with performance results that reasonably compared to previous case results.

MLM believes that BNSF, as it has done in the past, will invest in infrastructure improvements and make operational adjustments as demand requires and that best fits their strategies. The improvements that BNSF might make may be different than those MLM introduced into the model over the course of the simulation analyses. BNSF reviewed the draft analysis, and elected to not endorse or refute the results.



Key Findings

- The mainline system in the Pacific Northwest does not currently experience significant delays.
- As projected rail traffic grows, capacity on the region's rail system can likely be maintained through a combination of infrastructure improvements (such as additional track) and operating procedures.
- In order to accommodate high-case traffic growth in the out years, the height of the Stampede Pass Tunnel will likely need to be increased to allow for double-stack traffic and auto carriers.
- In order to accommodate high-case traffic growth in the out years, the Sandpoint (Lake Pend Oreille) and Pasco (Columbia River) bridges will likely need to be expanded two tracks
- Terminals are more likely to experience delays than are mainline track segments. (Modeling terminal operations was not part of scope of work for this project, and may require further research).

Model Network and Route Description

This section provides a description of the rail network used in the rail capacity analysis. Figure 5-1 below displays BNSF's rail network in the Pacific Northwest, with subdivision names and key stations included for reference. The subdivision names are used below when describing the results of the rail capacity analysis.

Figure 6-1: BNSF Pacific Northwest Mainline Rail Network

Source: BNSF

Sandpoint Junction to Spokane

This section of railroad is part of the Spokane Subdivision. The line between Spokane and Sandpoint, Idaho, experiences high levels of traffic because it handles a large share of BNSF traffic moving between the Pacific Northwest and the Midwest (e.g. Chicago) and the Southeast (e.g. Memphis). In addition to BNSF trains, the Montana Rail Link (MRL) main line connects to the BNSF main line at Sandpoint Junction. BNSF dispatches the route between Sandpoint and Spokane.

Spokane to Pasco

Just west of Spokane (at Latah Junction) the BNSF main line splits into two routes. The southern route is the BNSF Lakeside Subdivision, which runs between Spokane and Pasco. The northern route is the Columbia River Subdivision which runs between Spokane and Wenatchee. The Lakeside Subdivision is heavily utilized by manifest trains, unit bulk trains, intermodal/container trains moving to and from Portland, and two daily Amtrak trains.

Pasco to Vancouver

The BNSF Fallbridge Subdivision runs between Pasco and Vancouver, WA, following the north bank of the Columbia River. In order to handle an increased number of heavy unit trains (such as grain and oil trains), BNSF has begun to operate loaded unit trains westbound on the Fallbridge Subdivision, while sending the eastbound empty trains via other routes. The Fallbridge Subdivision also handles two daily Amtrak trains that run between Portland and Spokane, as well as all BNSF trains moving between the Pacific Northwest and California. The California trains use the Fallbridge Subdivision as far as Wishram, where the trains turn south and run towards California.

Vancouver to Seattle

The BNSF Seattle Subdivision runs between Vancouver and Seattle. From Vancouver to Tacoma, Union Pacific (UP) trains operate over the BNSF line via trackage rights, and the Seattle

Subdivision also hosts multiple Amtrak movements. BNSF controls train movements on the Subdivision. Between Tacoma and Seattle, UP exits the BNSF trackage and runs on its own route to Black River Junction, approximately 10 miles south of Seattle. BNSF and UP share trackage between Black River and Argo, where UP exits to their own yard. BNSF also hosts Sound Transit commuter rail operations between Tacoma and Seattle.

Seattle to Everett

The BNSF Scenic Subdivision runs along Puget Sound from Seattle to Everett. In addition to BNSF traffic, this subdivision hosts multiple Amtrak trains and weekday Sound Transit commuter trains. Most of this subdivision includes multiple main tracks, but there are two very short single track sections.

Everett to Canadian Border

The Bellingham Subdivision runs between Everett and the Canadian border at Blaine. This subdivision is a single track railroad with sidings. All BNSF unit trains that move to or from Canadian locations use this line, as well as manifest trains that handle local Vancouver BC traffic and traffic interchanged with Canadian railroads. Two pairs of round trip Seattle-Vancouver Amtrak trains also use the line.

The Sumas Subdivision provides an alternate route for BNSF Canadian traffic. The Sumas Subdivision diverges from the Bellingham Subdivision at Burlington, WA. This line handles one train per day in each direction, as well as handling local on line traffic and interchange traffic from Canadian Pacific at Sumas.

Everett to Wenatchee, Wenatchee to Spokane

The BNSF Scenic Subdivision runs from Seattle through Everett, and then runs east-west between Everett and Wenatchee. The BNSF Columbia River Subdivision runs between Wenatchee and Latah Junction, near Spokane.

The Scenic Subdivision features relatively steep 2.2% grades on both sides of Stevens Pass, and an eight-mile tunnel at the summit. These heavy grades restrict the operation of loaded unit trains over the route.

Auburn to Ellensburg, Ellensburg to Pasco

The Stampede Subdivision runs between Auburn and Ellensburg, and the Yakima Valley Subdivision runs between Ellensburg and SP&S Junction, near Pasco. BNSF operates the combined Stampede and Yakima Valley Subdivisions as an eastbound directional railroad. Currently there are no through trains that run from Pasco to Auburn.

The Stampede Subdivision features a 2.2% grade on both sides of Stampede Pass, and a two-mile tunnel at the summit of the pass. The tunnel is not tall enough to allow double-stacked containers and some other types of freight cars, so the route is currently restricted to lower-profile cars.

Methodology

Model Simulation

To meet the goals of the study, computer model simulation was utilized to determine the impact of existing and projected future rail operations within BNSF's Pacific Northwest rail network. Model simulation is an important tool in providing data for analytical studies in complex rail environments. All simulations were performed with the Rail Traffic Controller (RTC) model. RTC is used by all Class 1 railways in North America and has been accepted as the primary tool utilized in rail simulation analysis.

Analyses Performed

The RTC model creates a large amount of data as it performs the simulations. This data is analyzed to determine where conflicts occur, or how operations change as infrastructure or rail traffic levels are modified.

Delay Analysis

MLM utilized the data to develop two major analysis applications involving delay. The RTC model defines delay as time that a train must wait because the route it needs to take is unavailable.

The first analysis MLM performed was to estimate minutes of delay for each 10 train miles operated (referred to as "D/10"), within each network segment. The D/10 measurement allows comparison between cases that have differing number of trains and track configurations.

The second type of analysis performed was to locate delays that exceeded 30 minutes (referred to as "D>30"). Based upon MLM's experience with railroad operations, there are always going to be some delays in a railway network. However, some delays indicate problem areas, which is why D>30 delays are evaluated.

MLM ran each scenario over a three day period. The results of the D/10 and D>30 models were averaged over all three analysis days of the simulations.

With the data that RTC collects for each train movement, average velocity over a designated line segment can be calculated. This can be done for all freight operations on a line segment, or it can be broken down by train type.

Train Volumes

The model creates an output file that records every train that passes through every node of the network. MLM has developed an analysis that allows any specific node to be queried to find out all the trains that pass through the node, what time the train arrived and departed the node, and how fast the train was operating at the node.

This information was used to develop train volumes at locations through the PNW rail network. On many line segments, this involved analyzing multiple locations because of junctions or major industries, which alter the train counts from one location to the next. The train counts were recorded so that volume changes could be compared with delay results. Train volumes for each scenario are shown in Table 5-1 at the end of this memo.

Grade Crossing Analysis

MLM was also asked to supply model results to the team completing a separate analysis of grade crossing conflicts. The Road-Rail Conflict Study is being conducted by a team led by The

Transpo Group, under contract to the Joint Transportation Committee (JTC) of the Washington State Legislature.

The Transpo team provided MLM with a list of grade crossing locations for which data was required. MLM analyzed how often and for how long these grade crossings were occupied by rail movements. To do this, nodes were included in the model network that represented the location of the various crossings being studied. The model records when the head end of a train enters each node and when the rear end of that train departs the node.

All nodes associated with the specified crossings were analyzed to develop this information for the simulations; in some cases, this meant two or more nodes had to be analyzed for a single crossing because multiple tracks ran through the crossing. In the Base Case analysis, there were approximately 190 nodes that were analyzed to include all the crossings that were provided for analysis.

Analysis Segments

In this study, analysis was performed by subdivision. For each simulation, an analysis of delay and grade crossing occupancy was made for eleven segments on the network. A list of the specific locations is contained in *Appendix A*.

Data Sources

Data from BNSF was not available for use in the rail simulation analysis, so MLM used other sources, including data from previous analyses, to create a rail operating plan for the current analysis. One of the sources used to create the operating plan was 2012 data from BNSF's signal system provided to MLM for an earlier analysis.

The second source that MLM utilized was a list of all active trains on BNSF's rail system for one day in November 2013 and then another list for one day in February 2016. The lists included every active train symbol running on BNSF's northern corridor on those days.

Another source that was used in previous analyses was a monitoring website called ATCS Monitor. ATCS stands for Advanced Train Control System, which is a method used by railroads to dispatch and monitor their train operations. ATCS Monitor was developed by radio enthusiasts who determined that the signals sent between dispatching centers and wayside signals could be captured and decoded to understand how a rail line was being dispatched. While ATCS Monitor data was not available for the current study, ATCS Monitor data from earlier studies was extremely helpful in determining timing of trains, as well as developing estimated schedules.

Schedule Development

After the ATCS Monitor data had been recorded and analyzed, patterns were documented for traffic along line segments. MLM understands that the train identifications may not be exact; however they create a very good representation of the traffic that moves over each line segment.

Train departure times were estimated based on BNSF documents from Portland/Vancouver, and observed ATCS Monitor departures from Seattle/Tacoma, Pasco and Spokane. Once manifest and intermodal trains had been assigned, the unit trains were added to the appropriate sections based on the operating plan.

Results and Analysis of Scenarios

The following sections of this report briefly describe the results and the capacity analysis of the simulations.

Train Volume Growth and Track Improvements

Train Volume Growth

This section reviews how growth was calculated for various commodities for the simulations. Growth for international containers, domestic intermodal, vehicles, manifest, grain, oil, and coal were calculated using various methodologies. As noted above, all train types were modeled, including international cargo, domestic cargo, and passenger trains. International train volumes were based on the Marine Cargo Forecast results, described in previous chapters. Domestic train volumes were based on current conditions and anticipated growth factors. Passenger train volumes were based on existing conditions and planned additions.

A detailed discussion on train volume growth methodologies is contained in *Appendix A*.

Track Improvements by Simulation

Track improvements were added to the model in all of the simulations, based on areas of congestion that were observed after analyzing the simulation outputs. Track improvements that were included in the Base P5 Case were in addition to the track configuration used in the Base Case. A list of the improvements included in the Base P5 case (2020) can be found in *Appendix A*. Similarly, a list of improvements included in the Base P10 (2025) and the Base P15 (2030) simulation cases is contained in *Appendix A*.

Segment Results and Analysis

The following sections of the report briefly address the capacity findings from each of the simulations. A brief summary of the findings and MLM's conclusions starts each simulation's Results and Analysis section.

Base Case Analysis Results

Base Case Conclusions

The Base Case conditions indicate that BNSF does not currently have capacity issues on most of line segments in the PNW. Between terminals, trains ran efficiently for the most part. The terminals in the PNW appear to be a larger concern for rail capacity in the PNW.

It should be noted that the scope of the project did not include detailed simulation of operations within the terminals, so delays that were found in the Base Case are likely an understatement of actual delays occurring at terminals in actual operations.

Grade Crossing Occupancy Analysis

A grade crossing analysis was performed for each simulation case, the results of which are included in a separate spreadsheet.

A list of all trains that operated through the crossings was also provided by line segment. The simulation day, train identification number, train length and train type were provided in the list, along with the entrance, clearing and total occupancy times.

Line Segment Capacity Observations

The following section briefly reviews the capacity observations by line segment (and by terminal where it is integral to the operation) for the Base Case.

Spokane Subdivision

The Spokane Subdivision (Sandpoint to Irvin) operated **well below** estimated sustainable capacity, with a D/10 calculation of 1.6 minutes of delay per 10 miles operated. Hauser Terminal also operated **well below** estimated sustainable capacity, at 6.2 minutes of delay per 10 miles. Hauser operations were simplified (in the simulation) and likely do not represent the full range of potential delays that can occur in a major terminal. Freight train velocity on the Spokane Subdivision was 32.3 miles per hour on average.

Spokane Terminal and Lakeside Subdivision

Spokane Terminal (Irvin to Latah Junction, Latah Junction to Lakeside Junction, Lakeside Junction to Sunset Junction) operated **well below** estimated sustainable capacity, at 4.3 minutes of delay per 10 miles operated.

The Lakeside Subdivision (Lakeside Junction to Glade) also operated **well below** estimated sustainable capacity, with 2.5 minutes of delay per 10 miles operated. The new segments of second main track that BNSF installed in 2014/2015 alleviated locations that experienced notable delays in previous analyses. Average velocity for freight traffic on the route was 30.9 mph.

Pasco Terminal and Fallbridge Subdivision

Pasco Terminal (Glade to SP&S Junction) operated **within** estimated sustainable capacity, with 11.7 minutes of delay per 10 miles operated. Pasco is a major classification yard for BNSF, which means many trains terminate and originate at the terminal. At the same time, a very high percentage of empty unit trains and all loaded unit trains passed through the terminal.

The Fallbridge Subdivision (SP&S Junction to McLoughlin) operated **well below** estimated sustainable capacity, with 3.9 minutes of delay per 10 miles operated. However, the subdivision had the highest number of delays exceeding 30 minutes (23.7/day). Single track meets and overtakes were the main contributor to the delays. Velocity also showed that the subdivision operated relatively efficiently, with freight traffic operating at an average of 30.3 mph.

Vancouver Terminal

In past analyses, Vancouver Terminal (McLoughlin to Portland, Columbia River Bridge to Felida) operated approaching or at estimated sustainable capacity. In the current analysis, Vancouver Terminal operated **well below** estimated sustainable capacity, with 9.3 minutes of delay per 10 miles operated. There were three major changes that facilitated this improvement: "east bypass" route, an additional single track connection between the Seattle and Fallbridge subdivisions, and the new connection to the Port of Vancouver.

Seattle Subdivision

The Seattle Subdivision (Felida to Nelson Bennett) operated **well below** estimated sustainable capacity, with 0.9 minutes of delay per 10 miles. Areas of minor congestion occurred around Kalama and Longview, where trains diverge to large industrial facilities. Average freight train velocity for the subdivision was 32.2 mph, indicating the subdivision operated efficiently throughout the analysis.

Seattle Tacoma (SeaTac) Terminal

The SeaTac Terminal (Nelson Bennett Tunnel to MP 8, Scenic Sub) operated **well below** estimated sustainable capacity, with 5.3 minutes of delay per 10 miles operated. While the overall number is very good, there were times when the terminal became congested. Sound Transit Commuter operations between Everett and King Street Station and King Street Station and Tacoma/Lakewood caused much of the congestion.

Scenic Subdivision (West)

The Scenic Subdivision extends between Seattle (MP 0) and Wenatchee. However, for purposes of this analysis, it was divided into west and east segments. The Scenic Subdivision West extended from MP 8 to MP 28 (MP 8 to Mukilteo). It operated **well below** estimated sustainable capacity, with 1.5 minutes of delay per 10 miles operated.

A portion of the Scenic Subdivision was included in the SeaTac Terminal analysis segment. Most of the freight trains that experienced delays because of Sound Transit commuter trains were delayed in the SeaTac portion of the subdivision.

Bellingham Subdivision and Everett Terminal

Everett Terminal (MP 28 Scenic Subdivision to Bridge 38, Bridge 38 to PA Junction, Everett Junction to PA Junction) operated **within** estimated sustainable capacity, at 19.3 minutes of delay per 10 miles operated. The Everett passenger station, shared by Sound Transit and Amtrak, is located on a single track segment of the Scenic Subdivision between Everett Junction and PA Junction. When these trains were operating, freight trains could not leave Delta Yard without delaying the passenger trains. Additionally, limited capacity on the Bellingham Subdivision led to yard delays.

The Bellingham Subdivision operated **within** estimated sustainable capacity, at 6.8 minutes of delay per 10 miles operated. This was the highest D/10 statistic for any of the line segments that were studied. Amtrak trains also delayed trains along the Bellingham Sub, as did single track meets of opposing freight trains. The average freight velocity on the Bellingham Subdivision was 20.7 mph. This is notably lower than the velocities on other subdivisions.

Scenic Subdivision (East) and Columbia River Subdivision

The Scenic Subdivision East (PA Junction to Wenatchee) and the Columbia River Subdivision (Wenatchee to Latah Junction) were included in the analysis; however the simulation was not as detailed as other segments of the railroad. This was done to expedite each simulation at the request of the client.

The Scenic Subdivision East operated **within** estimated sustainable capacity, at 6.4 minutes of delay per 10 miles operated, while the Columbia River Subdivision operated **well below** estimated sustainable capacity, at 1.7 minutes of delay per 10 miles operated. Scenic Subdivision trains averaged a velocity of 20.5 mph, reflecting the slow track speed and delay issues attendant with the grades, curves and the Cascade Tunnel. Average velocity of trains on the Columbia River Subdivision was 36.5 mph, reflecting how efficiently the subdivision operated under the traffic levels that were included in the analysis.

Stampede Subdivision and Yakima Valley Subdivision

The Stampede Subdivision (Auburn to Ellensburg) and the Yakima Valley Subdivision (Ellensburg to SP&S Junction) both operated **well below** estimated sustainable capacity, at 1.0 minutes of delay per 10 miles operated. Similar to the Scenic (east) and Columbia River Subs, the

Stampede and Yakima Valley Subs were not simulated with the same level of detail as other subdivisions. Again, this was done at the client's request to expedite the analyses. The Stampede and Yakima Valley Subs operated most trains in an eastbound direction. The average velocity of trains using these subdivisions was 30 mph.

Base Case Plus 5 Years (Base P5) Analysis Results

Base P5 Conclusions

Based on the results of the simulations through Base P5 (2020), MLM believes BNSF has sufficient line segment capacity to accommodate the growth projected for five years. This projection excludes coal trains serving the proposed Millennium Bulk Terminal in Longview and oil trains serving the proposed Vancouver Energy terminal in Vancouver.

In the opinion of MLM, the greatest concern for rail capacity in the PNW in this time frame is BNSF's terminals, especially Hauser, Pasco, and Everett. Additionally, there are intermittent constraints in the Seattle/Tacoma terminal. Detailed terminal operations, however, were not within the scope of the WPPA 2017 study analysis.

As mentioned, the Base P5 simulation did not include large unit train growth projects such as Millennium coal trains and Vancouver Energy oil trains. These projects were included in the Base P10 and Base P15 simulations, however, and the results are noted in descriptions of those simulations.

There were similar impacts between freight and passenger trains between Seattle and Tacoma as in the Base Case.

Base P5 Grade Crossing Occupancy Analysis and Train Volumes

Additional grade crossing information related to the Base P5 simulation has been included in spreadsheet. This is in addition to the Base Case spreadsheet that describes grade crossing occupancies for that simulation. Train volumes are shown in Table 5-1 below.

Base P5 Line Segment Capacity Observations

Spokane Subdivision

The Spokane Subdivision operated **well below** estimated sustainable capacity, at 1.9 minutes of delay per 10 miles operated (1.6 minutes of delay in the Base Case). Infrastructure improvements mitigated the growth in traffic on the line segment. Hauser Terminal also operated **well below** estimated sustainable capacity, at 4.4 minutes of delay per 10 miles (6.2 minutes of delay in the Base Case). Simplified terminal operations (in the model) likely understated the actual amount of delay. Freight train velocity on the Spokane Subdivision was 32.0 miles per hour on average (32.3 mph in Base Case).

Spokane Terminal and Lakeside Subdivision

Spokane Terminal also operated **well below** estimated sustainable capacity, at 3.8 minutes of delay per 10 miles operated (4.3 minutes in Base Case).

The Lakeside Subdivision also operated **well below** estimated sustainable capacity, with 3.3 minutes of delay per 10 miles operated (2.5 minutes in Base Case). Train volume growth was responsible for the increase in delay. Average velocity for freight traffic on the route was 29.5 mph (30.9 mph in Base Case).

Pasco Terminal and Fallbridge Subdivision

Pasco Terminal operated **within** estimated sustainable capacity, with 14.8 minutes of delay per 10 miles operated (11.7 minutes in Base Case). Congestion caused by growth around the single track Columbia River Bridge impacted Pasco's delay minutes.

The Fallbridge Subdivision operated **well below** estimated sustainable capacity, with 3.5 minutes of delay per 10 miles operated (3.9 minutes in the Base Case). Rerouting eastbound traffic from the Fallbridge Subdivision to the Stampede Subdivision accounted for the improvement in delay. Velocity also showed that the subdivision operated relatively efficiently, with freight traffic operating at an average of 31.3 mph (30.3 mph in Base Case).

Vancouver Terminal

Vancouver Terminal operated **well below** estimated sustainable capacity, with 7.5 minutes of delay per 10 miles operated (9.3 minutes in Base Case). Some new infrastructure on the Seattle Subdivision north of the terminal assisted with the improved delay.

Seattle Subdivision

The Seattle Subdivision operated **well below** estimated sustainable capacity, with 1.5 minutes of delay per 10 miles (0.9 minutes in Base Case). The two main tracks over the entire length of the subdivision minimized delays. Most of the delays exceeding 30 minutes continued to occur between Longview and Kalama, where large numbers of trains enter or leave the main line. One other location that experienced repetitive delay was at Nisqually Junction, where the BNSF Seattle Subdivision and the new Amtrak route between Tacoma and Nisqually (i.e. Point Defiance Bypass) converge. Average freight train velocity for the subdivision was 32.2 mph (32.2 mph in Base Case), indicating that the subdivision continued to operate efficiently.

Seattle Tacoma (SeaTac) Terminal

The SeaTac Terminal operated **well below** estimated sustainable capacity, with 6.7 minutes of delay per 10 miles operated (5.3 minutes in Base Case). Passenger operations were once again a contributor to the delays. As discussed in the Base Case analysis, Sound Transit Commuter operations between Everett and King Street Station and King Street Station and Tacoma/Lakewood caused much of the congestion.

Scenic Subdivision West

The Scenic Subdivision West operated **well below** estimated sustainable capacity, with 1.3 minutes of delay per 10 miles operated (1.5 minutes in Base Case). No improvements were included in the Base P5 case in this segment.

Bellingham Subdivision and Everett Terminal

Everett Terminal operated **within** estimated sustainable capacity, at 19.5 minutes of delay per 10 miles operated (19.3 minutes in Base Case). This number remained very close to the boundary between **within** and **at or approaching** estimated sustainable capacity (>20 minutes of delay per 10 miles). As in the Base Case, passenger operations on single track were responsible for many of the delays. A short single track section at Mukilteo also caused delays that led to this Base P5 analysis result.

The Bellingham Subdivision operated **well below** estimated sustainable capacity, at 3.8 minutes of delay per 10 miles operated (6.8 minutes in Base Case). Train mix and reroutes of

traffic through the terminal were responsible for the improvement. The average freight velocity on the Bellingham Subdivision was 23.6 mph (20.7 mph in Base Case).

Scenic Subdivision (East) and Columbia River Subdivision

The Scenic Subdivision East operated **within** estimated sustainable capacity, at 4.3 minutes of delay per 10 miles operated (6.4 minutes in Base Case), while the Columbia River Subdivision operated **well below** estimated sustainable capacity, at 1.6 minutes of delay per 10 miles operated (1.7 minutes in Base Case). Velocity for trains on the Scenic Subdivision averaged 22.0 mph (20.5 mph in the Base Case), while velocity for trains on the Columbia River Subdivision averaged 36.7 mph (36.5 mph in Base Case).

Stampede Subdivision and Yakima Valley Subdivision

The Stampede Subdivision and the Yakima Valley Subdivision both operated **well below** estimated sustainable capacity, at 0.5 minutes of delay per 10 miles operated. Since most of the trains operated in an easterly direction, there were minimal meets that caused delays. The average velocity of trains using these subdivisions was 30.7 mph (30.0 mph in the Base Case).

Base Case Plus 10 Years (Base P10) Analysis Results

Base P10 Conclusions

The Base P10 simulation showed that the projected growth trains over the 10 year time frame will create congestion if no line segment infrastructure improvements are constructed. However, with infrastructure improvements (such as those added in the simulation), each of the major line segments operated efficiently. MLM placed improvements at locations where the simulation indicated they were needed; BNSF will perform their own analyses and may make improvements in locations that are different from MLM's. However, MLM is confident that BNSF will address the capacity issues as they arise when the traffic actually materializes.

Base P10 Train Volumes and Grade Crossing Occupancy Analysis

There was a notable increase in train volumes on certain line segments in the Base P10 (2025) simulation compared to the Base P5 simulation totals. These major increases represent the inclusion of growth as projected in the Marine Cargo Forecast, as well as growth associated with large unit train projects such as Millennium Bulk Terminal coal trains and Vancouver Energy oil trains. For each loaded train that was added for those projects, there was a corresponding empty train that had to be added as well. Some of the line segments, such as the Lakeside and Spokane Subdivisions, handled both the loaded and empty movements. Other line segments, such as the Fallbridge or Stampede/Yakima Valley Subdivisions, only handled either the loaded or the empty movement, but not both. Train volumes are shown by line segment in Table 5-1 below.

Additional grade crossing information related to the Base P10 simulation has been included in spreadsheet.

Base P10 Line Segment Capacity Observations

The following section briefly reviews the capacity observations by line segment (and by terminal where it is integral to the operation) for the Base P10 simulation.

Spokane Subdivision

The Spokane Subdivision operated **well below** estimated sustainable capacity, at 1.4 minutes of delay per 10 miles operated (1.6 in the Base Case, 1.9 in Base P5). Additional infrastructure that

completed the second main track across the entire subdivision (except for the Sandpoint Bridge) accounted for the improvement even with increased train volumes. Hauser Terminal also operated **well below** estimated sustainable capacity, at 4.5 minutes of delay per 10 miles (6.2 in the Base Case, 4.4 in Base P5), although again, MLM suspects the delays are understated because of simplified terminal operations (in the model). Freight train velocity on the Spokane Subdivision was 32.9 miles per hour on average (32.3 mph in Base Case, 32.0 in Base P5).

Spokane Terminal and Lakeside Subdivision

Spokane Terminal also operated **well below** estimated sustainable capacity, at 5.2 minutes of delay per 10 miles operated (4.3 in Base Case, 3.8 in Base P5). Trains accessing multiple junctions within the terminal accounted for most of the increased delay.

The Lakeside Subdivision also operated **well below** estimated sustainable capacity, with 3.9 minutes of delay per 10 miles operated (2.5 in Base Case, 3.3 in Base P5). This subdivision experienced growth of 20 trains per day, and only the inclusion of large additional sections of second main track kept delay at the levels that were developed. Average velocity for freight traffic on the route was 28.1 mph (30.9 in Base Case, 29.5 in Base P5).

Pasco Terminal and Fallbridge Subdivision

Pasco Terminal operated **within** estimated sustainable capacity, with 16.4 minutes of delay per 10 miles operated (11.7 in Base Case, 14.8 in Base P5). The Columbia River Bridge at Pasco remained a concern in the Base P10 simulation. BNSF routing protocol will likely have all westbound loaded unit trains running from Pasco to Vancouver via the Fallbridge Subdivision, and most or all eastbound unit empties returning to Pasco via the Yakima Valley Subdivision. These two subdivisions converge at SP&S Junction, which is just west of the Columbia River Bridge. Therefore, all projected unit train growth, whether it is coal, oil or grain, will cross this bridge twice; once when loaded, and then again when empty.

The Fallbridge Subdivision operated **well below** estimated sustainable capacity, with 3.7 minutes of delay per 10 miles operated (3.9 in the Base Case, 3.5 in Base P5). Some capacity improvements and additional rerouting of eastbound traffic to the Stampede Subdivision contributed to this result. A slight decrease in velocity also reflected the increased train movements, with freight traffic operating at an average of 30.6 mph (30.3 in Base Case, 31.3 in Base P5).

Vancouver Terminal

Vancouver Terminal operated **within** estimated sustainable capacity, with 11.4 minutes of delay per 10 miles operated (9.3 in Base Case, 7.5 in Base P5). The increase in delay minutes reflects the impact of additional train movements through the terminal.

Seattle Subdivision

The Seattle Subdivision operated **well below** estimated sustainable capacity, with 0.8 minutes of delay per 10 miles (0.9 in Base Case, 1.5 in Base P5). The two main tracks over the entire length of the subdivision again minimized delays. There were very few delays that exceeded 30 minutes on the Seattle Subdivision during the Base P10 simulation. Where they did occur was generally in the vicinity of Kalama and Longview. Average velocity for freight train on the subdivision was 30.0 mph (32.2 in Base Case, 32.2 in Base P5).

Seattle Tacoma (SeaTac) Terminal

The SeaTac Terminal operated **well below** estimated sustainable capacity, with 6.1 minutes of delay per 10 miles operated (5.3 in Base Case, 6.7 in Base P5). As has been observed in all the previous simulations, passenger operations were once again a major contributor to the delays.

Scenic Subdivision (West)

The Scenic Subdivision West operated **well below** estimated sustainable capacity, with 3.9 minutes of delay per 10 miles operated (1.5 in Base Case, 1.3 in Base P5). Increased growth train volumes accounted for the increase in the delay statistic.

Bellingham Subdivision and Everett Terminal

Everett Terminal operated **within** estimated sustainable capacity, at 15.4 minutes of delay per 10 miles operated (19.3 in Base Case, 19.5 in Base P5). The improvement was because some trains were rerouted through the west side of the terminal rather than passing through or stopping in Delta Yard.

The Bellingham Subdivision operated **within** estimated sustainable capacity, at 4.6 minutes of delay per 10 miles operated (6.8 in Base Case, 3.8 in Base P5). Infrastructure improvements and rerouting trains through Everett were responsible for the delay improvement. The average freight velocity on the Bellingham Subdivision was 23.1 mph (20.7 in Base Case, 23.6 in Base P5).

Scenic Subdivision (East) and Columbia River Subdivision

The Scenic Subdivision East operated **within** estimated sustainable capacity, at 6.3 minutes of delay per 10 miles operated (6.4 in Base Case, 4.3 in Base P5), while the Columbia River Subdivision operated **well below** estimated sustainable capacity, at 1.7 minutes of delay per 10 miles operated (1.7 in Base Case, 1.6 in Base P5). Scenic Subdivision trains averaged a velocity of 20.4 mph (20.5 in the Base Case, 22.0 in Base P5), and Columbia River Subdivision trains averaged velocity of 35.8 mph (36.5 in Base Case, 36.7 in Base P5).

Stampede Subdivision and Yakima Valley Subdivision

The Stampede Subdivision and the Yakima Valley Subdivision both operated **well below** estimated sustainable capacity, at 1.8 minutes of delay per 10 miles operated (1.0 in Base Case, 0.5 in Base P5). Even with a large increase in train volumes, the directional nature of the route allowed trains to move with minimal delay. Most of the delays accumulated near SP&S Junction (near Pasco) for trains waiting to move through Pasco Yard. The average velocity of trains using these subdivisions was 28.7 mph (30.0 in the Base Case, 30.7 in Base P5).

Base Case Plus 15 Years (Base P15) Analysis Results

Base P15 Conclusions

Traffic growth associated with the Base P15 simulation was significant. In order to mitigate congestion on the PNW rail network caused by the new trains, MLM was forced to add infrastructure and operating modifications to the model. Major modifications were made to the Lakeside and Fallbridge Subdivisions, as well as improvements to the signal system and increased tunnel height on the Stampede and Yakima Valley Subdivisions. Beyond the physical improvements, operating changes were also required to maintain a fluid railroad network at the projected train volumes.

The largest of these operating changes was the rerouting of trains to the Stampede/Yakima Valley Subdivisions. In previous simulations, only empty unit trains used this route to return to Pasco and then east. In the Base P15 simulation, MLM had to assume that manifest trains destined for Pasco and Spokane from Everett, Seattle and Tacoma would use the route, in addition to empty unit trains. Also, some intermodal trains from Portland and Tacoma were rerouted via the Stampede/Yakima Valley Subdivisions to Pasco prior to proceeding east.

Many of the Everett, Seattle and Tacoma manifest trains that previously had moved to Pasco via the Seattle and Fallbridge Subs were reassigned to the Stampede Pass to minimize the amount of eastbound traffic using the Fallbridge route.

MLM made the assumption that, should the projected high-case train volumes materialize, BNSF would increase the height of the Stampede Pass tunnels to allow international and domestic double-stack trains to operate via that route. Clearance for that type of traffic would also allow manifest trains containing auto carriers to operate via the route. With infrastructure improvements and the operational modifications, MLM believes BNSF will have enough line segment capacity to accommodate traffic into the 2030 time frame.

The operating modifications that rerouted many of the trains are discussed in *Appendix A*. Train volumes by line segment are shown in Table 5-1 below. Additional grade crossing information related to the Base P15 simulation has been included in the spreadsheet.

Base P15 Line Segment Capacity Observations

The following section of the memo briefly reviews the capacity observations by line segment and terminal for the Base P15 simulation.

Spokane Subdivision

The Spokane Subdivision operated **well below** estimated sustainable capacity, at 2.8 minutes of delay per 10 miles operated (1.6 BC, 1.9 P5, 1.4 P10). No additional infrastructure was added in the P15 simulation. Additional train counts over the route were responsible for the delay increase. Hauser Terminal also operated **well below** estimated sustainable capacity, at 7.5 minutes of delay per 10 miles (6.2 BC, 4.4 P5, 4.5 P10), although it is likely these numbers are understated. Freight train velocity on the Spokane Subdivision was 29.8 miles per hour on average (32.3 mph BC, 32.0 P5, 32.9 P10).

Spokane Terminal and Lakeside Subdivision

Spokane Terminal also operated **well below** estimated sustainable capacity, at 4.4 minutes of delay per 10 miles operated (4.3 BC, 3.8 P5, 5.2 P10). The model included a new connection between UP and BNSF lines near Cheney, which improved traffic flows even under the train volume increases in the P15 simulation.

The Lakeside Subdivision also operated **well below** estimated sustainable capacity, with 0.4 minutes of delay per 10 miles operated (2.5 BC, 3.3 P5, 3.9 P10). Completing the addition of a second main track across the subdivision was responsible for the improvement in train delay. Average velocity for freight traffic on the route was 36.1 mph (30.9 BC, 29.5 P5, 28.1 P10).

Pasco Terminal and Fallbridge Sub.

Pasco Terminal operated **above** estimated sustainable capacity, with 26.2 minutes of delay per 10 miles operated (11.7 BC, 14.8 P5, 16.4 P10). This is a notable increase from the P10 delay statistics; MLM is concerned that, at this level of delay, it is likely that the terminal would not be

LUBA No. 2020-009
Page 5609

capable of operating for long periods without experiencing delays that potentially could affect all movements through Pasco. The single track bridge over the Columbia River and the coal spraying track were mainly responsible for the delay increase.

The Fallbridge Subdivision (SP&S Junction to McLoughlin) operated **well below** estimated sustainable capacity, with 2.3 minutes of delay per 10 miles operated (3.9 BC, 3.5 P5, 3.7 P10). The average velocity of trains between Vancouver and Pasco improved due to reducing the number of eastbound trains on the subdivision. The only eastbound trains left on the subdivision were Amtrak and trains moving to/from the south at Wishram. Freight traffic operated at an average of 33.2 mph (30.3 BC, 31.3 P5, 30.6 P10), which was notably higher than previous cases.

Vancouver Terminal

Vancouver Terminal operated **within** estimated sustainable capacity, with 12.5 minutes of delay per 10 miles operated (9.3 BC, 7.5 P5, 11.4 P10). The increase in delay minutes reflects the impact of the additional loaded coal and grain trains that had to move through the terminal between the Fallbridge and Seattle Subdivisions, and additional UP grain and intermodal trains that passed through the terminal.

Seattle Subdivision

The Seattle Subdivision operated **well below** estimated sustainable capacity, with 1.1 minutes of delay per 10 miles (0.9 BC, 1.5 P5, 0.8 P10). Average freight train velocity for the subdivision was 27.7 mph (32.2 BC, 32.2 P5, 30.0 P10). The decrease in velocity reflects the increased unit traffic that was added to the route, which generally runs at a reduced velocity compared to manifest or intermodal operations.

Seattle Tacoma (SeaTac) Terminal

The SeaTac Terminal operated **well below** estimated sustainable capacity, with 7.9 minutes of delay per 10 miles operated (5.3 BC, 6.7 P5, 6.1 P10). Delays associated with passenger trains between Seattle and TR Junction in Tacoma continued to contribute to terminal freight congestion.

Scenic Subdivision (West)

The Scenic Subdivision West operated **well below** estimated sustainable capacity, with 2.7 minutes of delay per 10 miles operated (1.5 BC, 1.3 P5, 3.9 P10).

Bellingham Subdivision and Everett Terminal

Everett Terminal operated **approaching or at** estimated sustainable capacity, at 22.0 minutes of delay per 10 miles operated (19.3 BC, 19.5 P5, 15.4 P10). Passenger trains continued to create terminal delays, as did restricted capacity on the Bellingham Subdivision and on the Scenic Subdivision (East). Trains were frequently held in the yard until capacity north or east of the terminal became available.

The Bellingham Subdivision operated **within** estimated sustainable capacity, at 5.6 minutes of delay per 10 miles operated (6.8 BC, 3.8 P5, 4.6 P10). Additional traffic to/from British Columbia contributed to the increase in delay on the subdivision and within Everett Terminal. The average freight velocity on the Bellingham Subdivision was 22.4 mph (20.7 BC, 23.6 P5, 23.1 P10).

Scenic Subdivision (East) and Columbia River Subdivision

The Scenic Subdivision East operated **within** estimated sustainable capacity, at 5.0 minutes of delay per 10 miles operated (6.4 BC, 4.3 P5, 6.3 P10), while the Columbia River Subdivision

operated **well below** estimated sustainable capacity, at 2.0 minutes of delay per 10 miles operated (1.7 BC, 1.6 P5, 1.7 P10). Trains on the Scenic Subdivision averaged velocity of 21.3 mph (20.5 BC, 22.0 P5, 20.4 P10), and trains on the Columbia River Subdivision averaged 35.6 mph (36.5 BC, 36.7 P5, 35.8 P10).

Stampede Subdivision and Yakima Valley Subdivision

The Stampede Subdivision and the Yakima Valley Subdivision both operated **well below** estimated sustainable capacity, at 1.8 minutes of delay per 10 miles operated (1.0 BC, 0.5 P5, 1.8 P10). An upgraded signal system was added to the subdivision to accommodate the projected number of trains. Congestion near SP&S junction continued to be the main cause of delay on the subdivision. The average velocity of trains using these subdivisions was 28.6 mph (30.0 BC, 30.7 P5, 28.7 P10).

Base P20 (2035) Static Analysis

In addition to the four simulation analyses discussed above, MLM utilized the 'High' growth projection developed by in the Marine Cargo Forecast to estimate train volumes in 2035, over the various segments of the network previously described. Since a model simulation analysis was not performed for the segments, MLM did not attempt to identify potential capacity improvements that might be necessary to accommodate train volume growth. A general discussion of the impacts that the train volume growth contained in the 2035 Static Analysis is contained in *Appendix A*.

Also, since a model simulation analysis was not performed for the P20 analysis, specific road/rail crossing conflict information was not developed.

The table below recaps the estimated train volumes for all the simulation cases and the 2035 Static Analysis.

Table 6-1: Three Day Average Train Volume Summary, Through Base P20

Location	Subdivision	Milepost	Trains per Day				
			Base Case	Base P5 (2020)	Base P10 (2025)	Base P15 (2030)	Base P20 (2035)
E. Spokane	Spokane	63	66	69	93	111	119
Lind	Lakeside	91	42	46	66	88	93
Plymouth	Fallbridge	190	38	38	47	51	54

Chapter 7
Port Infrastructure and Access

Introduction and Background

A summary of each of the 16 participating ports was prepared to enhance this year's Marine Cargo Forecast and to get a better understanding of current and future infrastructure needs. To accomplish this, the 16 partner Ports were interviewed and the findings were summarized into a Port Profile for each of the participating Ports. This detailed summary of each of the 16 ports can be found in *Appendix B*:

Figure 7-1: Participating Ports

It should be noted that although this sample of ports represents both large and small, urban and rural ports, the ports self-selected to participate in this study by providing funding for the 2017 Marine Cargo Forecast.

The participating ports included:

- Anacortes
- Bellingham
- Benton
- Clarkston
- Everett
- Grays Harbor
- Kalama
- Longview
- Olympia
- Pasco
- Port Angeles

- Seattle (Northwest Seaport Alliance)
- Tacoma (Northwest Seaport Alliance)
- Vancouver, USA
- Walla Walla
- Whitman County

Initial Findings

- In general, the ports are trying to grow their traditional lines of business, versus expand into new areas.
- Containers, bulk and breakbulk remain the areas of concentration.
- There are local access/ congestion issues that will require infrastructure improvements to meet future growth.
- There are many port or port related projects that lack full funding to implement the project

Port Summaries

Each Port summary has been tailored to local characteristics. The individual port summaries collected the following information:

- A short overview of the Port
- Description of existing facilities – public and private
- Description of future facilities – public and private
- Description of cargo
  - Opportunities
  - Threats
  - Modal share
- Overview of port access
  - Current projects
  - Future projects
- Discussion of other issues
- Description of access
  - Truck
  - Rail
  - Barge
  - Pipeline
- Future cargo activities
- List of new terminals
- Identification of access challenges/ projects
- Other challenges/ issues
- Maps
    - Location and Access

The intent of the summaries is to (1) provide a current overview of the current public and private port facilities, (2) to identify future port projects, and (3) to identify port access projects and issues.

For example, Bellingham harbor has an array of public and private terminals.

Table 7-1: Example of Public and Private Terminal Summary for the Bellingham Harbor

Public/ Private	Terminal Name	Owner	Operator	City/ Area	Purpose
Public	Bellingham Shipping Terminal	Port of Bellingham	Port of Bellingham	Bellingham	General cargo, logs, bulks
Private	BP Cherry Point Refinery north dock	British Petroleum	British Petroleum	Cherry Point	Crude oil unloading
Private	BP Cherry Point Refinery south dock	British Petroleum	British Petroleum	Cherry Point	Petroleum product loading
Private	Gateway Pacific	SSA	SSA	Cherry Point	Exports of coal, mineral bulks, grain
Private	Intalco Company Aluminum Wharf	Intalco	Intalco	Cherry Point	Alumina receipts
Private	Conoco Phillips Ferndale Refinery	Conoco Phillips	Conoco Phillips	Cherry Point	Crude oil receipts and petroleum product shipments
Private	Bellingham Cold Storage	Bellingham Cold Storage	Bellingham Cold Storage	Bellingham	Fish/seafood

Example of a Port Summary – Grays Harbor

Overview

The Port of Grays Harbor is Washington's only deep-water port on the Pacific Coast. Centrally located between Seattle and Portland, the Port has highway access via the four-lane highway from Interstate 5 and rail service provided by Puget Sound & Pacific with connections to Burlington Northern Santa Fe and Union Pacific. The continuous rail loop throughout the marine terminal complex is designed to handle and store unit-trains as well as smaller sets of rail cars. Specializing in heavy-lift, roll-on/roll-off, autos, wheeled vehicles, project cargoes, liquid bulks and bulk cargoes; the Port of Grays Harbor efficiently handles a multitude of diverse cargoes from breakbulk and agricultural products to liquid bulk. Located within Foreign Trade Zone 173 are over 110,000 square feet of covered, secured on-dock warehouse space and adjacent paved cargo yard dockside available for short and long term storage.

Table 7-2: Existing Terminals – Grays Harbor

Terminal Name	Owner	Operator	City/ Area	Purpose
Terminal 1	Port of Grays Harbor	REG Grays Harbor and Westway Terminal	Hoquiam	Liquid bulk
Terminal 2	Port of Grays Harbor	AGP	Aberdeen	Grain and grain products
Terminal 3	Port of Grays Harbor	Willis Enterprises	Hoquiam	Wood chips
Terminal 4	Port of Grays Harbor	PLS, Pasha	Aberdeen	Autos, Ro-ro, logs, general cargo
Sierra Pacific Marine Terminal	Sierra Pacific	Sierra Pacific Ind.	Aberdeen	Lumber, logs and wood chips
Terminal 1	Port of Grays Harbor	REG Grays Harbor and Westway Terminal	Hoquiam	Liquid bulk
Terminal 2	Port of Grays Harbor	AGP	Aberdeen	Grain and grain products

Rail Service

Rail Service is available through both BNSF and UPRR, via Genesee & Wyoming's Puget Sound and Pacific Railroad. The Port of Grays Harbor's marine terminal rail system features more than 50,000 ft. of rail. This provides two continuous loop tracks serving terminals 1, 2 and 4 and the cargo storage facilities. Utilizing this unique state-of-the-art rail infrastructure, unit trains can be continuously loaded or unloaded at AGP storage silos or Pasha Automotive Services processing center.

Highway Access

Interstate 5 via Hwy 101 and US 12

Barge Facilities

Terminal 3 wood chip loading facility and Sierra Pacific for logs, lumber and wood chip loading.

Table 7-3: Future Terminals – Grays Harbor

Terminal Name	Owner	Operator	City/ Area	Purpose
Terminal 1	Port of Grays Harbor	Westway Terminals	Hoquiam	Liquid bulk – crude oil storage
Terminal 3	Port of Grays Harbor		Hoquiam	Existing pier with adjacent uplands (150 acres) planned for dry bulk storage and vessel loading. Site needs rail realignment to allow for unit train receiving and handling. Dry bulk storage facility and ship loader to facilitate the transfer of dry bulk from unit trains to storage and then delivery to vessel. New rail alignment is needed to mitigate impact of unit train traffic on local freight service roads.

Future cargo opportunities

- New Cargo types include: Inbound automotive, liquid bulks and dry bulks
- Anticipate a gradual recovery from 2014 peak with average 8% year over year growth.
- It is anticipated that the new cargo will follow the current modal splits: 75% rail and 25% truck

Existing Access Routes

- Truck – US101, US12 and SR8
- Rail – BNSF 80%, UP 20%
- Barge – Columbia River and Puget Sound
- Pipeline – N/A

Access Issues

- Truck – US12 in East Aberdeen
- Rail – BNSF Junction (Centralia)
- Barge – N/A
- Pipeline – N/A

Access Projects

Current Access Projects include:

- East Aberdeen Mobility Project
  - The freight community is actively seeking funding for Pre design study. Once completed PE, ROW and Construction funds will be sought.
  - Strategic Partners – WSDOT, City of Aberdeen, PSAP railroad, Port of Grays Harbor, Grays Harbor Council of Governments and Grays Harbor County.
  - Co-lead/ project sponsor – City of Aberdeen
  - Current funding gap – $500,000 for pre-engineering study.
  - Total estimated project cost – $22 million

- Past Federal Funding – Alternatives Analysis was funded through STP. No other federal grants initiated to date.
- Key reports/studies that document access project: East Aberdeen Mobility Project Preferred Alternative Selection Report. Project also documented in the Southwest Washington RTPO Regional Transportation Plan and WSDOT 2014 Freight Mobility Plan.
- Project is at the local level and will be integrated into the RTPO TIP as funds become available.
- Project will be integrated into the STIP when federal funds are secured.

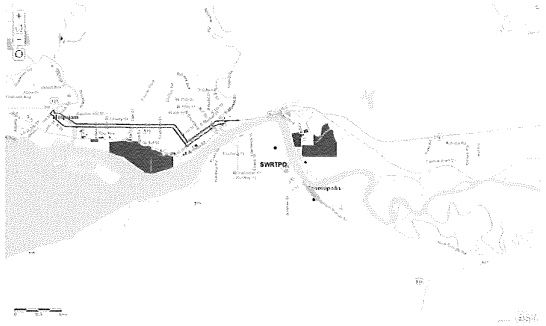
Other Issues

No other critical issues were identified

Table 7-4: Grays Harbor Historical Cargo Statistics (metric tons)

Year	Metric Tons
2011	1,233,845
2012	1,850,465
2013	2,384,242
2014	2,628,515
2015	2,203,943

Figure 7-2: Location of Port Facilities – Grays Harbor



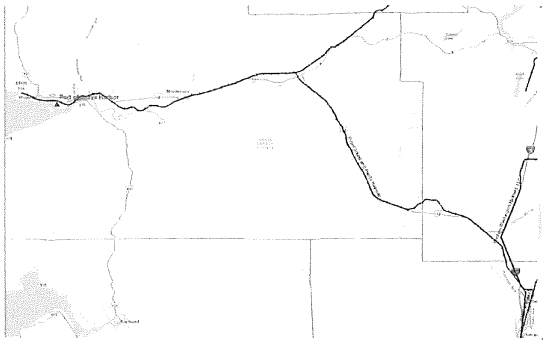


Figure 7-3: Location of Rail Lines – Grays Harbor

Themes Gathered from Interviews

Based upon the interviews the following themes emerged:

Cargo facilities

The ports in Washington state are actively preparing for the future. This includes planning for modernization of aging terminals and facilities, converting aging facilities for use in new lines of businesses, building brand new facilities, and expanding existing facilities to meet anticipated cargo growth.

Port Road and Rail Access- (First and Last Mile issues)

Road and Rail access issues can be segmented into three main categories

- Road access to port facilities through urbanized areas
- Road access to new facilities through rural areas
- Road / rail grade crossing conflicts

Adequate, well maintained road access is important to all of Washington's ports. Without uncongested road access, the port cannot meet customer and community expectations as economic engines for their communities. Most of the sixteen ports interviewed reported that they work in concert with their local jurisdictions to ensure the first and last mile roadways are adequate to meet the needs of their supply chains. Challenges occur when local land use plans or patterns encroach near the ports. This is especially noticeable where the same access routes are used by both local and port traffic. This can be further exacerbated in smaller urbanized areas such as Clarkston and Grays Harbor where retail and port traffic share the same routes. In larger cities like Seattle, the expansive needs of a larger city with its diverse population and businesses provide additional stresses on access and mobility issues.

The development of new facilities put additional pressures on mobility and access. Notable examples include the greenfield developments at Barlow Point in Longview and Kalama Methanol Manufacturing and Exporting Facility (KMMEF) in Kalama. Each of these projects has unique access challenges because of their additional traffic demands on local roads. In some cases, local roads have the capacity to meet future needs. In other cases, such as Barlow Point, new intersections may have to be built and current intersection expanded. Furthermore, capacity of the roads may need to be expanded with additional turning lanes to improve the flow of traffic as growth occurs.

Road and rail grade crossings continue to be an area of conflict within and near ports. Multiple studies are currently underway to help communities and states prioritize crossing improvements. In Washington State the Joint Transportation Committee (JTC) completed a Road-Rail Conflict Study called *The Prioritization of Prominent Road-Rail Conflicts in Washington State*. This project developed a systems-based approach for prioritizing and addressing at-grade crossing impacts and needs on a statewide basis. The 2017 Legislature has directed the Freight Mobility Strategic Investment Board to update the Road-Rail Conflict study using data from the 2017 Marine Cargo Forecast.

A second study is being conducted by the Transportation Research Board (TRB) of the National Science Academies, NHRCP 25-50: *Prioritization Procedure for Proposed Road-Rail*

Grade Separation Projects along Specific Rail Corridors[28]. The TRB study is developing a comprehensive set of criteria that balance economic and social benefits and costs. The goal is to provide a model that can be used by local jurisdictions to prioritize grade crossing separation project investments along a rail corridor.

First and Last mile rail issues were less apparent in the responses to the interviews than expected. This may be due to recent investments by railroads, both mainline and short-lines, that have greatly improved rail access to the ports. Interestingly, large rail projects that have traditionally appeared on rail project lists such as Bullfrog Junction in Tacoma, the Bi-directional running through the Columbia Gorge, the crowning of Stampede Pass were not mentioned as needs by the ports. This may be due to the way the information was gathered for this forecast. Port participants may have interpreted the questions about access to be literally "at the Port gates".

Dredging

Dredging is an issue for Ports throughout the state. Dredging is necessary on an on-going basis to maintain authorized water depth in navigation channels, connecting channels, and marine terminal berths. In some cases, dredging is also needed to deepen channels and marine terminals to handle larger vessels.

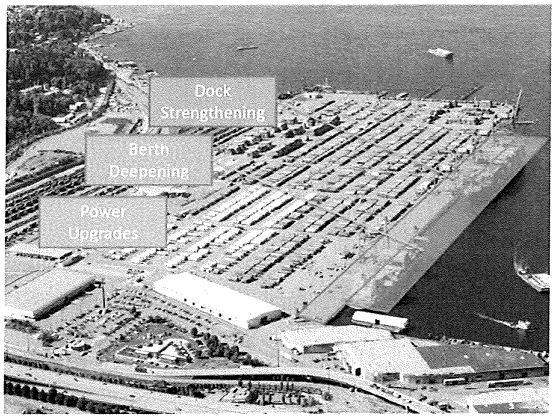
Dredging is paid for by different entities, depending upon where it is performed. Dredging is a federal responsibility when it comes to the operation and maintenance of federal navigation channels, which are significant components of the supply chain in the Pacific Northwest. Deepening projects are considered an improvement, and thus are cost-shared by the federal government with local sponsors. Dredging alongside marine terminal berths and in marinas is the sole responsibility of the local port.

Funding for continued maintenance dredging is a concern for most ports throughout the region, while funding and permitting for deepening projects is more localized. For example, several ports in the Puget Sound need to deepen access channels and marine terminal berths in order to accommodate the next generation of container ships. On the Lower Columbia River, water depth alongside marine terminals is matched to the depth of the deepened navigation channel, so maintenance of the existing channel is a continuing concern.

Examples of Project Types

Modernization of Aging Facilities

Container facilities preparing for "Big ships"



Northwest Seaport Alliance - Seattle Harbor Terminal 5

The NWSA is planning to modernize the 172-acre Terminal 5 to make it ready for mega ships. This includes upgrading the power, dock and berth "understructure to allow a future operator to acquire and install super-post -Panamax cranes on this modernized terminal. This is the last terminal in the north harbor upgrading in order to install the super-post- Panamax cranes. The upgrade is part of the Alliance's long-term growth strategy to move 3.5 million TEU's annually through the north harbor.

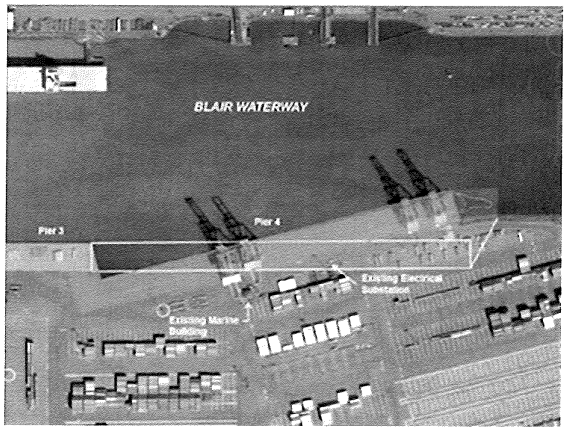
LUBA No. 2020-009
Page 5620

Figure 7-4: Aerial View of Terminal 5



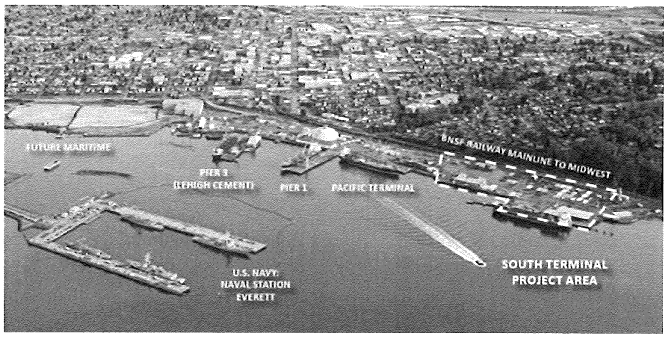
Northwest Seaport Alliance - Tacoma Harbor Terminal 4 Modernization

Terminal 4, part of the Husky Container Terminal, has become outdated in the face of modern containerized ship building trends. With wharfs constructed at odd alignments and cranes unable to handle increasingly larger ships, Terminal 4 needs improvements. The Port began phased improvements of the container terminal by upgrading the adjacent Terminal 3 in 2014. The second phase involves the removal of contaminated sediment under the Terminal 4 Pier; construction is currently underway. The final phase, for which the Port is seeking federal funds, would reconstruct the Terminal 4 pier, aligning it with the neighboring Pier 3 to create one contiguous 2,960-foot-long pier structure capable of simultaneously berthing two ultra-large container ships. The new pier structure will also be designed to accommodate modern 24-container wide, 100-guage cranes needed to work larger vessels.

The planned $113 million upgrades to Terminal 4 will allow the Husky Container Terminal to increase the size of ships it can handle. Today, the terminal can serve ships that carry 6,500 Twenty Foot Equivalent Unit (TEU) containers. After the improvements, the terminal will be able to handle 18,000 TEU vessels with the new cranes, increasing cargo throughput capacity across the pier from about 767,000 TEUs annually to an estimated 1.3 million TEUs. It is the increased throughput that will create the demand for new family wage jobs in the region. This project will be completed in 2018.

LUBA No. 2020-009
Page 5621

Figure 7-5: Aerial View of Terminal 4



Port of Everett - South Terminal Intermodal Modernization

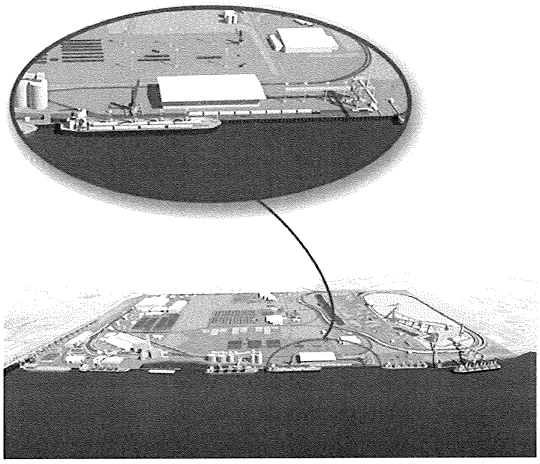
The Port of Everett's South Terminal Intermodal Modernization project will redevelop their south terminal to meet current and future multi-modal freight shipping needs of the region and nation.

This project allows the Port to efficiently and safely serve larger vessels that are currently being chartered by eight shipping lines, in particular Panamax class ships carrying containerized aerospace cargo. Notably, the Port of Everett serves as an extension of the aerospace manufacturing process, and plays a critical role in the just-in-time-delivery schedule. It transports **all** of the oversized parts for the 747, 767 (military and commercial), 777, K-C46 Tanker and soon to be 777X airplane programs. It also serves as a backup facility for the 787 Dreamliner program.

Figure 7-6: Aerial View of the Port of Everett

This project is necessary for the Port to meet the heavier containers being used to transport the airplane parts for the new Boeing 777X program and other breakbulk export cargoes that utilize port facilities. The wharf strengthening is needed for the intermodal transfer of goods from ship to shore, and the rail infrastructure is needed to stage the cargo for transport to the inland states without creating congestion on the BNSF mainline to the Midwest. This project has been fully funded and will begin construction in the fall of 2017.

Modernization of Non-Container facilities



Ports reinvest in infrastructure to remain competitive

Port of Longview – Multi-Cargo Modernization

The Port of Longview's $31.4 million Multi-Cargo Modernization project will reinvigorate two general cargo docks into a premiere west coast heavy-lift and bulk cargo handling facility. This project is vital to strengthening local infrastructure that moves cargo in support of international trade for the benefit of our local, regional and national economies.

The project will rehabilitate and modernize 1,500 lineal feet of Berth 6 & 7 bulk and breakbulk cargo facilities to optimize increased cargo handling omni-dock operations. The terminal improvements include installation of a dual wastewater and stormwater collection system, strengthening decking and piling to withstand dual pick, breakbulk heavy loads, upgrading on-dock rail systems, and deepening the berths to take advantage of the recently deepened federal navigation channel.

Figure 7-7: Port of Longview Modernization

Conversion of Aging Facilities to New Lines of Business

Ports increase economic vitality through new opportunities

Port of Port Angeles - Marine Trades Industrial Park

The Marine Trades Industrial Park or (MTIP) includes existing businesses west of Cedar Street and south of Marine Drive and the former K-Ply site, all located along the industrial portion of the Port Angeles waterfront. Currently the Port is in Phase 1 of the master planning process to identify projected land and infrastructure needs to accommodate projected growth based on interviews with owners of existing key businesses and Port staff. The master plan developed as part of Phase 1 of the master planning effort will identify alternatives for future development of the entire Marine Trades Area (MTA). The MTA is an approximately 77-acre area along the Port Angeles waterfront that includes Terminals 1 and 3. The boundary includes the "K-Ply Site", an 18-acre parcel at the east end of the MTA that was recently the site of a soil contamination cleanup project. Cleanup was

completed in late spring of 2016, and the site is now ready for development as the Marine Trades Industrial Park (MTIP).

The MTA includes several existing businesses, including Westport Marine, Platypus Marine, Vigor Industrial, and a few smaller businesses that are either marine-related or general commercial in nature. These businesses have communicated to the Port that one of their top priorities is the development of a new boat wash down facility that will enhance their existing operations and attract new business to the Port. Currently, the Port is studying this requested improvement.

First and Last Mile Access Challenges

Road access to port facilities through urbanized areas

Northwest Seaport Alliance - Seattle Harbor Terminal 5 Access Improvements

One example of road access challenges is truck access to the modernized NWSA North Harbor Terminal 5. In the redevelopment of T-5 to a modern terminal that can handle up to 18,000 TEU ships, the port realizes that the current road access to T-5 must be improved. In their Environmental Impact Study, three alternatives were evaluated:

- Alt 1- no action 647K TEUs / yr.- 70% trucked off dock
- Alt 2 -1.3 M TEUs / yr. -50% trucked off dock 650K TEUs
- Alt 3 -1.7 M TEUs /yr. – 50% trucked off dock 850K TEUs

The port is studying proposed mitigation options for anticipated increases in truck traffic to and from the terminal. Alternatives include the closure of the Terminal 5 leg of the 5-legged intersection and upgrading signals to rail yards on Lower Spokane St & East Marginal Way.

More on the project can be found at http://www.portseattle.org/Environmental/Environmental-Documents/SEPA-NEPA/Pages/default.aspx

Port of Clarkston – Access Improvements

In smaller urbanized areas, such as Clarkston, ports continue to have road access issues. The Port of Clarkston identified three road access challenges to get trucks to and from their terminals:

- Highway 12 Bridge into Idaho is a major chokepoint for freight (AP1)
- Congestion North (at 4 way stop) at 5th St and Fair St. This is the intersection in front of Walmart and Costco. (AP2)
- 5th and Bridge Street- at this intersection there are continuous conflicts between transit buses and truck traffic traveling to the ports terminals.
- 6th St. in Clarkston is a challenge for log trucks (AP4)

All four access points are outside of the port's ownership, so the port must rely on local and state agencies to prioritize these projects and fund solutions.

Road Access to New Port Facilities through Rural Areas

Port of Kalama – Access Improvements

- Kalama Methanol Manufacturing and Exporting Facility (KMMEF)

Rural areas have many of the same challenges as urban areas. In the Port of Kalama, the development of the Kalama Methanol Manufacturing and Exporting Facility (KMMEF) has

prompted the port to evaluate road access issues near the site. They are examining access issues for both the construction, and post construction periods.

Road Access and Modal Conflicts

Port of Grays Harbor – East Aberdeen Mobility Project

In Aberdeen, traffic congestion caused by Port of Grays Harbor rail traffic closes off access to a main retail hub for up to 30 minutes, multiple times per day. The community and the port are jointly working on solutions to this access challenge. Known as The East Aberdeen Mobility Project (formerly Wishkah Mall Access), one identified solution is the construction of a grade separation over the PSAP railroad tracks to allow separation of rail and road.

Future Modal Conflicts

Port Longview – Barlow Point

The Port of Longview is in the final planning process for the development of 280 acres of greenfield properties along the Columbia River. Initial master plans show that road and rail investments will need to be made to ensure good road and rail access to the property. The final design of these access improvements will be dependent on the final customer and their respective use of the property.

Port Infrastructure Project List for 16 Participating Ports

The development of the list of port related projects began with the interviews of the 16 participating ports during the summer of 2016. This effort was integrated with the FMSIB / WSDOT effort to prepare a prioritized project list required under FAST Act for distribution of the National Highway Freight Program formula money.

Due to the specific planning processes identified in FAST ACT, Cities, counties, and ports were to coordinate with MPOs and RTPOs before submitting projects to the 2016 list. This is a new, and different process for many Washington ports. Although, some of the ports are very active in their local transportation planning organizations, many are not. Thus, not all port projects were included in the lists that were submitted to WSDOT from their respective planning organizations.

To help with this change in the planning process, the consultant team provided guidance to each port on how to get their projects into the WAFAC list. Most were successful; however, for a variety of reasons, some projects failed to get onto the WAFAC list.

There is continuous work underway to better communicate the process, and ensure that the process continues to evolve and improve over time. The project list included in this study (*Appendix B*) is a combination of (a) projects that ports self-submitted,(b) port related projects that are on the WAFAC list and (c) projects submitted by parties other than ports (e.g. local governmental agencies ,cities and counties). It is the intent of this study to be as inclusive as possible when identifying projects that are important to ports that participated in this study.

Table 7-5: Summary of Port Infrastructure Projects

Port	Road	Rail	New Terminal Facilities	Terminal Modernization	Terminal Infrastructure	Dock	Dredging	Bus. Park Infrastructure	Buildings	Prop. Purchases	ITS	Grade Separations	Studies - Feasibility	Studies - Road/ Rail	Summary
Anacortes							1								1

Funding Challenges

Most of the project on the Port Infrastructure Project list lack full funding. There are always many more project needs than available dollars. As has been the case for many years, there are many more good projects that need funding than funds available. To try to focus federal investments into projects that align with Federal and State priorities, the Fixing America's Surface Transportation (FAST) Act, passed in December 2015, provides a structured project identification process. It is recommended that ports become educated on the process, and actively engage as soon as possible.

At the federal level, progress has been made through the enactment of the FAST Act to provide states and local officials with guidance on federal funding priorities. This includes the planning requirements as detailed above regarding State Freight Plans and state Freight Advisory Committees. The result of the FAST Act is that the key criteria for accessing Federal funds is that projects align with state and federal priorities, not just a local priority. This may put additional pressure on smaller ports and communities that have traditionally had a hard time competing at the national level. There are two avenues to federal funding under the National Highway Freight Program: formula money allocated to the state and then assigned to projects within the state and FASTLANE discretionary grants.

National Highway Freight Formula Program Eligibility

The FAST Act established the National Highway Freight Program, which provides states with formula funding to be used for projects on the National Highway Freight Network. Washington State expects to receive about $20 million per year from 2016 to 2020. Funds apportioned to the State for the national highway freight program may be obligated to carry out one or more of the following:

i. Development phase activities, including planning, feasibility analysis, revenue forecasting, environmental review, preliminary engineering and design work, and other preconstruction activities.
ii. Construction, reconstruction, rehabilitation, acquisition of real property (including land relating to the project and improvements to land), construction contingencies, acquisition of equipment, and operational improvements directly relating to improving system performance.
iii. Intelligent transportation systems and other technology to improve the flow of freight, including intelligent freight transportation systems.
iv. Efforts to reduce the environmental impacts of freight movement.
v. Environmental and community mitigation for freight movement.
vi. Railway-highway grade separation.
vii. Geometric improvements to interchanges and ramps.
viii. Truck-only lanes.
ix. Climbing and runaway truck lanes.
x. Adding or widening of shoulders.
xi. Truck parking facilities eligible for funding under section 1401 of MAP-21 (23 U.S. Code §137).
xii. Real-time traffic, truck parking, roadway condition, and multimodal transportation information systems.
xiii. Electronic screening and credentialing systems for vehicles, including weigh-in-motion truck inspection technologies.
xiv. Traffic signal optimization, including synchronized and adaptive signals.
xv. Work zone management and information systems.
xvi. Highway ramp metering.
xvii. Electronic cargo and border security technologies that improve truck freight movement.
xviii. Intelligent transportation systems that would increase truck freight efficiencies inside the boundaries of intermodal facilities.
xix. Additional road capacity to address highway freight bottlenecks.
xx. Physical separation of passenger vehicles from commercial motor freight.
xxi. Enhancement of the resiliency of critical highway infrastructure, including highway infrastructure that supports national energy security, to improve the flow of freight.
xxii. A highway or bridge project, other than a project described in clauses (i) through (xxi), to improve the flow of freight on the National Highway Freight Network.

xxiii. Any other surface transportation project to improve the flow of freight into and out of a facility, including projects (i) within the boundaries of public or private freight rail or water facilities (including ports); and (ii) that provide surface transportation infrastructure necessary to facilitate direct intermodal interchange, transfer, and access into or out of the facility.

National Highway Freight Program Project Screening

Projects published on this list are required to meet the following screening requirements:

- **Network Screening**: Projects are required to be located on the National Highway Freight Network, which is currently in development (the Primary Highway Freight System and remainder of Interstate system have been established; Critical Urban and Rural Freight Corridors are to be designated by September). A state may obligate apportioned funds for projects on any component of the National Highway Freight Network. Projects that do not meet these requirements will not advance to the next screening for consideration.
- **Regional Screening**: Projects are required to be supported by the regional transportation planning organization. If a project is not in a current regional plan, a letter from the metropolitan or regional planning organization must be submitted with the project. Tribal projects may be submitted directly to WSDOT; regional coordination is encouraged. Projects that do not meet these requirements will not advance to the next screening for consideration.
- **Scheduling Screening**: Projects are required to identify the scheduled year that funding is expected to be used. The program is funded through FY2020 under the FAST Act, and projects must be scheduled no later than June 30, 2020, to become eligible for funding. For construction projects, this is the year for construction. If projects are not ready for construction, the scheduled year for development phase activities should be provided. Projects scheduled beyond June 30, 2020 will be considered long-range investments without identified federal funding.
- **Funding Screening**: Projects are required to demonstrate fiscal constraint and quantify the gap in current funding. Fund sources and commitments must be identified and documented as part of the submission. Updated project costs were to be provided in state FY2017 dollars. Projects that did not meet these requirements were not considered.

National Highway Freight Program Project Prioritization

The prioritized project list was delivered to the legislature for funding consideration. Submitted projects were prioritized based on readiness. WAFAC categorized projects eligible to use formula funding, based on three tiers.

- Tier 1 will be composed of screened projects that are scheduled July 2016 to June 2018.
- Tier 2 will be composed of screened projects that are scheduled July 2018 to June 2020.
- Tier 3 will be composed of screened projects that are scheduled July 2020 to June 2035.

Specifically, federal funding available under FASTLANE discretionary grants must align with the following requirements:

Nationally Significant Freight & Highway Projects Program Requirements

The FAST Act also established the Nationally Significant Freight & Highway Projects Program, administered as the INFRA (Infrastructure for Rebuilding America) grant program. Eligible project costs include:

1) development phase activities, including planning, feasibility analysis, revenue forecasting, environmental review, preliminary engineering and design work, and other preconstruction activities; and
2) construction, reconstruction, rehabilitation, acquisition of real property (including land related to the project and improvements to the land), environmental mitigation, construction contingencies, acquisition of equipment, and operational improvements directly related to improving system performance.

The US Secretary of Transportation may select a project for funding under this section only if the Secretary determines that:

1) the project will generate national or regional economic, mobility, or safety benefits;
2) the project will be cost effective;
3) the project will contribute to the accomplishment of one or more of the national goals described under section 150 of Title 23, United States Code;
4) the project is based on the results of preliminary engineering;
5) with respect to related non-Federal financial commitments:
   - one or more stable and dependable sources of funding and financing are available to construct, maintain, and operate the project; and
   - contingency amounts are available to cover unanticipated cost increases;
6) the project cannot be easily and efficiently completed without other Federal funding or
7) financial assistance available to the project sponsor; and
8) the project is reasonably expected to begin construction not later than 18 months after thedate of obligation of funds for the project.

Nationally Significant Freight & Highway Projects Program Screening

Projects published on this freight grant list will need to meet the following criteria:

Network Screening: Eligible projects include the following only:

- Highway freight projects on the National Highway Freight Network;
- Highway or bridge projects carried on the National Highway System;
- Railway-highway grade crossing or grade separation projects; or
- Freight intermodal or rail projects.

Regional Screening: Projects are required to be supported by the regional transportation planning organization. If a project is not in a current regional plan, a letter from the metropolitan or regional planning organization must be submitted with the project. Tribal projects may be submitted directly to WSDOT; regional coordination is encouraged.

Funding Screening: Projects must be reasonably expected to begin construction not later than 18 months after the date of obligation of funding. The estimated end date of the final Notice of

Funding Opportunity for the INFRA grant program has a projected latest date of spring 2020; the program is funded at approximately $900 million per year.

Minimum project costs for large projects is $100 million; the funding gap is required to be at least $25 million. For small projects, less than $100 million, the funding gap is required to be at least $5 million.

Projects are required to demonstrate availability of sufficient funds (Federal, state, local, and private), less the grant request, to cover at least 40 percent of total project costs (INFRA grants may be used for up to 60 percent of the future eligible project costs, and total federal assistance may be up to 80 percent of project costs). Fund sources and commitments must be identified and documented as part of the submission. Updated project costs should be provided in state FY2017 dollars.

Summary

As detailed in the Port Infrastructure Project list, ports in Washington have a multitude of investment needs. Finding funding for these investments will continue to be a challenge because local port and communities do not have the resources to fully self-fund these improvements. With the need to find outside funding for port projects, it has become mandatory that ports actively participate in their local and regional planning organizations and planning processes. The FAST Act requires listing of projects in these broad-based regional and state planning activities to be eligible for new federal funding.

Prior to the FAST Act, Washington ports could independently do their planning under the Washington State Growth Management Act. With the enactment of FAST Act at the federal level, it is no longer a choice to participate in regional transportation planning efforts if a port is interested in pursuing federal funding for a port or port-related project in the future.

Table 7-6: Summary of Port Infrastructure Projects

Proj #	Port Priority	WSDOT No.	Project Name	Location Description	Latitude / Longitude	Brief Description	Improve Type	Port District	Project Owner	Submitting Authority	Ref.	PE Year	ROW Year	Const. Year	Project Cost / Funding Gap	% Gap
1	high		Pier 2 Export Initiative	Anacortes	48.521944 / 122.612778	The Port's primary bulk cargo facility, Pier 2 will require dredging to deepen its draft from -36.5' MLLW to -45 MLLW to accommodate larger, Panamax sized vessels and retain shipping and family-wage jobs. This project will complete the following five items: 1. Relocation of the facility's manufacturing and storage structure 2. Purchase and operation of a new mobile bulk shiploader 3. Repairs to the Pier's bulkhead wall 4. Relocation/reinstallation of the existing breasting dolphins 5. Berth deepening to allow larger ships to berth at the Pier and leave fully loaded	Dredging/ Terminal Infrastructure	Anacortes	Port of Anacortes	Port of Anacortes		2017	N/A	2017-2018	$11,801,200 / $6,767,305	57%
2			Squalicum Waterway Maintenance Dredging	Bellingham		The USACE has not performed maintenance dredging in the Squalicum Waterway since 2004, and heavy sedimentation has since caused a navigation hazard which threatens continued use of the waterway by commercial vessels loading and off-loading cargo. Commercial vessels have recently grounded in the Squalicum Waterway and the Puget Sound Pilots Association has warned about this navigation hazard. Cargo vessels operating in the Squalicum Waterway are currently limited by tidal restrictions. The need for maintenance dredging grows increasingly urgent to protect the over 2,000 jobs and hundreds of millions of dollars in gross annual revenue which rely on a maintained federal navigation channel.	Dredging	Bellingham	US Army Corp of Engineers/ Port of Bellingham	Port of Bellingham		2017	N/A	2018-2019	/ $750,000	
3	1		Richland Inland Port	Richland		The City of Richland and the Port of Benton have commissioned a joint Rail Master Plan to assess the feasibility of an inland container port. The Richland Inland Port will provide a transportation option to Eastern Washington agricultural exporters that face long dray operations to reach ports in Seattle and Tacoma. This project includes rail and road improvements and will have multiple phases. The rail serves both class I railroads.	Rail	Benton	Port of Benton & City of Richland	Port of Benton	-	2018 Phase 1 Tie replacement, Phase 2 Rail upgrades, Phase 3 Track resurfacing	N/A	2018 Phase 1 Tie replacement, 2018 Phase 2 Rail upgrades, 2019 Phase 3 Track resurfacing	$2.9m (phase 1), Rail upgrade taking rail from 90# to 136# $4.8m (phase 2), Track resurfacing $705k (phase 3) / $000,000	100%

29		43	Industrial Way / Oregon Way Intersection Project	Project is located on State Route (SR) 432, a designated National Highway System (NHS) route.		Project is located at the intersection of Industrial Way (State Route (SR) 432) and SR 433, a critical connection of two Highways of Statewide Significance that support significant passenger and freight truck movement. Intersection is currently operating close to Level of Service (LOS) E and is projected to fail (LOS F) in 2040.	Road	Longview	Cowlitz County	CWCOG	2016-2019 RTIP/STIP	2016	2018	2020	$95,000,000 / $7,559,304	8%
30		40	SR 432 Corridor Improvements - Phase II	The project is located on SR 432 between MP 7.04, California Way and SR 432 Intersection, and MP 7.62, SR 432 off-ramp; and on SR 411 at MP 0.03, SR 432 on-ramp.	46.115836 / -122.931154	This project will relieve congestion, increase capacity, and improve safety on the SR 432 Corridor at two locations: SR 432 / SR 411 interchange off-ramp and on-ramp; and SR 432 / California Way intersection. This corridor is critical to the economic vitality of the region and the state, providing access to intermodal businesses and the Port of Longview. The SR 432/ SR 411 interchange improvements will increase capacity and safety by constructing a second left turn lane from the westbound SR 432 off-ramp to SR 411/3rd Avenue, and improve efficiency and increase safety for eastbound traffic by realigning the eastbound on-ramp to SR 432. Improvements to the SR 432 / California Way intersection will eliminate closely spaced, offset intersections by realigning California Way to create a single four-legged intersection at SR 432 / Industrial Way / California Way. Eliminating the offset will result in more efficient signal operation and turning movements, reducing travel time and congestion. Realignment of California Way will require right-of-way acquisition of 4 parcels and relocation of three existing businesses. Two existing railroad crossings will be widened to accommodate the new alignment.	Road	Longview	City of Longview	CWCOG: Longview-Kelso-Rainier MPO	http://industrialoregonway.org/wp-content/uploads/2015/08/SR_432_FINAL%20Concept%20Development%20Report_Combined.pdf	2017	2017	2020	$9,500,000 / $5,320,000	56%

Background

The objective of Task 2 of ICF's contract with Oregon DEQ is to update the 2014 illustrative compliance scenarios, develop new 2017 illustrative compliance scenarios to represent the available compliance options from 2016-2025, and create a Scenario Adjustment Tool (SAT) so DEQ can perform minor periodic update to the scenarios. This report presents the methodology and results for the 2017 illustrative compliance scenarios.

Introduction

In 2014, ICF developed four compliance scenarios based on two fuel scenarios (alternative vehicle technologies vs biofuel blending) and two different diesel baselines (B2 vs B5). Table 1 below shows the compliance scenario matrix.

Compliance Scenarios	Scenario 1 – Advanced Vehicle Technology	Scenario 2 – Higher Biofuel Blending
B2 Diesel Baseline (2010)	1 – B2	2 – B2
B5 Diesel Baseline (2015)	1 – B5	2 – B5

Table 1. 2014 Compliance Scenarios

The 2017 Illustrative Compliance Scenarios build on the 2014 scenarios. Since DEQ moved forward with a B5 baseline, for the rest of the report we will remove the B2 and B5 nomenclature and call the scenarios – Scenario 1 and Scenario 2. The underlying premise of each scenario remains the same where Scenario 1 relies on advanced vehicle technologies (e.g. plug-in electric vehicles (PEVs), natural gas vehicles (NGVs), and heavy-duty hybrid electric vehicles (HEVs)) and Scenario 2 relies on a higher blending of biofuels.

Also added to this analysis is Scenario 3. Unlike Scenarios 1 and 2 which look at the minimal avenues to compliance (total credits balancing total deficits) over the ten year compliance period, Scenario 3 looks past 2025 to 2026 and 2027 where a 10% carbon intensity reduction is maintained. Scenario 3 also limits credit banking in the early and uses a hybridized approach towards the potential across alternative fuels to contribute to carbon intensity reductions and generation of credits.

VISION Modeling

ICF updated the Oregon VISION model with the AEO2016 Base Case VISION model projections for values including annual vehicle sales and new vehicle fuel economy. This updated model was used for the 2017 Illustrative Compliance scenarios. Consistent with the previous analysis, US sales projections for light- (autos and trucks separately), medium-, and heavy-duty vehicles were scaled based on the latest 10 years (2006-2015) of Oregon's

proportion of US sales. Table 2 below shows Oregon's portion of US sales based on the updated AEO2016 projections.

Vehicle Class	10yr Average of Oregon Portion of AEO2016 US Sales
Light-Duty Autos	1.08%
Light-Duty Trucks	0.93%
Medium-Duty Trucks (Class 3-6)	2.35%
Heavy-Duty Trucks (Class 7-8)	1.36%

Table 2. Oregon Portion of US Sales by Vehicle Class

The VISION model utilizes national data to determine vehicle life expectancy and annual vehicle miles traveled (VMT) that ultimately combine with the Oregon fleet projections to determine fuel consumption. This data may not be consistent with Oregon's vehicle fleet and resulting projections for diesel fuel are consistently low due to the high volume of pass through truck traffic. Calibration of the model is required to match historical Oregon fuel consumption with VISION results. The VISION model was calibrated by scaling it to actual VMT so that approximate historical fuel consumption match as closely as possible.

The figures below show the results from calibrating the light-duty gasoline consumption and heavy-duty diesel consumption with a vehicle miles traveled (VMT) scaling factors of 1.01 and 1.66, respectively. The figures also includes the adjusted fuel consumption projections from the updated 2014 illustrative compliance scenarios for comparison.

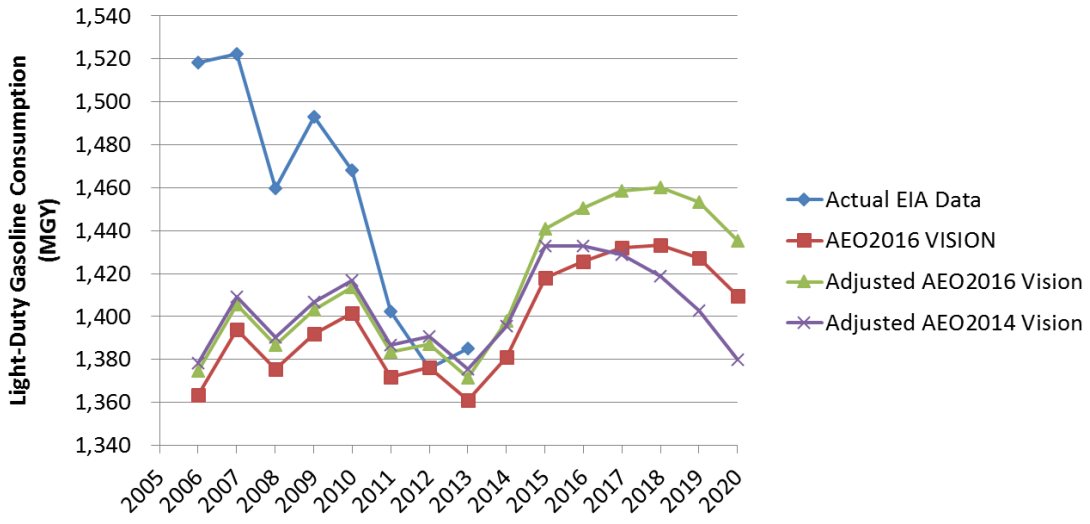

Figure 1 Actual Oregon and VISION Projected Light-Duty Gasoline Consumption

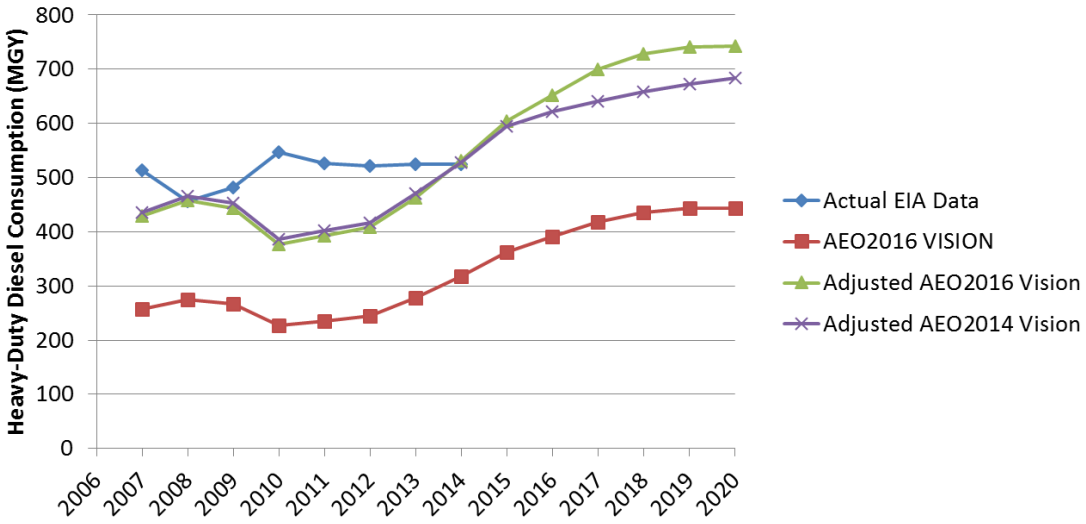

Figure 2 Actual Oregon and VISION Projected Heavy-Duty Diesel Consumption

Figures 1 and 2 above show that AEO2016 has more aggressive sales projections for light, medium and heavy duty vehicles than AEO2014 resulting in increased projected fuel consumption.

Clean Fuels Standards

The gasoline and diesel standards for 2016-2025 are shown in the table below.

Fuel	Gasoline Standard (gCO2e/MJ)	Diesel Standard (gCO2e/MJ)
2016	98.37	99.39
2017	98.13	99.14
2018	97.63	98.64
2019	97.14	98.15
2020	96.15	97.15
2021	95.17	96.15
2022	93.69	94.66
2023	92.21	93.16
2024	90.73	91.67
2025	88.76	89.68
2026[1]	*88.76*	*89.68*
2027	*88.76*	*89.68*

Table 3. Gasoline and Diesel Standards

Vehicle Populations

PEV Vehicle Populations – Zero Emission Vehicle (ZEV) Mandate

The California Air Resources Board recently published an Advanced Clean Cars Midterm Review[2]. In this review ARB developed three compliance scenarios for California and for Section 177 (S177) ZEV States, states that are administering the California ZEV requirements pursuant to section 177 of the federal Clean Air Act. There are currently nine (9) S177 states: Connecticut, Maine, Maryland, Massachusetts, New Jersey, New York, Oregon, Rhode Island, and Vermont.

Table 4 compares the total plug-in electric vehicle (PEV), battery electric vehicle (BEV) and plug-in hybrid electric vehicle (PHEV) sales from 2011-2016 as tracked by ZEV Fact sales dashboard[3].

[1] For Scenario 3, it is assumed that the 2025 standard of a 10% carbon intensity reduction remains in place.
[2] https://www.arb.ca.gov/msprog/acc/acc-mtr.htm
[3] http://www.zevfacts.com/sales-dashboard.html

State	Total PEV Sales	BEV Sales	PHEV Sales
CT	4,903	1,832	3,070
ME	1,134	203	931
MD	7,863	2,892	4,971
MA	8,467	3,262	5,205
NJ	10,946	3,991	6,955
NY	19,274	5,497	13,777
OR	10,825	6,600	4,225
RI	841	236	605
VT	1,521	305	1,216
OR % of S177 States	16.5%	26.6%	10.3%

Table 4. 2011-2016 ZEV Sales from ZEV Facts for S177 States

The results from the three scenarios developed by ARB for the S177 States are shown in Table 5 below. The names of the scenarios are Mid Range, Low Tech and High Tech.

Year	Mid Range Scenario		Low Tech Scenario		High Tech Scenario	
	BEV Sales	PHEV Sales	BEV Sales	PHEV Sales	BEV Sales	PHEV Sales
2018	9,863	58,654	3,075	27,860	8,703	45,498
2019	18,743	72,614	7,375	36,767	17,712	59,598
2020	29,505	92,374	13,702	65,734	29,320	72,356
2021	39,078	105,304	9,962	73,569	41,810	81,066
2022	42,699	109,491	14,391	88,042	44,891	90,212
2023	48,698	119,000	16,862	98,286	52,327	97,958
2024	54,081	127,766	19,208	108,163	60,452	105,116
2025	59,200	136,668	21,548	118,308	68,891	112,311

Table 5. ARB Forecasted Annual PEVs Sales for S177 States

The Low Tech Scenario assumes a lower percentage of auto makers are making only ZEVs than the High Tech Scenario resulting the Low Tech Scenario relying heavily on PHEVs and increased used of banked credits. Since over 16% of total S177 PEV sales have occurred in Oregon but over 26% of BEV sales have been in Oregon, ICF made the assumption to apply Oregon's share of current PEV sales to the High Tech Scenario to forecast Oregon's PEV sales from the ZEV Mandate.

Table 6 below shows Oregon forecasted PEV sales and their percentage of forecast light-duty vehicle sales. For Scenario 3, ICF forecasted 2026 and 2027 sales assuming a similar increase in annual sales as from 2024 to 2025.

Year	Oregon PEV Forecast		% of Light-Duty Vehicle Sales
	BEV Sales	PHEV Sales	
2018	1,432	7,488	5%
2019	2,915	9,809	7%
2020	4,825	11,908	10%
2021	6,881	13,342	12%
2022	7,388	14,847	13%
2023	8,612	16,122	15%
2024	9,949	17,300	16%
2025	11,338	18,484	17%
2026[4]	*12,921*	*19,749*	*19%*
2027	*14,724*	*21,101*	*21%*

Table 6. Oregon Forecasted Annual PEVs Sales Resulting from the ZEV Mandate

ICF assumed that there will be a 50/50 split between PHEV10 and PHEV40. An important update from AEO2016 that will have an effect on the scenarios is an update to the percent vehicle miles traveled (VMT) that PHEV40 operate in all electric mode. In AEO2014 the all-electric mile VMT was 54% but AEO2016 has an updated value of 62%. Each PHEV40 will now consume 15% more electricity and 17% less gasoline.

Medium- and Heavy-Duty Vehicle Populations

In Scenario 1, the assumption is made that HEVs achieve 10% sales penetration and natural gas 6.5% sales penetration in the medium- and heavy-duty markets by 2025. The business as usual (BAU) case and Scenario 2 do not included medium- and heavy-duty HEVs. Scenario 3 increases the sales penetration of HEVs from 10 to 12% and natural gas vehicles from 6.5% to 8% in the medium- and heavy-duty markets from 2025 to 2027.

Additional Electric Vehicles

Credits from other sources of electricity including transit buses, forklifts and fixed guideway were also included in the scenarios. The credits included were using a similar methodology to the Task 3 Additional Electrification report, but instead of a 2015 baseline, the credits were calculated using a 2012 baseline for technologies using a fuel displacement credit calculation methodology for forklifts and fixed guideway.

For Scenarios 1 and 2, the conservative assumption was made of 100 electric transit buses in Oregon in 2025 and linear interpolation from 5 transit buses this year and an estimated 15 total electric transit buses in 2018. For Scenario 3, a more aggressive assumption was made of 150

[4] ICF forecasted values for 2026 and 2027. Values 2018 – 2025 are based on the Advanced Clean Cars Midterm Review.

electric transit buses by 2022 and continuing that growth till 2027 where there would be 320 total electric transit buses.

Table 7 below includes the credits generated from transit buses starting in 2017 (using an EER of 2.7 in 2017 and 4.2 from 2018+), credits from fixed guideway starting in 2018 and credits from forklifts in 2019.

Year	Transit Buses – Scenarios 1/2	Transit Buses – Scenario 3	Forklifts	Fixed Guideway	Scenario 1/2 Total	Scenario 3 Total
2017	265	265			265	265
2018	1,583	1,583		18,741	20,324	20,324
2019	2,829	5,134	81,196	18,847	102,872	105,177
2020	4,028	8,572	90,311	18,792	113,131	117,675
2021	5,190	11,907	91,922	18,732	115,844	122,561
2022	6,270	14,928	92,813	18,509	117,591	126,250
2023	7,295	17,896	93,639	18,272	119,205	129,807
2024	8,266	20,713	94,438	18,028	120,732	133,179
2025	9,201	23,188	94,374	17,605	121,181	135,167
2026	N/A	26,316	99,224	17,845	N/A	143,386
2027	N/A	29,445	104,289	18,088	N/A	151,821

Table 7. Annual and Total Credit Generation Potential from Fixed Additional Electricity

Fuel Availability

Carbon Intensity

Table 8 on the following page shows the carbon intensities and gasoline and diesel fuel standards utilized for the 2017 illustrative compliance scenarios which are consistent with the carbon intensities utilized for the updated 2014 illustrative compliance scenarios.

Fuel	Carbon Intensity (gCO2e/MJ)
Gasoline Blendstock	100.77
ULSD	101.65
NW Corn Ethanol	53.81
MW Corn Ethanol	69.89
Low CI Corn Ethanol	57.58
Sugarcane Ethanol	51.04
MW Soybean BD	58.25
NW Canola BD	57.84
NW Yellow Grease BD	18.12
Waste Oil RD	19.25
NW Tallow BD	37.93
Tallow RD	19.25
CNG	79.93
Electricity	120.27
RNG (CNG)	40.00
Corn Oil BD	36.89
Sorghum Ethanol	75.00

Table 8. Oregon Clean Fuel Program Carbon Intensities

Assumptions for Fuels that Substitute for Gasoline

For ethanol, there is corn ethanol production capacity of over 200 million gallons per year within the Pacific Northwest Region consisting of Oregon, Washington and Idaho. These producers fall into the category of NW corn ethanol with carbon intensities ranging from 53.81-54.00 g/MJ. In the scenarios below, the total volume of NW corn ethanol consumed never exceeds 103 MGY so there is ample supply in the region.

For renewable natural gas (RNG), the limitation for consumption in Oregon is dependent on demand and not supply. There is sufficient supply from landfills, wastewater treatment plants and other sources like waste feedstock digesters in the U.S. to achieve demand. In 2016, RNG generated over 188 million D3 RINs[5] which are equivalent to approximately 114 million diesel gallon equivalents (DGE). California consumed 87 million DGEs of that volume leaving almost 30 million DGEs available to generate CFP credits in Oregon.

Table 9 below presents the assumptions for fuels that substitute for gasoline.

[5] https://www.epa.gov/fuels-registration-reporting-and-compliance-help/2016-renewable-fuel-standard-data

Fuel	Assumption
Corn Ethanol, NW	Pacific Ethanol Columbia has a production capacity of 40 MGPY and all of it would stay in Oregon.
Corn/Sorghum Ethanol, Low CI	An additional 160 MGPY of capacity exists in the Pacific NW region in addition to the Pacific Ethanol Columbia facility and up to 150 MGPY of low CI corn ethanol would be available to Oregon.
Corn Ethanol, MW	The balance of ethanol needed will be MW corn.
Sugarcane Ethanol	Up to 50 million gallons per year of sugarcane ethanol would be available to Oregon.
Cellulosic Ethanol	Will be consumed if necessary to meet the standard.
Electricity	For Scenario 1, all PHEVs to be PHEV40s.
Renewable Natural Gas (RNG)	For Scenario 1, up to 90% of natural gas consumption could be from RNG. For Scenario 2, up to 99% could be from RNG.
Natural Gas	The balance of natural gas consumed will be fossil.
Propane	Maximum of 1% of total natural gas consumption.

Table 3. Fuels That Substitute for Gasoline

Assumptions for Fuels that Substitute for Diesel

For biodiesel, the national biodiesel production capacity is in excess of 2.3 billion gallons per year[6]. In 2016, 1.568 billion gallons of biodiesel were produced, with approximately 10% from canola oil, 10% from corn oil, 10% from animal fat or tallow and 12.6% from waste grease or used cooking oil[7].

Table 10 presents the assumptions for fuels that substitute for diesel.

[6] https://www.eia.gov/biofuels/biodiesel/production/biodiesel.pdf
[7] https://www.eia.gov/biofuels/biodiesel/production/table3.pdf

Fuel	Assumption
Canola Oil Biodiesel	Maintain the current canola portion of biodiesel consumption of 77%.
Waste Grease/UCO Biodiesel	Maintain the current waste grease/used cooking oil portion of biodiesel consumption of 11%.
Soy Biodiesel	Will be the balance biodiesel after accounting for the other feedstocks.
Corn Oil Biodiesel	Will be consumed if necessary to meet the standard.
Renewable Diesel	A conservative assumption was made to remain at a an average statewide 2% blend with a maximum of 10 million gallons per year from tallow and the balance from waste oil
Renewable Natural Gas (RNG)	Up to 90% of natural gas consumption could be from RNG.
Natural Gas	The balance of natural gas consumed will be fossil.
Propane	Maximum of 1% of total natural gas consumption.

Table 4. Fuels That Substitute for Diesel

Overview of Compliance Scenarios

Based on the assumptions described above for the fuels available and vehicle populations, ICF developed two compliance scenarios that achieve compliance with the Clean Fuels Program by balancing the cumulative deficits and credits over the 10 year compliance period. Scenario 3 is a hybrid of Scenario 1 (advanced technology) and Scenario 2 (high biofuels) that minimizes early banking of credits while looking at the compliance requirements for 2026 and 2027 and looks at the potential of all technologies and fuels to contribute without the constraint of balancing total deficits and total credits at the end of 2025.

Table 11 summarizes the assumptions for each scenario.

Maximums for Scenario Assumptions	2017 Scenario 1 (Advanced Technology)	2017 Scenario 2 (High Biofuels)	2017 Scenario 3 (Hybrid)
Ethanol: • Max ethanol blend is E15 • NW Corn - 40 MGPY max • Low CI Corn - 150 MGPY max • Sugarcane - 50 MGPY max • Max 85% of FFV miles on E85	• Maintained E10 blend rate • 40 MGPY of NW corn • Balance from low CI corn ethanol (max 102 MGPY) • No sugarcane ethanol	• Maintained E10 blend rate • 40 MGPY of NW Corn • Low CI corn ethanol when needed • No sugarcane ethanol	• Maintained E10 blend rate • 40 MGPY of NW corn • Balance from low CI corn ethanol (max 102 MGPY) • Starting in 2024, 50 MGY of sugarcane ethanol • Ramped up E85 consumption by 5% per year starting in 2023, ending with 25% FFV VMT from E85 in 2027
Biodiesel (BD): • Max BD blend is B10 • Waste Oil BD – 50 MGPY max Renewable Diesel (RD): • Max RD blend is R5 • Tallow RD - 10 MGPY max • Waste Oil RD - 50 MGPY max	• Increased BD blend from 5% to 9% from 2017 to 2025 • Maintained canola/soy/used oil ratios until 2018 • Increase waste oil BD to 15 MGPY in 2018, max 30 MGPY in 2025 • RD maintained at 2% • 10 MGPY from tallow and balance waste oil	• Increased BD blend from 5% to 10% from 2017 to 2020 • Increased waste oil BD to 25 MGPY in 2017 up to 50 MGPY in 2022 • RD maintained at 2% then increased to 3% blend till 2025 • 10 MGPY from tallow and balance waste oil till 2021	• Increased BD blend from 5% to 10% from 2019 to 2025 • Increased waste oil BD to 25 MGY in 2021 up to 50 MGY in 2027 • RD increased from 2% to 5% of diesel pool from 2020 to 2025 • 10 MGY from tallow and balance from waste oil
Natural Gas (NG):	• The NG MD and HD new vehicle market share was increased steadily from 2017 (1%) till 2022 (6.5%) and staying constant resulting in 5% of diesel pool consumption being NG in 2025 • By 2019, 90% of NG from biogas	• BAU vehicle market share • By 2019, 100% of NG from biogas, 11.1 MGPY in 2025	• The NG MD and HD new vehicle market share was increased steadily from 2017 (1%) till 2027 (8%) resulting in 6% of diesel pool consumption being NG in 2027 • By 2019, 90% of NG from biogas
Advanced Vehicles: • Achieves ZEV compliance • BAU vehicle populations in 2025: ▪ 70,000 BEVs ▪ 62,000 PHEV10 • 62,000 PHEV40 163,000 PEVs in ZEV compliance years	• All PHEVs are PHEV40 • MD-HD HEV sales increased to 10% market share by 2025	Same as BAU	• All PHEVs are PHEV40 • MD-HD HEV sales increased to 10% market share by 2025 and 12% by 2027

Table 5. Overview of 2017 Illustrative Compliance Scenarios

2016 Clean Fuels Program Data

ICF used actual information reported to DEQ for 2016 for the following:

- The biodiesel feedstock breakdown is currently 77% canola, 12% soy and 11% used cooking oil. This information was used to establish the assumptions of what carbon intensities were used to calculate compliance with the standards.
- The percentage of fuel being imported as B5 or E10 was 12.5% and 1.8%, respectively, in 2016. Since DEQ established default B5 and E10 carbon intensities, there is a slight difference in credit generation due to the use of different carbon intensities of the ethanol and biodiesel portions of the finished fuels. For the ethanol portion of the default E10, the carbon intensity is 69.89 versus 58.58 for a typical low CI corn. Similarly, for the biodiesel portion of the default B5, the carbon intensity is 58.25 versus 57.84 for a typical

NW canola biodiesel. Using the B5/E10 carbon intensities typically results in less credits than by specifying the actual biodiesel/ethanol used.

To test the potential impact of this, ICF ran Scenario 2 (higher biofuels) using the current volume of finished B5/E10 as reported to DEQ in 2016 and another run if the B5/E10 were reported with their typical biodiesel/ethanol. This resulted in less than a 0.2% difference in the generation of credits so it is not a critical issue impacting credit generation.

Results

Credits and Deficits

For each scenario, a table and a figure are presented. The tables show the annual credits and deficits generated and cumulative (banked) credits and the cumulative credits and deficits in last column. The figures show the same information but in a stacked bar chart. Each colored stacked bar represents credits generated from low carbon fuels; the stacked bars are grouped by biofuels for blending at the bottom and advanced vehicle technologies at the top. The blue line represents the deficits from forecasted gasoline blendstock and ultra-low sulfur diesel (ULSD) consumption. When the bars in years 2016-2021 exceed the blue line, annual credits exceed annual deficits and banked credits are generated for future compliance. When the bars fall short of the blue line in years 2022-2025, banked credits are used to meet annual compliance. The black credit bank line was added to Scenario 3 to highlight the size of the credit bank.

Table 11. Ethanol Volumes (in millions of Gallons) in Scenario 3

Each gasoline refueling station dispenses approximately 1.5 million gallons of gasoline per year. If an E85 pump were added to an existing station and it dispenses 0.5 million gallons per year, 18 E85 pumps would be needed in 2023, 35 in 2024, 53 in 2025, 71 in 2026 and 88 in 2027. Currently there are five (5) E85 stations in Oregon[8].

Table 23. GHG Emissions Reductions from the BAU (million metric tons and Percent)

The reductions in Table 29 are compared to the BAU (which includes the ZEV Program and increased light-duty fuel economy standards) and only represent those reductions that would be directly attributed to the Clean Fuels Program. Both of the baseline scenarios achieved similar cumulative reductions which were expected since the compliance period was looking to achieve the same carbon intensity reductions. The updated 2014 illustrative compliance scenarios achieved cumulative reductions of 2.9% and 3.0 for Scenarios 1-B5 and 2-B5, respectively. The reduction in cumulative emissions (Scenarios 1 and 2) attributable to the Clean Fuels Program is due to the increased contribution of the ZEV Mandate (mainly from the AEO2016 increase of PHEV eVMT) towards compliance which is also included in the BAU case and the inclusion of additional electricity credit generation.

Conclusions

The following are key highlights from the 2017 Updated Illustrative Compliance Scenarios:

- Over-compliance in the early years of the program reduces the need for new infrastructure (e.g. E85, liquid fuel storage), international biofuels (i.e. imported RD) and reduces compliance costs. Credits can be banked and used later and do not lose their compliance value. Banking credits when the standard is lower reduces compliance costs and eases compliance in later years. In the scenarios, between 20-42% of the credits are banked annually in years 1-5, which is lower that what was seen in the CA LCFS (35-59% annual credits banked in years 1-5). 13-15% of total credits required for compliance in the Oregon program were banked in these scenarios.
- The Clean Fuels Program can be achieved through a diverse fuel supply. All of the scenarios required a combination of ethanol, biodiesel and renewable diesel from various feedstocks, electricity, natural gas, renewable natural gas, and propane for compliance.
- Eight (8) years of overlap between the post-2017 Zero Emission Vehicle (ZEV) Program eases the burden of compliance. The ZEV Program generates between 17-21% of the cumulative credits (an increase from 14-17% in the updated 2014 illustrative compliance scenarios) needed over the compliance period.
- Renewable natural gas is a key fuel for Clean Fuels Standard compliance. In the advanced technology scenarios, renewable natural gas generated 11% of the credits necessary for compliance.
- Without blend limitations and infrastructure requirements, renewable diesel, even in small volumes, is necessary for compliance, but Scenario 2 only moderately strayed from a 2% renewable diesel blend reaching a maximum of 31 MGPY. Scenario 3 reaches a 5% blend rate, but only in 2025.
- The results of Scenario 3 show that through a combined approach of Scenarios 1 and 2 there is potential for meeting the 2016 – 2025 CFP requirements without exhausting the bank of credits and to nearly reach annual credit generation and deficit generation parity in 2027.

Petroleum Overview

At the national level, consumption of each petroleum product is assumed to equal "product supplied." Product supplied measures the disappearance of petroleum products from primary sources, i.e., refineries, natural gas-processing plants, blending plants, pipelines, and bulk terminals. In general, product supplied of each product in any given period is computed as follows: field production, plus refinery production, plus imports, plus unaccounted-for crude oil minus stock change, minus crude oil losses, minus refinery inputs, and minus exports.

Data on state-level product supplied by sector are not available. The methods of estimating consumption by state and sector are discussed in the individual subsections.

The petroleum products included in the State Energy Data System (SEDS) are explained in this section. For 10 of these products, the means of estimating their consumption by state is described in individual sections. The 10 petroleum products are

- asphalt and road oil
- aviation gasoline
- distillate fuel oil
- hydrocarbon gas liquids
- jet fuel
- kerosene
- lubricants
- motor gasoline
- petroleum coke
- residual fuel oil

The remaining products are described in the section "Other Petroleum Products" and include the following:

- crude oil, including lease condensate
- miscellaneous petroleum products
- petrochemical feedstocks, naphtha less than 401˚F
- petrochemical feedstocks, other oils equal to or greater than 401˚F
- petrochemical feedstocks, still gas
- special naphthas
- still gas
- waxes
- unfinished oils
- motor gasoline blending components
- aviation gasoline blending components

The last petroleum documentation section, "Petroleum Summaries," describes how the petroleum products are combined for each major end-use sector's estimated consumption.

Additional notes

1. SEDS assumes U.S. consumption of each petroleum product equals its total product supplied. Occasionally, product supplied for some petroleum products can have negative values (see Energy Information Administration (EIA) *Petroleum Supply Annual* Explanatory Notes, http://www.eia.gov/petroleum/supply/monthly/pdf/psmnotes.pdf). No attempt is made to adjust for negative product supplied values in SEDS.
2. Beginning in the 2016 SEDS data cycle, "hydrocarbon gas liquids" (which covers normal butane, butylene, ethane, ethylene, isobutane, isobutylene, natural gasoline (pentanes plus), propane, and propylene) replaces "liquefied petroleum gases" (which includes all hydrocarbon gas liquids except natural gasoline) as a petroleum product. The definition of "other petroleum products" is revised to exclude petroleum coke and natural gasoline (formerly pentanes plus). Petroleum coke is reported as a separate product and natural gasoline is included in hydrocarbon gas liquids.

Table TN4.1 summarizes the petroleum products' end-use assignments in SEDS. Shown in this table are the first four letters of the seven-letter variable names used to identify all energy sources. The first two letters identify the petroleum product and the next two letters identify the end-use sector. For example, the table shows that the aviation gasoline estimated to be consumed by the transportation sector is all aviation gasoline consumed, and

Table TN4.1. Summary of petroleum products in the State Energy Data System

Petroleum products	Residential sector estimated consumption (RC)		Commercial sector estimated consumption (CC)		Industrial sector estimated consumption (IC)		Transportation sector estimated consumption (AC)		Electric power sector estimated consumption (EI)		Total sector estimated consumption (TC)

that there is some estimated consumption of lubricants in the industrial and transportation sectors, while distillate fuel oil is consumed in every sector.

LUBA No. 2020-009
Page 5672

Asphalt and Road Oil

Physical units

There are no state-level consumption data for asphalt and road oil available. Before 2009, state-level sales data are used to apportion national-level consumption numbers to the states. From 2009 forward, state-level production of hot-mix asphalt and warm-mix asphalt, excluding reclaimed asphalt pavement, are used to allocate national-level consumption to the states.

The asphalt and road oil sales and production data are in short tons, while the consumption data are in thousand barrels. Because the tonnage data are used only to apportion the U.S. consumption data to the states, they do not need to be converted into thousand barrels.

The five data series that are used to estimate consumption of asphalt and road oil are (where "ZZ" in the variable name represents the two-letter state code that differs for each state)

ASINPZZ = asphalt sold for use in the industrial sector of each state, in short tons (through 2008);

ASPRPZZ = asphalt (hot-mix and warm-mix) production excluding reclaimed asphalt pavement in each state, in short tons (for 2009 forward);

ASTCPUS = asphalt total consumption in the United States, in thousand barrels (includes road oil from 1983 forward);

RDINPZZ = road oil sold for use in the industrial sector of each state, in short tons (through 1982); and

RDTCPUS = road oil total consumption in the United States, in thousand barrels (through 1982).

Consumption of all asphalt and road oil is assigned to the industrial sector because asphalt and roal oil are mostly used in construction activity. ASTCPUS represents total U.S. consumption of asphalt, and RDTCPUS represents total U.S. consumption of road oil. Both are the "product supplied" data series in the publication *Petroleum Supply Annual,* published by the U.S. Energy Information Administration (EIA). Beginning in 1983, asphalt product supplied includes road oil, and RDTCPUS is entered as zero in SEDS.

Before 2009, state-level asphalt sales data are used to allocate the U.S. consumption value to the states. ASINPZZ represents all asphalt sold as paving products, as roofing products, and for all other uses. RDINPZZ represents all sales of road oil. These data are collected and published by the Department of Interior (1960–1977), EIA (1978–1980), and the Asphalt Institute (1981–2008). Values for RDINPZZ for 1981 and 1982 are estimated as described under "Additional Notes" in this section. Beginning with 1983 data, when road oil is included in asphalt product supplied data, RDINPZZ is entered as zero in SEDS.

To calculate state consumption estimates of asphalt, total sales of asphalt and road oil in the United States to the industrial sector are first calculated as the sum of the state data:

ASINPUS = ΣASINPZZ
RDINPUS = ΣRDINPZZ

Each state's consumption of asphalt in the industrial sector (ASICPZZ) is calculated to be in proportion to each state's sales:

ASICPZZ = (ASINPZZ / ASINPUS) * ASTCPUS
ASICPUS = ΣASICPZZ
RDICPZZ = (RDINPZZ / RDINPUS) * RDTCPUS
RDICPUS = ΣRDICPZZ

Beginning in 2009, state-level asphalt sales data are no longer available from the Asphalt Institute. To estimate state-level consumption, state-level production of hot-mix asphalt and warm-mix asphalt (HMA/WMA) excluding reclaimed asphalt pavement (RAP), ASPRPZZ, is used to allocate U.S. consumption to the states. These data are collected by the National Asphalt Pavement Association (NAPA). HMA/WMA is used by the paving industry and contains about 5% asphalt binder, the petroleum product measured in SEDS. The use of recycled materials reduces the need of asphalt binder. Hence RAP tonnage is removed from HMA/WMA tonnage to derive the state allocators. While estimates of HMA/WMA tonnage are available from the source for all states, RAP estimates are withheld for some states and are estimated in SEDS.

ASPRPUS = ΣASPRPZZ

Each state's consumption of asphalt in the industrial sector (ASICPZZ) is calculated to be in proportion to each state's HMA/WMA production:

ASICPZZ = (ASPRPZZ / ASPRPUS) * ASTCPUS
ASICPUS = ΣASICPZZ

Because all asphalt and road oil are assumed to be used in the industrial sector, their total consumption in each state equals the industrial sector consumption:

LUBA No. 2020-009
Page 5673

ASTCPZZ = ASICPZZ
RDTCPZZ = RDICPZZ

Asphalt and road oil consumption are added together:

ARICPZZ = ASICPZZ + RDICPZZ
ARICPUS = ΣARICPZZ
ARTCPZZ = ASTCPZZ + RDTCPZZ
ARTCPUS = ΣARTCPZZ

British thermal units (Btu)

Asphalt and road oil have a heat content value of about 6.636 million Btu per barrel. This factor is applied to convert asphalt and road oil estimated consumption from physical units to Btu:

ARICBZZ = ARICPZZ * 6.636
ARICBUS = ΣARICBZZ

Because all asphalt and road oil are assumed to be used by the industrial sector, total asphalt and road oil consumption in each state and in the United States is assumed to equal the industrial sector consumption:

ARTCBZZ = ARICBZZ
ARTCBUS = ARICBUS

Additional notes

The federal government stopped collecting asphalt and road oil sales data after 1980. For 1981 through 2008, the source for these numbers was the Asphalt Institute. When companies did not respond to the voluntary survey, the Asphalt Institute did not estimate quantities to compensate for the nonresponse. This could cause large fluctuation in sales from year to year for some states.

For most years through 2008, asphalt and road oil sales data for Maryland and the District of Columbia are published combined to avoid disclosure of proprietary data. Before being entered into SEDS, the combined data are allocated to each state based on their reported sales in 1974. In this allocation procedure 99.4% is allocated to Maryland and 0.6% to the District of Columbia.

The EIA report series "Sales of Asphalt," and predecessor reports, which are the source for road oil sales by state (RDINPZZ) in SEDS for 1960 through 1980, was discontinued after the 1980 report. For 1981 and 1982, state estimates of road oil sales were created by first converting the annual total U.S. road oil product supplied data into short tons (one short ton contains 5.5 barrels of road oil). Then, the U.S. total road oil product supplied, in short tons, was disaggregated to each state in proportion to the state's share of total U.S. asphalt sales as reported in the Asphalt Institute's *Report on Sales of Asphalt in the U.S.*

For 2009 forward, production data from NAPA are used as state allocators.

Data sources

ASINPZZ — Asphalt sold to the industrial sector by state.

- 1960 through 1977: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Sales of Asphalt," the specific tables are
  - 1960 through 1962: Table 6.
  - 1963 through 1977: Table 5.
- 1978 through 1980: EIA, *Energy Data Reports*, "Sales of Asphalt," Table 2.
- 1981 through 1986: The Asphalt Institute, *Asphalt Usage 1987 United States and Canada*, Table B.
- 1987 and 1988: The Asphalt Institute, *Asphalt Usage 1988 United States and Canada*, Tables A and B for state data. *Asphalt Usage 1989 United States and Canada*, page 2 for revised U.S. totals. The Asphalt Institute did not publish corresponding revised state data but did advise EIA on an estimation procedure to adjust 19 state values to sum to the revised U.S. totals.
- 1989 through 1997: The Asphalt Institute, *Asphalt Usage United States and Canada*, table titled "U.S. Asphalt Usage."
- 1998 and 1999: The Asphalt Institute, *Asphalt Usage United States and Canada*, table titled "1998 vs. 1999 U.S. Asphalt Usage." 1998 data for Delaware, New Hampshire, Rhode Island, and Vermont are repeated for 1999 because nonresponse to the survey caused those states data for 1999 to be more than 75% lower than their 1998 values.
- 2000 through 2008: The Asphalt Institute, http://www.asphaltinstitute.org/, *Asphalt Usage Survey for the United States and Canada*, table titled "U.S. Asphalt Usage."

ASPRPZZ — Hot-mix asphalt and warm-mix asphalt production excluding reclaimed asphalt pavement by state.

- 2009 forward: National Asphalt Pavement Association, *Asphalt Pavement Industry Survey on Recycled Materials and Warm-Mix Asphalt*

LUBA No. 2020-009
Page 5674

Usage, http://www.asphaltpavement.org/recycling.

ASTCPUS — Asphalt total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

RDINPZZ — Road oil sold to the industrial sector by state (through 1982).

- 1960 through 1977: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Sales of Asphalt." The specific tables are
  - 1960 through 1962: Table 6.
  - 1963 through 1977: Table 5.
- 1978 through 1980: EIA, *Energy Data Reports*, "Sales of Asphalt," Table 2.
- 1981 and 1982: EIA estimates. (See explanation in "Additional Notes" on page 32.)

RDTCPUS — Road oil total consumption in the United States (through 1982).

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 2.

Aviation Gasoline

Physical units

The three data series used to estimate consumption of aviation gasoline are

AVMIPZZ	=	aviation gasoline issued to the military in each state, in thousand barrels;
AVNMMZZ	=	aviation gasoline sold to nonmilitary users in each state, in thousand gallons; and
AVTCPUS	=	aviation gasoline total consumption in the United States, in thousand barrels.

The U.S. Department of Transportation, Federal Highway Administration publishes the nonmilitary aviation gasoline sales data by state (AVNMMZZ) in *Highway Statistics*.

AVMIPZZ is the issues of aviation gasoline to the military in each state and is obtained from the U.S. Department of Defense, Defense Logistics Agency.

Total U.S. consumption of aviation gasoline (AVTCPUS) is the product supplied data series in the publication *Petroleum Supply Annual,* published by the U.S. Energy Information Administration (EIA).

The state-level data series are summed to provide totals for the United States:

AVMIPUS = ΣAVMIPZZ
AVNMMUS = ΣAVNMMZZ

The state sales of nonmilitary aviation gasoline data are converted from thousand gallons to thousand barrels (42 gallons = 1 barrel):

AVNMPZZ = AVNMMZZ / 42

The U.S. nonmilitary sales is the sum of the states' sales:

AVNMPUS = ΣAVNMPZZ

The total sales of aviation gasoline is estimated as the sum of nonmilitary sales and military issues:

AVTTPZZ = AVNMPZZ + AVMIPZZ
AVTTPUS = ΣAVTTPZZ

All aviation gasoline is assumed to be used by the transportation sector. An estimate of aviation gasoline consumption by the transportation sector

LUBA No. 2020-009
Page 5675

by state (AVACPZZ) is calculated by assuming that each state consumes aviation gasoline in proportion to the amount sold to that state:

AVACPZZ = (AVTTPZZ / AVTTPUS) * AVTCPUS
AVACPUS = ΣAVACPZZ

Total aviation gasoline consumption in each state, AVTCPZZ, equals the transportation sector consumption in each state:

AVTCPZZ = AVACPZZ

British thermal units (Btu)

Aviation gasoline has a heat content value of about 5.048 million Btu per barrel. This factor is applied to convert aviation gasoline estimated consumption from physical units to Btu:

AVACBZZ = AVACPZZ * 5.048
AVACBUS = ΣAVACBZZ

Because all aviation gasoline is assumed to be used for transportation, aviation gasoline total consumption in each state and in the United States equals the transportation sector consumption:

AVTCBZZ = AVACBZZ
AVTCBUS = ΣAVTCBZZ

Additional note

In 2015, the Federal Highway Administration revised its methods of estimating aviation gasoline use. Estimates from 2015 forward are not compatible with data before 2015.

Data sources

AVMIPZZ — Aviation fuel issued to the military in the United States by state.

- 1960 through 1974: No data are available. The 1977 data are used for each year.
- 1975 and 1976: No consistent data series are available. The 1977 data are used for both years.
- 1977 through 1988: U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center, Defense Energy Information System, military retail issues based on fiscal year data. The District of Columbia issues are assumed to be zero; therefore, values reported for the District of Columbia are added to Maryland.
- 1989 and 1990: U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center. State data for the fiscal year from two databases are summed: Defense Fuel Automated Management System (military wholesale issues) and Into-Plane Database (military purchases from commercial airports). Into-plane values reported for the District of Columbia are added to Virginia.
- 1991 through 2003: U.S. Department of Defense, Defense Logistics Agency, Defense Energy Supply Center. State data for the calendar year from two databases are summed: Defense Fuel Automated Management System (military wholesale issues) and Into-Plane Database (military purchases from commercial airports). Into-plane values reported for the District of Columbia are added to Virginia.
- 2004 forward: U.S. Department of Defense, Defense Logistics Agency Energy. State data for product 130, Aviation Gasoline, Grade 100LL, by calendar year were used.

AVNMMZZ — Aviation gasoline sold to nonmilitary users by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24.
- 1965 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-24 (1965), Table MF-24 (1966 through 2006), and Table 8.4.3 (2007 forward).

AVTCPUS — Aviation gasoline total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

LUBA No. 2020-009
Page 5676

Distillate Fuel Oil

Physical units

Because state-level and end-use consumption data for distillate fuel oil (except for that consumed by the electric power sector) are not available, sales of distillate fuel oil into or within each state, published by the U.S. Energy Information Administration (EIA) in the *Fuel Oil and Kerosene Sales Report,* are used to estimate distillate fuel oil consumption. The following variable names have been assigned to the sales series, in thousand barrels ("ZZ" in the variable names represents the two-letter state code that differs for each state):

DFBKPZZ = distillate fuel oil sales for vessel bunkering use (i.e., the fueling of commercial or private boats, such as pleasure craft, fishing boats, tugboats, and ocean-going vessels, including vessels operated by oil companies, and fueling for other marine purposes), excluding that sold to the military;

DFCMPZZ = distillate fuel oil sales to commercial establishments for space heating, water heating, and cooking;

DFIBPZZ = distillate fuel oil sales to industrial establishments for space heating and for other industrial use (i.e., for all uses to mines, smelters, plants engaged in producing manufactured products, in processing goods, and in assembling), including farm use;

DFMIPZZ = distillate fuel oil sales to the military, for all uses;

DFOCPZZ = distillate fuel oil sales for oil company use, including all fuel oil, crude oil, or acid sludge used as fuel at refineries, by pipelines, or in field operations;

DFOFPZZ = distillate fuel oil sales as diesel fuel for off-highway use in construction (i.e., earthmoving equipment, cranes, stationary generators, air compressors, etc.) and for off-highway uses other than construction (i.e., logging);

DFONPZZ = distillate fuel oil sales as diesel fuel for on-highway use (i.e., as engine fuel for trucks, buses, and automobiles);

DFOTPZZ = distillate fuel oil sales for all other uses not identified in other sales categories;

DFRRPZZ = distillate fuel oil sales to the railroads for use in fueling trains, operating railroad equipment, space heating of buildings, and other operations; and

DFRSPZZ = distillate fuel oil sales to the residential sector for space heating, water heating, and cooking, excluding farm houses.

Three additional data series are used in calculating distillate fuel oil consumption estimates:

DKEIPZZ = distillate fuel oil (including kerosene-type jet fuel before 2001) consumed by the electric power sector, in thousand barrels;

JKEUPZZ = kerosene-type jet fuel consumed by electric utilities, in thousand barrels (through 1982); and

DFTCPUS = distillate fuel oil total consumption in the United States, in thousand barrels.

Distillate fuel oil consumed by the electric power sector is collected by EIA on Form EIA-923, "Power Plant Operations Report," and predecessor forms. (See Note 4 at the end of this distillate fuel oil section for further information on changes in this series' data definitions.) Before 2001, the data series DKEIPZZ includes kerosene-type jet fuel consumed at electric utilities that is identified as JKEUPZZ. The kerosene-type jet fuel is subtracted from the distillate fuel oil data and accounted for in the jet fuel data described in a following section of this documentation. Data for kerosene-type jet fuel consumed by electric utilities are available for 1972 through 1982 only. Consumption in all other years is assumed to be zero. From 2001 forward, jet fuel consumed by the electric power sector is grouped under waste/other oil and is not accounted for in SEDS. DKEIPZZ is continued to be used to represent distillate fuel oil consumed by the electric power sector.

Total consumption of distillate fuel oil in the United States, DFTCPUS, is the product supplied series in the EIA publication *Petroleum Supply Annual*. From 2011 forward, product supplied of distillate fuel oil includes all biodiesel blended into distillate fuel oil. Before 2011, only the portion of biodiesel that was reported as refinery and blender net input was included.

All of the state-level data series listed above are summed to provide totals for the United States.

Next, the variables are combined as closely as possible into the major end-use sectors used in SEDS. The residential sector sales and the commercial sector sales contain only DFRSPZZ and DFCMPZZ, respectively.

The sales of distillate fuel oil to the industrial sector for each state, DFINPZZ, is the sum of the distillate fuel oil sales for industrial use, including industrial space heating and farm use (DFIBPZZ), for oil company use (DFOCPZZ),

LUBA No. 2020-009
Page 5677

for off-highway use (DFOFPZZ), and for all other uses (DFOTPZZ). Data for DFOTPZZ are available through 1994. Starting in 1995, consumption is assumed to be zero:

DFINPZZ = DFIBPZZ + DFOCPZZ + DFOFPZZ + DFOTPZZ
DFINPUS = ΣDFINPZZ

The sales of distillate fuel oil to the transportation sector for each state, DFTRPZZ, is the sum of the distillate fuel oil sales for vessel bunkering, military use, railroad use, and the diesel fuel used on-highway:

DFTRPZZ = DFBKPZZ + DFMIPZZ + DFRRPZZ + DFONPZZ
DFTRPUS = ΣDFTRPZZ

Sales of distillate fuel oil to the residential, commercial, industrial, and transportation sectors are added to create a subtotal of sales to all sectors other than the electric utility sector, DFNDPZZ:

DFNDPZZ = DFRSPZZ + DFCMPZZ + DFINPZZ + DFTRPZZ
DFNDPUS = ΣDFNDPZZ

For 2001 forward, consumption of distillate fuel oil by the electric power sector (DFEIPZZ) is the same as the input series DKEIPZZ:

DFEIPZZ = DKEIPZZ

Before 2001, DFEIPZZ is calculated by subtracting the kerosene-type jet fuel consumed by electric utilities from DKEIPZZ:

DFEIPZZ = DKEIPZZ - JKEUPZZ

For all years, the U.S. total for this data series is summed:

DFEIPUS = ΣDFEIPZZ

The estimated U.S. distillate fuel oil consumption by all sectors other than the electric power sector, DFNCPUS, is calculated by subtracting the distillate fuel oil consumption by the electric power sector from the total U.S. distillate fuel oil consumption:

DFNCPUS = DFTCPUS - DFEIPUS

This U.S. subtotal of distillate fuel oil consumption by the four end-use sectors, DFNCPUS, is apportioned to the states by use of the end-use sectors' state-level sales data. The assumption is made that each state consumes distillate fuel oil in proportion to the amount of sales to that state:

DFNCPZZ = (DFNDPZZ / DFNDPUS) * DFNCPUS

The end-use sectors' subtotal for each state, DFNCPZZ, is further divided into estimates for the four end-use sectors in proportion to each sector's sales. The estimated residential sector consumption in each state, DFRCPZZ, is calculated:

DFRCPZZ = (DFRSPZZ / DFNDPZZ) * DFNCPZZ
DFRCPUS = ΣDFRCPZZ

The commercial sector's estimated consumption in each state, DFCCPZZ, is calculated:

DFCCPZZ = (DFCMPZZ / DFNDPZZ) * DFNCPZZ
DFCCPUS = ΣDFCCPZZ

The industrial sector's estimated consumption in each state, DFICPZZ, is calculated:

DFICPZZ = (DFINPZZ / DFNDPZZ) * DFNCPZZ
DFICPUS = ΣDFICPZZ

The transportation sector's estimated consumption in each state, DFACPZZ, is calculated:

DFACPZZ = (DFTRPZZ / DFNDPZZ) * DFNCPZZ
DFACPUS = ΣDFACPZZ

Total state distillate fuel oil consumption is the sum of the end-use sectors' consumption subtotal and the electric power sector consumption:

DFTCPZZ = DFNCPZZ + DFEIPZZ

British thermal units (Btu)

The factor for converting distillate fuel oil from physical unit values to Btu, DFTCKUS, is calculated annually for 1994 forward by EIA as a consumption-weighted average of the heat contents of three categories of distillate fuel oil based on its sulfur content. DFTCKUS is shown in Table B1 on page 179. For 1960 through 1993, a fixed factor of 5.825 million Btu per barrel is used:

DFTCKUS = factor for converting distillate fuel oil from physical units to Btu.

This factor is applied to convert distillate fuel oil estimated consumption

LUBA No. 2020-009
Page 5678

for the five consuming sectors from physical units to Btu as shown in the following example:

DFRCBZZ = DFRCPZZ * DFTCKUS

Total Btu consumption of distillate fuel oil is the sum of the consumption by the end-use sectors and for electricity generation:

DFTCBZZ = DFRCBZZ + DFCCBZZ + DFICBZZ + DFACBZZ + DFEIBZZ

The U.S. Btu consumption estimates are calculated as the sum of all the states' data.

In the SEDS consumption tables, "Estimates of Energy Consumption by the Electric Power Sector," the data used in the column headed "Distillate" is the variable DKEIP, which includes keorsene-type jet fuel before 2001, in physical units. The Btu variable, DKEIB, is calculated as follows (See page 58 for description of JKEUB):

DKEIBZZ	=	DFEIBZZ	for 2001 forward
DKEIBZZ	=	DFEIBZZ + JKEUBZZ	before 2001
DKEIBUS	=	ΣDKEIBZZ	

Additional notes

1. "Deliveries" data are actually called "shipments" in the source document for 1960 and 1961; "consumption" for 1962 through 1966; "shipments" for 1967; "sales" from 1968 through 1978; "deliveries" for 1979 through 1987; and "sales" for 1988 forward.
2. State data for the variables DFONPZZ (on-highway use), DFOFPZZ (off-highway use), and DFOTPZZ (other) for 1967 are unavailable from published sources. These three variables compose the miscellaneous use category for distillate fuel oil, which is known for all years by state. State estimates of DFONPZZ and DFOFPZZ for 1967 were developed by dividing the 1966 values for DFONPZZ and DFOFPZZ by the 1966 total miscellaneous use for each state and applying these percentages to the 1967 total miscellaneous use for each state. The 1967 state estimates for DFOTPZZ are the remainder of the 1967 miscellaneous category after DFONPZZ and DFOFPZZ have been subtracted.
3. In 1979, EIA implemented a new survey form, EIA-172, to obtain deliveries of fuel oil and kerosene data and updated the list of respondents. (A detailed explanation is published in the *Energy Data Report,* "Deliveries of Fuel Oil and Kerosene in 1979.") In this survey form, certain end-use categories were redefined—in many cases to collect more disaggregated data. The reclassifications resulted in some end-use categories that were no longer comparable with those in previous surveys. Where discontinuities occurred, estimates for the pre-1979 years have been made in the State Energy Data System (SEDS) to conform with the 1979 fuel oil deliveries classifications. The pre-1979 deliveries estimates are not published in this report, but are used in SEDS to disaggregate the known U.S. total product supplied (consumption) into state and major end-use sector consumption estimates.

   For distillate fuel oil deliveries in 1979, the end-use categories called "residential," "commercial," "industrial," and "farm" are available. The pre-1979 deliveries categories are called "heating" and "industrial" (which included farm use). While the pre-1979 categories individually are not continuous with the 1979 categories, their subtotals are related. That is, a general comparison can be made between the sum of residential, commercial, industrial, and farm deliveries in 1979 and the sum of heating and industrial deliveries in the pre-1979 years. Therefore, the following method was applied to present a comparable series for distillate fuel oil delivered to the residential, commercial, and industrial sectors:
   - For each of the pre-1979 years, a subtotal was created for each state by adding each state's heating and industrial deliveries categories. A comparable 1979 subtotal was created by adding each state's residential, commercial, industrial, and farm deliveries categories.
   - Residential, commercial, and industrial (including farm) shares of the subtotal in 1979 were calculated for each state.
   - These 1979 end-use shares were then applied to each pre-1979 subtotal of distillate fuel oil deliveries in each state to create state estimates of end-use deliveries for 1960 through 1978.

   The 1980 through 1982 distillate fuel oil deliveries data are based on the same survey as that used for 1979; therefore, the 1980 through 1982 data are directly comparable to 1979 data.

   In 1984, EIA again updated the list of respondents for this survey, and the Form EIA-172 became the Form EIA-821, "Annual Fuel Oil and Kerosene Sales Report." EIA did not conduct a fuel oil and kerosene deliveries survey for 1983. The 1983 estimates in SEDS are based on 1984 data obtained from the Form EIA-821. Statistical procedures and methodologies used for the Form EIA-821 differ from those used in previous years. Therefore, the 1983 and forward sales data may not be directly comparable to the pre-1983 data. (In the source document, the deliveries data for 1983 forward are reported in thousand gallons. These

LUBA No. 2020-009
Page 5679

data are first converted to thousand barrels before being entered into SEDS.)

Some of the No. 2 diesel fuel reported as sold to the commercial and industrial sectors, DFCMPZZ and DFINPZZ, on the EIA forms may also be included in the on-highway data, DFONPZZ, obtained from the Federal Highway Administration. Included in the commercial sector is some diesel fuel consumed by government vehicles and school buses, and included in the industrial sector is some diesel fuel consumed by fleets of trucks. Because the specific quantities involved are unknown, SEDS reflects the diesel fuel consumption as reported in the EIA *Petroleum Marketing Monthly* and no attempt has been made to adjust the end-use reporting.

4. The data on fuel oil consumed by the electric power sector for all years and states are actual fuel oil consumption numbers collected from electric power plants on Form EIA-923, "Power Plant Operations Report," and predecessor forms. Due to changes in fuel oil reporting classifications on the predecessor forms over the years, it is not possible to develop a thoroughly consistent series for all years. However, over time, data more accurately disaggregating fuel oil into distillate fuel oil and residual fuel oil have become available. For 1960 through 1969, only data on total fuel oil consumed at electric utilities by state are available. For 1970 through 1979, fuel oil consumed by plant type (internal combustion and gas turbine plants combined and steam plants) by state are available. For 1980 through 2000, data on consumption of light fuel oil at all plant types combined and consumption of heavy fuel oil at all plant types combined are available by state. For 2001 forward, data on consumption of distillate fuel oil and residual fuel oil are available. In SEDS, the following assumptions have been made:
   - 1960 through 1969—state estimates of fuel oil consumption by plant type have been created for each year by applying the shares of steam plants (primarily residual fuel oil) and internal combustion and gas turbine plants (primarily distillate fuel oil plus small amounts of jet kerosene) by state in 1970 to each year's total fuel oil consumption at electric utilities for 1960 through 1969.
   - 1970 through 1979—fuel oil consumed by steam plants is assumed to equal residual fuel oil consumption, and fuel oil consumed by internal combustion and gas turbine plants is assumed to equal distillate fuel oil plus jet kerosene consumption.
   - 1980 through 2000—total heavy oil consumption at all plant types is assumed to equal residual fuel oil consumption, and total light oil consumption at all plant types is assumed to equal distillate fuel oil plus jet kerosene consumption.

   The data series thus derived for SEDS for residual fuel oil and distillate fuel oil consumption by the electric power sector is considered to be actual consumption by the electric power for each state and each year.

Data sources

DFBKPZZ — Distillate fuel oil sales for vessel bunkering use by state, excluding that sold to the military.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Shipments of Fuel Oil and Kerosene." The specific tables are

- 1988 forward: EIA, *Fuel Oil and Kerosene Sales*, also available at http://www.eia.gov/dnav/pet/pet_cons_821dst_a_EPD0_VRS_Mgal_a.htm.

DFTCKUS — Factor for converting distillate fuel oil from physical units to Btu.

- 1960 through 1993: EIA adopted the Bureau of Mines thermal conversion factor of 5.825 million Btu per barrel, from the Bureau of Mines internal memorandum "Bureau of Mines Standard Average Heating Value of Various Fuels, Adopted January 3, 1950."
- 1994 forward: EIA calculates the national annual average thermal conversion factor, which includes biodiesel blended into distillate fuel oil, by using heat content values of three sulfur-content categories of distillate fuel oil, weighted by quantity consumed. See Appendix B Table B1 on page 179.

DFTCPUS — Distillate fuel oil total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

DKEIPZZ — Distillate fuel oil consumed by the electric power sector, including kerosene-type jet fuel before 2001.

- EIA, Form EIA-923, "Power Plant Operations Report," and predecessor forms. The following assumptions have been made:
  - 1960 through 1969: Only total fuel oil consumed at electric utilities by state is available. State estimates of distillate fuel oil consumption were created for each year by applying the shares of internal

LUBA No. 2020-009
Page 5683

combustion and gas turbine plants (primarily distillate fuel oil plus small amounts of jet fuel) by state from 1970 to each year's total fuel oil consumption at electric utilities for 1960 through 1969.
- 1970 through 1979: Fuel oil consumed by plant type by state is available. Fuel oil consumed by internal combustion and gas turbine plants combined is assumed to equal distillate and jet fuel consumption.
- 1980 through 2000: Consumption of light fuel oil at all plant types by state is available. This is assumed to equal distillate and jet kerosene consumption.
- 2001 forward: Consumption of distillate fuel oil is available.

JKEUPZZ — Kerosene-type jet fuel consumed by the electric utility sector (through 1982). (See data sources for JKEUPZZ under "Jet Fuel" on page 59.)

Hydrocarbon Gas Liquids (1960–2009)

Hydrocarbon gas liquids (HGL) cover natural gas liquids (ethane, propane, normal butane, isobutane, and natural gasoline) and refinery olefins (ethylene, propylene, butylene, and isobutylene). Refinery olefins are olefins produced at refineries and do not include olefins produced by the manufacturing industries. The State Energy Data System (SEDS) assumes that, except for propane, all other HGL products are consumed only by the industrial sector.

Historically, SEDS produced consumption estimates for liquefied petroleum gases (LPG), which included ethane/ethylene, isobutane/isobutylene, normal butane/butylene, propane/propylene, butane-propane mixtures, and ethane-propane mixtures. Pentanes plus (natural gasoline) and three other former products (natural gasoline, plant condensate, and unfractionated streams) were covered in "other petroleum products."

In mid-2010s, the U.S. Energy Information Administration (EIA) began using hydrocarbon gas liquids to describe the nine products and separated the refinery olefins from the natural gas liquids in its product supplied data for 2010 forward. SEDS adopted the HGL definition and applied new estimation methodologies for the individual HGL products for 2010 forward (see page 51). For 1960 through 2009, SEDS assumes HGL consumption to be the sum of LPG and pentanes plus (natural gasoline) consumption. The term "LPG" is no longer used after 2009.

Liquefied petroleum gases (LPG)

Physical units

For 1960 through 2007, the following data series on LPG sales in thousand gallons are used in SEDS to estimate LPG consumption by state.

LGCBMZZ = LPG sold for internal combustion engine fuel use. Included are sales for use in highway vehicles, forklifts, industrial tractors, and for use in oil field drilling, and production equipment, etc.;

LGHCMZZ = LPG sold for residential and commercial use. Included are sales for nonfarm private households for space heating, cooking, water heating, and other household uses, such as clothes drying and incineration. Also included are sales to nonmanufacturing organizations, such as motels, restaurants, retail stores, laundries, and other service enterprises, primarily for use in space heating, water heating, and cooking; and

LUBA No. 2020-009
Page 5684

LGTTPZZ = LPG total sales for all uses.

Data before 1984 were available from the Bureau of Mines reports, U.S. Energy Information Administration (EIA) reports, or were estimated by EIA. From 1984 through 2007, data were extracted from American Petroleum Institute's (API) *Sales of Natural Gas Liquids and Liquefied Refinery Gases*. Withheld state-level sales data are first estimated by EIA by using previous year's data and ensuring all subtotals match the source document.

The U.S. totals for each of these state-level data series are calculated as the sum of the state values.

Total U.S. consumption of LPG is the product supplied data series in EIA *Petroleum Supply Annual*:

LGTCPUS = LPG total consumption in the United States, in thousand barrels (through 2009).

Another variable is used in SEDS to estimate LPG consumption by the transportation sector:

LGTRSUS = the transportation sector share of LPG internal combustion engine sales (through 2009).

Its computation is described in detail in Note 2 on page 45.

Similarly, variables are used in SEDS to estimate LPG consumption by the residential and commercial sectors:

LGRCSZZ = the residential sector share of LPG residential and commercial sales (through 2009); and

LGCCSZZ = the commercial sector share of LPG residential and commercial sales (through 2009).

Their computation is described in detail in Note 3 on page 45.

Because the LPG sales data are in gallons, they must be converted to barrels (42 U.S. gallons per U.S. barrel) to be comparable to total consumption estimates. The formulas for calculating state sales data are

LGCBPZZ = LGCBMZZ / 42
LGCBPUS = ΣLGCBPZZ
LGHCPZZ = LGHCMZZ / 42
LGHCPUS = ΣLGHCPZZ

It is also assumed that LPG sales to the residential and commercial sectors are equal to the consumption in those sectors. LPG consumption by the residential sector is estimated to be the residential share of propane sales for the residential and commercial sectors:

LGRCPZZ = LGHCPZZ * LGRCSZZ

LPG consumption by the commercial sector is estimated to be the commercial share of propane sales for the residential and commercial sectors:

LGCCPZZ = LGHCPZZ * LGCCSZZ

LPG consumption by the transportation sector is estimated to be the transportation share of the sales for internal combustion engine fuel:

LGACPZZ = LGCBPZZ * LGTRSUS

An estimate of each state's total LPG consumption (LGTCPZZ) is made by allocating the U.S. total consumption to the states in proportion to each state's share of the U.S. total sales:

LGTCPZZ = (LGTTPZZ / LGTTPUS) * LGTCPUS

Industrial sector consumption (LGICPZZ) for each state is the difference between the state's total LPG consumption and the sum of its residential, commercial, and transportation sectors' consumption:

LGICPZZ = LGTCPZZ- (LGACPZZ + LGCCPZZ + LGRCPZZ)

U.S. totals for the four end-use sector consumption estimates are calculated as the sums of the state estimates.

For 2008 and 2009, the API report only covers sales of propane (including propylene). A new methodology is developed to estimate state-level propane consumption and all other LPG consumption. For propane consumption, API's state shares of propane sales are applied to the U.S. propane product supplied published in EIA's *Petroleum Supply Annual* (PSA).

In SEDS, it is assumed that LPG consumed by the residential, commercial, and transportation sectors and for internal combustion fuel is solely propane. The propane consumption for the residential and consumption sectors and for internal combustion engine fuel use are assigned to LGHCMZZ and LGCBMZZ respectively. The same methodology used for 1960 through 2007 to derive LPG consumption for the residential, commercial, and transportation sectors is maintained:

LUBA No. 2020-009
Page 5685

LGCBPZZ = LGCBMZZ / 42
LGHCPZZ = LGHCMZZ / 42
LGRCPZZ = LGHCPZZ * LGRCSZZ
LGCCPZZ = LGHCPZZ * LGCCSZZ
LGACPZZ = LGCBPZZ * LGTRSUS

LPG consumption for the industrial sector, LGICP, is estimated by summing the estimates for the four components:

- Propane — State-level industrial consumption is calculated by subtracting residential, commercial, and transportation sector consumption from total propane consumption.
- Ethane — Data on ethane feed slate capacity of ethylene steam crackers published by the *Oil and Gas Journal* (OGJ) are used to compute a set of state-level preliminary ethane demand, using an ethylene yield factor of 0.8 and a conversion factor of 16.85 barrels per metric ton. Ethane estimates for the two largest consuming states, Louisiana and Texas (where most, if not all, flexible crackers are located), are further adjusted so that the sum of all states' ethane consumption matches the U.S. ethane product supplied published in PSA.
- Normal butane (n-butane) consumed by steam crackers is estimated using data on n-butane feed slate capacity from OGJ and applied them to the U.S. ethylene feed slate demand for n-butane, also available from OGJ. N-butane for other uses, defined as U.S. n-butane total product supplied less ethylene feed slate demand, is allocated to Texas.
- Isobutane — The U.S. product supplied of isobutane is allocated to Texas.

N-butane and isobutane used in gasoline blending and alkylation at the refineries are accounted for in intermediate product processing and not considered end-use consumption.

U.S. totals for the four end-use sector consumption estimates are calculated as the sums of the state estimates.

Total LPG consumption, LGTCP, is the sum of the four end-use sectors' LPG consumption:

LGTCPZZ = LGACPZZ + LGCCPZZ + LGICPZZ + LGRCPZZ

British thermal units (Btu)

The Btu consumption of LPG for the United States, LGTCBUS, is extracted from EIA's *Annual Energy Review* and *Monthly Energy Review*. It is calculated by multiplying total physical unit consumption (LGTCPUS) with an average conversion factor for LPG. The factor for converting LPG from physical unit values to Btu, LGTCKUS, is calculated annually for 1967 through 2009 by EIA as a consumption-weighted average of the heat contents of the component products (ethane, propane, normal butane, and isobutane) as shown in Appendix B, beginning on page 197. For 1960 through 1966, EIA adopted the 1967 calculated average heat content of 3.810 million Btu per barrel.

LGTCBUS = LPG total consumption in the United States, in billion Btu (through 2009); and
LGTCKUS = Factor for converting U.S. consumption of LPG from physical units to Btu (through 2009).

Because the residential, commercial, and transportation sectors consume mainly propane, it is more appropriate to use the heat content of propane (3.841 million Btu per barrel) to convert LPG consumption for these three sectors into Btu:

LGACBZZ = LGACPZZ * 3.841
LGCCBZZ = LGCCPZZ * 3.841
LGRCBZZ = LGRCPZZ * 3.841

The U.S. totals for the three sectors are the sum of the state estimates.

Industrial sector consumption for the United States is calculated by subtracting the three sectors' consumption estimates from the total:

LGICBUS = LGTCBUS - (LGACBUS + LGCCBUS + LGRCBUS)

Industrial sector consumption for each state is estimated by allocating the U.S. industrial consumption to the states in proportion to the physical unit share:

LGICBZZ = (LGICPZZ / LGICPUS) * LGICBUS

Total estimated consumption of LPG is the sum of the end-use consumption estimates:

LGTCBZZ = LGACBZZ + LGCCBZZ + LGICBZZ + LGRCBZZ

The average conversion factor for industrial consumption of LPG, LGICKUS, is calculated for use in the price computation:

LGICKUS = LGICBUS / LGICPUS

Page 5686

Additional notes

1. Sales data for Maryland and the District of Columbia (D.C.) are combined in the source documents through 2009. Sales data are published in six categories through 2007. The percentages shown in Table TN4.2 are applied to disaggregate the state data in each of the sectors for these years. For 2008 and 2009, the same percentages for the residential and commercial, and internal combustion engine fuel shown in Table TN4.2 are applied to the combined Maryland and D.C. sales for those sales categories. The percentages for the remaining categories are combined using the 2007 data for those categories, resulting in 99.79% for Maryland and 0.21% for D.C. These percentages are applied to the remaining volumes of the combined Maryland and D.C. sales.
2. Sales of LPG for internal combustion engine fuel use are divided between the transportation sector and the industrial sector by using LGTRSUS, the transportation sector's share of internal combustion engine use. LGTRSUS is estimated from data on "special fuels used on highways," a category that includes only LPG and diesel fuel. The special fuels data are published by the U.S. Department of Transportation, Federal Highway Administration (see MGSFPZZ on page 71). The quantity of LPG included in special fuels is estimated each year. LGTRSUS is then derived by dividing the quantity of LPG included in special fuels used on highways by the quantity of LPG sold for internal combustion engine use. This U.S. factor is applied to the internal combustion engine use of each state. LGTRSUS values are shown in Table TN4.3.
3. The shares of propane used by the residential (LGRCS) and commercial (LGCCS) sectors for each state are based on propane sales data in the API report for 2003 through 2009. The average shares of 2003 through 2008 are applied to the earlier years. Data for LPG sold for residential and commercial use are then split into the two end-use sectors using these two variables.
4. LPG sales data by state and end-use categories for 1960 through 1982 are from EIA's "Sales of Liquefied Petroleum Gases and Ethane." In 1979, EIA modified the LPG sales survey, Form EIA-174, and changed the list of respondents. Because of the updated sampling frame, the 1979 through 1982 sales data may not be directly comparable to the pre-1979 sales when a different estimation procedure was used. Explanation of the discontinuities caused by the change in the 1979 sampling frame are provided in EIA's *Energy Data Report,* "Sales of Liquefied Petroleum Gases and Ethane in 1979." Because of the change in survey techniques used for measuring LPG sales, many states' data were withheld from publication in the 1979 through 1982 LPG sales reports to avoid disclosure of company-level data. The consumption estimates in SEDS use all data published in the 1979 through 1982 LPG sales reports and estimates prepared by EIA's Office of Oil and Gas for data that were withheld from publication. (See Note 5 following for estimation procedures.) Some end-use categories changed in 1979 due to redefinition of the classifications. One of these changes, for example, occurred with LPG sold to farms for household heating and cooking. Before 1979 these sales were reported as part of the residential and commercial category, while in 1979 they were counted in the farm use category that goes into the industrial sector in SEDS. No attempt has been made to adjust for this type of inconsistency. The Form EIA-174 was cancelled after collection of 1982 data. The 1983 LPG consumption estimates are based on the assumption that LPG end-use sector demand in 1983 occurred in the same proportion as 1982 sector demand within each state; i.e., the 1983 LPG product supplied figure was allocated to the states by using the distribution of volumes consumed for 1982.

Table TN4.2. Percentages used to disaggregate Maryland and D.C. combined LPG sales data, 1960 through 2007

Sales Category	Maryland	D.C.
Residential and commercial	99.9%	0.1%
Internal combustion engine fuel	98.9%	1.1%
Industrial	99.4%	0.6%
Chemical	100.0%	0.0%
Utility gas	100.0%	0.0%
Miscellaneous	100.0%	0.0%

5. The following procedures were used to estimate the state end-use sales that were withheld from publication in the 1979-1982 LPG sales reports:
   - For each year, missing state total sales were estimated by allocating the sum of the missing state sales within each Petroleum Administration for Defense (PAD) district to the individual states, in proportion to the sum of the known end-use sales for those states.
   - Missing PAD district end-use totals for 1979 and 1980 were obtained by using the 1980 and 1981 sales reports. Missing PAD district chemical sales were estimated by allocating the total missing volume of chemical sales to the PAD district in proportion to the number of chemical plants in each PAD district. The remaining PAD district end-use totals were obtained by subtraction. For 1981 and 1982, no PAD district estimations were necessary because all PAD district end-use totals are known.
   - The published data and the estimated state and PAD district end-use totals were used to estimate missing state end-use

sales volumes within a PAD district: missing state end-use sector values were estimated by allocating the missing volume for the state approximately proportional to the PAD district end-use sector totals.

6. Before 1979, state data for chemical use of LPG were withheld from publication, although they were included in the U.S. total in the tables in EIA's "Sales of Liquefied Petroleum Gases and Ethane" reports. Beginning in 1979, state-level chemical use data were published in the LPG sales reports, but data for several states were withheld. Estimates for the withheld data for chemical use sales for 1979 and 1980 were created by using the estimation procedure described in Note 5 on page 45. Then the published and the estimated state data for 1979 were used to create state shares of the total U.S. chemical use sales. These percentage shares (shown in Table TN4.4) were applied to the total U.S. LPG chemical use sales in 1960 through 1978 to create state chemical use estimates. The chemical use estimates were added to the states' total LPG sales series, LGTTPZZ.
7. For 1984 through 2007, the American Petroleum Institute (API), the Gas Processors Association, and the National LP-Gas Association jointly sponsored an LPG sales survey. The results are published in the API's report *Sales of Natural Gas Liquids and Liquefied Refinery Gases*.

Table TN4.4. State shares of the total U.S. LPG sold for chemical use, 1960 through 1978

State	Percent	State	Percent
Alabama	0.000	Montana	0.000
Alaska	0.589	Nebraska	0.000
Arizona	0.000	Nevada	0.000
Arkansas	0.000	New Hampshire	0.000
California	2.667	New Jersey	2.040
Colorado	0.232	New Mexico	0.603
Connecticut	0.053	New York	0.000
Delaware	0.811	North Carolina	0.327
District of Columbia	0.000	North Dakota	0.000
Florida	0.000	Ohio	1.103
Georgia	0.699	Oklahoma	0.309
Hawaii	0.000	Oregon	0.000
Idaho	0.000	Pennsylvania	0.354
Illinois	7.066	Rhode Island	0.000
Indiana	0.243	South Carolina	0.021
Iowa	0.900	South Dakota	0.000
Kansas	0.451	Tennessee	0.000
Kentucky	2.548	Texas	57.425
Louisiana	20.566	Utah	0.000
Maine	0.012	Vermont	0.000
Maryland	0.050	Virginia	0.025
Massachusetts	0.009	Washington	0.000
Michigan	0.151	West Virginia	0.286
Minnesota	0.000	Wisconsin	0.000
Mississippi	0.315	Wyoming	0.091
Missouri	0.054	United States	100.000

These data include sales of natural gasoline (pentanes plus); the natural gasoline data were removed by EIA before use in SEDS.

For 1997 through 2007, API incorporated additional imports and exports data in their estimates. Those trade data are also removed by EIA before use in SEDS.

Natural gasoline (formerly pentanes plus)

Before 2010, natural gasoline (formerly called pentanes plus) consumption is assumed to be equal to historical pentanes plus consumption, which included historical natural gasoline, plant condensate, pentanes plus, and unfractionated streams.

NATCPUS	=	historical natural gasoline (including isopentane) total consumption in the United States, in thousand barrels (through 1983);
PLTCPUS	=	plant condensate total consumption in the United States, in thousand barrels (through 1983);
PPTCPUS	=	pentanes plus (natural gasoline) total consumption in the United States, in thousand barrels (1984 through 2009); and
USTCPUS	=	unfractionated streams total consumption in the United States, in thousand barrels (through 1983).

All natural gasoline consumption is assumed to be in the industrial sector. This section covers natural gasoline consumption for 1960 through 2009.

For 2010 forward, SEDS reports natural gasoline (pentanes plus) as a HGL product. See Hydrocarbon Gas Liquids (2010 Forward).

Physical units

Natural gasoline (formerly pentanes plus) is used mainly as petrochemical feedstocks in the same way as naphtha. All natural gasoline consumption is assumed to be in the industrial sector.

Historical natural gasoline (including isopentane), plant condensate, and unfractionated streams are discontinued from the source after 1983. Beginning in 1984, historical natural gasoline and plant condensate are reported together as a new product, pentanes plus; and unfractionated streams are discontinued because its components are reported separately as liquefied petroleum gases. These products are used mostly as petrochemical feedstocks.

To allocate the U.S. consumption of these products to the states, the state shares of capacity of steam crackers using napthas (FNCASZZ) are used. The method of estimation of FNCASZZ is discussed on page 84.

Historical natural gasoline (including isopentane) state and U.S. consumption are estimated:

```
NATCPZZ  =  NATCPUS * FNCASZZ
NAICPZZ  =  NATCPZZ
NAICPUS  =  NATCPUS
```

Pentanes plus (natural gasoline) state and U.S. consumption are estimated:

```
PPTCPZZ  =  PPTCPUS * FNCASZZ
PPICPZZ  =  PPTCPZZ
PPICPUS  =  PPTCPUS
```

Plant condensate state and U.S. consumption are estimated:

```
PLTCPZZ  =  PLTCPUS * FNCASZZ
PLICPZZ  =  PLTCPZZ
PLICPUS  =  PLTCPUS
```

Unfractionated streams state and U.S. consumption are estimated:

```
USTCPZZ  =  USTCPUS * FNCASZZ
USICPZZ  =  USTCPZZ
USICPUS  =  USTCPUS
```

British thermal units (Btu)

Btu estimates for the four historical natural gasoline (pentanes plus) products are developed by multiplying each individual product's estimated consumption in physical units by its respective approximate heat content conversion factor. The calculations performed to estimate total Btu consumption and industrial use Btu consumption by state and for the United States are

```
NATCBZZ  =  NATCPZZ * 4.638
NATCBUS  =  ΣNATCBZZ
NAICBZZ  =  NATCBZZ
NAICBUS  =  NATCBUS
PLTCBZZ  =  PLTCPZZ * 5.418
PLTCBUS  =  ΣPLTCBZZ
PLICBZZ  =  PLTCBZZ
PLICBUS  =  PLTCBUS
```

LUBA No. 2020-009
Page 5691

PPTCBZZ = PPTCPZZ * 4.638
PPTCBUS = ΣPPTCBZZ
PPICBZZ = PPTCBZZ
PPICBUS = PPTCBUS
USTCBZZ = USTCPZZ * 5.418
USTCBUS = ΣUSTCBZZ
USICBZZ = USTCBZZ
USICBUS = USTCBUS

Additional note

Before the 2010 cycle, natural gasoline (pentanes plus) was allocated to the states in proportion to the value of shipments or value added in the manufacture of industrial organic chemicals from the Economic Censuses collected by the U.S. Census Bureau. Organic chemical manufacturing was used because state-level data for petrochemical manufacturing were not available. This resulted in the allocation of petrochemical feedstocks to more than 25 states, most of which did not produce petrochemicals. The steam cracker capacity shares, while requiring estimations, are better allocators.

Data sources

NATCPUS — Natural gasoline total consumption in the United States (through 1983).

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys. "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 through 1983: EIA, *Petroleum Supply Annual*, Table 2.

PLTCPUS — Plant condensate total consumption in the United States (through 1983).

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys. "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 through 1983: EIA, *Petroleum Supply Annual*, Table 2.

PPTCPUS — Pentanes plus (natural gasoline) total consumption in the United States.

- 1960 through 1983: Data were reported separately as natural gasoline, isopentane, and plant condensate.
- 1984 through 2009: EIA, *Petroleum Supply Annual*, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1984 through 2004: Table 2.
  - 2005 through 2009: Table 1.

USTCPUS — Unfractionated streams total consumption in the United States (through 1983).

- 1960 through 1978: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1, included in "Plant Condensate."
- 1979 and 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 through 1983: EIA, *Petroleum Supply Annual*, Table 2, column titled "Products Supplied."

Hydrocarbon gas liquids (HGL)

Before 2010, HGL consumption is defined as the sum of LPG and pentanes plus (natural gasoline). Because pentanes plus is only used in the industrial sector, HGL consumption in the other end-use sectors is equal to LPG consumption:

HLRCPZZ = LGRCPZZ
HLCCPZZ = LGCCPZZ
HLACPZZ = LGACPZZ

HLRCBZZ = LGRCBZZ
HLCCBZZ = LGCCBZZ
HLACBZZ = LGACBZZ

Before 1984, industrial sector HGL consumption is equal to:

HLICPZZ = LGICPZZ + NATCPZZ + PLTCPZZ + USTCPZZ
HLICBZZ = LGICBZZ + NATCBZZ + PLTCBZZ + USTCBZZ

For 1984 through 2009, industrial sector HGL consumption is equal to:

HLICPZZ = LGICPZZ + PPICPZZ
HLICBZZ = LGICBZZ + PPICBZZ

Total HGL consumption is the sum of the end-use consumption estimates:

HLTCPZZ = HLACPZZ + HLCCPZZ + HLICPZZ + HLRCPZZ
HLTCBZZ = HLACBZZ + HLCCBZZ + HLICBZZ + HLRCBZZ

LUBA No. 2020-009
Page 5692

Total U.S. HGL consumption in physical unit is the sum of the product supplied of LPG and pentanes plus:

Before 1984:

HLTCPUS = LGTCPUS + NATCPUS + PLTCPUS + USTCPUS

For 1984 through 2009:

HLTCPUS = LGTCPUS + PPTCPUS

The U.S. totals for all other HL consumption series are calculated as the sum of the state values.

Hydrocarbon Gas Liquids (2010 Forward)

Hydrocarbon gas liquids (HGL) cover natural gas liquids (ethane, propane, normal butane, isobutane, and natural gasoline) and refinery olefins (ethylene, propylene, butylene, and isobutylene). Refinery olefins are olefins produced at refineries and do not include olefins produced by the manufacturing industries. The State Energy Data System (SEDS) assumes that, except for propane, all other HGL products are consumed only by the industrial sector.

For 2010 forward, the U.S. Energy Information Administration (EIA) publishes U.S. products supplied data for total HGL and the nine HGL products, which are used to define U.S. consumption in SEDS:

- HLTCPUS = hydrocarbon gas liquids total consumption in the United States, in thousand barrels;
- BQTCPUS = normal butane total consumption in the United States, in thousand barrels;
- BYTCPUS = butylene from refineries total consumption in the United States, in thousand barrels;
- EQTCPUS = ethane total consumption in the United States, in thousand barrels;
- EYTCPUS = ethylene from refineries total consumption in the United States, in thousand barrels;
- IQTCPUS = isobutane total consumption in the United States, in thousand barrels;
- IYTCPUS = isobutylene from refineries total consumption in the United States, in thousand barrels;
- PPTCPUS = natural gasoline (pentanes plus) total consumption in the United States, in thousand barrels;
- PQTCPUS = propane total consumption in the United States, in thousand barrels; and
- PYTCPUS = propylene from refineries total consumption in the United States, in thousand barrels.

Natural gasoline (pentanes plus), which was included in "other petroleum products" through 2015 SEDS reports, is included here in HGL.

SEDS estimates state-level HGL consumption using a combination of EIA estimates, American Petroleum Institute's (API) *Sales of Natural Gas Liquids and Liquefied Refinery Gases* (for 2010 through 2016), Propane Education & Research Council's (PERC) *Retail Propane Sales Report* (for 2017), and *Oil and Gas Journal* (OGJ) ethylene steam cracker capacity data.

LUBA No. 2020-009
Page 5693

Residential sector

Physical units

SEDS assumes all residential sector HGL consumption to be equal to residential propane consumption.

PQRCPZZ = propane consumed by the residential sector, in thousand barrels.

For 2010 through 2016, propane consumed by the residential sector is derived from API's *Sales of Natural Gas Liquids and Liquefied Refinery Gases*, sales of odorized propane for the residential sector and sales for retailers. For 2017, propane consumed by the residential sector is derived from PERC's *Retail Propane Sales Report*, sales of odorized propane for the residential sector and for cylinder markets. Sales data are reported in gallons and are converted to barrels (42 U.S. gallons per U.S. barrel) for total SEDS residential propane consumption estimates.

Residential sector HGL consumption in each state, HLRCPZZ, equals residential propane consumption:

HLRCPZZ = PQRCPZZ

The U.S. totals for the state data series are calculated as the sum of the state values.

Commercial sector

Physical units

SEDS assumes all commercial sector HGL consumption to be equal to commercial propane consumption.

PQCCPZZ = propane consumed by the commercial sector, in thousand barrels.

Propane consumed by the commercial sector is derived from sales of odorized propane for the commercial sector reported in the API report (2010-2016) or the PERC report (2017). Sales data are reported in gallons and are converted to barrels (42 U.S. gallons per U.S. barrel) for total SEDS commercial consumption estimates.

Commercial sector HGL consumption in each state, HLCCPZZ, equals commercial propane consumption:

HLCCPZZ = PQCCPZZ

The U.S. totals for the state data series are calculated as the sum of the state values.

Industrial sector

For 2010 forward, industrial sector consumption is developed for nine HGL components: normal butane, butylene, ethane, ethylene, isobutane, isobutylene, natural gasoline (pentanes plus), propane, and propylene.

Propane physical units

Beginning in 2010, a new methodology is developed to estimate the consumption of propane in the United States by the industrial sector and allocation to the states.

PQICPZZ = propane consumed by the industrial sector, in thousand barrels.

Propane consumed by the industrial sector is defined by two categories: other odorized industrial propane and industrial propane for chemical use. To calculate other odorized industrial propane consumption, SEDS subtracts the sum of residential, commercial, and transportation sectors' propane consumption for each state from the state's total odorized propane sales, available in the API report (2010-2016) or the PERC report (2017). To calculate industrial propane for chemical use for the United States, U.S. total odorized propane sales are subtracted from U.S. total propane consumption. SEDS uses propane chemical feedstock capacity of ethylene steam crackers from OGJ (2010-2014) or estimated by EIA (2015 forward) to allocate consumption to states. The sum of other odorized industrial propane consumption and industrial propane consumption for chemical use is equal to SEDS total industrial propane consumption. Data originally reported in gallons are converted to barrels (42 U.S. gallons per U.S. barrel) for total SEDS industrial consumption estimates.

Other HGL physical units

SEDS assumes all other HGL products (normal butane, butylene, ethane, ethylene, isobutane, isobutylene, natural gasoline, and propylene) are consumed only by the industrial sector.

BQTCPZZ = normal butane total consumption, in thousand barrels;
BYTCPZZ = butylene from refineries total consumption, in thousand barrels;
EQTCPZZ = ethane total consumption, in thousand barrels;

LUBA No. 2020-009
Page 5694

EYTCPZZ = ethylene from refineries total consumption, in thousand barrels;
IQTCPZZ = isobutane total consumption, in thousand barrels;
IYTCPZZ = isobutylene from refineries total consumption, in thousand barrels;
PPTCPZZ = natural gasoline (pentanes plus) total consumption, in thousand barrels; and
PYTCPZZ = propylene from refineries total consumption, in thousand barrels.

State-level estimates for other HGL products are derived by applying state shares estimated by EIA to the U.S. product supplied for each HGL type.

For normal butane, SEDS estimates state allocations using capacities from *Oil and Gas Journal* (OGJ) ethylene crackers feed slates for n-butane, scaled to total U.S. normal butane product supplied from EIA's *Petroleum Supply Annual* (PSA). All consumption is assumed to be in Louisiana and Texas.

For butylene, SEDS estimates state allocations using SEDS naphtha feedstock capacity shares, based on OGJ data, scaled to total U.S. butylene product supplied from PSA. All consumption is assumed to be in Louisiana and Texas.

For ethane, SEDS estimates state allocations using ethane feedstock plant nameplate capacities from OGJ (2010-2014) or compiled by EIA (2015 forward) for plants in Illinois, Iowa, and Kentucky. Capacities from those three states is subtracted from total U.S. ethane product supplied from PSA and the remainder is allocated to Louisiana and Texas using their ethane feedstock capacity shares.

For ethylene, SEDS estimates state allocations using total U.S. ethylene product supplied from PSA and allocated proportionally to states based on SEDS ethane consumption estimates.

For isobutane, SEDS assumes all U.S. consumption is in Texas.

For isobutylene, SEDS estimates state allocations using SEDS naphtha feedstock capacity shares, based on OGJ data, scaled to total U.S. isobutylene product supplied from PSA. All consumption is assumed to be in Louisiana and Texas.

For natural gasoline, SEDS estimates state allocations using SEDS naphtha feedstock capacity shares, based on OGJ data, scaled to total U.S. natural gasoline product supplied from PSA. All consumption is assumed to be in Louisiana and Texas.

For propylene, SEDS estimates state allocations using EIA estimated plant production capacities of products using propylene as feedstock, scaled to total U.S. propylene product supplied from PSA. All consumption is assumed to be in California, Illinois, Kentucky, Louisiana, New Jersey, Ohio, Pennsylvania, Texas, and West Virginia.

Industrial sector consumption by state for each of the other HGL products is equal to its total consumption. For example,

BQICPZZ = BQTCPZZ

Total industrial HGL consumption for each state is equal to:

HLICPZZ = BQICPZZ + BYICPZZ + EQICPZZ + EYICPZZ + IQICPZZ + IYICPZZ + PPICPZZ + PQICPZZ + PYICPZZ

The U.S. totals for the state data series are calculated as the sum of the state values.

Transportation sector

Physical units

SEDS assumes all transportation sector HGL consumption to be equal to transportation propane consumption.

Beginning in 2010, a new methodology is developed to estimate the consumption of propane in the United States by the transportation sector and allocation to the states:

PQACPZZ = propane consumed by the transportation sector, in thousand barrels.

Total U.S. consumption of propane in the United States by the transportation sector, in British thermal units (Btu), comes from the U.S. Energy Information Administration's (EIA) *Annual Energy Outlook*, Table 37, "Transportation Sector Energy Use by Fuel Type Within a Mode." The Btu consumption values are converted to barrels using propane's heat content of 3.841 million Btu per barrel.

For 2010 through 2016, SEDS assumes that 65% of propane is consumed by fleet vehicles, including all medium-duty and heavy-duty vehicles and some light-duty vehicles. The remaining 35% is consumed by other light-duty vehicles.

To allocate medium-duty and heavy-duty vehicles to the states, SEDS uses propane consumption data from Form EIA-886 "Annual Survey of Alternative

LUBA No. 2020-009
Page 5695

Fueled Vehicles" to calculate state shares. For light-duty vehicles, SEDS uses the U.S. Department of Transportation, Federal Highway Administration publication, *Highway Statistics*, Table VM-2, "Vehicle-miles of travel, by functional system" to calculate state shares. Lastly, the state allocations for the two categories are summed together to calculate the final state consumption.

For 2017, to allocate the U.S. consumption of propane by the transportation sector to the states, SEDS uses unpublished propane autogas sales data from PERC to compute state shares.

Transportation sector HGL consumption in each state, HLACPZZ, equals transportation propane consumption:

HLACPZZ = PQACPZZ

The U.S. totals for the state data series are calculated as the sum of the state values.

Total

Physical units

Total HGL consumption is the sum of the end-use consumption estimates:

HLTCPZZ = HLACPZZ + HLCCPZZ + HLICPZZ + HLRCPZZ

Total propane consumption is also calculated:

PQTCPZZ = PQACPZZ + PQCCPZZ + PQICPZZ + PQRCPZZ

All sectors

British thermal units (Btu)

Btu estimates for each of the nine HGL products in this group are developed by multiplying the estimated consumption of each individual product in physical units by its respective heat content conversion factor. The calculations performed to estimate residential, commercial, industrial, and total propane Btu consumption, and industrial and total other HGL Btu consumption by state and for the United States are

BQICBZZ = BQICPZZ * 4.353
BQICBUS = ΣBQICBZZ
BQTCBZZ = BQTCPZZ * 4.353
BQTCBUS = ΣBQTCBZZ
BYICBZZ = BYICPZZ * 4.377
BYICBUS = ΣBYICBZZ
BYTCBZZ = BYTCPZZ * 4.377
BYTCBUS = ΣBYTCBZZ
EQICBZZ = EQICPZZ * 2.783
EQICBUS = ΣEQICBZZ
EQTCBZZ = EQTCPZZ * 2.783
EQTCBUS = ΣEQTCBZZ
EYICBZZ = EYICPZZ * 2.436
EYICBUS = ΣEYICBZZ
EYTCBZZ = EYTCPZZ * 2.436
EYTCBUS = ΣEYTCBZZ
IQICBZZ = IQICPZZ * 4.183
IQICBUS = ΣIQICBZZ
IQTCBZZ = IQTCPZZ * 4.183
IQTCBUS = ΣIQTCBZZ
IYICBZZ = IYICPZZ * 4.355
IYICBUS = ΣIYICBZZ
IYTCBZZ = IYTCPZZ * 4.355
IYTCBUS = ΣIYTCBZZ
PPICBZZ = PPICPZZ * 4.638
PPICBUS = ΣPPICBZZ
PPTCBZZ = PPTCPZZ * 4.638
PPTCBUS = ΣPPTCBZZ
PQACBZZ = PQACPZZ * 3.841
PQACBUS = ΣPQACBZZ
PQCCBZZ = PQCCPZZ * 3.841
PQCCBUS = ΣPQCCBZZ
PQICBZZ = PQICPZZ * 3.841
PQICBUS = ΣPQICBZZ
PQRCBZZ = PQRCPZZ * 3.841
PQRCBUS = ΣPQRCBZZ
PYICBZZ = PYICPZZ * 3.835
PYICBUS = ΣPYICBZZ
PYTCBZZ = PYTCPZZ * 3.835
PYTCBUS = ΣPYTCBZZ

Estimated consumption of HGL in Btu is the sum of the Btu consumption of each product by the corresponding sector. The state and U.S. totals are calculated:

HLACBZZ = PQACBZZ

HLACBUS = ΣHLACBZZ
HLCCBZZ = PQCCBZZ
HLCCBUS = ΣHLCCBZZ
HLICBZZ = BQICBZZ + BYICBZZ + EQICBZZ + EYICBZZ + IQICBZZ + IYICBZZ + PPICBZZ + PQICBZZ + PYICBZZ
HLICBUS = ΣHLICBZZ
HLRCBZZ = PQRCBZZ
HLRCBUS = ΣHLRCBZZ

Total HGL and propane consumption in Btu are the sum of the sectors:

PQTCBZZ = PQACBZZ + PQCCBZZ + PQICBZZ + PQRCBZZ
PQTCBUS = ΣPQTCBZZ

HLTCBZZ = HLACBZZ + HLCCBZZ + HLICBZZ + HLRCBZZ
HLTCBUS = ΣHLTCBZZ

Additional calculations

HGL products other than propane are combined for use in the estimation of prices and expenditures. They include normal butane, butylene, ethane, ethylene, isobutane, isobutylene, natural gasoline, and propylene. The variables are calculated in Btu, for each state and the United States:

OHICBZZ = BQICBZZ + BYICBZZ + EQICBZZ + EYICBZZ + IQICBZZ + IYICBZZ + PPICBZZ + PYICBZZ
OHICBUS = ΣOHICBZZ

The average factor for converting hydrocarbon gas liquids consumed by the industrial sector from physical units to Btu is calculated as

HLICKZZ = HLICBZZ / HLICPZZ
HLICKUS = HLICBUS / HLICPUS

HLTCKZZ = HLTCBZZ / HLTCPZZ
HLTCKUS = HLTCBUS / HLTCPUS

Data sources

BQTCPUS — Normal butane total consumption in the United States.
BQTCPZZ — Normal butane total consumption by state.

- 2010 forward: Estimated using EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied," Table 1 and ethylene crackers feed slates for n-butane from the *Oil and Gas Journal*. For 2015, information on n-butane feed slate capacity of ethylene steam crackers are no longer available from OGJ. The 2014 volumes are used for 2015 forward.

BYTCPUS — Butylene from refineries total consumption in the United States.
BYTCPZZ — Butylene from refineries total consumption by state.

- 2010 forward: Estimated using EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied," Table 1 and state's share of U.S. capacity of steam crackers using naphtha as feedstocks (FNCAS):

Jet Fuel

Jet fuel is used primarily for transportation, although small amounts of kerosene-type jet fuel are also used in the electric power sector. There are two types of jet fuel with different heat contents, kerosene-type jet fuel (JK) and naphtha-type jet fuel (JN), which are added in the State Energy Data System (SEDS) to give total jet fuel (JF). Beginning in 2005, naphtha-type jet fuel is included in "Miscellaneous Petroleum Products" in the data source, and is assigned a zero value in SEDS.

Kerosene-type jet fuel

Physical units

Data series used to calculate kerosene-type jet fuel consumption estimates are ("ZZ" in the variable name represents the two-letter state code that differs for each state)

JKTCPUS	=	kerosene-type jet fuel total consumption, in thousand barrels;
JKEUPZZ	=	the electric utility sector consumption of kerosene-type jet fuel in each state, in thousand barrels (through 1982); and
JKTTPZZ	=	kerosene-type jet fuel total sold, in thousand gallons.

Total U.S. consumption of kerosene-type jet fuel, JKTCPUS, is the product supplied data series in the publication *Petroleum Supply Annual,* published by the U.S. Energy Information Administration (EIA).

Kerosene-type jet fuel consumed by electric utilities, JKEUPZZ, is published by EIA in the *Cost and Quality of Fuels for Electric Utility Plants*. These data are available for 1972 through 1982 only. Consumption from 1983 forward is assumed to be zero in SEDS. Beginning in 2001, jet fuel used for power generation is included in waste/other oil in the source data file. Data for waste/other oil are not processed in SEDS because waste oil is not primary energy—consumption of the petroleum products that produced the waste oil has already been accounted for. As such, a small volume of jet fuel used for power generation is included in the transportation sector consumption.

Kerosene-type jet fuel total sold, JKTTPZZ, was collected by the Ethyl Corporation, Petroleum Chemicals Division, for 1960 through 1983, and is collected by EIA for 1984 forward. The Ethyl Corporation data are sales to commercial users and are used to represent total sales based on the assumption that there is little military use of kerosene-type jet fuel during

LUBA No. 2020-009
Page 5699

1960 through 1983. (See Note 1 in the "Additional Notes" section for the source reference for this assumption.) EIA data for 1984 forward include commercial and military sales. Data for 1984 through 1993 are taken from the EIA *Petroleum Marketing Annual* (PMA). Data for 1994 forward are taken from unpublished data in thousand gallons and are available in thousand gallons per day in PMA (through 2009) and on the EIA website. Before 1994, withheld data are estimated by using averages of published months to fill in withheld months; subtracting published states from published PAD district totals; and assigning values based on previous years' quantities. Beginning in 1994, withheld data are estimated using historical growth rates or state shares. They include Arizona (2009), Connecticut (2011), Delaware (1995, 1997, 1998, and 2013–2017), Hawaii (2002–2004 and 2008–2011), Iowa (2010), Nevada (2010 and 2011), New Hampshire (2009), Oregon (2002–2004 and 2008), Rhode Island (2011 and 2012), Tennessee (2010), and Vermont (2009 and 2012). Kerosene-type jet fuel sales in the District of Columbia are assumed to be zero (1994–2017).

U.S. totals for the two state data series are calculated as the sum of the state data.

Most kerosene-type jet fuel is used by the transportation sector. The transportation sector consumption for the United States (JKACPUS) is estimated as the difference between the total kerosene-type jet fuel consumed and the electric utility consumption:

JKACPUS = JKTCPUS - JKEUPUS

It is assumed that kerosene-type jet fuel consumption in each state is in proportion to the amount sold in each state:

JKACPZZ = (JKTTPZZ / JKTTPUS) * JKACPUS

Total kerosene-type jet fuel by state is estimated as

JKTCPZZ = JKACPZZ + JKEUPZZ

British thermal units (Btu)

Kerosene-type jet fuel has a heat content value of about 5.670 million Btu per barrel. This factor is applied to convert kerosene-type jet fuel from physical units to Btu:

JKACBZZ = JKACPZZ * 5.670
JKACBUS = ΣJKACBZZ
JKEUBZZ = JKEUPZZ * 5.670
JKEUBUS = ΣJKEUBZZ
JKTCBZZ = JKTCPZZ * 5.670
JKTCBUS = ΣJKTCBZZ

Additional notes

1. An assumption is made that kerosene-type jet fuel use by the military in 1960 through 1983 is negligible. This assumption is based on product definitions from the American Petroleum Institute's *Standard Definitions for Petroleum Statistics,* Technical Report No. 1, Third Edition (1981), page 13, which states that kerosene-type jet fuel is used primarily by commercial aircraft engines.
2. Ethyl Corporation jet fuel sales to commercial users by state include some sales data that were improperly allocated between the states of Illinois and Indiana for 1960 through 1973. To adjust for this error, the average relative proportions of Illinois and Indiana sales from 1974 through 1978 were applied to the sum of the Illinois and Indiana sales in 1960 through 1973. From 1974 through 1983, sales data were correctly allocated.
3. Jet fuel sales in Illinois decreased sharply from 1984 forward, while sales in Indiana increased by about the same amount. It is possible that jet fuel for use at Chicago, Illinois, airports may have been purchased in Indiana. The same anomaly may have happened between New York and New Jersey beginning in 1981, when jet fuel for consumption at New York City airports may have been purchased in New Jersey. This is an inherent problem when using sales data as an indication of consumption, and no attempt has been made to adjust the numbers.
4. Before 1964, kerosene-type jet fuel was included in the total kerosene product supplied data in the source, the U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 2, "Salient Statistics of the Major Refined Petroleum Products in the United States." Table TN4.5 summarizes the derivation of kerosene and jet fuel consumption estimates (columns 4 and 5) from data published in the source (columns 1, 2,and 3) for 1960 through 1963. For 1964 and years following, kerosene and kerosene-type jet fuel are reported separately in the source documents.
5. Kerosene-type jet fuel consumed by electric utilities, JKEUPZZ, is published in the EIA *Cost and Quality of Fuels for Electric Utility Plants*. These data are available for 1972 through 1982 only. Consumption in all other years is assumed to be zero. State-level data for 1972 through 1974 are not available. The percentage of each state's consumption

LUBA No. 2020-009
Page 5700

Table TN4.5. Estimate of U.S. consumption of kerosene and jet fuel for 1960 through 1963 (Thousand barrels)

Year	(1) Kerosene demand, including commercial jet fuel	(2) Jet fuel demand, military use only	(3) Sales of kerosene for commercial jet fuel use	(4) Estimated kerosene consumption (1) – (3)	(5) Estimated total jet fuel consumption (2) + (3)
1960	132,499	102,803	33,159	99,340	135,962
1961	144,435	104,436	47,187	97,248	151,623
1962	164,167	112,401	66,134	98,033	178,535
1963	172,212	115,237	75,236	96,976	190,473

of the total U.S. consumption in 1975 was used to apportion the 1972 through 1974 national data to the states.

Data sources

JKEUPZZ — Kerosene-type jet fuel consumed by electric utilities by state (through 1982).

- 1960 through 1971: No data available. Values are assumed to be zero.
- 1972 through 1974: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Sales of Fuel Oil and Kerosene," Table 15 footnote for U.S. value. These data were apportioned to the states by using the 1975 state proportions of the 1975 U.S. total from the source below.
- 1975 through 1979: Office of Electric Power Regulation, Federal Energy Regulatory Commission, *Annual Summary of Cost and Quality of Electric Utility Plant Fuels*, "Fuel Oil Deliveries for Combustion Turbine and Internal Combustion Units."
- 1980 through 1982: EIA, *Cost and Quality of Fuel for Electric Utility Plants*, Table 30.

JKTTPZZ — Kerosene-type jet fuel total sold by state.

- 1960 through 1983: Ethyl Corporation, Petroleum Chemicals Division, *Yearly Report of Gasoline Sales by States*, "Aviation Turbine Fuel Sales."
- 1984 and 1985: EIA, *Petroleum Marketing Annual 1985*, Volume2.
  - 1984: Table A6.
  - 1985: Table 34.
- 1986 through 1988: EIA, *Petroleum Marketing Annual*, Table 46.
- 1989 through 1993: EIA, *Petroleum Marketing Annual*, Table 48.
- 1994 forward: Unpublished data in thousand gallons from Form EIA-782C, "Monthly Report of Prime Supplier Sales of Petroleum Products Sold for Local Consumption." Data published in thousand gallons per day in EIA, *Petroleum Marketing Annual*, http://www.eia.gov/oil_gas/petroleum/data_publications/petroleum_marketing_annual/pma_historical.html and on the Prime Supplier Sales Volumes website at http://www.eia.gov/dnav/pet/pet_cons_prim_a_EPJK_P00_Mgalpd_a.htm.

  - 2007 through 2009: Table 46.
  - 2010 forward: Web table only, at http://www.eia.gov/dnav/pet/pet_cons_prim_a_EPJK_P00_Mgalpd_a.htm.

JKTCPUS — Kerosene-type jet fuel total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Naphtha-type jet fuel

Physical units

Two data series are used to estimate naphtha-type jet fuel consumption:

JNTCPUS = naphtha-type jet fuel total consumption, in thousand barrels; and

JNMIPZZ = naphtha-type jet fuel issued to the military in each state, in thousand barrels.

Total U.S. consumption of naphtha-type jet fuel, JNTCPUS, is the product supplied data series in the publication *Petroleum Supply Annual,* published by EIA. Beginning in 2005, it is included in "Miscellaneous Petroleum Products," and is assigned a zero value in SEDS.

It is assumed that all naphtha-type jet fuel is used in military aircraft engines. (See the Additional Notes at the end of this section for the source reference for this assumption.) Data on naphtha-type jet fuel issued to the military in each state, JNMIPZZ, are from the U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center.

The total U.S. military issues is the sum of the state data:

JNMIPUS = ΣJNMIPZZ

An estimate of naphtha-type jet fuel consumption by state, JNTCPZZ, is calculated by assuming that each state consumes naphtha-type jet fuel in proportion to the amount issued to the military in that state:

JNTCPZZ = (JNMIPZZ / JNMIPUS) * JNTCPUS

All naphtha-type jet fuel is assumed to be used for transportation purposes so the transportation consumption equals the estimated total consumption for each state and for the United States:

JNACPZZ = JNTCPZZ
JNACPUS = JNTCPUS

British thermal units (Btu)

Naphtha-type jet fuel has a heat content value of about 5.355 million Btu per barrel. This factor is applied to convert naphtha-type jet fuel from physical units to Btu:

JNTCBZZ = JNTCPZZ * 5.355
JNTCBUS = ΣJNTCBZZ

Naphtha-type jet fuel consumed in the transportation sector is equal to total consumption.

JNACBZZ = JNTCBZZ
JNACBUS = JNTCBUS

Additional notes

1. An assumption is made that the naphtha-type jet fuel is for military use only. This assumption is based on product definitions from the American Petroleum Institute's *Standard Definitions for Petroleum Statistics*, Technical Report No. 1, Third Edition (1981), page 13, which states that naphtha-type jet fuel is used primarily by military aircraft engines.
2. Data on naphtha-type jet fuel issued to the military for each state (JNMIPZZ) are obtained from the U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center. There are no data available for 1960 through 1974, and the data available for 1975 and 1976 are not consistent; therefore, the 1977 values are used for 1960 through 1976 in SEDS. The data are reported by fiscal year for 1977 through 1988 and are taken from the Defense Energy Information System. For 1989 and 1990, fiscal-year data from two databases, Defense Fuel Automated Management System and the Into-Plane Database, are summed. For 1991 and 1992, data from the same two databases, reported by calendar year, are used.
3. Because total naphtha-type jet fuel product supplied is assumed to be zero beginning in 2005, naphtha-type jet fuel issued to the military is also assumed to be zero for 2005 forward.

Data sources

JNMIPZZ — Naphtha-type jet fuel issued to the military in the United States.

- 1960 through 1974: No data are available. The 1977 data are used for each year.
- 1975 and 1976: No consistent data series are available. The 1977 data are used for both years.
- 1977 through 1987: The U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center, Defense Energy Information System, military retail issues based on fiscal year data. The District of Columbia issues are assumed to be zero; therefore, values reported for the District of Columbia are added to Maryland.
- 1988: U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center, average of 1987 data (see source above) and 1989 data (see source below).
- 1989 and 1990: U.S. Department of Defense, Defense Logistics Agency, Defense Fuel Supply Center, Defense Fuel Automated Management System, military wholesale issues based on fiscal year data.

LUBA No. 2020-009
Page 5702

- 1991 through 2004: U.S. Department of Defense, Defense Logistics Agency, Defense Energy Supply Center. State data for the calendar year from two databases are summed: Defense Fuel Automated Management System (military wholesale issues) and Into-Plane Database (military purchases from commercial airports). Into-plane values reported for the District of Columbia are added to Virginia.
- 2005 forward: Value entered in SEDS as zero.

JNTCPUS — Naphtha-type jet fuel total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Data not reported separately. Volumes are included in "Miscellaneous Products" in the *Petroleum Supply Annual*, Table 1. Value entered in SEDS as zero.

Jet fuel totals

Physical units

The following calculations are used to provide total jet fuel consumption estimates by end use in physical units:

JFACPZZ = JKACPZZ + JNACPZZ
JFACPUS = ΣJFACPZZ
JFEUPZZ = JKEUPZZ
JFEUPUS = JKEUPUS
JFTCPZZ = JFACPZZ + JFEUPZZ
JFTCPUS = ΣJFTCPZZ

British thermal units (Btu)

The following calculations are used to provide total jet fuel consumption estimates by end use in Btu:

JFACBZZ = JKACBZZ + JNACBZZ
JFACBUS = ΣJFACBZZ
JFEUBZZ = JKEUBZZ
JFEUBUS = JKEUBUS
JFTCBZZ = JFACBZZ + JFEUBZZ
JFTCBUS = ΣJFTCBZZ

LUBA No. 2020-009
Page 5703

Kerosene

Physical units

Because state-level and end-use consumption data for kerosene are not available, four data series published by the U.S. Energy Information Administration (EIA) representing sales of kerosene into or within each state are used to estimate kerosene consumption. The fifth data series, the U.S. total consumption, is the product supplied series from the EIA *Petroleum Supply Annual*. The sales series are used to apportion the known U.S. total consumption into state-level estimates of end-use consumption. The following variable names have been assigned to the five data series ("ZZ" in the variable names represents the two-letter state code that differs for each state):

KSCMPZZ = kerosene sold to the commercial sector, in thousand barrels;
KSIHPZZ = kerosene sold to the industrial sector, in thousand barrels;
KSOTPZZ = kerosene sold for all other uses, including farm use, in thousand barrels;
KSRSPZZ = kerosene sold to the residential sector, in thousand barrels; and
KSTCPUS = kerosene total consumption in the United States, in thousand barrels.

U.S. sales totals for each of the four state-level series are created by summing the state values.

The variables are combined as closely as possible into the major end-use sectors used in SEDS. The residential and commercial sectors contain only KSRSPZZ and KSCMPZZ, respectively.

The sales of kerosene to the industrial sector, KSINPZZ, for each state is the sum of kerosene sold for industrial heating and processing (KSIHPZZ) and kerosene sold for all other uses (KSOTPZZ), including farm use. Sales of kerosene to the industrial sector are calculated:

KSINPZZ = KSOTPZZ + KSIHPZZ
KSINPUS = ΣKSINPZZ

Total sales of kerosene in each state is the sum of these three sectors' sales:

KSTTPZZ = KSRSPZZ + KSCMPZZ + KSINPZZ
KSTTPUS = ΣKSTTPZZ

An estimate of each state's total consumption of kerosene is made by disaggregating the U.S. total consumption to the states in proportion to each state's sales share of the U.S. total sales:

KSTCPZZ = (KSTTPZZ / KSTTPUS) * KSTCPUS

Each state's residential sector sales percentage of total sales is applied to the state's estimated total consumption to create estimated residential sector consumption for the state, KSRCPZZ:

KSRCPZZ = (KSRSPZZ / KSTTPZZ) * KSTCPZZ

The commercial sector's estimated consumption in each state, KSCCPZZ, is calculated:

KSCCPZZ = (KSCMPZZ / KSTTPZZ) * KSTCPZZ

The industrial sector's estimated consumption in each state, KSICPZZ, is calculated:

KSICPZZ = (KSINPZZ / KSTTPZZ) * KSTCPZZ

U.S. totals for the three sectors' consumption estimates are the sums of the states' estimated consumption.

Data on kerosene consumed by the electric power sector are not separately available before 2003. Beginning in 2003, kerosene used for power generation is included in waste/other oil in the source data file. Data for waste/other oil are not processed in SEDS because waste oil is not primary energ—consumption of the petroleum products that produced the waste oil has already been accounted for. While kerosene consumption by the electric power sector is not separately shown, there is no underestimation of total kerosene consumption because U.S. product supplied covers all uses and sales of kerosene to the industrial sector cover the electric power sector.

British thermal units (Btu)

Kerosene has a heat content value of about 5.670 million Btu per barrel. This factor is applied to convert kerosene estimated consumption from physical units to Btu:

KSRCBZZ = KSRCPZZ * 5.670
KSCCBZZ = KSCCPZZ * 5.670
KSICBZZ = KSICPZZ * 5.670

Total estimated consumption of kerosene in Btu is the sum of the end-use

LUBA No. 2020-009
Page 5704

consumption estimates:

KSTCBZZ = KSRCBZZ + KSCCBZZ + KSICBZZ

The U.S. Btu consumption estimates for the three consuming sectors and the U.S. total are calculated as the sum of the state-level data.

Additional notes

1. See Note 4 at the end of the "Kerosene-type jet fuel" section on page 58 for comments concerning the inclusion of kerosene-type jet fuel with the kerosene total product supplied before 1964 in the source documents.
2. "Sales" data are actually called "shipments" in the source documents for 1960 and 1961; "consumption" for 1962 through 1966; "shipments" for 1967; "sales" from 1968 through 1978; "deliveries" for 1979 through 1983; and "sales" for 1984 forward.
3. In 1979, EIA implemented a new survey form, EIA-172, to obtain deliveries of fuel oil and kerosene data and updated the list of respondents. (A detailed explanation is published in the *Energy Data Report* "Deliveries of Fuel Oil and Kerosene in 1979.") In this survey form, certain end-use categories were redefined—in many cases, to collect more disaggregated data. The reclassifications resulted in some end-use categories that were no longer comparable with those in previous surveys. Where discontinuities occurred, estimates for the pre-1979 years have been made in SEDS to conform with the 1979 kerosene deliveries classifications. The pre-1979 deliveries estimates are not published in this report but are used in SEDS to disaggregate the known U.S. total product supplied (consumption) into state and major end-use sector consumption estimates.

   For kerosene deliveries in 1979, the end-use categories called "residential," "commercial," and "industrial" are available. The pre-1979 deliveries category called "heating" is related to the sum of "residential," "commercial," and "industrial" in 1979. Therefore, the following method was applied to present a comparable series for kerosene delivered to the residential, commercial, and industrial sectors:
   - A 1979 subtotal for heating was created by summing each state's residential, commercial, and industrial deliveries categories, thereby creating a comparable deliveries subtotal for all years.
   - Residential, commercial, and industrial shares of the heating subtotal in 1979 were calculated for each state.
   - These 1979 end-use shares were then applied to each pre-1979 heating subtotal in each state to create state estimates of end-use deliveries for 1960 through 1978.

   The 1980 through 1982 kerosene deliveries data are based on the same survey as that used for 1979; therefore, the 1980 through 1982 data are directly comparable to 1979 data.
4. In 1984, EIA again updated the list of respondents for this survey, and the Form EIA-172 became the Form EIA-821, "Annual Fuel Oil and Kerosene Sales Report." EIA did not conduct a fuel oil and kerosene sales survey for 1983. The 1983 estimates in SEDS are based on 1984 data obtained from the Form EIA-821. Statistical procedures and methodologies used for the Form EIA-821 differ from those used in previous years and are described in the July 1985 issue of the EIA, *Petroleum Marketing Monthly*. Therefore, the 1983 and forward sales data may not be directly comparable to the pre-1983 data. (In the source document, the sales data for 1983 forward are reported in thousand gallons. These data were first converted to thousand barrels before being entered into SEDS.)
5. In 1975 through 1977, the industrial sector consumption of kerosene includes small quantities of kerosene-type jet fuel that were produced as jet fuel and sold as kerosene.

- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Lubricants

Physical units

For 1960 through 2009, three data series are used to estimate state consumption of lubricants. The two state-level sales data series are used to apportion the U.S. total consumption data to the states and the end-use sectors within the states. ("ZZ" in the variable names represents the two-letter state code that differs for each state):

LUINPZZ	=	lubricants sold to the industrial sector, in thousand barrels;
LUTRPZZ	=	lubricants sold to the transportation sector, in thousand barrels; and
LUTCPUS	=	lubricants total consumption in the United States, in thousand barrels.

Data for the first two variables are developed from the U.S. Census Bureau reports "Sales of Lubricating and Industrial Oils and Greases" in the *Current Industrial Reports* series. These series were discontinued in 1977 and the method of estimation for 1978 forward is explained in Note 1 at the end of this "Lubricants" section. The third variable for lubricants is the product supplied data series in the U.S. Energy Information Administration's (EIA) *Petroleum Supply Annual.* The first two variables are used for apportioning the third into state total consumption and state end-use consumption estimates.

Total sales of lubricants for each state, LUTTPZZ, is created by adding the industrial and transportation sales:

LUTTPZZ = LUINPZZ + LUTRPZZ

U.S. sales totals are calculated by summing the state sales data.

Each state's proportion of total U.S. sales is used to calculate each state's estimated consumption of lubricants:

LUTCPZZ = (LUTTPZZ / LUTTPUS) * LUTCPUS

Each state's estimated total consumption of lubricants is further divided into end-use estimates in proportion to that state's sales by sector as a portion of total sales in the state. Lubricants consumed by state for industrial use, LUICPZZ, and for transportation use, LUACPZZ, are calculated:

LUICPZZ = (LUINPZZ / LUTTPZZ) * LUTCPZZ
LUACPZZ = (LUTRPZZ / LUTTPZZ) * LUTCPZZ

LUBA No. 2020-009
Page 5707

The consumption of lubricants in the United States by these two end-use sectors is created by summing the state estimates.

Beginning in 2010, a new methodology is developed to estimate the consumption of lubricants in the United States for the industrial and transportation sectors and allocation to the states.

LUACPZZ = lubricants consumed by the transportation sector, in thousand barrels;
LUACPUS = lubricants consumed by the transportation sector, United States, in thousand barrels;
LUICPZZ = lubricants consumed by the industrial sector, in thousand barrels;
LUICPUS = lubricants consumed by the industrial sector, United States, in thousand barrels; and
LUTCPUS = lubricants total consumption in the United States, in thousand barrels.

Using data from Kline & Company, Inc. on finished lubricant demand for three market segments (industrial, consumer total, and commercial total) and two additional product types covered in the industrial market segment (marine and railroad), shares are compiled for the industrial sector and for the four categories in the transportation sector Table TN4.6.

The shares are applied to U.S. total lubricant consumption to derive U.S. lubricant consumption for the industrial sector, LUICPUS, and for the four transportation categories, which sum to LUACPUS.

State allocators for the consumption of lubricants by the industrial sector are estimated using the use table of the latest benchmark input-output (I-O) accounts and real state gross domestic product (GDP) by industry, both published by the U.S. Department of Commerce, Bureau of Economic Analysis (BEA). One of the commodities in the I-O accounts is "other petroleum and coal products manufacturing" (North American Industry Classification System, NAICS, code 324190), which is mostly lubricants. First, SEDS compiles lubricant input per dollar output for 25 industries in the agriculture, mining, construction, and manufacturing sectors using the benchmark I-O accounts use table. Then, the industrial inputs are multiplied by the real state GDP for the 25 industries. Lastly, the products are summed to the state level and are used to derive state shares for lubricant consumption by the industrial sector.

Table TN4.6. Shares of finished lubricant demand for five product categories, 2010 forward

Year	Industrial	Consumer Total	Commercial Total	Marine	Railroad
2010	46.8%	26.9%	22.0%	3.2%	1.2%
2011	46.2%	27.2%	22.2%	3.3%	1.2%
2012	46.6%	27.1%	22.0%	3.1%	1.2%
2013	46.6%	27.0%	22.0%	3.1%	1.2%
2014	46.7%	27.0%	22.1%	3.1%	1.2%
2015	46.6%	27.0%	22.1%	3.0%	1.2%
2016	46.7%	27.0%	22.0%	3.0%	1.2%
2017	46.8%	26.9%	22.1%	3.0%	1.2%

State-level consumption of lubricants by the industrial sector, LUICPZZ, is calculated by applying the state allocators to the U.S. consumption.

State allocators for the consumption of lubricants for each of the four categories in the transportation sector are derived using the following SEDS data series:

- Motor gasoline consumption by the transportation sector (MGTRP) to allocate U.S. consumer total demand to the states
- Distillate fuel oil sales as diesel fuel for on-highway use (DFONP) to allocate U.S. commercial total demand to the states
- Distillate and residual fuel oil sales for vessel bunkering use (DFBKP and RFBKP) to allocate U.S. marine demand to the states
- Distillate fuel oil sales for railroad use (DFRRP) to allocate U.S. railroad demand to the states

State-level consumption of lubricants by the transportation sector, LUACPZZ, is the sum of the four data series.

British thermal units (Btu)

Lubricants have a heat content value of about 6.065 million Btu per barrel. This factor is applied to convert lubricants estimated consumption from physical units to Btu:

LUICBZZ = LUICPZZ * 6.065
LUACBZZ = LUACPZZ * 6.065

The state total consumption in Btu is the sum of the two sectors' consumption in Btu:

LUTCBZZ = LUICBZZ + LUACBZZ

The U.S. sector and total consumption estimates in Btu are calculated as the sum of the state data.

LUBA No. 2020-009
Page 5708

Table TN4.7. Lubricants sales data used in consumption estimates, 1960 through 2009

Year of sales data	Year of consumption estimates
1960	1960 and 1961
1962	1962 through 1964
1965	1965 and 1966
1967	1967 and 1968
1969	1969 and 1970
1971	1971 and 1972
1973	1973 and 1974
1975	1975 and 1976
1977	1977 through 2009

Additional notes

1. The lubricants sales data (LUINPZZ and LUTRPZZ) were published about every other year by the U.S. Census Bureau until the discontinuation of the series after 1977. Each year's sales data have been used to calculate that year's and at least one other year's consumption estimates. Table TN4.7 specifies which years of consumption estimates depend on which years of the sales data.
2. The sales data from the source document for LUINPZZ and LUTRPZZ are available in incompatible units. The industrial series, LUINPZZ, is oils and greases sold for industrial lubricating and other uses measured in thousand gallons. The transportation series, LUTRPZZ, is oils and greases sold for automotive and aviation uses measured in thousand pounds. Before use in SEDS, these were converted to thousand barrels by dividing the oil data by 42 gallons per barrel and dividing the greases data by 300 pounds per barrel. In the source document, some state data are not published to avoid disclosing figures for individual companies. The undisclosed data were entered as zero in SEDS.

Data sources

LUACPZZ — Lubricants consumed by the transportation sector by state.

- 2010 forward: Estimated by EIA using state allocators derived from selected SEDS consumption series.

LUACPUS — Lubricants consumed by the transportation sector, United States.

- 2010 forward: Estimated by EIA based on Kline & Company data on finished lubricant demand for consumer total, commercial total, marine, and railroad use.

LUICPZZ — Lubricants consumed by the industrial sector by state.

- 2010 forward: Estimated by EIA using state allocators derived from U.S. Department of Commerce, Bureau of Economic Analysis, 2012 benchmark input-output accounts and real State Gross Domestic Products by Industry in chained (2012) dollars.

LUICPUS — Lubricants consumed by the industrial sector, United States.

- 2010 forward: Estimated by EIA based on Kline & Company data on finished lubricant demand for industrial (less marine and railroad) use.

LUINPZZ — Lubricants sold to the industrial sector by state (through 2009). Calculated from

- U.S. Department of Commerce, Census Bureau, *Current Industrial Reports*, "Sales of Lubricating and Industrial Oils and Greases," for 1960, 1962, 1965, 1967, 1969, 1971, 1973, 1975, and 1977. (See explanation in Notes 1 and 2, on page 67.)

LUTCPUS — Lubricants total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

LUTRPZZ — Lubricants sold to the transportation sector by state (through 2009). Calculated from

- U.S. Department of Commerce, Census Bureau, *Current Industrial Reports*, "Sales of Lubricating and Industrial Oils and Greases," for 1960, 1962, 1965, 1967, 1969, 1971, 1973, 1975, and 1977. (See explanation in Notes 1 and 2, on page 67.)

LUBA No. 2020-009
Page 5709

Motor Gasoline

Physical units

Twelve data series are used to estimate the state end-use consumption of motor gasoline. Eleven of the series are from the U.S. Department of Transportation, Federal Highway Administration publication, *Highway Statistics*, and represent sales of motor gasoline. The sales data are categorized as sales for highway and non-highway use:

- **Highway use** sales data (MGMFP) are from the Highway Statistics Table 8.4.2 (previously Table MF-21); however, they are reduced by the amount of highway "special fuels" (MGSFP) used in each state each year as reported on Table 8.4.2. Special fuels are primarily diesel fuels, not motor gasoline, and are included in the transportation sector of distillate fuel oil and other energy sources.
- **Non-highway use** sales are further subdivided into sales for: (1) state, county, and municipal non-highway use of motor fuel (MGPNP) from Table 8.4.2, and (2) private and commercial use. Data for the components of private and commercial non-highway use are reported in Table 8.4.3 (previously Table MF-24):
  - agricultural use (MGAGP)
  - industrial and commercial use (MGIYP)
  - construction use (MGCUP)
  - marine use (MGMRP), through 2014
  - boating use (MGBTP), 2015 forward
  - lawn and garden use (MGLGP), 2015 forward
  - recreational vehicle use (MGRVP), 2015 forward
  - miscellaneous use (MGMSP)

Another component of the private and commercial non-highway series is aviation gasoline (AVNMM), which is discussed under the "Aviation Gasoline" section of this documentation.

The twelfth motor gasoline data series (MGTCPUS) is the total U.S. consumption of motor gasoline published in the product supplied series in the U. S. Energy Information Administration publication *Petroleum Supply Annual*. It includes fuel ethanol blended into motor gasoline. Before 1993, motor gasoline product supplied was underreported because the reporting system was not collecting all fuel ethanol blending and there was a misreporting of motor gasoline blending components that were blended into finished motor gasoline. To adjust for the underreporting, fuel ethanol consumption was added to total energy consumption by end-use before 1993 (see Section 7).

The twelve motor gasoline data series are ("ZZ" in the variable names represent the two-letter state code that differs for each state)

MGAGPZZ	=	motor gasoline sold for agricultural use in each state, in thousand gallons;
MGBTPZZ	=	motor gasoline sold for boating use in each state, in thousand gallons;
MGCUPZZ	=	motor gasoline sold for construction use in each state, in thousand gallons;
MGIYPZZ	=	motor gasoline sold for industrial and commercial use in each state, in thousand gallons;
MGLGPZZ	=	motor gasoline sold for lawn and garden use in each state, in thousand gallons;
MGMFPZZ	=	motor fuel sold for highway use in each state, in thousand gallons;
MGMRPZZ	=	motor gasoline sold for marine use in each state, in thousand gallons (through 2014);
MGMSPZZ	=	motor gasoline sold for miscellaneous and unclassified uses in each state, in thousand gallons;
MGPNPZZ	=	motor fuel sold for public non-highway use in each state, in thousand gallons;
MGRVPZZ	=	motor gasoline sold for recreational vehicle use in each state, in thousand gallons;
MGSFPZZ	=	special fuels (primarily diesel fuel with small amounts of liquefied petroleum gases) sold in each state, in thousand gallons; and
MGTCPUS	=	motor gasoline total consumption in the United States, in thousand barrels.

U.S. totals for the eleven state-level series named above are calculated as the sum of the state data.

The transportation sector accounts for most of the motor gasoline sales. Before 2015, sales to the transportation sector is estimated to be the sum of motor fuel sales for marine use and for highway use (minus the sales of special fuels, which are primarily diesel fuels and are accounted for in the transportation sector of distillate fuel oil). Sales of motor gasoline to the transportation sector in each state (MGTRPZZ) is calculated:

MGTRPZZ = MGMFPZZ + MGMRPZZ - MGSFPZZ

Beginning in 2015, marine use is no longer available to calculate MGTRPZZ and two new sales categories, boating use (MGBTP) and recreational vehicle

LUBA No. 2020-009
Page 5710

use (MGRVP), are now included in the definition of transportation sector sales:

MGTRPZZ = MGMFPZZ + MGBTPZZ + MGRVPZZ - MGSFPZZ

Before 2015, two sales data series are added to estimate motor gasoline sales to the commercial sector: miscellaneous (including unclassified) and public non-highway sales. Sales of motor gasoline to the commercial sector in each state (MGCMPZZ) is calculated:

MGCMPZZ = MGMSPZZ + MGPNPZZ

Beginning in 2015, a new sales category, lawn and garden use (MGLGP), is allocated to commercial sector sales:

MGCMPZZ = MGMSPZZ + MGPNPZZ + MGLGPZZ

Sales of motor gasoline for use in the industrial sector in each state (MGINPZZ) is calculated as the sum of the sales for agricultural use, for construction use, and for industrial and commercial use:

MGINPZZ = MGAGPZZ + MGCUPZZ + MGIYPZZ

Total sales of motor gasoline in each state (MGTTPZZ) is calculated as the sum of the sales to the major sectors:

MGTTPZZ = MGCMPZZ + MGINPZZ + MGTRPZZ

U.S. totals for the three end-use sectors' sales and for total sales are calculated as the sum of the states' sales.

The motor gasoline sales data for the three end-use sectors in each state are used to apportion the U.S. total consumption of motor gasoline to the states and to the major end-use sectors within each state.

Total consumption of motor gasoline in each state (MGTCPZZ) is calculated according to each state's share of the total sales:

MGTCPZZ = (MGTTPZZ / MGTTPUS) * MGTCPUS

The commercial sector estimated consumption of motor gasoline (MGCCPZZ) is calculated:

MGCCPZZ = (MGCMPZZ / MGTTPZZ) * MGTCPZZ

The industrial sector estimated consumption (MGICPZZ) is calculated:

MGICPZZ = (MGINPZZ / MGTTPZZ) * MGTCPZZ

The transportation sector estimated consumption (MGACPZZ) is calculated:

MGACPZZ = (MGTRPZZ / MGTTPZZ) * MGTCPZZ

The consumption of motor gasoline by major end-use sector in the United States is estimated by summing the states' estimated consumption.

British thermal units (Btu)

A national factor, MGTCKUS, is used to convert motor gasoline consumption from physical units to British thermal units for each state. A constant heat content of 5.253 million Btu per barrel is used for 1960 through 1992. Beginning in 1993, an annual average factor is calculated by EIA. The factors, listed in Table B1 on page 179, are used for each state:

MGCCBZZ = MGCCPZZ * MGTCKUS
MGICBZZ = MGICPZZ * MGTCKUS
MGACBZZ = MGACPZZ * MGTCKUS

Total Btu consumption of motor gasoline is the sum of the consumption by the commercial, industrial, and transportation sectors.

MGTCBZZ = MGCCBZZ + MGICBZZ + MGACBZZ

The U.S.-level Btu consumption estimates are calculated by summing the state data.

Additional note

In 2015, the Federal Highway Administration revised its methods of estimating non-highway use of motor gasoline. (See Off-Highway and Public-Use Gasoline Consumption Estimation Models used in the Federal Highway Administration.) Estimates from 2015 forward are not compatible with data before 2015.

Additional calculations

To assist data users in the analysis of consumption of renewable energy sources, which include fuel ethanol, versus non-renewable energy sources, which include motor gasoline, a new data series, motor gasoline excluding fuel ethanol, is created for each state and the United States: Before 1993, fuel ethanol was not included in the motor gasoline data series from the source:

MMTCB = MGTCB

LUBA No. 2020-009
Page 5711

From 1993 forward

MMTCB = MGTCB - EMTCB

EMTCB is fuel ethanol minus denaturant. See discussion on fuel ethanol in Section 5, "Renewable Energy."

Motor gasoline excluding fuel ethanol is used only in the tables showing energy consumption by source. For consumption by end-use sector, motor gasoline is defined as the product consumed by the end-users, that is, including fuel ethanol.

Data sources

MGAGPZZ — Motor gasoline sold for agricultural use by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24.
- 1965 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-24 in 1965, Table MF-24 (1966 through 2006), and Table 8.4.3 (2007 forward).

MGBTPZZ — Motor gasoline sold for boating use by state.

- 2015 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table 8.4.3.

MGCUPZZ — Motor gasoline sold for construction use by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24.
- 1965 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-24 in 1965, Table MF-24 (1966 through 2006), and Table 8.4.3 (2007 forward).

MGIYPZZ — Motor gasoline sold for industrial and commercial use by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24.
- 1965 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-24 in 1965, Table MF-24 (1966 through 2006), and Table 8.4.3 (2007 forward).

MGLGPZZ — Motor gasoline sold for lawn and garden use by state.

- 2015 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table 8.4.3.

MGMFPZZ — Motor fuel sold for highway use by state.

- 1960 through 1995: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics Summary to 1995*, Table MF-221 gives revised U.S. totals. State revisions can be calculated by adding data from Tables MF-225 and MF-226.
- 1996 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table MF-21 (1996 through 2006) and Table 8.4.2 (2007 forward).

MGMRPZZ — Motor gasoline sold for marine use by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24.
- 1965 through 2014: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-24 in 1965, Table MF-24 (1966 through 2006), and Table 8.4.3 (2007 through 2014).

MGMSPZZ — Motor gasoline sold for miscellaneous uses by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-24. Sum of the "Miscellaneous" column plus the "Unclassified" column minus the "Total Classified" column.
- 1965: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, Table G-24. Sum of the "Miscellaneous" column plus the "Unclassified" column minus the "Total Classified" column.
- 1966 through 1981: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table MF-24, sum of the "Miscellaneous" and the "Unclassified" columns.

LUBA No. 2020-009
Page 5712

- 1982 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table MF-24 (1982 through 2006) and Table 8.4.3 (2007 forward), the "Miscellaneous" column.

MGPNPZZ — Motor fuel sold for public non-highway use by state.

- 1960 through 1964: U.S. Department of Commerce, Bureau of Public Roads, *Highway Statistics*, Table G-21.
- 1985, 1987, and 1992: Unpublished revised state data comparable to the U.S. values published in *Highway Statistics Summary to 1995*, Table 221.
- 1965 through 1984, 1986, 1988 through 1991, and 1993 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics* http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table G-21 in 1965, Table MF-21 (1996 through 2006), and Table 8.4.2 (2007 forward).

MGRVPZZ — Motor gasoline sold for recreational vehicle use by state.

- 2015 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table 8.4.3.

MGSFPZZ — Special fuels sales by state (primarily diesel fuel with small amounts of liquefied petroleum gases).

- 1960 through 1995: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics, Summary to 1995*, Table MF-225.
- 1996 forward: U.S. Department of Transportation, Federal Highway Administration, *Highway Statistics*, http://www.fhwa.dot.gov/policyinformation/statistics.cfm, Table MF-21 (1996 through 2006) and Table 8.4.2 (2007 forward).

MGTCKUS — Factor for converting motor gasoline from physical units to Btu.

- 1960 through 1992: EIA adopted the Bureau of Mines thermal conversion factor of 5.253 million Btu per barrel for "Gasoline, Motor Fuel" as published by the Texas Eastern Transmission Corporation in Appendix V of *Competition and Growth in American Energy Markets 1947-1985*, a 1968 release of historical and projected statistics. The factor excludes oxygenates.
- 1993 forward: EIA calculates the national annual average thermal conversion factor, which includes fuel ethanol blended into motor gasoline (shown in Appendix B Table B1 on page 179). For 1993-2006, it also includes methyl tertiary butyl ether (MTBE) and other oxygenates blended into motor gasoline.

MGTCPUS — Motor gasoline total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*. "Petroleum Statement, Annual," Table 1.

  For 1960 through 1963, motor gasoline was combined with aviation gasoline and published as "gasoline" in the source table. Table 19 in the "Petroleum Statement, Annual" titled "Salient Statistics of Aviation Gasoline" provided separate data for aviation gasoline for those years. The aviation gasoline data from the second table were subtracted from the gasoline data in the first table to derive the motor gasoline consumption series used in SEDS.
- 1976 through 1980: EIA, *Energy Data Reports*. "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

LUBA No. 2020-009
Page 5713

Petroleum Coke

Physical units

Seven data series are used to estimate the consumption of petroleum coke. Five are measures of petroleum coke consumption and two are indicators of industrial activity used to apportion U.S. industrial petroleum coke consumption to the states. ("ZZ" in the variable name represents the two-letter state code that differs for each state):

PCTCPUS	=	petroleum coke total consumption in the United States, in thousand barrels;
PCEIMZZ	=	petroleum coke consumed by the electric power sector in each state, in thousand short tons;
PCC3MZZ	=	petroleum coke consumed for combined-heat-and-power in the commercial sector in each state, in thousand short tons;
PCI3MZZ	=	petroleum coke consumed for combined-heat-and-power in the industrial sector in each state, in thousand short tons;
PCRFPZZ	=	petroleum coke used at refineries as both catalytic and marketable coke in each state, or group of states, or Petroleum Administration for Defense (PAD) district, in thousand barrels;
CTCAPZZ	=	catalytic cracking charge capacity of petroleum refineries in each state, in barrels per calendar day (1960 through 1979) and barrels per stream day (1980 forward); and
AICAPZZ	=	aluminum ingot production capacity in each state, in short tons.

The total consumption of petroleum coke in the United States (PCTCPUS) is the product supplied series from the U.S. Energy Information Administration (EIA) *Petroleum Supply Annual*.

Information on the amount of petroleum coke consumed for the purpose of generating electricity is available from Form EIA-923, "Power Plant Operations Report," and predecessor forms. For the electric power sector (PCEIM), these data are available for 1970 forward. Before 1970, consumption is assumed to be zero. For 1989 forward, the electric power sector includes petroleum coke consumed by electric utilities and independent power producers whose primary business is to sell electricity or electricity and heat. Quantities of petroleum coke used by commercial (PCC3M) and industrial (PCI3M) facilities in combined-heat-and-power units are also available and are included in the commercial and industrial sectors, respectively.

The data for petroleum coke used to generate electricity are in thousand short tons and are converted into thousand barrels in the State Energy Data System (SEDS) by applying a conversion factor of five barrels per short ton, and the U.S. value is the sum of the state data:

PCEIPZZ = PCEIMZZ * 5
PCEIPUS = ΣPCEIPZZ
PCCCPZZ = PCC3MZZ * 5
PCCCPUS = ΣPCCCPZZ
PCI3PZZ = PCI3MZZ * 5
PCI3PUS = ΣPCI3PZZ

To estimate U.S. industrial consumption of petroleum coke, U.S. electric power and commercial consumption are subtracted from the total U.S. petroleum coke product supplied:

PCICPUS = PCTCPUS - PCEIPUS - PCCCPUS

In addition to combined-heat-and-power generation, petroleum coke is used in the industrial sector as catalyst coke at refineries in a process for increasing the yield of gasoline from crude oil (catalytic cracking) and for other industrial uses (mainly for conversion into electrodes that are consumed in the production of aluminum).

Through 2012, state-level estimates of the refinery consumption of petroleum coke are calculated by assuming that each state consumes petroleum coke in proportion to the catalytic cracking charge capacity (CTCAPZZ) of the refineries in the state. The U.S. total for the state-level data allocating series is calculated by summing the state data.

CTCAPUS = ΣCTCAPZZ

Petroleum coke consumed by refineries for 1960 through 1980 is available for some states while quantities for other states are grouped (G1 through G7 as indicated by GZ in the following formulas). The group quantities are allocated to the states within each group in proportion to each state's portion of the group's catalytic cracking charge capacity. For 1981 forward, PAD district data (P1 through P5 as indicated by PZ in the following formulas) are allocated in the same way to the states within each district:

PCRFPZZ = PCRFPZZ, or
PCRFPZZ = (CTCAPZZ / CTCAPGZ) * PCRFPGZ (1 through 7), or

LUBA No. 2020-009
Page 5714

PCRFPZZ = (CTCAPZZ / CTCAPPZ) * PCRFPPZ (1 through 5)
PCRFPUS = ΣPCRFPZZ

Beginning in 2013, SEDS incorporates unpublished state-level refinery fuel consumption data that satisfied two statistical disclosure rules – that there are at least three refineries not of the same company in the state and that no one refinery uses more than 60% of the particular fuel. For petroleum coke, data for eight to nine states are usable. They are subtracted from the PAD district data, and the remainders are allocated to the remaining states using CTCAPZZ.

U.S. petroleum coke used at combined-heat-and-power plants (PCI3PUS) and at refineries (PCRFPUS) are subtracted from the U.S. industrial sector consumption to derive U.S. consumption of petroleum coke for all other industrial uses:

PCOCPUS = PCICPUS - PCI3PUS - PCRFPUS

State-level estimates of petroleum coke consumed by other industrial users, mainly aluminum production, are assumed to be in proportion to each state's aluminum ingot production capacity (AICAPZZ). For 1993 forward, state-level aluminum production capacity is adjusted to account for under-utilization of the plants. Although AICAPZZ is measured in short tons, it is not converted to thousand barrels because it is used only as a state-level allocator. The U.S. total is calculated as the sum of the state data and other industrial use of petroleum coke is allocated to the states as follows:

AICAPUS = ΣAICAPZZ
PCOCPZZ = (AICAPZZ / AICAPUS) * PCOCPUS

Industrial sector petroleum coke consumption by state is the sum of combined-heat-and-power industrial use, consumption at refineries, and all other industrial uses:

PCICPZZ = PCI3PZZ + PCRFPZZ + PCOCPZZ

Total petroleum coke consumption by state is the sum of commercial, industrial, and electric power sector use:

PCTCPZZ = PCCCPZZ + PCICPZZ + PCEIPZZ

British thermal units (Btu)

Two series are used to convert petroleum coke from physical unit values to Btu:

PCCTKUS = factor for converting catalyst petroleum coke from physical units to Btu; and
PCMKKUS = factor for converting marketable petroleum coke from physical units to Btu.

For 2004 forward, PCCTKUS adopts a fixed value of 6.287 million Btu per barrel and PCMKKUS adopts a fixed value of 5.719 million Btu per barrel. For 1960 through 2003, a fixed factor of 6.024 million Btu per barrel is used for both series. See explanation in Appendix B.

These factors are applied to convert estimated petroleum coke consumption from physical units to Btu by state:

PCCCBZZ = PCCCPZZ * PCMKKUS
PCI3BZZ = PCI3PZZ * PCMKKUS
PCOCBZZ = PCOCPZZ * PCMKKUS
PCRFBZZ = PCRFPZZ * PCCTKUS
PCEIBZZ = PCEIPZZ * PCMKKUS

Petroleum coke consumed in the industrial sector is the sum of

PCICBZZ = PCI3BZZ + PCRFBZZ + PCOCBZZ

Total Btu consumption of petroleum coke is the sum of the consumption by the end-use sectors and for electricity generation:

PCTCBZZ = PCCCBZZ + PCICBZZ + PCEIBZZ

The U.S. totals are the sum of the states' values.

Additional notes

The source for petroleum coke used at refineries, PCRFPUS and PCRFPGZ, is the EIA *Petroleum Supply Annual* and predecessor reports. For 1960 through 1980, the data are provided in thousand short tons. For consistency with later years' data, the 1960 through 1980 data are first converted into thousand barrels before being used in SEDS. For 1960 through 1967, the data are published for Texas and New Mexico and for groups of other states. For 1968 through 1980, the data are given for 19 individual states with the remaining states are combined into seven groups. The data for 1960 through 1967 are disaggregated into the 19 states and seven groups used for the later years, before being entered into SEDS, by using the proportions of the 1968 data, which was published in both formats. For 1981 forward, the data are published by PAD districts only. For 2013 forward, unpublished state-level data that

LUBA No. 2020-009
Page 5715

satisfied statistical disclosure rules are incorporated in SEDS.

Data sources

AICAPZZ — Aluminum ingot production capacity in each state.

- 1960 through 1973: American Bureau of Metal Statistics, *Year Book*.
- 1974 through 1994: American Bureau of Metal Statistics, *Non-Ferrous Metal Data*, table titled "Aluminum Ingot Production Capacity." Note: Capacities for individual plants owned by one company have been withheld since 1986. The company's total capacity has been apportioned to the individual plants on the basis of their proportional capacities in 1985.
- 1995 forward: U.S. Department of the Interior, U.S. Geological Survey, *Minerals Yearbook*.

CTCAPZZ — Catalytic cracking charge capacity of petroleum refineries by state.

- 1960: Data are unavailable from published reports. The 1961 values are used for 1960.
- 1961 through 1963: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Refineries in the United States." The specific tables are
  - 1961 and 1962: Table 7, under "Cracking Capacity" column heading "Charge."
  - 1963: Table 6, under "Catalytic-Cracking Capacity" column heading "Charge."
- 1964 through 1976: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Refineries in the United States and Puerto Rico," Table 2, all entries next to "Cat. Ck." summed by state.
- 1977: EIA, *Energy Data Reports*, "Petroleum Refineries in the United States and Puerto Rico," Table 2, all entries next to "Cat. Ck." summed by state.
- 1978: EIA, *Energy Data Reports*, "Petroleum Refineries in the United States and U.S. Territories," Table 2, all entries next to "Cat. Ck." summed by state.
- 1979 and 1980: EIA, *Energy Data Reports*, "Petroleum Refineries in the United States and U.S. Territories." The specific tables are
  - 1979: Table 2, sum of "Catalytic Cracking" columns, "Fresh" and "Recycle."
  - 1980: Table 1, sum of "Catalytic Cracking (fresh)" and "Catalytic Cracking (recycle)" columns.
- 1981 through 2004: EIA, *Petroleum Supply Annual*, sum of "Catalytic Cracking (Fresh)" and "Catalytic Cracking (Recycled)" columns in the following tables:
  - 1981 through 1983: Table 1.
  - 1984: Table 30.
  - 1985 through 1989: Table 29.
  - 1989 through 1994: Table 36.
  - 1995: Data series became biannual. 1994 data used for 1995.
  - 1996: Table 36.
  - 1997: 1996 data used for 1997.
  - 1998 through 2004: Table 36, http://www.eia.gov/petroleum/supply/annual/volume1/.
- 2005 forward: EIA, *Refinery Capacity Report*, Table1, http://www.eia.gov/petroleum/refinerycapacity/.

PCC3MZZ — Petroleum coke consumed for combined-heat-and-power in the commercial sector by state.

- 1960 through 1988: No data available. Values are assumed to be zero.
- 1989 forward: EIA, Form EIA-923, "Power Plant Operations Report," and predecessor forms.

PCCTKUS — Factor for converting petroleum coke, catalyst coke from physical units to Btu.

- 1960 through 2003: EIA adopted the Bureau of Mines thermal conversion factor of 6.024 million Btu per barrel, from the Bureau of Mines internal memorandum "Bureau of Mines Standard Average Heating Value of Various Fuels, Adopted January 3, 1950."
- 2004 forward: Assumed by EIA to be 6.287 million Btu per barrel or equal to the thermal conversion factor for residual fuel oil.

PCEIMZZ — Petroleum coke consumed by the electric power sector by state.

- 1960 through 1969: No data available. Values are assumed to be zero.
- 1970 forward: EIA, Form EIA-923, "Power Plant Operations Report," and predecessor forms.

PCI3MZZ — Petroleum coke consumed for combined-heat-and-power in the industrial sector by state.

- 1960 through 1988: No data available. Values are assumed to be zero.

LUBA No. 2020-009
Page 5716

- 1989 forward: EIA, Form EIA-923, "Power Plant Operations Report," and predecessor forms.

PCMKKUS — Factor for converting petroleum coke, marketable coke from physical units to Btu.

- 1960 through 2003: EIA adopted the Bureau of Mines thermal conversion factor of 6.024 million Btu per barrel, from the Bureau of Mines internal memorandum "Bureau of Mines Standard Average Heating Value of Various Fuels, Adopted January 3, 1950."
- 2004 forward: EIA adopts the thermal conversion factor of 5.719 million Btu per barrel, calculated by dividing 28,595,925 Btu per short ton for petroleum coke (from U.S. Department of Energy, Argonne National Laboratory, "The Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation Model" (GREET), version GREET1_ October 2013) by 5.0 barrels per short ton (as given in the Bureau of Mines Form 6-1300-M and successor EIA forms).

PCRFPZZ, PCRFPGZ, or PCRFPPZ — Petroleum coke consumed at refineries (both catalyst and marketable) by state or groups of states.

- 1960: No data available. The 1961 value is used for 1960.
- 1961 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual." The specific tables are
  - 1961 and 1962: Table 18.
  - 1962 through 1966: Table 19.
  - 1967: Table 18.
  - 1968: Table 19.
  - 1969 through 1972: Table 18.
  - 1973 and 1974: Table 21.
  - 1975: Table 22.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual." The specific tables are
  - 1976: Table 22.
  - 1977: Table 21.
  - 1978 through 1980: Table 20.
- 1981 through 2004: EIA, *Petroleum Supply Annual*. The specific tables are
  - 1981 and 1982: Table 17.
  - 1983: Table 15.
  - 1984: Table 44.
  - 1985: Table 43.
  - 1986 through 1988: Table 38.
  - 1989 through 1992: Table 45.
  - 1995 and 1997: Table 36.
    1993 and 1994, 1996, and 1998 through 2004: http://www.eia.gov/petroleum/supply/annual/volume1/, Table 47.
- 2005 forward: EIA, *Refinery Capacity Report*, Table 12 (2006-2008), Table 12a (2009), and Table 10a (2010 forward), http://www.eia.gov/petroleum/refinerycapacity/. Also available at http://www.eia.gov/dnav/pet/pet_pnp_capfuel_a_(na)_8FPP0_Mbbl_a.htm.

PCTCPUS — Petroleum coke total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*. "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Report*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Residual Fuel Oil

Physical units

Because state-level end-use consumption data for residual fuel oil (with the exception of electric power sector data) are not available, sales of residual fuel oil into or within each state, published by the U.S. Energy Information Administration (EIA) in the *Fuel Oil and Kerosene Sales Report*, are used to estimate residual fuel oil consumption. The following variable names have been assigned to the sales series, in thousand barrels ("ZZ" in the following variable names represents the two-letter state code that differs for each state):

RFBKPZZ = residual fuel oil sold for vessel bunkering use (i.e., the fueling of commercial or private boats, such as pleasure craft, fishing boats, tugboats, and ocean-going vessels, including vessels operated by oil companies, and fueling for other marine purposes), excluding sales to the military;

RFCMPZZ = residual fuel oil sold to the commercial sector;

RFIBPZZ = residual fuel oil sold to industrial establishments for space heating and for other industrial use (i.e., for all uses to mines, smelters, plants engaged in producing manufactured products, in processing goods, and in assembling);

RFMIPZZ = residual fuel oil sold to the military, regardless of use;

RFMSPZZ = residual fuel oil sold for all other uses not identified in other sales categories;

RFOCPZZ = residual fuel oil sold for oil company use, including all fuel oil, crude oil, or acid sludge used as fuel at refineries, by pipelines, or in field operations; and

RFRRPZZ = residual fuel oil sold to the railroads for use in fueling trains, operating railroad equipment, space heating of buildings, and other operations.

Two other data series that represent consumption of residual fuel oil are

RFEIPZZ = residual fuel oil consumed by the electric power sector in each state, in thousand barrels; and

RFTCPUS = residual fuel oil total supplied in the United States, in thousand barrels.

Residual fuel oil consumed by the electric power sector (RFEIPZZ) is collected by EIA on Form EIA-923, "Power Plant Operations Report," and predecessor forms. (See Note 3 at the end of this residual fuel oil section for further information on changes in this series' data definitions.)

Total U.S. consumption of residual fuel oil, RFTCPUS, is the product supplied series in EIA's publication *Petroleum Supply Annual*.

All state-level data series listed above are summed to provide totals for the United States.

The data series are then combined as closely as possible into the major end-use sectors used in the State Energy Data System (SEDS). No residual fuel oil is sold to the residential sector. Residual fuel oil sales to the commercial sector is the RFCMPZZ series.

The sales of residual fuel oil to the industrial sector in each state, RFINPZZ, is the sum of the residual fuel oil sold for industrial use, including industrial heating and processing (RFIBPZZ), for oil company use (RFOCPZZ), and for all other uses (RFMSPZZ):

RFINPZZ = RFIBPZZ + RFOCPZZ + RFMSPZZ
RFINPUS = ΣRFINPZZ

The sales of residual fuel oil to the transportation sector in each state, RFTRPZZ, is the sum of the residual fuel oil sales for vessel bunkering (RFBKPZZ), military use (RFMIPZZ), and railroad use (RFRRPZZ):

RFTRPZZ = RFBKPZZ + RFMIPZZ + RFRRPZZ
RFTRPUS = ΣRFTRPZZ

Sales of residual fuel oil to the commercial, industrial, and transportation sectors are added to create a subtotal of sales to all sectors other than the electric power sector (RFNDPZZ):

RFNDPZZ = RFCMPZZ + RFINPZZ + RFTRPZZ
RFNDPUS = ΣRFNDPZZ

The estimated residual fuel oil consumption for the United States by all sectors other than the electric power sector (RFNCPUS) is calculated by subtracting the total residual fuel oil consumption for the electric power sector from the total U.S. residual fuel oil consumption:

RFNCPUS = RFTCPUS - RFEIPUS

This U.S. subtotal of residual fuel oil consumption by the end-use sectors combined (RFNCPUS) is apportioned to the states by using the states' end-

LUBA No. 2020-009
Page 5718

use sector sales data. The assumption is made that each state consumes residual fuel oil in proportion to the amount sold in that state:

RFNCPZZ = (RFNDPZZ / RFNDPUS) * RFNCPUS

The end-use sectors' subtotal for each state is further divided into estimates for each sector in proportion to each sector's sales. The estimated commercial sector consumption in each state, RFCCPZZ, is calculated:

RFCCPZZ = (RFCMPZZ / RFNDPZZ) * RFNCPZZ

The industrial sector's estimated consumption in each state, RFICPZZ, is calculated:

RFICPZZ = (RFINPZZ / RFNDPZZ) * RFNCPZZ

The transportation sector's estimated consumption in each state, RFACPZZ, is calculated:

RFACPZZ = (RFTRPZZ / RFNDPZZ) * RFNCPZZ

The consumption of residual fuel oil in the United States by the major end-use sectors is estimated by adding the states' estimated consumption.

Total state residual fuel oil consumption is the sum of the end-use sectors' consumption subtotal and the electric power sector consumption:

RFTCPZZ = RFNCPZZ + RFEIPZZ

British thermal units (Btu)

Residual fuel oil has a heat content value of about 6.287 million Btu per barrel. This factor is applied to convert residual fuel oil estimated consumption from physical units to Btu as shown in the following example:

RFCCBZZ = RFCCPZZ * 6.287

Total Btu consumption of residual fuel oil is the sum of the consumption by the end-use sectors and for electricity generation:

RFTCBZZ = RFCCBZZ + RFICBZZ + RFACBZZ + RFEIBZZ

The U.S.-level Btu consumption estimates are calculated as the sum of the states' Btu consumption.

Additional notes

1. "Sales" data are actually called "shipments" in the source documents for 1960 and 1961; "consumption" for 1962 through 1966; "shipments" for 1967; "sales" from 1968 through 1978; "deliveries" for 1979 through 1983; and "sales" for 1984 forward.
2. In 1979, EIA implemented a new survey form, EIA-172, to obtain deliveries of fuel oil and kerosene data and updated the list of respondents. (A detailed explanation is published in the *Energy Data Report,*"Deliveries of Fuel Oil and Kerosene in 1979.") In the new survey form, certain end-use categories were redefined—in many cases, to collect more disaggregated data. The reclassifications resulted in some end-use categories that were no longer comparable with those in previous surveys. Where discontinuities occurred, estimates for the pre-1979 years have been made in SEDS to conform with the 1979 fuel oil deliveries classifications. The pre-1979 deliveries estimates are not published in this report but are used in SEDS to disaggregate the known U.S. total product supplied (consumption) into state and major end-use sector consumption estimates.

   For residual fuel oil deliveries in 1979, the end-use categories "commercial" and "industrial" are available. The pre-1979 deliveries categories are called "heating" and "industrial." While the pre-1979 categories individually are not continuous with the 1979 categories, their subtotals are related. That is, a general comparison can be made between the sum of commercial and industrial deliveries in 1979 and the sum of heating and industrial deliveries in the pre-1979 years. Therefore, the following method was applied to present a comparable series for residual fuel oil delivered to the commercial and industrial sectors:
   - For each of the pre-1979 years, a subtotal was created for each state by adding each state's heating and industrial deliveries categories. A comparable 1979 subtotal was created by adding each state's commercial and industrial deliveries categories.
   - Commercial and industrial shares of the subtotal in 1979 were calculated for each state.
   - These 1979 end-use shares were then applied to each pre-1979 subtotal of residual fuel oil deliveries in each state to create state estimates of end-use deliveries for 1960 through 1978.

   The 1980 through 1982 residual fuel oil deliveries data are based on the same survey as that used for 1979; therefore, the 1980 through 1982 data are directly comparable to 1979 data.

   In 1984, EIA again updated the list of respondents for this survey, and the Form EIA-172 became the Form EIA-821, "Annual Fuel Oil and Kerosene Sales Report." EIA did not conduct a fuel oil and kerosene sales survey

LUBA No. 2020-009
Page 5719

for 1983. The 1983 estimates in SEDS are based on 1984 data obtained from the Form EIA-821. Statistical procedures and methodologies used for the Form EIA-821 differ from those used in previous years. Therefore, the 1983 and forward sales data may not be directly comparable to the pre-1983 data. (In the source document, the sales data for 1983 forward are reported in thousand gallons. These data were first converted to thousand barrels before being entered into SEDS.)

3. The data on fuel oil consumed by the electric power sector for all years and states are actual fuel oil consumption numbers collected from electric power plants on Form EIA-923, "Power Plant Operations Report," and predecessor forms. Due to changes in fuel oil reporting classifications on the predecessor forms over the years, it is not possible to develop a thoroughly consistent series for all years. However, over time, data more accurately disaggregating fuel oil into distillate fuel oil and residual fuel oil have become available. For 1960 through 1969, only data on total fuel oil consumed at electric utilities by state are available. For 1970 through 1979, fuel oil consumed by plant type (internal combustion and gas turbine plants combined and steam plants) by state are available. For 1980 through 2000, data on consumption of light oil at all plant types combined and consumption of heavy oil at all plant types combined are available by state. For 2001 forward, data on consumption of distillate fuel oil and residual fuel oil are available. In SEDS, the following assumptions have been made:
   - 1960 through 1969—state estimates of fuel oil consumption by plant type have been created for each year by applying the shares of steam plants (primarily residual fuel oil) and internal combustion and gas turbine plants (primarily distillate fuel oil plus small amounts of jet kerosene) by state in 1970 to each year's total fuel oil consumption at electric utilities for 1960 through 1969.
   - 1970 through 1979—fuel oil consumed by steam plants is assumed to equal residual fuel oil consumption, and fuel oil consumed by internal combustion and gas turbine plants is assumed to equal distillate fuel oil plus jet kerosene consumption.
   - 1980 through 2000—total heavy oil consumption at all plant types is assumed to equal residual fuel oil consumption, and total light oil consumption at all plant types is assumed to equal distillate fuel oil plus jet kerosene consumption.

   The data series thus derived for SEDS for residual fuel oil and distillate fuel oil consumption by the electric power sector is considered to be actual consumption by the electric power sector for each state and each year.

RFEIPZZ — Residual fuel oil consumed by the electric power sector.

- EIA, Form EIA-923, "Power Plant Operations Report," and predecessor forms. The following assumptions have been made:
  - 1960 through 1969: Only total fuel oil consumed at electric utilities by state is available. State estimates of residual fuel oil consumption were created for each year by applying the shares of steam plants (primarily residual fuel oil) by state from 1970 to each year's total fuel oil consumption at electric utilities for 1960 through 1969.
  - 1970 through 1979: Fuel oil consumed by plant type by state is available. Fuel oil consumed by steam plants is assumed to equal residual fuel oil consumption.
  - 1980 through 2000: Consumption of heavy fuel at all plant types by state is available. This is assumed to equal residual fuel oil consumption.
  - 2001 forward: Consumption of residual fuel oil is available.

RFIBPZZ — Residual fuel oil sold to industrial establishments for heating and for other industrial use.

- 1960 through 1978: EIA, estimates based on statistics of industrial sector deliveries of residual fuel from the EIA, *Energy Data Report*, "Deliveries of Fuel Oil and Kerosene in 1979," Table 2. State ratios based on 1979 industrial sector deliveries were applied to each state's sum of heating plus industrial deliveries categories from the fuel oil deliveries reports for each year 1960 through 1978. (See explanation in Note 2, on page 77.)
- 1979 and 1980: EIA, *Energy Data Report*, "Deliveries of Fuel Oil and Kerosene," Table 2.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 5.

- 1979 and 1980: EIA, *Energy Data Reports*, "Deliveries of Fuel Oil and Kerosene," Table 2.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 5.

Note: Data for 1983 forward are published in thousand gallons. They are converted to thousand barrels by dividing by 42 before being entered into SEDS.

- 1983: EIA, *Petroleum Marketing Monthly*, July 1985 issue, Table A13.
- 1984 through 1987: EIA, *Petoleum Marketing Monthly*, also available at http://www.eia.gov/dnav/pet/pet_cons_821rsd_a_EPPR_VOC_Mgal_a.htm.
- 1988 forward: EIA, *Fuel Oil and Kerosene Sales*, also available at http://www.eia.gov/dnav/pet/pet_cons_821rsd_a_EPPR_VOC_Mgal_a.htm.

RFRRPZZ — Residual fuel oil sold for use by railroads by state.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Shipments of Fuel Oil and Kerosene." The specific tables are
  - 1960 and 1961: Table 16.
  - 1962 and 1963: Table 15.
  - 1964 and 1965: Table 14.
  - 1966 through 1975: Table 10.
- 1976 through 1978: EIA, *Energy Data Reports*, "Sales of Fuel Oil and Kerosene," Table 10.
- 1979 and 1980: EIA, *Energy Data Reports*, "Deliveries of Fuel Oil and Kerosene," Table 2.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 5.

Note: Data for 1983 forward are published in thousand gallons. They are converted to thousand barrels by dividing by 42 before being entered into SEDS.

- 1983 through 1987: EIA, *Petroleum Marketing Monthly*. The specific tables are
  - 1983: July 1985 issue, Table A13.
  - 1984 and 1985: July 1986 issue, Table A3.
  - 1986 and 1987: June 1988 issue, Table A5.
- 1988 and 1989: EIA, *Fuel Oil and Kerosene Sales 1989*, Table 5.
- 1990 forward: Series discontinued. Volumes are included with "All Other" data (in SEDS).

RFTCPUS — Residual fuel oil total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

LUBA No. 2020-009
Page 5722

Other Petroleum Products

"Other petroleum products" (OP) is the sum of 11 petroleum products. These products, in thousand barrels, are

ABTCPUS = aviation gasoline blending components total consumption in the United States;
COTCPZZ = crude oil (including lease condensate) total consumption in each state;
FNTCPUS = petrochemical feedstocks, naphtha less than 401°F, total consumption in the United States;
FOTCPUS = petrochemical feedstocks, other oils equal to or greater than 401°F, total consumption in the United States;
FSTCPUS = petrochemical feedstocks, still gas, total consumption in the United States (through 1985);
MBTCPUS = motor gasoline blending components total consumption in the United States;
MSTCPUS = miscellaneous petroleum products total consumption in the United States;
SGTCPUS = still gas total consumption in the United States;
SNTCPUS = special naphthas total consumption in the United States;
UOTCPUS = unfinished oils total consumption in the United States; and
WXTCPUS = waxes total consumption in the United States.

It is assumed that all of the products in "other petroleum products" are used by the industrial sector. State estimates are created for other petroleum products by using the following six variables to allocate the products to the states:

COCAPZZ = atmospheric crude oil distillation operable capacity (operating capacity before 2013) at refineries in each state as of January 1 of the following year, adjusted with information on new, shutdown, and reactivated refineries during the year, in barrels per calendar day;
FNCASZZ = state's share of U.S. capacity of steam crackers using naphtha as feedstocks;
FOCASZZ = state's share of U.S. capacity of steam crackers using other oils as feedstocks;
OCVAVZZ = value of shipments (value added before 2001) for the industrial organic chemical manufacturing industry in each state, in million dollars;
PIVAVZZ = value of shipments (value added before 2001) for the paint and coating manufacturing industry in each state, in million dollars; and
CGVAVZZ = value of shipments (value added before 2001) for the corrugated and solid fiber box manufacturing industry in each state, in million dollars.

Value of shipments and value added are two measures of manufacturing activity, both from the Department of Commerce *Economic Census* (previously, *Census of Manufactures*) reports. Value of shipments is a close approximation of gross output, adjusted for inventory changes. Value added excludes the cost of materials from gross output. Before 2001, value added data were used to allocate the national consumption of selected petroleum products to the states. From 2001 forward, value of shipments data are used instead. The change was made because gross output is considered a better indicator of consumption of fuel and feedstock than value added.

Crude oil

Crude oil is normally processed in refineries to produce petroleum products and rarely used directly (as energy consumption). Before 1983, crude oil burned on leases and by pipelines as fuel was reported as either distillate or residual fuel oil and was included in product supplied for those products. For 1983 through 2009, crude oil used directly in petroleum industry operations was reported as product supplied in the U.S. Energy Information Administration's (EIA) *Petroleum Supply Annual*. Beginning in 2010, crude oil product supplied, and therefore consumption, is assumed equal to zero.

Physical units

State estimates for crude oil consumed in petroleum industry operations are the data series COTCPZZ. The U.S. total for this data series is summed:

COTCPUS = ΣCOTCPZZ

Industrial consumption equals total consumption of crude oil:

COICPZZ = COTCPZZ
COICPUS = COTCPUS

British thermal units (Btu)

Crude oil has a heat content value of about 5.800 million Btu per barrel. The calculations performed to estimate total Btu consumption and industrial use

LUBA No. 2020-009
Page 5723

Btu consumption by state and for the United States are

COTCBZZ = COTCPZZ * 5.800
COTCBUS = ΣCOTCBZZ
COICBZZ = COTCBZZ
COICBUS = COTCBUS

Data source

COTCPZZ — Crude oil consumed in petroleum industry operations by state.

- 1960 through 1982: Crude oil used directly was included in distillate and residual fuel oil product supplied when reported to the U. S. Energy Information Administration. Zeros are entered for all years.
- 1983 through 2009: Data are available for Petroleum Administration for Defense (PAD) districts, not by state. State estimates are calculated by allocating all crude oil consumption to the six states (Alaska, California, Colorado, Louisiana, Texas, and Utah) that reported distillate and residual fuel oils consumed by pipeline and leases in 1982. (Data on pipeline and lease consumption of fuels are not available after 1982.) Each state's 1982 ratio of distillate and residual fuel oils consumed by pipeline and leases to its respective 1982 PAD district total consumption of those fuels is calculated. This ratio is then applied to the 1983 forward PAD district totals of crude oil product supplied. The 1982 ratios are taken from the Form EIA-90, "Crude Oil Stocks Report," and the crude oil product supplied data are taken from the EIA *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/. The specific tables are
  - 1983 through 1988: Tables 2 and 4 through 8.
  - 1989 through 2004: Tables 2, 4, 6, 8, 10, and 12.
  - 2005 through 2009: Tables 1, 3, 5, 7, 9, and 11.
- 2010 forward: Zeroes are entered for all years.

Aviation gasoline blending components; petrochemical feedstocks, still gas; motor gasoline blending components; still gas; and unfinished oils

Physical units

The five petroleum products in this category are consumed as refinery fuels. Beginning in 1986, still gas for petrochemical feedstocks and still gas for other uses are reported together in the source document. State consumption estimates of these products are created in proportion to each state's crude oil operable capacity at refineries (COCAPZZ). Before 2013, operating capacity was used. Occasionally, consumption for aviation gasoline blending components and unfinished oils will be negative. This can occur when such products have entered the primary supply channels with their production not having been reported (e.g., streams returned to refineries from petrochemical plants). The U.S. total for this variable is summed:

COCAPUS = ΣCOCAPZZ

Aviation gasoline blending components state and U.S. consumption are estimated:

ABTCPZZ = (COCAPZZ / COCAPUS) * ABTCPUS
ABICPZZ = ABTCPZZ
ABICPUS = ABTCPUS

Petrochemical feedstocks, still gas, state and U.S. consumption are estimated:

FSTCPZZ = (COCAPZZ / COCAPUS) * FSTCPUS
FSICPZZ = FSTCPZZ
FSICPUS = FSTCPUS

Motor gasoline blending components state and U.S. consumption are estimated:

MBTCPZZ = (COCAPZZ / COCAPUS) * MBTCPUS
MBICPZZ = MBTCPZZ
MBICPUS = MBTCPUS

Still gas state and U.S. consumption are estimated:

SGTCPZZ = (COCAPZZ / COCAPUS) * SGTCPUS
SGICPZZ = SGTCPZZ
SGICPUS = SGTCPUS

Unfinished oils state and U.S. consumption are estimated:

UOTCPZZ = (COCAPZZ / COCAPUS) * UOTCPUS
UOICPZZ = UOTCPZZ
UOICPUS = UOTCPUS

British thermal units (Btu)

Btu estimates for five products in this group are developed by multiplying

LUBA No. 2020-009
Page 5724

the estimated consumption of each individual product in physical units by its respective heat content conversion factor. The calculations performed to estimate total Btu consumption and industrial use Btu consumption by state and for the United States are

ABTCBZZ	=	ABTCPZZ * 5.048

UOICBUS	=	UOTCBUS

The factor for converting motor gasoline blending components from physical unit values to Btu, MBTCKUS, is fixed at 5.253 million Btu per barrel for 1960 through 2006, and at 5.222 million Btu per barrel for 2007 forward:

MBTCKUS	=	factor for converting motor gasoline blending components from physical units to Btu.

Data sources

ABTCPUS — Aviation gasoline blending components total consumption in the United States.

- 1960 through 1980: No data available. Values are assumed to be zero.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

COCAPZZ — Atmospheric crude oil distillation operable capacity (operating capacity before 2013) at refineries by state as of January 1 of the following year.

- 1960: U.S. Department of the Interior, Bureau of Mines, Petroleum Refineries, Including Cracking Plants, in the United States, Table 3.
- 1961 through 1963: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Refineries in the United States." The specific tables are
  - 1961 and 1962: Table 3.
  - 1963: Table 1.
- 1964 through 1976: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Refineries in the United States and Puerto Rico," Table 1.
- 1977: EIA, *Energy Data Reports*, "Petroleum Refineries in the United States and Puerto Rico," Table 1.
- 1978 through 1980: EIA, *Energy Data Reports*, "Petroleum Refineries in the United States and U.S. Territories," Table 1.
- 1981 through 2004: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/. The specific tables are
  - 1981 through 1983: Table 1.
  - 1984: Table 30.
  - 1985 through 1988: Table 29.
  - 1989 through 1994: Table 36.
  - 1995: Unpublished data based on Form EIA-810.
  - 1996 through 2004: Table 36.
- 2005 forward: EIA, *Refinery Capacity Report*, http://www.eia.gov/petroleum/refinerycapacity/, Table 1, supplemented with Table 11 data from 2011 forward.

FSTCPUS — Petrochemical feedstocks, still gas, total consumption in the United States (through 1985).

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, Petroleum Statement, Annual," Table 1.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 14.
- 1983 through 1985: EIA, *Petroleum Supply Annual*, Table 12.

LUBA No. 2020-009
Page 5725

MBTCPUS — Motor gasoline blending components total consumption in the United States.

- 1960 through 1980: No data available. Values are assumed to be zero.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

MBTCKUS — Factor for converting motor gasoline blending components from physical units to Btu.

- 1960 through 2006: EIA adopted the Bureau of Mines thermal conversion factor of 5.253 million Btu per barrel, from the Bureau of Mines internal memorandum "Bureau of Mines Standard Average Heating Value of Various Fuels, Adopted January 3, 1950."
- 2007 forward: EIA adopted the thermal conversion factor of 5.222 million Btu per barrel (124,340 Btu per gallon) for gasoline blendstock from U.S. Department of Energy, Argonne National Laboratory, "The Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation Model" (GREET), version GREET1_2013, October 2013.

SGTCPUS — Still gas total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 and 1982: EIA, *Petroleum Supply Annual*, Table 14.
- 1983 through 1985: EIA, *Petroleum Supply Annual*, Table 12.
- 1986 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1986 through 2004: Table 2.
  - 2005 forward: Table 1.

UOTCPUS — Unfinished oils total consumption in the United States.

- 1960 through 1980: No data available. Values assumed to be zero.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Petrochemical feedstocks, naphtha less than 401°F; and petrochemical feedstocks, other oils equal to or greater than 401°F

Physical units

Petrochemical feedstocks, naphtha and other oils, are consumed by the chemical industry in producing petrochemical "building blocks" (such as ethylene) that, in turn, are converted to such products as synthetic fibers, synthetic rubber, and plastics.

The chemical industry produces petrochemicals such as ethylene and propylene by steam cracking. To allocate the U.S. consumption of petrochemical feedstocks to the states, information on nameplate capacity and the share of naphtha and other oils in the feedstock mixture for all steam cracker plants producing ethylene is collected from various issues of the *Oil and Gas Journal* to derive the state shares of capacity of steam crackers using naphtha (FNCASZZ) and those using other oils (FOCASZZ). Based on the data collected for 1997 through 1999, 2002, 2004, 2008, and for 2010 forward, Texas and Louisiana are the only two states that use naphtha and other oils as feedstocks in their steam crackers. The shares for the interim years are interpolated using the compound annual growth rates of the years with data, and the shares for 1997 are used for the earlier years.

For 2015 forward, information on nameplate capacity and the share of naphthas and other oils in the feedstock mixture for steam cracker plants producing ethylene is not available from the *Oil and Gas Journal*. The 2014 values are used for 2015 forward.

Petrochemical feedstocks, naphtha less than 401°F, state and U.S. consumption are estimated:

FNTCPZZ = FNTCPUS * FNCASZZ
FNICPZZ = FNTCPZZ
FNICPUS = FNTCPUS

Petrochemical feedstocks, other oils equal to or greater than 401°F, state and U.S. consumption are estimated:

LUBA No. 2020-009
Page 5726

FOTCPZZ = FOTCPUS * FOCASZZ
FOICPZZ = FOTCPZZ
FOICPUS = FOTCPUS

British thermal units (Btu)

Btu estimates for the six petroleum products in this group are developed by multiplying each individual product's estimated consumption in physical units by its respective approximate heat content conversion factor. The calculations performed to estimate total Btu consumption and industrial use Btu consumption by state and for the United States are

FNTCBZZ = FNTCPZZ * 5.248
FNTCBUS = ΣFNTCBZZ
FNICBZZ = FNTCBZZ
FNICBUS = FNTCBUS
FOTCBZZ = FOTCPZZ * 5.825
FOTCBUS = ΣFOTCBZZ
FOICBZZ = FOTCBZZ
FOICBUS = FOTCBUS

Additional note

Before the 2010 cycle, the two products were allocated to the states in proportion to the value of shipments or value added in the manufacture of industrial organic chemicals from the Economic Censuses collected by the U.S. Census Bureau. Organic chemical manufacturing was used because state-level data for petrochemical manufacturing were not available. This resulted in the allocation of petrochemical feedstocks to more than 25 states, most of which did not produce petrochemicals. The steam cracker capacity shares, while requiring estimations, are better allocators.

Data sources

FNCASZZ — State's share of U.S. capacity of steam crackers using naphtha as feedstocks.

- 1960 through 1996: The share for 1997 is used.
- 1997 through 1999, 2002, 2004, 2008, and 2010 through 2014: *Oil and Gas Journal*, specific issues focusing on ethylene production, table on "International Survey of Ethylene from Steam Crackers."
- 2000, 2001, 2003, 2007, 2009, 2015 forward: EIA estimation, based on data available from the *Oil and Gas Journal*.

FNTCPUS — Petrochemical feedstocks, naphtha less than 401°F, total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
  - 1981 forward: EIA, *Petroleum Supply Annual*, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

FOCASZZ — State's share of U.S. capacity of steam crackers using other oils as feedstocks.

- 1960 through 1996: The share for 1997 is used.
- 1997 through 1999, 2002, 2004, 2008, and 2010 through 2014: *Oil and Gas Journal*, specific issues focusing on ethylene production, table on "International Survey of Ethylene from Steam Crackers."
- 2000, 2001, 2003, 2007, 2009, 2015 forward: EIA estimation, based on data available from the *Oil and Gas Journal*.

FOTCPUS — Petrochemical feedstocks, other oils equal to or greater than 401°F, total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Miscellaneous petroleum products

Physical units

Miscellaneous products include all finished products not classified elsewhere (e.g., petrolatum, lube refining byproducts (aromatic extracts and tars), absorption oils, ram-jet fuel, petroleum rocket fuels, synthetic natural gas feed

LUBA No. 2020-009
Page 5727

stocks, and specialty oils). It is assumed that the chief consuming industry for this product line is the organic chemical industry.

State estimates for these products are created in proportion to the value of shipments (value added before 2001) in the manufacture of industrial organic chemicals in each state (OCVAVZZ).

The U.S. total for the data series used to apportion these products to the states is summed:

OCVAVUS = ΣOCVAVZZ

Miscellaneous petroleum products state and U.S. consumption are estimated:

MSTCPZZ = (OCVAVZZ / OCVAVUS) * MSTCPUS
MSICPZZ = MSTCPZZ
MSICPUS = MSTCPUS

British thermal units (Btu)

EIA uses an average heat content value of 5.796 million Btu per barrel for miscellaneous petroleum products. The calculations performed to estimate total Btu consumption and industrial use Btu consumption by state and for the United States are

MSTCBZZ = MSTCPZZ * 5.796
MSTCBUS = ΣMSTCBZZ

Miscellaneous petroleum products consumed in the industrial sector is equal to total consumption.

MSICBZZ = MSTCBZZ
MSICBUS = MSTCBUS

Data sources

MSTCPUS — Miscellaneous petroleum products consumed in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, Mineral Industry Surveys, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1. Naphtha-type jet fuel volumes (JNTCPUS) are included in "Miscellaneous Products" in the *Petroleum Supply Annual*, Table 1.

OCVAVZZ — Value of shipments for the industrial organic chemicals manufacturing industry by state.

Note: Value added before 2001.

- 1960 through 1970: U.S. Department of Commerce, *1967 Census of Manufactures*, Volume II, Part 2, Standard Industrial Classification (SIC) 2818. The 1963 state data are used for the years 1960 through 1965, and the 1967 state data are used for 1966 through 1970.
- 1971 through 1980: U.S. Department of Commerce, *1977 Census of Manufactures*, Industry Series, SIC 2869. The 1972 state data are used for 1971 through 1975, and the 1977 state data are used for 1976 through 1980.
- 1981 through 1985: U.S. Department of Commerce, *1987 Census of Manufactures* (Final Report), Industry Series, SIC 2869. The 1982 state data are used for 1981 through 1985.
- 1986 through 1995: U.S. Department of Commerce, *1992 Census of Manufactures* (Final Report), Industry Series, SIC 2869. The 1987 state data are used for 1986 through 1990, and the 1992 state data are used for 1991 through 1995.
- 1996 through 2000: U.S. Department of Commerce, *1997 Economic Census, Manufacturing, Industry Series*, EC97M-3251A for North American Industry Classification System (NAICS) 325110 "Petrochemical Manufacturing" and EC97M-3251G for NAICS 325119 "All Other Basic Inorganic Chemical Manufacturing." The value added by manufacture for both categories are summed to create a data series generally comparable to the SIC 2869 used previously at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml.
- 2001 forward: U.S. Department of Commerce, *Economic Census*, Manufacturing, Geographic Area Series, column titled "Value of shipments" data for NAICS series 325110, 325120, and 325199 shown in the datasets at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml. See Additional Note 2 on page 89 for the methodology used to estimated withheld values.
  - 2001 through 2005: 2002 *Economic Census*.
  - 2006 through 2012: 2007 *Economic Census*.

LUBA No. 2020-009
Page 5728

– 2013 forward: 2012 *Economic Census.*

Special naphthas

Physical units

Special naphthas are used as paint and varnish thinners and dry cleaning liquids or solvents. This petroleum product is allocated to the states in proportion to the value of shipments (value added before 2001) in the manufacture of paints and allied products in each state (PIVAVZZ).

The U.S. total for the apportioning data series is calculated:

PIVAVUS = ΣPIVAVZZ

Special naphthas state and U.S. consumption are estimated:

SNTCPZZ = (PIVAVZZ / PIVAVUS) * SNTCPUS
SNICPZZ = SNTCPZZ
SNICPUS = SNTCPUS

British thermal units (Btu)

Special naphthas have a heat content value of about 5.248 million Btu per barrel. This factor is applied to convert special naphthas estimated consumption from physical units to Btu by state and the United States is the sum of the states:

SNTCBZZ = SNTCPZZ * 5.248
SNTCBUS = ΣSNTCBZZ

Special naphthas consumed in the industrial sector is equal to total consumption.

SNICBZZ = SNTCBZZ
SNICBUS = SNTCBUS

Data sources

PIVAVZZ — Value of shipments for the paint and coating manufacturing industry by state.

Note: Value added before 2001.

- 1960 through 1970: U.S. Department of Commerce, *1967 Census of Manufactures*, Volume II, Part 2, SIC 2851. The 1963 state data are used for the years 1960 through 1965, and the 1967 state data are used for 1966 through 1970.
- 1971 through 1980: U.S. Department of Commerce, *1977 Census of Manufactures*, Industry Series, SIC 2851. The 1972 state data are used for 1971 through 1975, and the 1977 state data are used for 1976 through 1980.
- 1981 through 1985: U.S. Department of Commerce, *1987 Census of Manufactures* (Final Report), Industry Series, SIC 2851. The 1982 state data are used for the years 1981 through 1985.
- 1986 through 1995: U.S. Department of Commerce, *1992 Census of Manufactures* (Final Report), Industry Series, SIC 2851. The 1987 state data are used for the years 1986 through 1990, and the 1992 state data are used for 1991 through 1995.
- 1996 through 2000: U.S. Department of Commerce, *1997 Economic Census, Manufacturing, Industry Series*, EC97M-3255A for NAICS 325510 "Paint and Coating Manufacturing," at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml.
- 2001 forward: U.S. Department of Commerce, *Economic Census*, Manufacturing, Geographic Area Series, column titled "Value of shipments" data for NAICS series 325510 shown in the data sets at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml. See Additional Note 2 on page 89 for the methodology used to estimated withheld values.
  - 2001 through 2005: 2002 *Economic Census.*
  - 2006 through 2012: 2007 *Economic Census.*
  - 2013 forward: 2012 *Economic Census.*

SNTCPUS — Special naphthas total consumption in the United States.

- 1960 through 1963: Data included in motor gasoline.
- 1964 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.

  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

LUBA No. 2020-009
Page 5729

Waxes

Physical units

Because petroleum waxes are very cost-effective moisture and gas barriers, food packaging is the largest market for petroleum waxes in the United States, accounting for more than 50% of petroleum wax consumption. Therefore, waxes are allocated to the states in proportion to the value of shipments (value added before 2001) in the manufacture of corrugated and solid fiber boxes (CGVAVZZ).

The U.S. total for this variable is summed:

CGVAVUS = ΣCGVAVZZ

State and U.S. consumption are estimated:

WXTCPZZ = (CGVAVZZ / CGVAVUS) * WXTCPUS
WXICPZZ = WXTCPZZ
WXICPUS = WXTCPUS

British thermal units (Btu)

Waxes have a heat content value of about 5.537 million Btu per barrel. This factor is applied to convert the estimated consumption of waxes from physical units to Btu by state and the United States is the sum of the states:

WXTCBZZ = WXTCPZZ * 5.537
WXTCBUS = ΣWXTCBZZ

Wax consumption in the industrial sector is equal to total consumption.

WXICBZZ = WXTCBZZ
WXICBUS = WXTCBUS

Data sources

CGVAVZZ — Value of shipments for the solid fiber box manufacturing industry by state.

Note: Value added before 2001. Before 1992, this series was value added for the sanitary food container manufacturing industry.

- 1960 through 1965: U.S. Department of Commerce, *1963 Census of Manufactures*, Volume II, Part 1, SIC 2654. The 1963 state data are used for the years 1960 through 1965.
- 1966 through 1970: U.S. Department of Commerce, *1967 Census of Manufactures*, Volume II, Part 2, SIC 2654. The 1967 state data are used for 1966 through 1970.
- 1971 through 1980: U.S. Department of Commerce, *1977 Census of Manufactures*, Industry Series, SIC 2654. The 1972 state data are used for 1971 through 1975, and the 1977 state data are used for 1976 through 1980.
- 1981 through 1990: U.S. Department of Commerce, *1982 Census of Manufactures* (Final Report), Industry Series, SIC 2654. The 1982 state data are used for 1981 through 1990.
- 1991 through 1995: U.S. Department of Commerce, *1992 Census of Manufactures* (Final Report), Industry Series, SIC 2653. The 1992 state data are used for 1991 through 1995.
- 1996 through 2000: U.S. Department of Commerce, *1997 Economic Census, Manufacturing, Industry Series*, EC97M-3222A for NAICS 322211 "Corrugated and Solid Fiber Box Manufacturing" at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml.
- 2001 forward: U.S. Department of Commerce, Economic Census, Manufacturing, Geographic Area Series, column titled "Value of shipments" data for NAICS series 322211 shown in the data sets at http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml. See Additional Note 2 on page 89 for the methodology used to estimated withheld values.
  - 2001 through 2005: 2002 *Economic Census.*
  - 2006 through 2012: 2007 *Economic Census.*
  - 2013 forward: 2012 *Economic Census.*

WXTCPUS — Waxes total consumption in the United States.

- 1960 through 1975: U.S. Department of the Interior, Bureau of Mines, *Mineral Industry Surveys*, "Petroleum Statement, Annual," Table 1.
- 1976 through 1980: EIA, *Energy Data Reports*, "Petroleum Statement, Annual," Table 1.
- 1981 forward: EIA, *Petroleum Supply Annual*, http://www.eia.gov/petroleum/supply/annual/volume1/, table on U.S. Supply, Disposition, and Ending Stocks of Crude Oil and Petroleum Products, column titled "Products Supplied." The specific tables are
  - 1981 through 2004: Table 2.
  - 2005 forward: Table 1.

Total other petroleum products

LUBA No. 2020-009
Page 5730

Physical units

Total other petroleum products is the sum of the 11 "other petroleum products." All of these products are consumed by the industrial sector. State and U.S. industrial use of these other petroleum products are calculated:

OPICPZZ = ABICPZZ + COICPZZ + FNICPZZ + FOICPZZ + FSICPZZ + MBICPZZ + MSICPZZ + SGICPZZ + SNICPZZ + UOICPZZ + WXICPZZ

OPICPUS = ΣOPICPZZ

Total consumption of these products is calculated:

OPTCPZZ = ABTCPZZ + COTCPZZ + FNTCPZZ + FOTCPZZ + FSTCPZZ + MBTCPZZ + MSTCPZZ + SGTCPZZ + SNTCPZZ + UOTCPZZ + WXTCPZZ

OPTCPUS = ABTCPUS + COTCPUS + FNTCPUS + FOTCPUS + FSTCPUS + MBTCPUS + MSTCPUS + SGTCPUS + SNTCPUS + UOTCPUS + WXTCPUS

British thermal units (Btu)

Estimated consumption of all 11 "other petroleum products" in Btu is the sum of the Btu consumption of each product by the industrial sector. The state and U.S. totals are calculated:

OPICBZZ = ABICBZZ + COICBZZ + FNICBZZ + FOICBZZ + FSICBZZ + MBICBZZ + MSICBZZ + SGICBZZ + SNICBZZ + UOICBZZ + WXICBZZ

OPICBUS = ΣOPICBZZ

State and U.S. total consumption of these products is calculated:

OPTCBZZ = ABTCBZZ + COTCBZZ + FNTCBZZ + FOTCBZZ + FSTCBZZ + MBTCBZZ + MSTCBZZ + SGTCBZZ + SNTCBZZ + UOTCBZZ + WXTCBZZ

OPTCBUS = ΣOPTCBZZ

Additional notes

1. The data for "value added" and "value of shipments" that are used to allocate some of the other petroleum products are from the U.S. Department of Commerce, Census Bureau, *Census of Manufactures* or *Economic Census* reports. For all years, several states' data were withheld from publication to avoid disclosing operations of individual companies. The total withheld data was apportioned to the withheld states on the basis of those states' proportional values in the previous census. In the 1992 *Census of Manufactures*, the total withheld value was apportioned to states with withheld data in proportion to the number of employees in that industry in each state. Beginning with the 1997 *Economic Census*, the published report tables do not list any states that have withheld data. Detailed data tables from "American FactFinder" on the U.S. Census Bureau website, http://factfinder.census.gov/faces/nav/jsf/pages/index.xhtml, are used to obtain the list of states with data withheld and the number of employees.
2. In 1982, all respondents to the *Census of Manufactures* survey were requested to report their inventories at cost or market before accounting adjustments for "last in, first out" cost. This is a change from prior years in which respondents were permitted to value their inventories by using any generally accepted accounting valuation method. So, data for value added by manufacture after 1982 are not comparable to the prior years' data.

LUBA No. 2020-009
Page 5731

Petroleum Aggregates

This section describes the method of estimating consumption by the major end-use sectors within the states for all petroleum data series. Table TN4.1 indicates which petroleum products are consumed in each of the five major end-use sectors. In the preceding portions of this section, end-use consumption estimates have been derived for each petroleum product. These petroleum product subtotals are now summed, in physical units of thousand barrels and in Btu, to create estimated end-use consumption for all petroleum products.

Residential sector

Petroleum products consumed by the residential sector are: distillate fuel oil (DF); kerosene (KS); and hydrocarbon gas liquids (HL). For the residential sector, the state and U.S. totals in physical units are

PARCPZZ = DFRCPZZ + HLRCPZZ + KSRCPZZ
PARCPUS = ΣPARCPZZ

State and U.S. totals in Btu are

PARCBZZ = DFRCBZZ + HLRCBZZ + KSRCBZZ
PARCBUS = ΣPARCBZZ

Commercial sector

The commercial sector's use of petroleum products includes: distillate fuel oil (DF); kerosene (KS); hydrocarbon gas liquids (HL); motor gasoline (MG); and residual fuel oil (RF). In physical units, the state and the U.S. totals for the commercial sector are calculated:

PACCPZZ = DFCCPZZ + HLCCPZZ + KSCCPZZ + MGCCPZZ + PCCCPZZ + RFCCPZZ
PACCPUS = ΣPACCPZZ

State and U.S. totals in Btu are

PACCBZZ = DFCCBZZ + HLCCBZZ + KSCCBZZ + MGCCBZZ + PCCCBZZ + RFCCBZZ
PACCBUS = ΣPACCBZZ

Industrial sector

Petroleum used in the industrial sector includes: asphalt and road oil (AR); distillate fuel oil (DF); kerosene (KS); hydrocarbon gas liquids (HL); lubricants (LU); motor gasoline (MG); petroleum coke (PC); residual fuel oil (RF); and the 11 products that are already summed in the "other petroleum products" (OP) subtotal. The state and U.S. total estimates in physical units are

PAICPZZ = ARICPZZ + DFICPZZ + HLICPZZ + KSICPZZ + LUICPZZ + MGICPZZ + OPICPZZ + PCICPZZ + RFICPZZ
PAICPUS = ΣPAICPZZ

State and U.S. totals in Btu are

PAICBZZ = ARICBZZ + DFICBZZ + HLICBZZ + KSICBZZ LUICBZZ + MGICBZZ + OPICBZZ + PCICBZZ + RFICBZZ
PAICBUS = ΣPAICBZZ

Transportation sector

Petroleum products used in the transportation sector are: aviation gasoline (AV); distillate fuel oil (DF); jet fuel (JF); hydrocarbon gas liquids (HL); lubricants (LU); motor gasoline (MG); and residual fuel oil (RF). The state and U.S. totals in physical units are

PAACPZZ = AVACPZZ + DFACPZZ + HLACPZZ + JFACPZZ + LUACPZZ + MGACPZZ + RFACPZZ
PAACPUS = ΣPAACPZZ

State and U.S. totals in Btu are

PAACBZZ = AVACBZZ + DFACBZZ + HLACBZZ + JFACBZZ + LUACBZZ + MGACBZZ + RFACBZZ
PAACBUS = ΣPAACBZZ

Electric power sector

Petroleum products consumed by the electric power sector are: distillate fuel oil (DF), jet fuel (JF), petroleum coke (PC), and residual fuel oil (RF). In physical units, the state and U.S. totals are

PAEIPZZ = DFEIPZZ + JFEUPZZ + PCEIPZZ + RFEIPZZ
PAEIPUS = ΣPAEIPZZ

LUBA No. 2020-009
Page 5732

State and U.S. totals in Btu are

PAEIBZZ = DFEIBZZ + JFEUBZZ + PCEIBZZ + RFEIBZZ
PAEIBUS = ΣPAEIBZZ

Total consumption of petroleum products

Total consumption of all petroleum products is the sum of all of the individual product totals. The state and U.S. physical unit totals are

PATCPZZ = ARTCPZZ + AVTCPZZ + DFTCPZZ + HLTCPZZ + JFTCPZZ + KSTCPZZ + LUTCPZZ + MGTCPZZ + OPTCPZZ + PCTCPZZ + RFTCPZZ
PATCPUS = ARTCPUS + AVTCPUS + DFTCPUS + HLTCPUS + JFTCPUS + KSTCPUS + LUTCPUS + MGTCPUS + OPTCPUS + PCTCPUS + RFTCPUS

State and U.S. totals in Btu are

PATCBZZ = ARTCBZZ + AVTCBZZ + DFTCBZZ + HLTCBZZ + JFTCBZZ + KSTCBZZ + LUTCBZZ + MGTCBZZ + OPTCBZZ + PCTCBZZ + RFTCBZZ
PATCBUS = ΣPATCBZZ

Additional calculations

A few petroleum products are combined for display in the "Other Petroleum" column in tables on total energy consumption and industrial sector energy consumption. They include asphalt and road oil, aviation gasoline (total energy only), kerosene, lubricants, petroleum coke, and the 11 petroleum products described in the "other petroleum products" section of the Technical Notes. The variables are calculated in physical unit and Btu, for each state and the United States:

P1TCP = ARTCP + AVTCP + KSTCP + LUTCP + OPTCP + PCTCP
P1TCB = ARTCB + AVTCB + KSTCB + LUTCB + OPTCB + PCTCB
P1ICP = ARICP + KSICP + LUICP + OPICP + PCICP
P1ICB = ARICB + KSICB + LUICB + OPICB + PCICB

Total petroleum typically reflects motor gasoline including fuel ethanol. To assist data users in the analysis of consumption of renewable energy sources, which include fuel ethanol, versus non-renewable energy sources, which include petroleum products and other fossil fuels, a new data series, total petroleum excluding fuel ethanol, is created for each state and the United States:

From 1993 forward

PMTCB = PATCB - EMTCB

Before 1993, fuel ethanol was not included in the motor gasoline data series from the source:

PMTCB = PATCB

Total petroleum excluding fuel ethanol is used only in the tables showing energy consumption by source. For consumption by end-use sector, total petroleum includes fuel ethanol, as it is included in motor gasoline as it is consumed by the end-users.

Conversion factors for all petroleum products consumed by each sector, as well as data for the residential and commercial sectors combined, are calculated for use in EIA's *Annual Energy Review* and *Monthly Energy Review*.

PARCKUS = PARCBUS / PARCPUS
PACCKUS = PACCBUS / PACCPUS
PAICKUS = PAICBUS / PAICPUS
PAACKUS = PAACBUS / PAACPUS
PAEIKUS = PAEIBUS / PAEIPUS
PATCKUS = PATCBUS / PATCPUS

Consumption of all petroleum products by the residential and commercial sectors combined, in physical units, in Btu, and the average conversion factor, are calculated:

PAHCPUS = PARCPUS + PACCPUS
PAHCBUS = PARCBUS + PACCBUS
PAHCKUS = PAHCBUS / PAHCPUS

Fossil Fuel Terminal Zoning Amendments

Discussion Draft

Comments Due by July 27, 2016

City of Portland
Bureau of Planning and Sustainability
June 2016

Bureau of Planning and Sustainability
Innovation. Collaboration. Practical Solutions.

How to Comment

The Fossil Fuel Terminal Zoning Amendments project would help implement new policy direction on fossil fuel distribution and storage facilities through changes to the Zoning Code. This proposal would restrict the development of new bulk fossil fuel terminals. However, proposed code changes would not inhibit improvements to existing terminals; they would instead accommodate seismic upgrades, access to greener fuels and capacity for regional growth.

Please submit comments or questions on the Discussion Draft by July 27, 2016.

Next Steps

Proposed Draft: Based on *Discussion Draft* feedback, a *Proposed Draft* will be published in early August 2016 for Planning and Sustainability Commission (PSC) consideration. At this time, Portlanders will be invited to submit public testimony to the PSC in writing or in person, at a public hearing scheduled for September 13, 2016. The Commission may amend the proposal and will subsequently vote to recommend the changes and draft plan to Portland City Council. This is called the *Recommended Draft*.

Recommended Draft: City Council will hold an additional public hearing and take formal public testimony on the Recommended Draft. The City Council may amend the Recommended Draft before they vote to adopt the code changes. This will likely occur in December 2016.

The Bureau of Planning and Sustainability is committed to providing equal access to information and hearings. If you need special accommodation, please call 503-823-7700, the City's TTY at 503-823-6868, or the Oregon Relay Service at 1-800-735-2900.

1. Introduction

In recent years, the rapid development of fossil fuel resources in the Western United States and Canada has prompted many proposals in the Pacific Northwest for large new fuel terminals and infrastructure projects. In early 2015, a proposal by Pembina for a propane terminal in Portland drew substantial public opposition, and Mayor Charlie Hales withdrew a proposal for a zoning amendment that the development would have required. In November 2015, Portland City Council adopted Resolution 37168 calling for opposition to expansion of fossil fuel infrastructure, while supporting infrastructure improvements to existing facilities. In June 2016, City Council adopted the 2035 Comprehensive Plan, which included Policy 6.48 to limit fossil fuel distribution and storage facilities to those needed to serve the regional market. This code-change project begins to implement the policy direction in the resolution by limiting new fossil fuel infrastructure.

Project summary

The Fossil Fuel Terminal Zoning Amendments project would restrict the development of large new Bulk Fossil Fuel Terminals, while providing for expansion at existing terminals and moderately sized new terminal development to accommodate the fuel needs of the region's growing population.

Proposed zoning code amendments:

- Identify "Bulk Fossil Fuel Terminals" as a regulated land use, characterized by marine, railroad, or pipeline transport access and storage capacity exceeding 150,000 barrels.
- Set storage capacity limits that allow for new terminal development large enough to accommodate forecast growth and prohibit development of larger terminals.
- Allow existing terminals to expand, particularly to support seismic upgrades and access to greener fuels.

Why is this important?

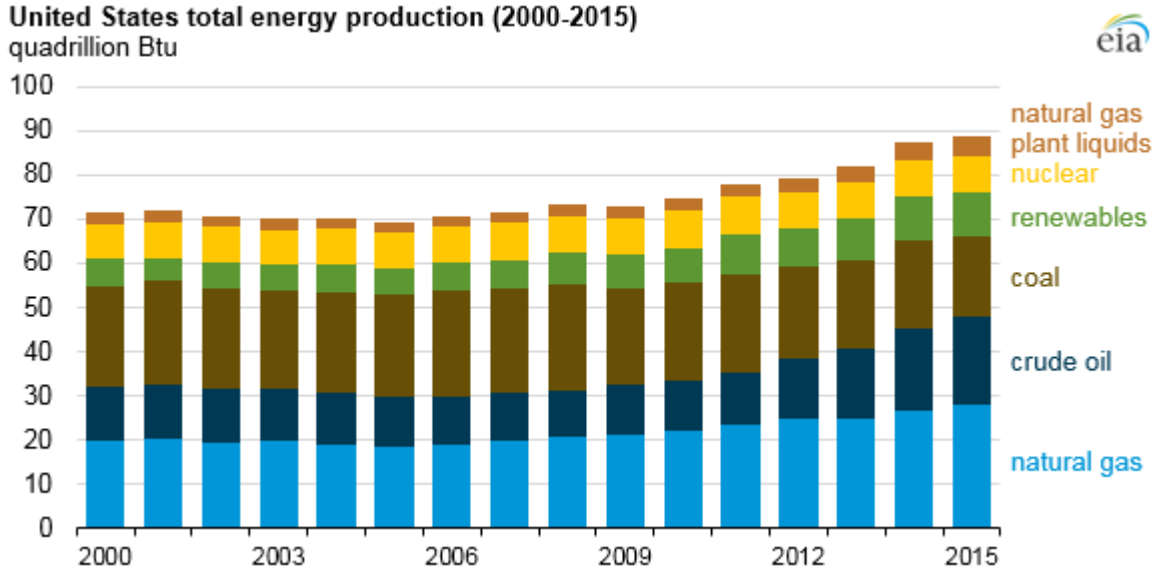
Fossil fuel distribution policy – New policy directions adopted by City Council in November 2015 and proposed in the 2035 Comprehensive Plan would limit fossil fuel distribution and storage facilities to those serving the regional market. City Council adopted these policies after holding public hearings and hearing testimony from hundreds of Portlanders.

Climate action goals – Fossil fuels are major contributors to climate change and pollution. The rapid development of fossil fuel resources in the Western United States and Canada has prompted many recent proposals for new export terminals in the Pacific Northwest. The City's Climate Action Plan seeks to reduce greenhouse gas emissions, however, and fossil fuels are the largest source of emissions.

Public safety and environmental protection – Several recent accidents involving fossil fuel distribution across the nation and in Oregon highlight public safety risks in cities and environmental risks along rivers.

Oregon's industrial and distribution center – Portland is Oregon's largest, most diverse distribution hub, and existing Portland petroleum terminals serve more than 90 percent of the statewide market. Proposed code changes would continue Portland's significant role by supporting existing facilities.

Project scope and timing



The energy distribution market in the Pacific Northwest is changing. Production of crude oil and natural gas, particularly from North Dakota, has substantially increased in the U.S. since 2009, as shown in Figure 1. In turn, several large new fuel distribution terminals have been proposed in the Pacific Northwest to access West Coast and export markets, as shown in Figure 2. Similar trends have occurred in Alberta and British Columbia.

This project is proposing a prompt, focused response to these market changes. Draft code amendments are being prepared for adoption by the end of 2016 to restrict development of large new fossil fuel terminals. The proposed size standards are sufficient to accommodate the fuel needs of the growing region, while restricting development of large new terminals that would conflict with City and State objectives on climate change and public safety.

Where are Portland's existing bulk fossil fuel terminals?

Portland's industrial districts are Oregon's largest seaport, rail hub, and truck distribution center. The Northwest Industrial District in Portland is also the end of the Olympic Pipeline, which supplies most of Oregon's petroleum fuels from Puget Sound refineries. The ten petroleum terminals located there are the gateway distribution facilities serving Oregon and Southern Washington markets. Additionally, NW Natural's GasCo terminal there provides peak-consumption storage of natural gas for much of the regional market. In Northwest Portland, these "tank farm" storage facilities have direct access to pipeline, deep-water port, railroad, and truck route infrastructure.

Figure 1. Increasing U.S. energy production

Source: U.S. Energy Information Administration, 2016

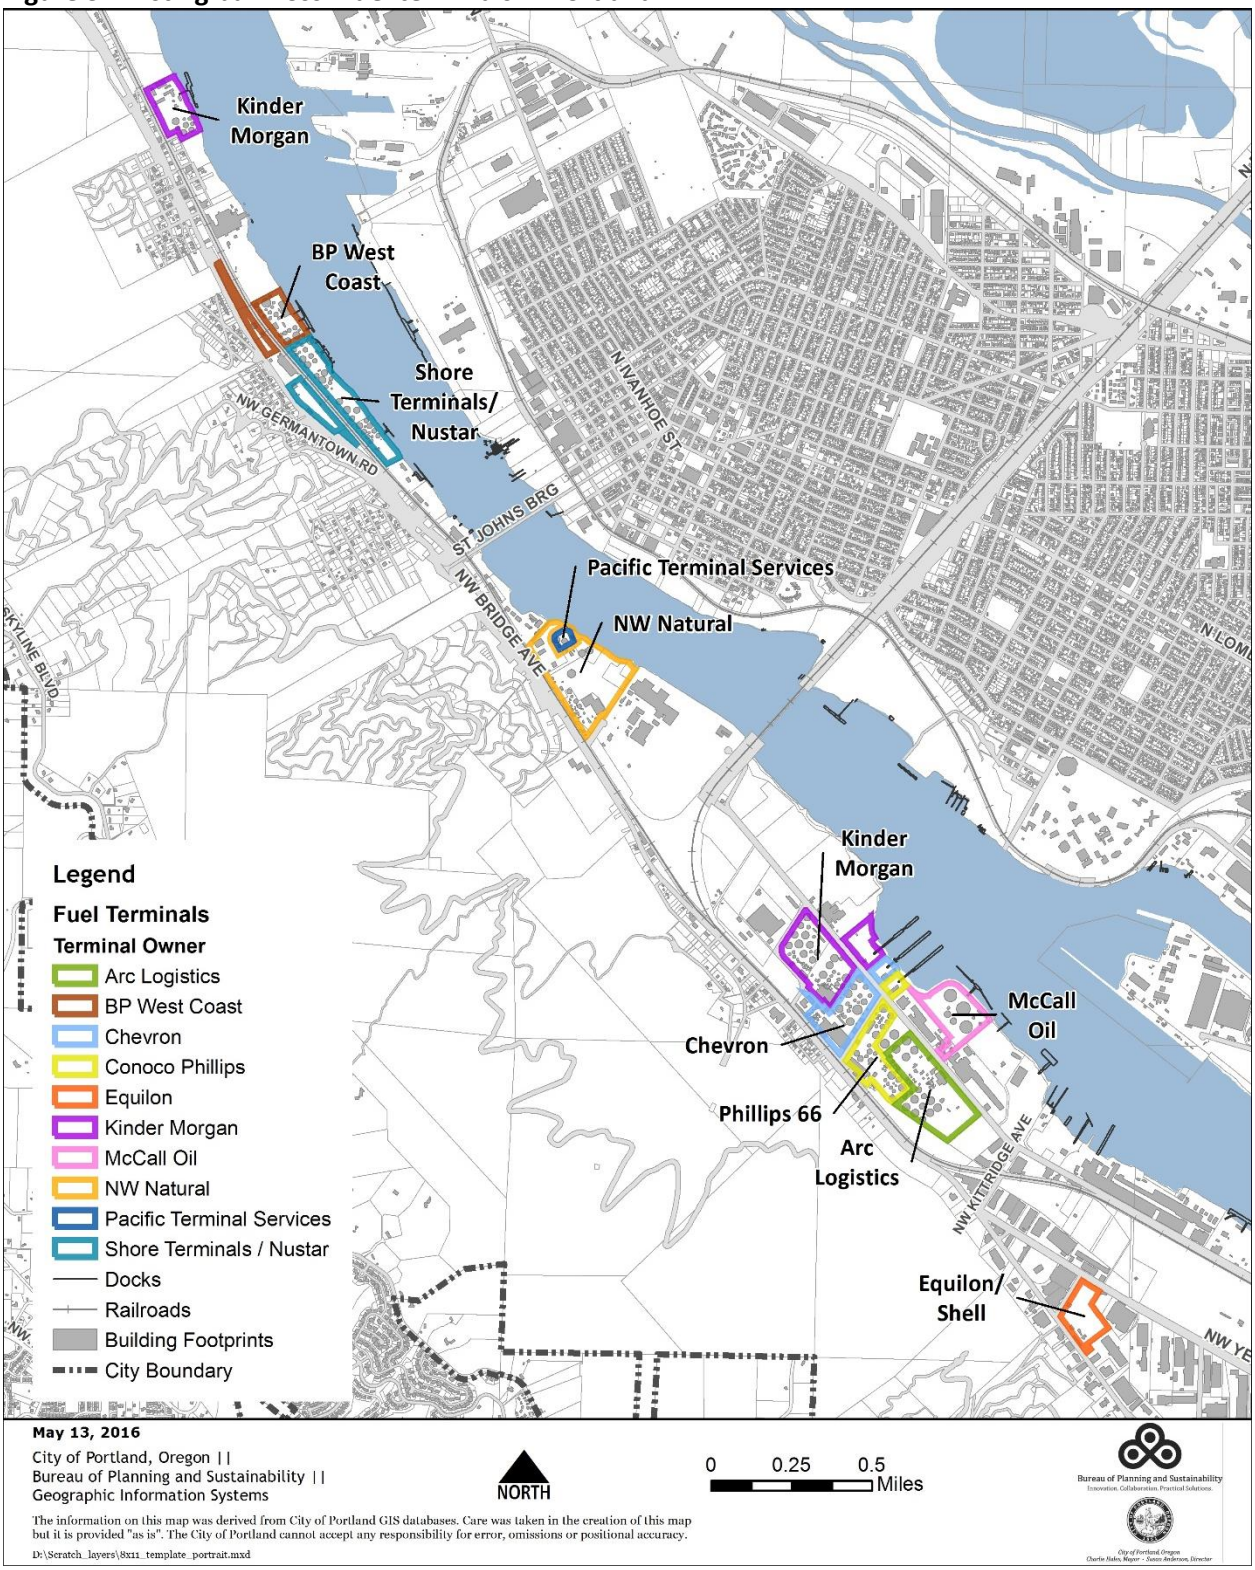


Figure 2. Examples of recent fossil terminal proposals in the Pacific Northwest

Operator	*Facility type*	*Location*	*Proposed new storage capacity*
Petroleum fuels			barrels
Vancouver Energy	Crude oil terminal	Vancouver WA	2,160,000
Imperium Renewables	Biofuels terminal	Grays Harbor WA	720,000
Gaseous fuels			gallons
Oregon LNG terminal	New LNG terminal	Warrenton OR	84,000,000
Jordan Cove LNG	New LNG terminal	Coos Bay OR	84,000,000
Pembina	Propane terminal	Portland	35,000,000
Haven Energy	Propane terminal	Longview WA	23,000,000
Coal			Stockpile acres
Millennium Bulk Terminal	Coal terminal	Longview WA	~20
Ambre Energy	Coal transload facility	St. Helens OR	no storage
Gateway Pacific Terminal	Coal terminal	Bellingham WA	80

Five petroleum terminals are located in the Willbridge area of NW Portland.

Figure 3. Existing bulk fossil fuel terminals in Portland

What's in this report?

This *Discussion Draft* is a roughly 80-percent draft of the project proposals, consisting of code change concepts instead of specific code language. The audience is the general public, including stakeholders, inter-governmental partners, implementers, and other interested parties. Project stakeholders include property owners, businesses, employees, residents, neighbors, business district and neighborhood associations, underrepresented and underserved groups, environmental groups and other community groups. Implementers include the real estate industry, development review staff and others who use the zoning code.

Your feedback on the Discussion Draft will help staff develop a Proposed Draft for the Planning and Sustainability Commission to consider.

This report consists of seven parts:

- **Section 1** introduces the project.
- **Section 2** describes how the proposed code changes implement City policies in Resolution 37168 and the 2035 Comprehensive Plan.
- **Section 3** summarizes public and stakeholder involvement activities that have helped shape and inform this project.
- **Section 4** describes background conditions that inform the proposed zoning concepts.
- **Section 5** describes the analysis of proposed zoning concepts, including related policy directions, implementation issues and rationale.

2. Policy direction

Section 2 describes how the proposed code changes implement relevant City policies in Resolution 37168 and the Comprehensive Plan and comply with federal limitations on interstate commerce.

City of Portland Fossil Fuel Resolution 37168

> BE IT RESOLVED, that the City Council will actively oppose expansion of infrastructure whose primary purpose is transporting or storing fossil fuels in or through Portland or adjacent waterways; and

The proposed zoning code changes are a key implementation action of Resolution 37168, adopted November 2015. Addressing the overall direction of the resolution to oppose expansion of fossil fuel distribution and storage infrastructure, this project proposes size standards that restrict development of large new fossil fuel terminals.

> BE IT FURTHER RESOLVED, that this Resolution does not restrict:
> 1. improvements in the safety, or efficiency, seismic resilience, or operations of existing infrastructure;
> 2. the provision of service directly to end users;
> 3. development of emergency backup capacity;
> 4. infrastructure that enables recovery or re-processing of used petroleum products; or
> 5. infrastructure that will accelerate the transition to non-fossil fuel energy sources; and

The project exempts existing terminals so that the new restrictions do not hinder or increase costs of these safety improvements (such as seismic retrofits) or new infrastructure that accelerates transition to non-fossil fuel energy (such as new tanks for blending biofuels with fossil fuels). The project does not propose restrictions on fossil fuel retailers (such as gasoline filling stations) or smaller regional distributors that receive and deliver fossil fuels exclusively by truck. The proposed code changes do not include size limits that would preclude development of emergency backup capacity. The proposed definition exempts the recovery or reprocessing of used petroleum products.

> BE IT FURTHER RESOLVED, that City bureaus are directed to examine existing laws, including those related to public health, safety, building, electrical, nuisance, and fire codes, and develop recommendations to address fossil fuels that strengthen public health and safety; and

The resolution broadly addresses fossil fuel infrastructure. The zoning code regulates land use patterns and development of fossil fuel distribution facilities on parcels. Zoning does not regulate the quantity of products handled (throughput) on developed sites or their destination (such as exports). Additional amendments to building, fire, and energy codes would need to be addressed in future projects.

> BE IT FURTHER RESOLVED, that the Bureau of Planning and Sustainability is directed to develop proposed code changes for Council consideration to advance the policies set forth in this Resolution; and

The proposed project will specifically implement this provision of the resolution.

> BE IT FURTHER RESOLVED, that prior to any further Council action, the mayor shall schedule (1) a work session to review any proposed code changes and (2) an executive session to review the legal considerations of any proposed code changes; and

The proposed project will implement this process requirement of the resolution.

> BE IT FURTHER RESOLVED, that the Bureau of Planning & Sustainability shall undertake an analysis of the economic impacts of any proposed Code changes to advance the policies set forth in this resolution, with a particular focus on potential impacts to local blue-collar jobs; and

This report includes summary analysis of economic impacts in Section 4, specifically addressing impacts on middle-wage blue collar jobs. The proposed code changes would allow for expansion at existing terminals and moderately sized new terminal development to accommodate regional demand and resulting forecast job growth.

> BE IT FURTHER RESOLVED, that the City and applicable bureaus shall seek and identify opportunities to invest in Portland's 'human infrastructure' by supporting programs to retrain our workforce as the city transitions to a clean energy economy; and

This provision of the resolution is expected to be implemented as a future action.

> BE IT FURTHER RESOLVED, that the City shall consult with its Tribal Government Partners, the State of Oregon, local governments, and other key stakeholder including labor, business, environment, neighborhoods and communities of color in advancing this policy;

The proposed project has sought input from and will continue to reach out to the entities identified above to implement this process requirement of the resolution.

Guiding principles of the 2035 Comprehensive Plan

The Comprehensive Plan sets five Guiding Principles, which encourage balanced, integrated multi-disciplinary approaches that must comply with the Plan. This project is consistent with the Guiding Principles because it promotes major benefits to human health and safety, environmental health and resilience and a balanced approach that integrates economic prosperity and equity.

Economic prosperity

> *Guiding Principle: Support a low-carbon economy and foster employment growth, quality education and training, competitiveness, and equitably-distributed household prosperity.*

Balanced approach - The proposed code changes would provide for expansion at existing fuel terminals and moderately sized new terminal development, accommodating regional demand for fuels and resulting forecast job growth and tax revenue. The proposed code restrictions on large new fossil fuel

terminals would also limit potential financial risks from a major accident involving fossil fuel infrastructure.

Human health

> *Guiding Principle:* Avoid or minimize negative health impacts and improve opportunities for Portlanders to lead healthy, active lives.

Major benefit – The proposed code changes would reduce the scale of low, but potentially catastrophic, safety risks associated with the growth of fossil fuel infrastructure, including oil train derailments, explosive accidents at LNG (liquefied natural gas) and LPG (liquefied petroleum gas) facilities, and seismic risks of tank farms. Fossil fuel emissions and coal dust are also significant sources of air pollution associated with respiratory disorders.

Environmental health

> *Guiding Principle: Weave nature into the city and foster a healthy environment that sustains people, neighborhoods, and wildlife. Recognize the intrinsic value of nature and sustain the ecosystem services of Portland's air, water, and land.*

Major benefit – The human health benefits described above also extend to environmental health. The proposed code changes would reduce the scale of environmental health risks associated with the growth of fossil fuel infrastructure, including oil train derailments along the Columbia River, LNG and LPG facilities in riparian areas, and seismic risks of tank farms along the Willamette River. Fossil fuel emissions are also a significant source of air pollution.

Equity

> *Guiding Principle: Promote equity and environmental justice by reducing disparities, minimizing burdens, extending community benefits, increasing the amount of affordable housing, affirmatively furthering fair housing, proactively fighting displacement, and improving socio-economic opportunities for under-served and under-represented populations. Intentionally engage under-served and under-represented populations in decisions that affect them. Specifically recognize, address, and prevent repetition of the injustices suffered by communities of color throughout Portland's history.*

Balanced approach - The proposed code changes would provide for expansion at existing fuel terminals and moderately sized new terminal development, accommodating regional demand for fossil fuels and associated middle-wage, industrial job growth that disproportionately benefits workers of color. Accommodating regional demand could also reduce regressive impacts of increasing fuel costs.

Resilience

> *Guiding Principle: Reduce risk and improve the ability of individuals, communities, economic systems, and the natural and built environments to withstand, recover from, and adapt to changes from natural hazards, human-made disasters, climate change, and economic shifts*.

Major benefit – The proposed code changes would restrict development of large new fossil fuel terminals that would conflict with City and State objectives on climate change and public safety. While fossil fuels like natural gas and propane have the potential to replace higher-carbon fuels, substituting these fuels for higher-carbon fuels does not begin to approach the goal of an 80% reduction in carbon emissions by 2050 established in Portland's Climate Action Plan or the State's 75% goal.

2035 Comprehensive Plan policies specifically implemented in this project

The proposed zoning changes in the project are implementing the following specific policies.

Overall project direction: Fossil fuel distribution

> *Policy 6.48 Fossil fuel distribution. Limit fossil fuel distribution and storage facilities to those necessary to serve the regional market.*

The proposed code changes would implement Policy 6.48 by restricting development of large new fossil fuel distribution terminals while accommodating forecast regional growth.

Related policy directions

> *Policy 4.81 Disaster-resilient development. Encourage development and site-management approaches that reduce the risks and impacts of natural disasters or other major disturbances and that improve the ability of people, wildlife, natural systems, and property to withstand and recover from such events.*
>
> *Policy 4.82 Portland Harbor facilities. Reduce natural hazard risks to critical public and private energy and transportation facilities in the Portland Harbor.*

Policies 4.81 and 4.82 are met by not restricting expansion or hindering safety or efficiency improvements at existing terminals. Incremental expansion at existing terminals provides an important pathway for safety improvements, providing financial return to cover improvement costs.

> *Policy 6.2 Diverse and expanding economy. Align plans and investments to maintain the diversity of Portland's economy and status as Oregon's largest job center with growth across all sectors (commercial, industrial, creative, and institutional) and across all parts of the city.*
>
> *Policy 6.5 Economic resilience. Improve Portland's economic resilience to impacts from climate change and natural disasters through a strong local economy and equitable opportunities for prosperity.*
>
> *Policy 6.6 Low-carbon and renewable energy economy. Align plans and investments with efforts to improve energy efficiency and reduce lifecycle carbon emissions from business operations. Promote employment opportunities associated with the production of renewable energy, energy efficiency projects, waste reduction, production of more durable goods, and recycling.*

The proposed code changes are consistent with Policies 6.2, 6.5, and 6.6, providing for incremental fossil fuel growth as part of a diverse, expanding economy and restricting development of large new fossil fuel terminals that conflict with resilience and climate action goals.

Existing Comprehensive Plan policies specifically implemented in this project

The 2035 Comprehensive Plan was adopted in June 2016 and is not expected to take effect until early 2018. In the meantime, the existing Comprehensive Plan is in effect.

> 7.6 Energy Efficient Transportation. Provide opportunities for non-auto transportation including alternative vehicles, buses, light rail, bikeways, and walkways. The City shall promote the reduction of gasoline and diesel use by conventional buses, autos and trucks by increasing fuel efficiency and by promoting the use of alternative fuels.
>
> 7.8 Energy Supply. The City shall promote conservation as the energy resource of first choice. The City shall also support environmentally acceptable, sustainable energy sources, especially renewable resources such as solar, wind, hydroelectric, geothermal, biomass (wood, farm and municipal waste), cogeneration, and district heating and cooling.

The proposed code changes are consistent with Policies 7.6 and 7.8, promoting the use of alternative energy sources by restricting development of large new fossil fuel terminals.

2015 Climate Action Plan

> Goal: Reduce local carbon emissions 80 percent from 1990 levels by 2050, with an interim goal of 40 percent by 2030.

As described in Section 4, lower-carbon fossil fuels like natural gas and propane have the potential to replace higher-carbon fuels, but they do not approach the goal of an 80% reduction in carbon emissions by 2050 in Portland's Climate Action Plan or the State's 75% goal. Investments in major infrastructure typically take decades to recoup, and the transition to renewables needs to go much faster than that to stabilize global emissions. The proposed code changes are consistent with the 80% goal of the Climate Action Plan by restricting development of large new fossil fuel terminals.

Federal jurisdiction on regulation of interstate commerce

Federal law restricts local regulatory authority over interstate commerce in various ways. The Proposed code changes would allow for expansion at existing terminals and moderately sized new terminal development, and they will not constrain interstate commerce or create a protectionist advantage to Oregon residents or businesses. Most of the existing fuel terminals are operated by international or national companies that are not headquartered in Oregon.

3. Public and stakeholder involvement

Section 3 summarizes public and stakeholder involvement activities that have helped shape and inform this project. These activities are further explained in Appendix A of this report.

What have we heard leading up to this project?

Public hearings at the Planning and Sustainability Commission and City Council on the Pembina terminal development proposal in 2014 and Resolution 37168 in 2015 drew testimony from hundreds of people. The overall theme of that testimony was strong objection to the Pembina project and support for the fossil fuel resolution. Primary reasons included the neighborhood safety and health risks and inconsistency with the City's climate action objectives. The Resolution also drew letters with strong opposition from state and regional business associations.

Following adoption of the Resolution in November 2015, City Council added the related Policy 6.48 on fossil fuel distribution to the draft 2035 Comprehensive Plan, reflecting the recently adopted policy direction in the Resolution. Public involvement in the Comprehensive Plan included public hearings in April 2016 on City Council amendments and thousands of comments on the 2035 Comprehensive Plan over the previous 8 years. The proposed code amendments are consistent with several sustainability-related policies in the Plan. Addressing issues with policy tradeoffs, the 2035 Comprehensive Plan calls for a balanced, integrated approach to implement multiple goals. As described in Section 2, the proposed code amendments provide major benefits toward implementing three of the Plan's five guiding principles and a balanced approach that integrates the other two guiding principles.

Public involvement activities in this project

Public involvement in concept development for the project consisted primarily of four stakeholder focus groups, which were held in June 2016 to review preliminary code concepts and help identify and understand potential implementation issues. The focus groups highlighted the range of stakeholder perspectives and interests concerning the proposed zoning changes. Figure 4 summarizes the themes of issues raised in the focus groups. Other outreach activities have included meetings with interagency partners, terminal operators, and other interested stakeholders. These activities and what we heard in them are further described in the appendix of this report.

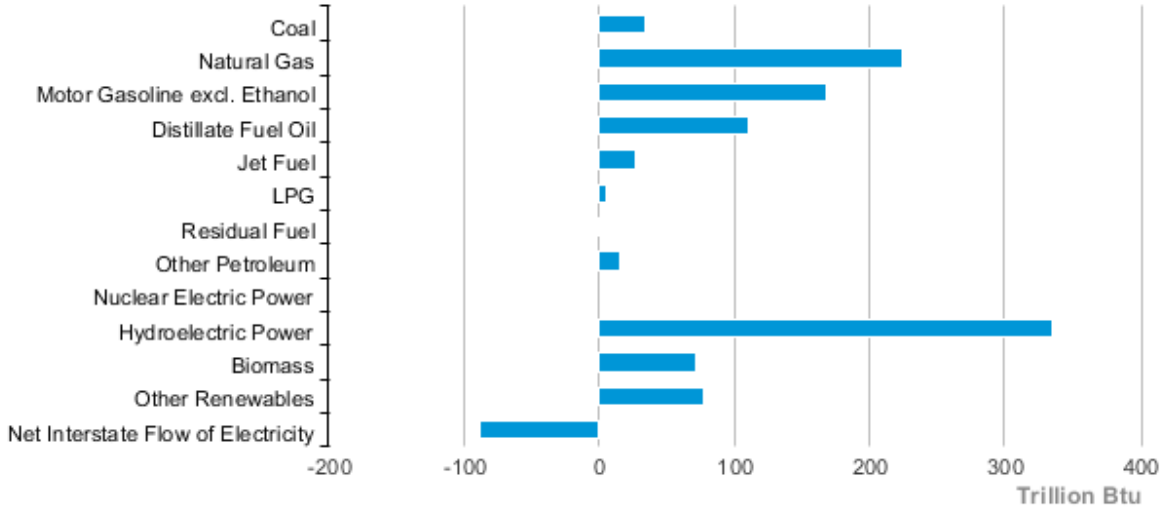
Inter-governmental coordination

An In-House Draft Report was circulated to inter-bureau partners in June 2016, and their comments have helped to shape and inform the Discussion Draft, particularly addressing code administration and legal limitations. Bureau of Planning and Sustainability staff will continue to meet with inter-governmental partners to refine responses to implementation issues.

Figure 4. Summary themes of stakeholder focus group comments

TOPIC	FUEL TERMINAL REPRESENTATIVES	ENVIRONMENTAL AND HEALTH ORGANIZATIONS	STATE AND REGIONAL BUSINESS ORGANIZATIONS	NEIGHBORHOOD AND EQUITY ORGANIZATIONS
Key issues	▸ We've operated safely for decades. We meet the federal/state low-carbon fuel standards. ▸ Difficult to participate: very quick process; emotionally driven; antitrust restrictions. ▸ Unintended impacts: harder to meet clean fuel standards; more trucks on road; costs to rest of the state.	▸ Looking for strong, model code. Expect community backlash if expectations not met. ▸ Safety needs to be integral with climate - Mosier oil train wreck; terminals in liquefaction soils. ▸ Include disaster risks in economic analysis. Bonding or insurance for worst case.	▸ Resolution requires more research on economic impacts, etc. ▸ How will the code hold up in 5 years? ▸ What is the goal? If climate or safety, zoning tool is not the right fit. ▸ Portland is not an economic island. Statewide impact. ▸ Big political decision. Don't rush it.	▸ Safety and pollution are our priority. Look closely at seismic and explosion risks. ▸ A reasonable expectation for growth is smart. ▸ This is aggressive. Without LNG, won't China burn more coal? ▸ Rail safety in the Gorge is also a key issue that this can't resolve.
New land use category	▸ If unclear, permit staff could be pressured - unpredictable results. ▸ Use federal West Coast PADD 5 "region."	▸ Regulate both existing and new facilities. ▸ New code must effectively implement the policy.	▸ Need clear definitions: region, export, end user. ▸ Do not make terminals non-conforming or an ambiguous limited use.	▸ Why allow it in IG2? ▸ A new export terminal in contaminated harbor is unlikely.
Definition of fossil fuels	▸ Natural gas considered a low carbon fuel by State, so why included here? ▸ Tomorrow's cleaner fuels won't meet today's definitions.	▸ Excluding methanol undermines policy. ▸ If end use is mostly fuel, then limit it. ▸ One new LNG tank is a big risk. So is coal.	▸ Federal and state are going a different direction, requiring cleaner fossil fuels. Why restrict cleaner fuels at cross purposes?	▸ Make way for bio-diesel as a cleaner fuel. ▸ Methanol not a fuel in Oregon - overreaching. ▸ Fuels are okay if they have no emissions.
Terminal development restrictions	▸ Some sites are already built-out. ▸ Our non-contiguous sites are connected by pipelines. ▸ Can't comment on size.	▸ Most prefer Option A. ▸ Caution about Commerce Clause. ▸ 1% annual growth metric is too high.	▸ Don't come at sideways. Unclear rationales will lead to appeals. ▸ Size limits would put region on "import diet." ▸ Dated, low forecast.	▸ Option C preferred. ▸ Allow for modest growth of LNG and oil; not coal. ▸ Review size limits every few years.

4. Background conditions



This section of the report describes background conditions that inform the proposed zoning concepts. Topics include access to energy, impacts on the economy, climate change impacts, and health and safety impacts of draft zoning code changes. Background information on changing energy markets in the Pacific Northwest and Portland's existing fossil fuel terminals is included in the Section 1. Legal and policy background information is presented in Section 2.

Access to energy

Energy consumption in Oregon

Oregon residents and businesses rely on fossil fuel distribution and storage facilities to meet their energy consumption needs. Estimated state energy consumption by fossil fuels and other sources are shown in Figure 5. Residents and businesses in much of Southern Washington also rely on Portland terminals for access to fuels.

Figure 5. Oregon energy consumption estimates, 2014

eia Source: Energy Information Administration, State Energy Data System

Five refineries in the Puget Sound area supply nearly all of the petroleum fuels consumed in Oregon, delivered primarily through the Olympic Pipeline that terminates at the cluster of 10 petroleum terminals in Northwest Portland. From there, petroleum products are delivered to Oregon and Southern Washington markets via truck, pipeline and barge. NW Natural supplies natural gas to its Western Oregon market area and operates peak-consumption storage terminals in Northwest Portland

and Newport. Thus, fossil fuel terminals in Portland are a primary statewide distribution hub location for transportation fuels and natural gas.

Figure 6. Estimated storage capacity at existing and proposed fuel terminals

Operator	*Facility type*	*Location*	*Site acres*	*Storage capacity*	*New Storage capacity*
Petroleum fuels					
Existing Portland terminals				bbls	2035 forecast
Chevron	Petroleum terminal	NW Portland	21	1,600,000	352,000

Terminology: bbls = barrels, Dth = decatherms, LNG = liquified natural gas, LPG = liquified propane gas, Bcf = billion cubic feet, AAG = average annual growth.

Sources: Oregon DEQ for petroleum tank data. NW Natural 2014 Integrated Resource Plan for existing capacity and forecast at 1.9% AAG. BST, Portland Harbor Forecast (2012) for petroleum terminals at 1.0% AAG.

Size of recently proposed terminals and expected growth at existing terminals

There is a wide margin between the size of recently proposed crude oil, coal, and LNG terminals proposed in the Pacific Northwest and the scale of expected growth of existing Portland fuel terminals that generally serve the regional market area, as shown in Figure 6. Proposed code changes for terminal size limitations within that margin would allow for expansion at existing terminals and moderately sized new terminal development to meet market area consumption needs, as described in Section 5.

Liquid bulk cargo in Portland Harbor is projected to expand at a range of 0.5% to 1.0% average annual growth (AAG) to 2040 (BST Associates, 2012), providing an estimate of market expansion needs for petroleum fuels. The 1.9% average annual growth forecast to 2034 (NW Natural 2014 Integrated Resource Plan) provides an estimate of market expansion needs for natural gas distribution facilities. Contradictory stakeholder comments were received that these growth projections are too high, too low, and could change substantially with market innovations. To address this uncertainty, code commentary will be proposed to consider future adjustments in storage capacity size limitations as needed to accommodate market changes over time.

Impacts of draft code changes on the economy

Jobs and wages at Portland's fuel terminals

In 2014, the 11 existing fuel terminals in Portland shown in Figure 3 provided approximately 280 jobs at their sites and supported an estimated 720 total jobs in the metropolitan area. The annual payroll at those terminals was $23 million, which supported total personal income of $92 million in the metropolitan area.

BPS calculated these supported employment and income estimates from the induced and indirect impacts from metropolitan area purchases by these firms and their employees. For example, the jobs of the Longshore Union workers who unload fuels from tankers at these fuel terminals are not counted as direct jobs at the terminal sites. The multipliers used for these calculations were estimated from the average employment and income effects of marine terminals in Portland (Martin Associates, 2012). The job and wage estimates were calculated from Quarterly Census of Employment and Wages (QCEW) data.

Portland's industrial area jobs have an important urban equity role in that they consist primarily of middle-wage jobs that do not require 4-year college degrees, which the overall economy has been losing since 2000. In contrast, jobs in commercial districts are concentrated primarily in low- and high-wage quartiles (fourths) of overall city employment. Middle-wage job growth supports the "income self-sufficiency" objectives of the Portland Plan and 2035 Comprehensive Plan (Policy 6.28) to expand access to self-sufficient wage levels.

Long-term job growth to 2035 is estimated at 1.6% average annual growth in the warehousing, transportation and utilities sector in Portland's 2016 Economic Opportunities Analysis and Metro's 2014 Urban Growth Report. Applying this growth rate to Portland's existing fuel terminals, approximately 110 net new permanent jobs is expected between 2014 and 2035, which is the equivalent of about four new terminals at their current average size. The total metropolitan area job impact of this fuel terminal expansion would be approximately 290 new jobs by 2035. If fuel terminal job growth occurred at a slower 1.0% average annual rate, matching the forecast growth of liquid bulk cargo volumes in Portland Harbor, approximately 65 net new terminal jobs would be generated by 2035, supporting a total 170

new jobs in the metro area. Pembina's proposed propane terminal in 2014 was estimated to create 30 to 40 new permanent jobs and 600-800 temporary construction jobs.

The Proposed code changes would allow for expansion at existing terminals and moderately sized new terminal development to accommodate regional demand and resulting job growth.

Tax revenues of new terminals

State and local revenues from income and property taxes vary widely by facility. For example, property taxes on the depreciated improvements value of existing fuel terminals is much lower than new construction. If fuel terminals added 110 net new direct jobs by 2035 and the resulting state and local tax revenues is typical of businesses and developed facilities in Portland's Working Harbor (Martin Associates, 2016), the estimated new state and local tax revenues in fiscal year 2035 (in 2015 dollars) are $1.6 million. In contrast, the proposed $500 million Pembina project was estimated to generate approximately $12 million in annual property tax revenue, reflecting the increased improvements value and property taxes of new construction.

The Proposed code changes would allow for expansion at existing terminals and moderately sized new terminal development and resulting state and local tax revenue. However, prohibiting large scale new terminals such as Pembina could result in similar levels of foregone property taxes.

Growth opportunities in fossil fuel distribution

The most recent cargo forecast for Portland Harbor in 2012 projected 1.0% AAG in liquid bulk tonnage to 2040 as a high scenario and 0.5% AAG as a low scenario (BST Associates, 2012). Based on this forecast, ECONorthwest (2012) estimated no additional land need for new liquid bulk terminals. Since 2012, several new fuel terminals have been proposed in the Pacific Northwest, as shown in Figure 2.

Updating the liquid bulk forecast at this point would be challenging for several reasons. Most of the recent fuel terminal proposals have since been abandoned or appear to be dormant. Policy and permitting uncertainty complicate the development feasibility of new terminals and transportation infrastructure. Crude oil prices have fallen sharply in 2015 and 2016, reducing the current market potential for major investments. Expanding global industrial product markets after the Great Recession slowed substantially in 2015. And energy distribution markets could change abruptly with continuing product innovations and location shifts in global production.

In the long term, Portland has competitive advantages for accommodating energy terminal development as a Pacific Rim gateway location to growing Asian markets, the Columbia River's low-gradient railroad access for heavy cargo through the Cascades, and Oregon's freight infrastructure hub. On the other hand, Portland's industrial land supply for continuing growth is limited, and expanding cargo markets for autos, grain and dry bulks are competing for current growth capacity.

Other economic impacts

Energy infrastructure and terminal investments appear to have low but potentially catastrophic risks of major accidents, as described below. Examples include seismic resilience of petroleum terminals in the event of a Cascadia Subduction Zone earthquake, oil train derailments, explosions at LNG (liquefied natural gas) and LPG (liquefied petroleum gas, such as propane) facilities, and others.

Clean Energy is a target industry in the City of Portland. An emerging cluster of Portland area business activity in solar and wind energy manufacturing, green building development, and other fields of sustainable urban innovation presents long-term business growth opportunities. Substantial local investment in fossil fuel infrastructure and large new terminals could hinder local growth momentum in Clean Energy industries.

Climate change impacts of draft code changes

Climate impact of fossil fuels

Fossil fuels are major contributors to climate change and pollution, as described in Portland's 2015 Climate Action Plan. Greenhouse gas emissions from the burning of fossil fuels and land use changes, including deforestation, are the primary causes of climate change. The Intergovernmental Panel on Climate Change's most recent report documents the overwhelming evidence that human activities have been the major driver of recent warming of the Earth's surface, and that climate change and its consequences will continue into the future (IPCC, 2013).

The magnitude of future climate impacts depends largely on the trajectory of future global greenhouse gas emissions. Greenhouse gas emissions from human activities have continued to rise in recent decades, reaching the highest rates in human history between 2000 and 2010 (IPCC, 2014). About half of all carbon dioxide emissions, the most prevalent greenhouse gas, between 1750 and 2010 occurred in the last 40 years. The energy, industry and transportation sectors have dominated these emissions increases. On the current trajectory, global transportation emissions will double by 2050.

Transition to "renewable" and "clean" fuels

The U.S. Environmental Protection Agency (USEPA) implements the federal Renewable Fuel Standard (RFS) that requires transportation fuel sold in the U.S. to contain a minimum volume of renewable fuels. The RFS originated with the Energy Policy Act of 2005 and was expanded and extended by the Energy Independence and Security Act of 2007 (EISA). Similarly, ODEQ implements the Oregon Clean Fuel Program. ODEQ describes "clean fuel" as a fuel with a lower carbon intensity than that of the fuel it replaces.

Examples of "clean fuels" in Oregon's program include most types of ethanol, biodiesel, natural gas, biogas, electricity, propane and hydrogen. The Oregon Clean Fuel Standard sets 2015 as a baseline that represents 10 percent ethanol blended with gasoline and 5 percent biodiesel blended with diesel. The rule also requires a 10 percent reduction in average carbon intensity from 2015 levels by 2025.

Terminal representatives and business stakeholders urged that proposed zoning code changes not create a disincentive or barrier to compliance with these federal and state rules, which may require additional tank capacity to implement. Environmental and public health organization representatives pointed out that City Resolution 37168 addresses fossil fuels generally, including lower-carbon fossil fuels like natural gas and propane. The proposed fuel terminal size limits and exemption for existing terminals are specifically intended to not hinder compliance with the renewable and clean fuel standards, as described in Section 5.

Velocity of transition to non-fossil fuel energy

Portland's Climate Action Plan sets a goal for an 80% reduction in greenhouse gas emissions by 2050. Oregon's climate action goals similarly call for 75% reduction by 2050. While fossil fuels like natural gas and propane have the potential to replace higher-carbon fuels, they don't begin to approach the 80% reduction that the City is striving for or the State's 75% goal. ODEQ estimates that the greenhouse gas emissions reduction from switching from gasoline to compressed natural gas, for example, is 18%; for propane, it is 15%. The lower-carbon fossil fuels do have appeal as a bridge to widespread use of renewable energy, but investments in major infrastructure typically take decades to recoup, and the transition to renewables needs to go much faster than that to stabilize global emissions.

During recent hearings and analysis on Resolution 37168 and the Pembina terminal proposal, the question of whether to differentiate between fossil fuels with different carbon content was widely discussed. In the lead up to the resolution, an option was proposed that would oppose new coal and oil infrastructure but allow for other fossil fuels that could show a likely net decrease in carbon emissions. City Council decided not to apply this option in the resolution.

Health, safety, and environmental impacts of draft code changes

Seismic resilience and liquefaction soils

The 2035 Comprehensive Plan sets policy direction (4.75 and 4.76) to encourage disaster-resilient development and specifically to reduce natural hazard risks to critical energy and transportation infrastructure in Portland Harbor.

The 2016 Critical Energy Infrastructure Hub Study underway by the Portland Bureau of Emergency Management includes a literature review and modeled risks of structural damage to critical infrastructure from earthquakes, floods, landslides, volcanic activity, wildfire, and other sources. Along with petroleum and natural gas infrastructure, the study is also assessing infrastructure risks to emergency services, transportation, electricity, potable water, and waste water. The study area includes the Northwest and Linnton industrial areas. PBEM has identified significant seismic risks at the fuel terminals from a major Cascadia Subduction Zone earthquake because of their location in a filled riverfront plateau area with high susceptibility location for soil liquefaction.

The project exempts existing terminals so that the new restrictions do not hinder or increase costs of safety improvements such as seismic retrofits. Future amendments to building and fire codes to improve seismic safety of fossil fuel infrastructure may also be adopted to implement Resolution 37168.

Safety of liquefied gas terminals

Liquified natural gas (LNG) and liquefied petroleum gas (LPG, such as propane) facilities pose safety risks from potential explosions and fire. The Pembina propane terminal, which was proposed in 2014 at the Port of Portland Terminal 6, is an apt case study. The Pembina terminal would have required environmental zoning code amendments that did not move forward.

The issue of safety risks was discussed extensively during review of the proposed Pembina terminal, and a quantitative risk assessment study was prepared to inform that review process (Det Norske Veritas (U.S.A.), Inc., 2015). The study estimated the risk from flammable releases, such as jet fires, pool fire, flash fire, vapor cloud explosions, fireball and Boiling Liquid Expanding Vapor Explosion (BLEVE). The risk

was presented as individual risk in the form of location-specific risk contours extending outward from the proposed facilities, and as societal risk in the form of potential loss of life and cumulative frequency of various accidents. The highest offsite risk level was found to be 1 fatality in 1,000 years in areas directly north and south of facility. The nearest residential zones are located beyond the risk level contour of one 1 fatality in 100 million years. The cumulative societal risk was estimated at 1 statistical fatality every 38 years. The study also include various facility design and siting recommendations to mitigate identified risks.

Another risk assessment (Northwest Citizen Science Initiative, 2015) on the Pembina project was presented by environmental groups and neighbors, including the Hayden Island Neighborhood Association. The analysis identifies additional sources of risk from BLEVE cascades, terrorist events, and magnitude 9 earthquakes. The authors recommend not locating a propane terminal within 10 miles of the Portland/Vancouver urban area.

Public safety risks from a new LNG or LPG facility are estimated to be very low relative to other urban hazards, although possible impacts could be catastrophic. The proposed code amendments are expected to reduce public safety risks by prohibiting development of large new LNG or LPG facilities.

Oil train accidents

On June 3, 2016 an oil train traveling through the Columbia River Gorge partially derailed in Mosier en route to Tacoma. The 16-car derailment resulted in a 1,000-barrel spill and fires that lasted nearly a day. Small amounts of oil reportedly reached the river, and nearby drinking water and wastewater facilities in Mosier were affected.

An Associated Press analysis of accident records found that 26 oil-train derailments or fires have occurred nationally in the last decade. The national geography of increasing oil extraction in the inland Great Plains states and refineries concentrated on the coasts is contributing to this trend. Risk of how often such derailments are likely to occur in the Columbia Gorge is disputed, with one estimate as high as one every 30 months.

Preliminary reporting on the cause of the Mosier derailment pointed to failed bolts in the track that are difficult to detect. Union Pacific reported that improvements are underway to replace bolts on 530 miles of curved track nationwide. Railroad safety is regulated at the federal level and monitored by the Federal Railroad Administration. A recent Government Accounting Office report has identified challenges and delays in implementing some federal rail safety regulations.

The proposed code amendments could incrementally reduce rail accident risks by limiting development of large new fossil fuel terminals at a West Coast rail hub location. However, restricting the location of new petroleum terminals in the City of Portland is not expected to substantially affect the volume of petroleum cargo transported by rail to Puget Sound refineries. The Portland/Vancouver area is a rail hub location, where West Coast rail lines running north-south intersect the low gradient east-west rail corridor along both sides of the Columbia River. Roughly half of the east-west rail cargo destined for the Seattle-Tacoma area, in addition to Oregon-bound rail cargo, moves through the Portland metropolitan area. Derailment risk within Portland is reduced by the numerous siding destinations and congestion of the "Portland Triangle" area where UP and BNSF lines come together. However, derailment risks to natural resources, especially along rivers, and to rural communities appear to be significant.

5. Code concepts and analysis

This section of the report describes the proposed zoning change concepts by topic area, including the related policy directions, implementation issues, and rationale for the proposed zoning changes. Specific code changes are not included in this report, but will be part of the Proposed Draft, which is scheduled to be completed in August 2016 and discussed by the Planning and Sustainability Commission in September 2016.

1. **Types of distribution and storage facilities to be regulated**

Policy direction:

- City Council Resolution 37168 (adopted November 2015) calls for opposing expansion of infrastructure for transportation and storage of fossil fuels, subject to various exceptions, including safety improvements, service to end users, and infrastructure that accelerates transition to non-fossil fuel energy.
- 2035 Comprehensive Plan Policy 6.48 Fossil Fuel Infrastructure (adopted June 2016, not effective until 2018) also calls for limiting fossil fuel distribution and storage facilities to those necessary to serve the regional market.

Preliminary code concepts:

- Limit development of new Bulk Fossil Fuel Terminals as a regulated land use.
- Bulk Fossil Fuel Terminals are engaged in freight movement or wholesaling of fossil fuels at facilities that are characterized by having (1) marine, pipeline or railroad transport access and (2) either transloading facilities for transferring a shipment between transport modes (such as from rail to ship) or bulk storage facilities exceeding 150,000 barrels (or 6.3 million gallons or equivalent) of fossil fuels. Examples include petroleum terminals, liquid natural gas terminals, and coal terminals. Functionally, these terminals are typically regional gateway facilities, where fossil fuels enter and exit the region, but the use classification is intended to be clearly identifiable and not rely on a definition of region.
- Exceptions that are not Bulk Fossil Fuel Terminals:
    - Retail sales of fossil fuels, such as gasoline or propane filling stations;
    - Distributors, wholesalers, and industrial service uses that receive and deliver fossil fuels exclusively by truck;
    - End-user facilities that store fossil fuels for primary use at or near the site, such as manufacturing, agriculture, and airports;
    - Uses that recover or reprocess used petroleum products;
    - Waste-related uses that transfer or store solid or liquid wastes, such as landfills.

Implementation issues:

- Definition of region – Portland is a regional distribution hub for energy and other products, and this zoning change is not intended to restrict energy access to the growing region. However, the regional market area of Bulk Fossil Fuel Terminals varies by product and is difficult to define. Portland's 10 petroleum terminals generally serve Oregon and Southern Washington. This

market area substantially exceeds the Portland metropolitan area, which is often colloquially referred to as the region. Some terminal representatives pointed out that the federal government's 5-state West Coast PADD 5 region is generally their regional market area. BDS staff commented that zoning does not regulate the target market (destination) of wholesale products, and the zoning code does not define region. Business organization representatives commented that the energy markets and related market areas are likely to change over time. Therefore, the proposed land use incorporates the concept of a regional market into the size limits, and a zoning definition of region is not proposed here.

- End users – Resolution 37168 lists a specific exception to not restrict service directly to end users. At a small scale, services to end users include retail gasoline filling stations, natural gas access lines in street right-of-way to residential and business customers, and heating oil tanks at home sites. Larger scale end users with fossil fuel storage and access infrastructure also include manufacturers, jet fuel facilities at the PDX Airport, vessel fuel facilities on Portland Harbor, and others, where use fossil fuels as an input. Again, the limits on new facilities are sized to apply only to larger distribution facilities.

- Interpretation of use category – Terminal and business representatives commented that ambiguity in the use description could result in conflicting expectations, pressured interpretations, appeals, and inconsistent code implementation. While underlying policy accommodates regional access and exceptions that may be difficult to clearly define, the land use designation is proposed to be defined by clear and objective size thresholds and marine/railroad/pipeline access.

2. **Definition of fossil fuels**

Policy direction: City Council Resolution 37168 applies to fossil fuel infrastructure and storage generally and does not distinguish among types or carbon intensity of fossil fuels.

Preliminary code concept:

- Definition of fossil fuels: petroleum products (such as crude oil and gasoline), coal, and gaseous fuels (such as natural gas and propane) that are made from decayed plants and animals that lived millions of years ago and are used primarily as a source of energy.
- Exclusion of non-fuel products – Petrochemicals that are used primarily for non-fuel products are excluded, such as plastics, lubricants, fertilizer, roofing, and paints.
- Methanol is included as a fossil fuel. Development of methanol storage and transportation facilities would be limited similarly to LNG and LPG terminals.
- Denatured ethanol and similar fuel additives and biodiesel/renewable diesel with less than 5% fossil fuel content are not fossil fuels.
- Biogas from wastewater treatment plants, anaerobic digesters, landfills and other sources is not a fossil fuel.

Implementation issues:

- Definition of fossil fuels – Definitions of fossil fuels vary by source. Here are some examples.

- Oregon Department of Environmental Quality (ODEQ) – Fossil fuels: fuels such as oil, natural gas, and coal that are made from decayed plants and animals that lived millions of years ago. These fuels are made of hydrogen and carbon (hydrocarbons).
- U.S. Environmental Protection Agency (USEPA), 40 C.F.R. § 60.41 - Fossil fuel means natural gas, petroleum, coal, and any form of solid, liquid, or gaseous fuel derived from such materials for the purpose of creating useful heat.
- Oregon Department of Energy Administrative Rule, OAR 345-001-0010 - "Fossil fuel" means natural gas, petroleum, coal and any form of solid, liquid or gaseous fuel derived from such materials that serves as useful energy.

- Renewable and clean fuel standards – As described in Section 4, USEPA implements the federal Renewable Fuel Standard (RFS) that requires transportation fuel sold in the U.S. to contain a minimum volume of renewable fuels. Similarly, ODEQ implements the Oregon Clean Fuel Program. ODEQ identifies examples of "clean fuels" in Oregon as most types of ethanol, biodiesel, natural gas, biogas, electricity, propane and hydrogen. Terminal representatives and business stakeholders urged that proposed zoning code changes not create a disincentive or barrier to compliance with these federal and state rules, which may require additional tank capacity to implement. Environmental and public health organization representatives pointed out that City Resolution 37168 addresses fossil fuels generally, including clean fuels. The proposed fuel terminal size limits and exemption for existing terminals will allow more than enough supply to comply with the renewable and clean fuel standards.

- *Methanol – Large methanol plants have recently been proposed in Tacoma, Kalama, and St. Helens. Methanol plants tend to have structural similarities to LNG and LPG terminals, including large-scale and gas pipeline access, and they can have similar safety and climate impacts. Stakeholder focus groups were asked whether any* special inclusions, such as methanol, should be considered. Most people commenting noted that methanol is primarily used in the production of plastics and other non-fuel uses. Views differed among environmental organizations commenting. Some noted that excluding it undermines the policy. The draft code concept proposes to prepare code amendments that limit development of large methanol plants similarly to LNG or LPG terminals.

- *Denatured ethanol* – A terminal operator pointed out that "pure" ethanol made from corn or other non-fossil source is required by the Alcohol and Tobacco Tax and Trade Bureau to be denatured in order to be transported to the site. Denatured ethanol typically contains up to 5% methanol, so that it is toxic and undrinkable. Storage of denatured ethanol is proposed to be exempted. In other words, denatured ethanol tanks would not be counted as part of the maximum storage capacity of fossil fuel terminals.

- Biogas products from landfills – BES staff commented that biogas from landfills and other sources are not fossil fuels and should not be restricted by the proposed zoning changes. The proposed description of fossil fuel terminals specifically excludes waste-related uses, such as landfills, which are regulated as a separate land use in the zoning code. Also, the proposed

definition of fossil fuels, described as being made from decayed plants and animals that lived millions of years ago, would not include biogas from a landfill.

3. Exemption of existing facilities

Policy direction:

- City Council Resolution 37168 includes various exemptions to not restrict safety or efficiency improvements, service to end users, emergency backup capacity, infrastructure for recovery or re-processing of used petroleum products, or infrastructure that will accelerate the transition to non-fossil fuel energy sources.
- 2035 Comprehensive Plan Policies 4.75 and 4.76 call for encouraging disaster-resilient development and reducing natural hazard risks to critical energy and transportation infrastructure in Portland Harbor.

Preliminary code concept:

- Bulk Fossil Fuel Terminals that were established before the effective date of these regulations, including the existing facilities identified in Figure 1, are allowed. Limitations on development of Bulk Fossil Fuel Terminals do not apply to these sites. Proposed code changes would not inhibit improvements at these existing facilities, including seismic upgrades, infrastructure for greener fuels, and expansion.
- Off-site (non-contiguous) expansion of existing facilities is subject to the proposed limitations on development of Bulk Fossil Fuel Terminals.
- Recognize that some existing terminal sites span both sides of streets, interconnected by pipelines within the street right-of-way.

Implementation issues:

- Non-conforming use status can be a disincentive for desired improvements. Zoning regulates new development. In contrast, existing development is "grandfathered in," meaning that preexisting uses can continue to operate and expand, subject to limitations. Significant improvements to non-conforming uses generally require a "non-conforming situation review." This discretionary public review process could add significantly to the cost and uncertainty of investments at fossil fuel terminals. The proposed limitation of fossil fuel terminal development would exempt existing facilities, in order to avoid the need for a non-conforming review and a resulting disincentive for seismic, efficiency, and clean fuel investments on existing facilities, consistent with policy direction in Resolution 37168 and the Comprehensive Plan.

- Divergent stakeholder views – Stakeholder focus group participants generally urged that existing fuel terminals should not be changed to a non-conforming use. Reasons ranged from providing a critical product to not discouraging desired improvements on existing facilities. However, comments from environmental and public health organizations generally supported restricting expansion of existing terminals, while some participants cautioned about political and legal tradeoffs of making the existing fuel terminals non-conforming.

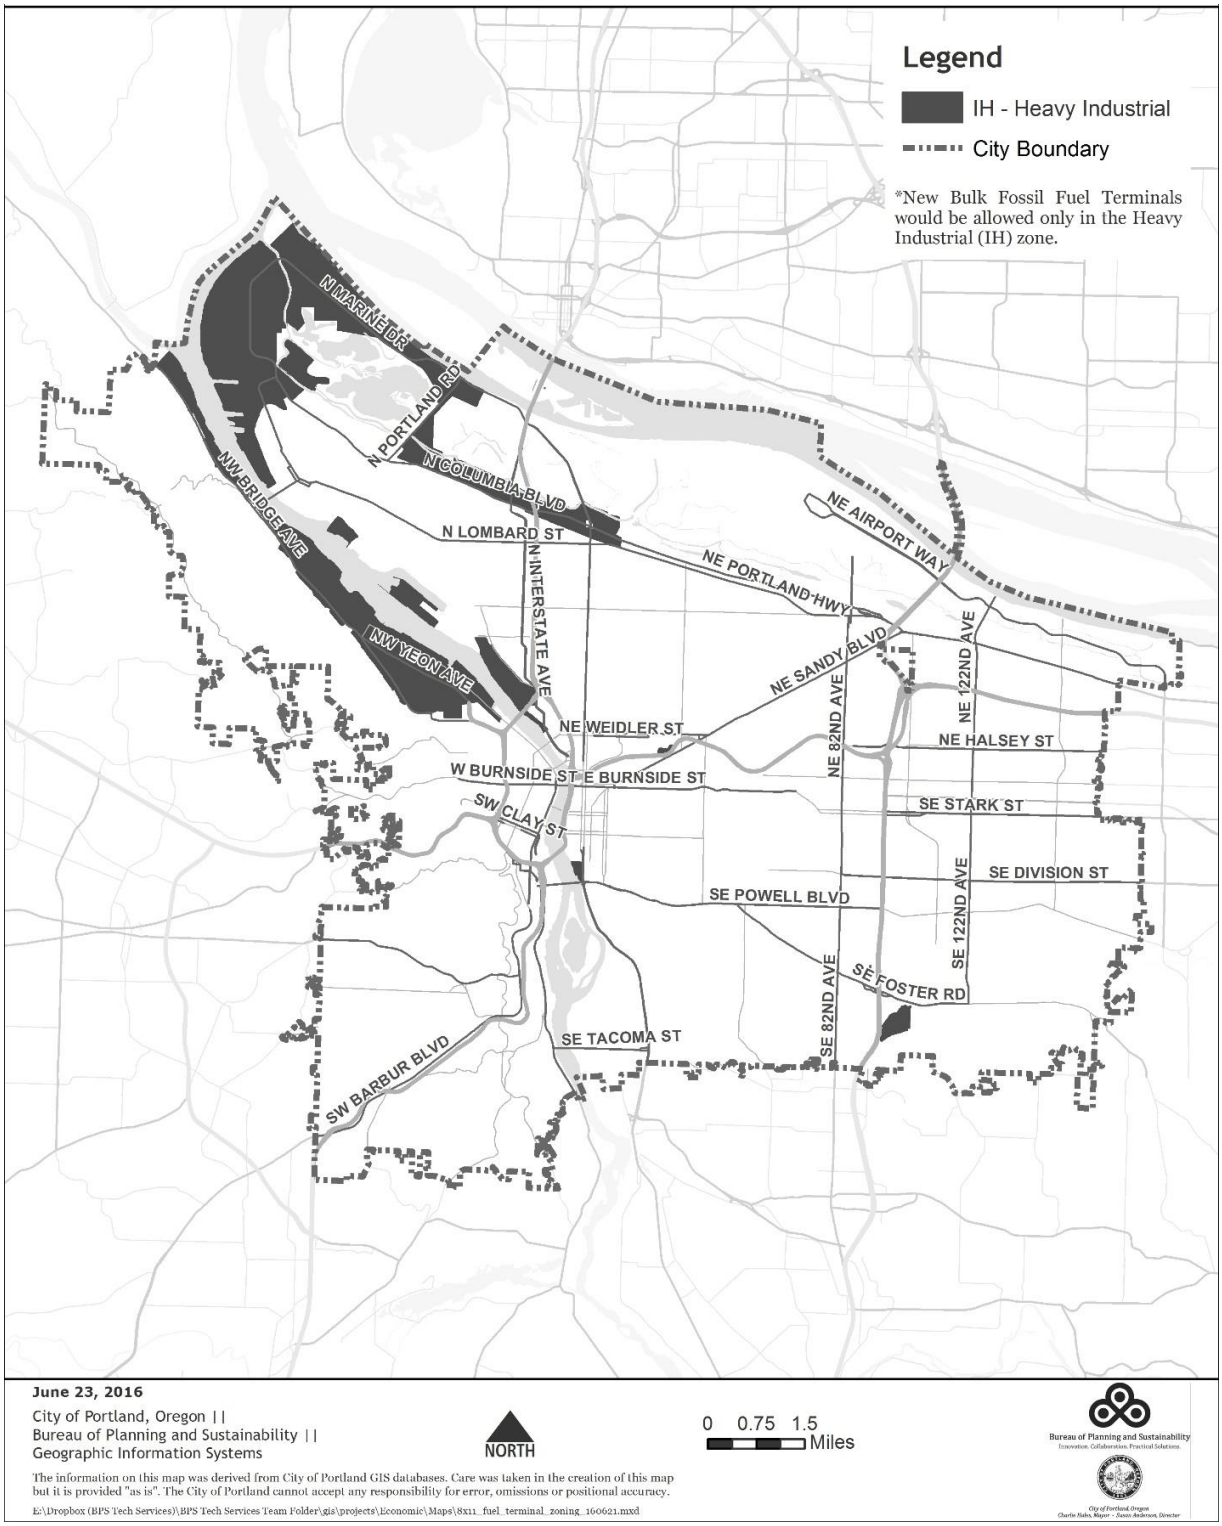
4. **Approach for limiting new storage facilities**

Policy direction: Limit fossil fuels distribution and storage facilities to those necessary to serve the regional market.

Preliminary code concept:

- Classify Bulk Fossil Fuel Terminals as a limited use in the Heavy Industrial (IH) zone and a prohibited use in all other base zones.
- *Limit the total capacity of storage facilities at new Bulk Fossil Fuel Terminals. Applying no size limits on existing terminals (see map). Maximum size limits of new* Bulk Fossil Fuel Terminals:

Fossil Fuel Type	**Maximum Storage Capacity**
Petroleum	*500,000 barrels*
Liquefied Natural Gas (LNG)	*7,000,000 gallons*
Other Liquified Gas Fuels	*7,000,000 gallons*
Coal	*Prohibited*



Implementation issues:

- Potential federal restrictions – Federal law restricts local regulatory authority over interstate commerce in various ways. The Proposed code changes would allow for expansion at existing terminals and moderately sized new terminal development, which will not constrain interstate commerce or create a protectionist advantage to Oregon residents or businesses. Most of the existing fuel terminals are operated by international or national companies that are not headquartered in Oregon.

- Providing regional market access to fuels – The fossil fuels consumed in Oregon are not extracted or refined in the state. As a result, fossil fuel terminals provide a needed service in distributing fuels to the growing population of the regional market area. Figure 6 in Section 4 indicates a wide margin between the size of recently proposed crude oil, coal, and LNG terminals proposed in the Pacific Northwest and the scale of expected growth by existing Portland fuel terminals that serve the regional market area. Proposed terminal size limitations within that margin would allow for expansion at existing terminals and moderately sized new terminal development to meet market area consumption needs.

- Balanced, integrated policy approach – The proposed limitations on fossil fuel distribution entail tradeoffs among public goals for environmental protection, public health and safety, meeting energy needs, and economic prosperity, as described in Section 4. The Comprehensive Plan calls for a balanced, integrated approach in land use regulations to meet these public objectives, as described in Section 2. The proposed size standards provide for significant environmental and safety benefits in limiting development of large new fossil fuel terminals, while providing for moderate expansion of fuel terminals to adequately meet regional energy needs and accommodate resulting economic benefits.

Figure 7. Fossil fuel terminal limitation area

The code concepts of this report are being published for public review and comments through July 27. Next steps will include discussions with community groups and preparation of code language to refine these code concepts in response to what we hear. A Proposed Draft is scheduled to be completed by mid-August 2016.

Appendix A: Stakeholder focus group results

Public involvement in the concept development for the Fossil Fuel Terminal Zoning Project consisted primarily of four stakeholder focus groups as well as meetings with fuel terminals and other individuals or organizations. The focus groups were held in June 2016. The purpose of the focus groups was to help identify and understand the issues that should help shape the preliminary zoning code being considered by this project. The focus groups also helped to expeditiously reach out to a broad range of stakeholders. While their perspectives and interests are shared on some topics, they diverge on other topics.

In addition to the stakeholder focus groups, BPS staff met with several fuel terminals to explain the proposal, answer questions, and discuss their individual concerns. This was needed because antitrust regulations constrained discussion about certain topics, for example supply chains, in the presence of representatives from other fuel terminals. Primarily, the terminal operators explained their operations and facilities, many of which differed substantially from other terminals.

Who participated?

Figure 8 lists the participants of the four focus groups conducted. Ten to twelve participants were invited to each meeting, although not everyone was able to attend. The first focus group consisted of fuel terminal representatives who have a direct stake in the proposed regulations. The second group was environmental and public health organizations, some of whom advocated for the resolution before City Council and have community safety and sustainability in mind. The third group were state and regional business and government organizations. Their interest was to protect the state economy by testing the proposal against economic realities. The fourth group was neighborhood and equity community organizations whose interests were to protect neighborhoods adjacent to the terminals and underserved communities who may rely on terminals for employment. Additionally, the Mayor's Office invited input from Native communities and tribal governments.

What discussion questions were asked?

The focus groups were provided background materials describing the preliminary code change concepts about two weeks before the focus group meetings. BPS staffed prompted the focus group across four topics:

1. Issues that should shape the project
2. Types of distribution and storage facilities to be regulated
3. Definition of fossil fuels
4. Zoning approach for limiting new storage facilities

In addition to specific questions within each topic, participants were invited to share any general and wrap-up comments during the focus group.

Figure 8. Stakeholder Focus Group Participants, June 2016.

STAKEHOLDER	DATE	ATTENDEES
Fuel terminal representatives	Thursday, June 02, 2016	Gilbert Betancourt, Phillips 66 Nick Giotta, Phillips 66 Stephanie Williams, Phillip 66 Andrew Holbrook, Kinder Morgan Shanna Brownstein, Northwest Natural Kevin Jones, McCall Oil Pamela Brady, BP West Coast Jerry Henderson, Chevron Kevin Buffum, Pacific Terminal Services Steve Kober, NuStar Will Rassmussen, WSPA Frank Holmes, WSPA Chris West, Pac/West and Arc Terminals Nathan Eggers, Arc Terminals Jerome Jackson, NuStar Rob Hill, NuStar Zach Klonoski, Mayor's Office

Neighborhood and equity organizations	Tuesday, June 14, 2016	Jeff Geisler, Hayden Island Neighborhood Association John Bradley, Northwest District Association Travis Argue, UA Local 290 Willy Myers, Columbia Pacific Building Trades

What we heard

For each topic area, the results of the focus groups are summarized in Figure 4 of Section 3. That table summarizes the main themes and concerns raised during the focus groups.

Key issues

Fuel terminal representatives objected to this policy direction in general. They discussed their safe operating history and commitment to implement the federal and state standards for renewable and clean fuels. There were challenges to participating in the conversation, but they agreed to work cooperatively on this project to get the code right. For example, anti-trust laws precluded the group from engaging in certain conversations because it would involve disclosing information about their supply chains and could be considered collusion in court of law. This group was concerned with the fast timeline and felt the policies should be discussed first.

They also felt the process was emotionally driven, not having considered the unintended consequences. For example, with renewable and clean fuel standards constantly in flux, they felt that zoning rules could make it more difficult to meet these standards. Restricting growth here in Portland at the end of the Olympic Pipeline could put more trucks on the road, instead of more efficient pipeline or rail transportation. The group asserted that there could also be significant economic impacts on the rest of the state, given that 95% of Oregon's fuel passes through Portland first. Lastly, fuel terminal representatives expressed concern for additional administrative burdens that a new land use category would bring. For example, what steps would be necessary for these firms to demonstrate that they were existing operations prior to the new zoning rules? Additionally, they warned that their site configuration may pose a challenge to effective zoning rules, as they are often non-contiguous operations connected by interconnected pipelines.

The environmental and public health organizations felt the policy direction was less aggressive toward fossil fuels than what the City Council resolution had proclaimed. They felt the resolution sought to outright prohibit new development and expansion on existing facilities. Because of this, they cautioned about community backlash if this proposal did not meet expectations. In this vein, they highlighted that Portland will be the first city to fully implement this type of policy, so the project could be an opportunity to set a strong precedent and model code for other cities. This group also felt that resident health and safety was also a top priority. They noted the seismic risks posed by fuel terminal tank farms that lie on liquefaction zones as well as the June 2016 oil train wreck in Mosier. For these reasons, they felt Portland Bureau of Emergency Management (PBEM) and other environmental justice groups should be involved in safety considerations. Lastly, the group felt the economic impact statement should include more than the impact on jobs. It should also consider the risks of economic and financial damages from a natural disaster. Members of this focus group offered to provide technical analysis on the impacts that the proposed options could have on the environment and public health and safety. Some noted that risks should be accounted for through bonding or insurance requirements under worst-case scenarios.

State and regional business organizations felt that this undertaking requires more research. The resolution set required tasks, including an economic impact analysis and an examination of relevant laws, and they felt these tasks should be completed before laying the groundwork through code development. They felt the marine cargo forecast for liquid bulks of 1% growth is outdated and too low. (Note, an opposite reaction was expressed by environmental and health organization representatives who felt this figure was too high.) Similarly, they feared that the code may not hold up well in five years

because of constantly changing energy markets. For example, in five years Portland could be shipping cleaner fuels to the Midwest. Some members expressed concern that the zoning code may not be the right tool to achieve some of the GHG (greenhouse gas) reduction and public safety goals that this resolution aimed to achieve. If the goal is public safety, then the City should require or create incentives for seismic upgrades. They stated that, if the goal is to reduce greenhouse gases, then prohibiting the export of cleaner-burning fuels, such as LNG (liquefied natural gas), may have the opposite intended effect. Lastly, the group asserted the important role that Portland's fuel terminal facilities play in rest of the state economy. They warned of political and economic repercussions that these decisions could have. They shared the view with fuel terminal representatives that this is a big political decision—the timeline is too short and the process should not be rushed.

Neighborhood and equity community organizations communicated that safety, pollution and accidental releases were their top priority when considering zoning for fuel terminals. They wanted a close examination of the seismic and explosion risks associated with fuel terminals. For example, which terminals are in liquefaction zones? Where are the storage tanks located in relation to neighborhoods? They sought honesty about the risks posed to the Linnton neighborhood specifically. Rail safety in the Columbia Gorge was also a key issue. The June 2016 incident in Mosier highlighted the risks. A potential solution they offered would be more pipelines, but they are difficult to get built. This group recognized the difficulty in managing competing values. They felt a reasonable expectation of growth is a smart idea. One participant described the proposal as aggressive, adding that by prohibiting LNG export terminals, global export destinations like China may end up burning dirtier fuels, such as coal. They felt this also meant Portland would forego export profits.

New land use category

Fuel terminal representatives were concerned for the clarity of the rules. They felt that the definition of "bulk terminal" is very important to be clear. If the definition was open to interpretation, then permit staff could be pressured. They warned that creating "bulk fuel terminal" as a specifically regulated use could lead to unpredictable results. This group was also concerned with the definition of "region." They were unsure if off-shore distribution was the issue, advocating for using the federally recognized West Coast region (PADD 5) as the definition of "regional market." PADD 5 includes Oregon, Washington, California, Nevada, Arizona, Alaska and Hawaii.

Environmental and public health organizations wanted to see the regulation go beyond new facilities and also look at limits on expansion at existing facilities. They felt the City Council resolution was clear and unambiguous about opposing expansion of fossil fuel infrastructure, which includes expansions at existing sites. They emphasized the importance for getting the right definition of "bulk terminal" and the associated size limit (or prohibition)—these must be correct in order to effectively implement the policy. Some members questioned whether seismic upgrades at existing facilities could be allowed but expansions prohibited. This group also urged the inclusion of PBEM's work on hazards in liquefaction zones in this project.

State and regional business organizations echoed the concerns for clear and correct definitions that the fossil fuel representatives posed. "Region," "export," "end user," and "fossil fuel" are all important terms to get right. They also were strongly opposed to making existing facilities non-conforming uses, as well as making them limited uses with unclear exceptions. This would expose projects to discretionary land use actions, which is costly and unpredictable, and hence risky. It would likely make improvements that the community values, such as seismic upgrades, more difficult to attain.

Neighborhood and equity community organizations were skeptical that a new export terminal would be proposed in the Portland area in the wake of Pembina. They felt that Superfund sites were too expensive to acquire and build on. The group also wondered whether a new zone for fossil fuels ought to be created instead of a land use. They questioned why it ought to be allowed in IG2.

Definition of fossil fuels

Fuel terminal representatives were primarily concerned with the long-term applicability of the proposed rules. Energy markets and new technologies are constantly in flux, and it is difficult to know what the size requirements might be for newer—perhaps cleaner—fuels, particularly blended fuels. This group sought clarification for what "green fuels" meant. They noted that the proposed inclusion of LNG among city-regulated fossil fuels is inconsistent with the State of Oregon's inclusion of LNG as a "clean fuel." They called for periodic review of the rules when tomorrow's cleaner fuels become known, as they may not meet today's definitions. They cautioned about unintended consequences of placing restrictions on fossil fuel terminals, such as potentially putting more trucks on the road by restricting growth at facilities with pipeline, marine and rail access. This may result in considerably more GHG emissions. They also felt that methanol should not be included in the list of regulated fuels because it is used more as a value-added commodity than a fuel. They shared this last viewpoint with most other focus groups, except the environmental and health organizations.

Environmental and public health organizations looked to the intent of the City Council resolution and noted that it included propane, methanol, natural gas and other low-carbon fuels. At the same time, they agreed that code changes should provide flexibility to meet Oregon's low carbon fuel standard. They noted that methanol is currently being used as a fuel, so excluding it undermines the policy. The group sought clarification on how to address non-fuels. Some suggested that the GHG emissions of these input commodities should help ground their use. Others thought that the proportions (e.g., in blended fuels) should be considered—if the product is mostly used as a fossil fuel, then it should be regulated and restricted. Lastly, they highlighted how even one new LNG tank in Portland is a major safety issue. Although not explosive, coal also poses a significant risk, especially in transportation. Because of these risks, they believed that the resolution should be implemented through health and safety standards.

State and regional business organizations expressed frustration that while the federal and state government are going one direction requiring cleaner-burning fuels, the City of Portland appears to be choosing to restrict distribution of these cleaner fuels in another policy direction. Some members thought the City could try to incentivize a higher blend of renewables, and others warned of the disincentives that could discourage investment—disincentives should limit GHG emissions, not seismic upgrades.

Neighborhood and equity community organizations thought that restricting methanol exports would be an overreach. They said it is not being used as a fuel in the United States, and instead it is a value-added product used in manufacturing of plastics and other goods. Including methanol would negatively impact the manufacturing sector that requires it as an input, and it could open the door to regulating other non-fuel commodities, such as paints and asphalt. In general, they felt that if we can make certain fuels cleaner burning, then it poses minimal threat. They asserted that, since there is no clear transitional path away from our dependency on fossil fuels, we should make way for cleaner alternatives, such as blended bio-diesel.

Terminal development restrictions

Fuel terminal representatives were concerned with potential restrictions precluding development on certain site configurations, which have some peculiarities. For example, where two existing tank farms are non-contiguous (e.g., at Willbridge) and are connected by facility pipelines, they should be allowed an option for expansion. Additionally, some sites may already be built out and cannot accommodate the new growth that is expected. This group could not comment on facility size and anticipated growth, because of anti-trust laws, but they noted that it is critically important. For this reason, they could not provide feedback on the implementation options presented.

Environmental and public health organizations generally preferred Option A. However, some recognized the legal challenges posed by federal restrictions. They wondered if health and human safety risks may provide a defensible rationale. Some members also noted that while prohibiting all new facilities and making existing facilities non-conforming uses might be more legally defensible, it is much less politically feasible. Finally, some members of this group were skeptical of the 1% annual growth forecast for liquid bulks. They felt this was too high, which is contrary to what the state and regional business organization representatives stated.

State and regional business organizations criticized the approach to implementing the City Council resolution. They felt that zoning to regulate tank size approaches the problem sideways, and the unclear rationale could lead to appeals and legal challenges. One participant advocated to prohibit exports more directly, rather than a sideways approach. They cautioned that tank size limits could essentially put the region on an "import diet," even if the intent of the limit is to reduce throughput. They did not think this proposal accounted for these unintended impacts. Docked ships in the harbor may need an LNG tank to power their facilities and improve air quality, for example. They also noted that there are economic advantages and efficiency gains to being a bigger facility, and placing restrictions on size will have consequences that we don't want—lower wages for example. Lastly, they felt the 1% annual growth forecast for liquid bulks was outdated—an updated forecast would be higher. This was the opposite of what environmental and public health organizations stated.

Neighborhood and equity community organizations generally preferred Option C, calling it a realistic proposal that allows for some growth but doesn't restrict it too much. While the group was fairly resolute that coal is not a good alternative, they recognized that LNG is a cleaner-burning fuel. However, since the facilities in the region are already at capacity, Option C would allow for some wiggle room for the region's growth. They felt it would allow the "invisible hand" to guide the market more easily. They recommended that the City review the size limits every few years as the market changes.

Fossil Fuel Terminal Zoning Amendments
Preliminary Code-Change Concepts, May 16, 2016

Project summary

The Fossil Fuel Terminal Zoning Amendments project would help implement new policy direction on fossil fuel distribution and storage facilities through changes to the Zoning Code. This proposal would restrict the development of *new* bulk fossil fuel terminals. However, proposed code changes would not inhibit *improvements to existing terminals*; they would instead accommodate seismic upgrades, access to greener fuels and capacity for regional growth.

Code change concepts

1. New land use type - Identify "Bulk Fossil Fuel Terminals" as a specifically regulated land use.
    - Use characteristics: These establishments are engaged in interregional transport and bulk storage of fossil fuels. Terminal activities may also include fuel blending, regional distribution, and wholesaling. Typical facilities have interregional freight access via ship, barge, pipeline or railroad to transport fuels to or from the site, and they have bulk storage scaled for large quantities to serve regional or larger markets. There is minimal on-site sales activity with the customer present. Regional market area varies by product and typically includes Oregon and southern Washington. This definition is intended to include the 11 bulk fossil fuel terminals in NW Portland shown on the table and map below, while not applying to the dozens of smaller fuel distributors in Portland.
    - Definition of fossil fuels: crude oil and refined petroleum products (such as gasoline), natural gas and related gaseous fuels (such as propane), and coal. Petroleum or gaseous products used primarily as raw materials to make other products such as plastics, fertilizer, paint, or other non-fuel products are not included.
        - *How should methanol be classified?* For example, methanol is used primarily for manufacture of plastics and other products, but sometimes is used as a fuel.
    - Examples: crude oil terminals, petroleum products terminals, natural gas terminals, propane terminals, and coal terminals.
    - Exceptions: gasoline stations and other retail sales of fossil fuels, fuel distributors that transport fuels exclusively by trucks, and manufacturers that utilize fossil fuels as an input.

2. Limits on new terminals
    - Proposed code changes would apply to new terminals added after the effective date of the code changes. The code changes are not intended to make existing terminals non-conforming or create an impediment to improvements at existing terminals. Here are three potential options.
        - *Option A: Prohibit new bulk fossil fuel terminals.* This option will not regulate development at existing terminals. It could limit competition among terminals and could preclude new facilities for innovative greener fuels.
        - *Option B: Prohibit new fossil fuel "marine" terminals. Marine terminals would include all fossil fuel export terminals.* This option would allow new terminals with access to pipelines and rail, but preclude river access for barges and tankers.
        - *Option C: Limit the size of storage facilities at new bulk fossil fuel terminal (no size limits on existing terminals). Size limits could vary by fossil fuel type (see table).*

Potential Size Limits for New Terminals

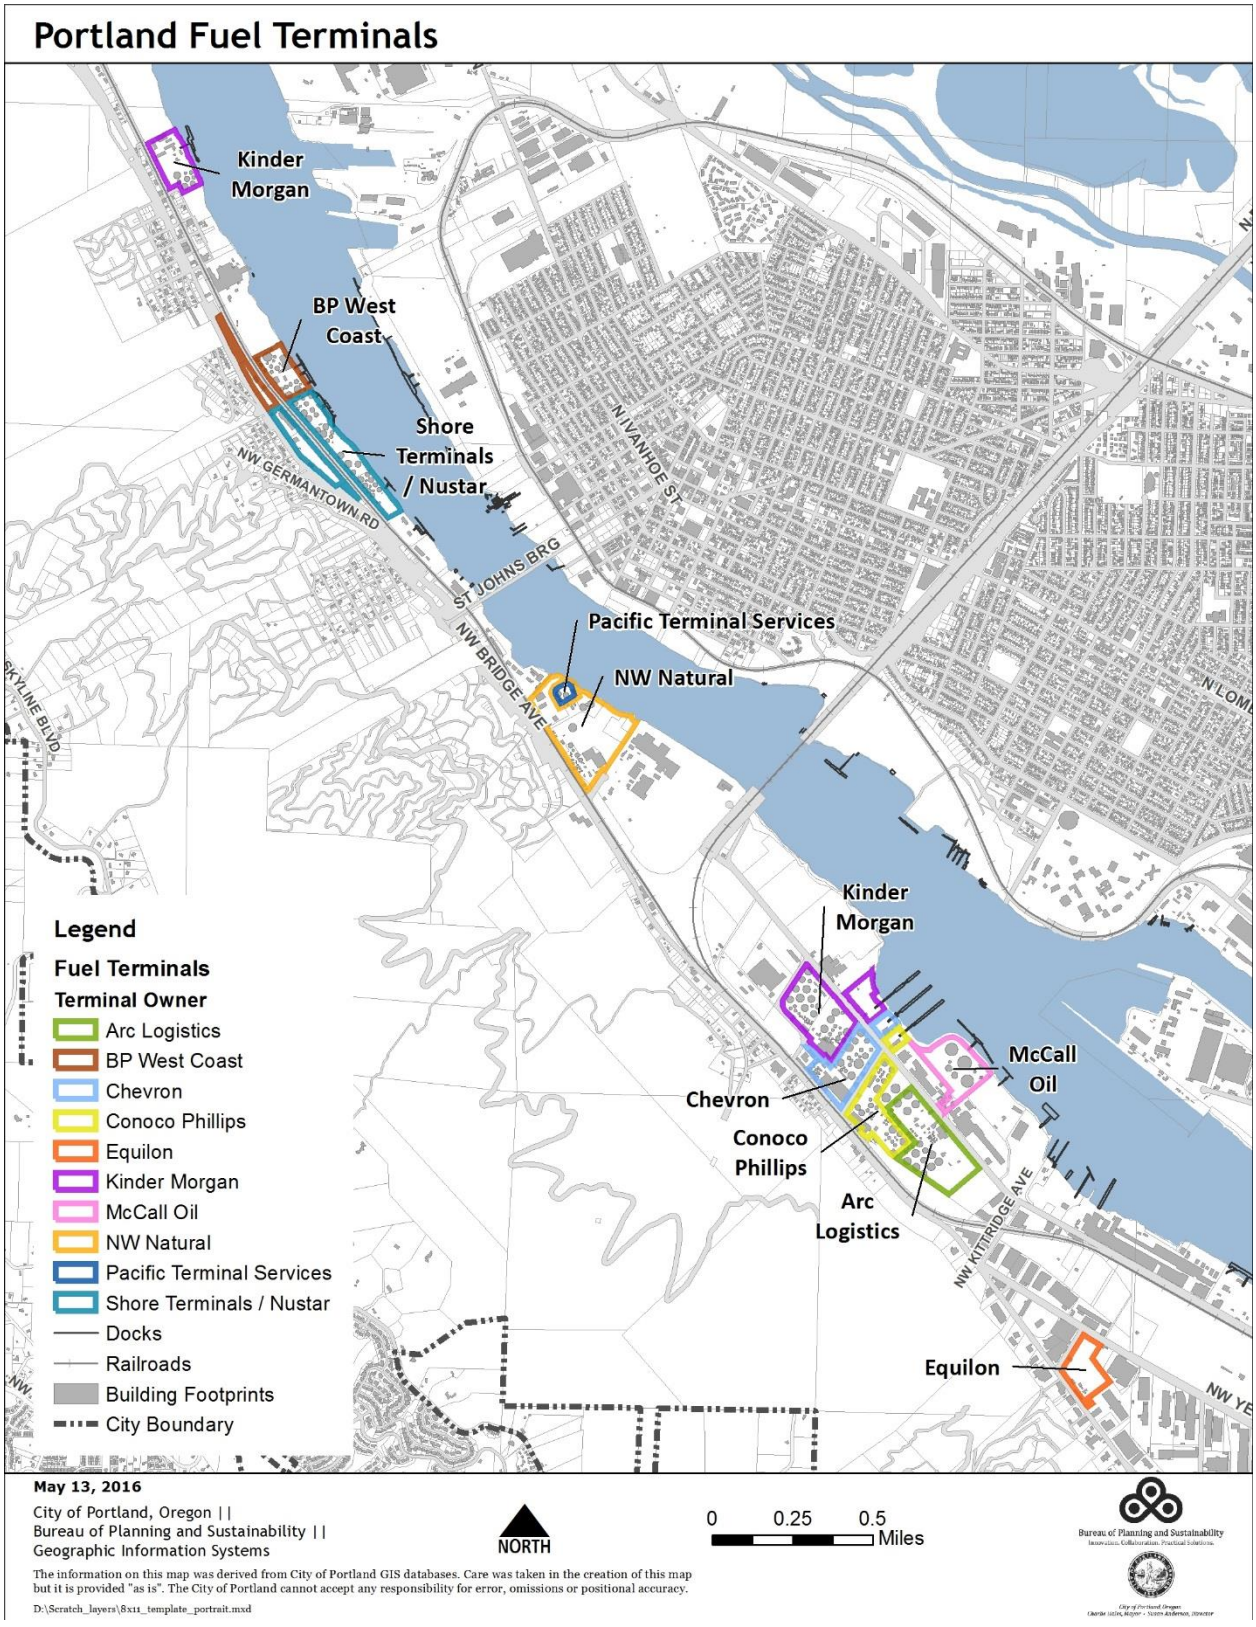
Fossil Fuel Type	**Maximum Storage Capacity**
Petroleum	*500,000 barrels*
Liquefied Natural Gas (LNG)	*7,000,000 gallons*
Liquefied Propane Gas (LPG)	*7,000,000 gallons*
Coal	*Prohibited*
Other	

New storage capacity for larger volumes would be prohibited. The capacity limits could be set to effectively preclude the range of recently proposed fossil fuel terminals in the Pacific Northwest, but would allow for growth at existing terminals. Size examples are shown on the table below.

Code implementation issues

- Project timing – This project is expected to be completed by the end of 2016. The timing provides for a prompt response to the changing fossil fuel distribution market and rapid development of fossil fuels in the Western U.S. and Canada. The fast timeline also limits the potential scope of the project.
- Others?

Code-concept questions for discussion



1. What issues need to be addressed for this code change to be appropriate and effective? Examples might be special circumstances or locations, unforeseen impacts, fairness considerations, or other concerns.
2. How should fossil fuels be defined in the zoning code? - The proposed code concept specifies fossil fuels by type, including petroleum products (e.g., gasoline), coal, and natural gas and related gaseous fuels (e.g., propane). Petrochemicals used primarily for non-fuel products are excluded, such as plastics, lubricants, fertilizer, roofing, and paints. Should any special inclusions be considered, such as methanol?
3. What zoning approach for limiting terminal storage capacity makes most sense? Option A prohibits all new terminals. Option B only prohibits new marine terminals. Option C allows for new terminals but limits their storage capacity. Do you prefer one of these options or another approach?

Estimated storage capacity at existing and proposed bulk fossil fuel terminals

RESOLUTION No. 37168 As Amended

Oppose expansion of infrastructure whose primary purpose is transporting or storing fossil fuels in or through Portland or adjacent waterways (Resolution)

WHEREAS, the rapid development of fossil fuel resources in the western U.S. and Canada has resulted in numerous facility and infrastructure projects proposed to transport coal, diluted bitumen, natural gas, propane or other fossil fuels through the West Coast; and

WHEREAS, fossil fuels pose risks to safety, health, and livability, including mobility of people, other freight, and other commercial vehicles; and

WHEREAS, fossil fuel infrastructure poses considerable risks in the event of a major earthquake; and

WHEREAS, the extraction and combustion of fossil fuels are significant sources of greenhouse gas emissions and major contributors to climate change and pollution; and

WHEREAS, coal contains toxic heavy metals, including mercury, arsenic and lead, and exposure to these toxic heavy metals is linked to cancer, birth defects and other health problems; and

WHEREAS, transportation of coal using open top rail cars results in significant volumes of materials escaping during transit, exposing communities to toxic heavy metals in coal dust and particulates at levels potentially harmful to adjacent communities, workers, wildlife and nature; and

WHEREAS, crude oil, including oil derived from the Bakken shale reservoir, is known to be volatile, highly flammable and to contain elevated levels of benzene, a potent carcinogen; and

WHEREAS, extraction of fossil fuels through fracking and tar sands processing, which has become widespread throughout the Western United States and Canada, has damaging impacts to human and environmental health and fracking increases the potential for earthquakes; and

WHEREAS, transporting crude oil, coal and other fossil fuels into Oregon involves traversing challenging mountain passes, areas laced with significant earthquake faults and numerous older unsafe bridges lacking appropriate infrastructure maintenance or upgrades, significantly increasing the risks of serious accidents; and

WHEREAS, given the record of crude oil and coal or other fossil fuel transport accidents, such as Lac Mégantic in 2013, the 1999 Bellingham pipeline leak or a coal train derailment, an event could have catastrophic effects if it occurred in any of Oregon's populated areas; and

WHEREAS, the risks posed by the transportation of fossil fuels through the Columbia Gorge are inconsistent with the Gorge's designation as a National Scenic Area; and

WHEREAS, historically, when environmental accidents do occur, litigation over damages is drawn out over years, deflecting blame while undercutting timely assistance to affected communities; and

WHEREAS, tribal communities in Oregon and Washington have expressed concerns about the safety risks of fossil fuel infrastructure and the related threats to human health, cultural heritage, and environmental quality; and

WHEREAS, economic opportunities presented by expanding fossil fuel infrastructure are modest, with few jobs and little value added when compared to the related environmental costs; and

WHEREAS, local, regional and global economies are transitioning to low-carbon energy sources, and West Coast businesses are leaders in providing energy efficiency and renewable energy technologies and services; and

WHEREAS, the future of the fossil fuel industry is questionable given global action to reduce greenhouse gas emissions; and

WHEREAS, climate change, if unchecked, will continue impact human health, natural systems, and infrastructure, creating new costs for individuals, businesses, and governments; and

WHEREAS, the City's *2015 Climate Action Plan* (adopted by Resolution 37135) identifies the need to establish a "fossil fuel export policy that considers lifecycle emissions, safety, economics, neighborhood livability and environmental impacts" (*Climate Action Plan*, action 3G, page 69); and

WHEREAS, the City and Multnomah County, working together with many individuals, and community and business partners, have reduced local carbon emissions 14 percent since 1990 while adding population and jobs; on a per person basis, carbon emissions have decreased 35 percent since 1990; and

WHEREAS, the *2015 Climate Action Plan* commits the City to continue to advance policy and programs to reduce local fossil fuel use both in the City's own operations and through community-wide initiatives; and

WHEREAS, in September 2015, the Council added fossil fuel companies to the City's Corporate Securities Do-Not-Buy List, committing the City to hold no financial stake in the 200 largest fossil fuel firms. Resolution 37153; and

WHEREAS, 27 Oregon and Washington communities have passed resolutions addressing fossil fuel transport and export, and hundreds of public officials, including the governors of Oregon and Washington, state and federal agencies, tribes, health organizations, religious leaders and other community leaders, have recognized the harms presented by fossil fuels to the environment and Northwest communities; and

WHEREAS, in 2012, the Council expressed opposition to coal trains traveling through Portland until a programmatic, comprehensive and area-wide Environmental Impact Statement and comprehensive Health Impact Assessment are completed. Resolutions 36959 and 36962; and

WHEREAS, the City is continuing to work with utilities to reduce coal and other fossil fuels in Portland's electricity supply;

NOW, THEREFORE, BE IT RESOLVED, that the City Council will actively oppose expansion of infrastructure whose primary purpose is transporting or storing fossil fuels in or through Portland or adjacent waterways; and

BE IT FURTHER RESOLVED, that this Resolution does not restrict:

1. improvements in the safety, or efficiency, seismic resilience, or operations of existing infrastructure;
2. the provision of service directly to end users;
3. development of emergency backup capacity;
4. infrastructure that enables recovery or re-processing of used petroleum products; or
5. infrastructure that will accelerate the transition to non-fossil fuel energy sources; and

BE IT FURTHER RESOLVED, that City bureaus are directed to examine existing laws, including those related to public health, safety, building, electrical, nuisance, and fire codes, and develop recommendations to address fossil fuels that strengthen public health and safety; and

BE IT FURTHER RESOLVED, that the Bureau of Planning and Sustainability is directed to develop proposed code changes for Council consideration to advance the policies set forth in this Resolution; and

BE IT FURTHER RESOLVED, that prior to any further Council action, the mayor shall schedule (1) a work session to review any proposed code changes and (2) an executive session to review the legal considerations of any proposed code changes; and

BE IT FURTHER RESOLVED, that the Bureau of Planning & Sustainability shall undertake an analysis of the economic impacts of any proposed Code changes to advance the policies set forth in this resolution, with a particular focus on potential impacts to local blue-collar jobs; and

BE IT FURTHER RESOLVED, that the City and applicable bureaus shall seek and identify opportunities to invest in Portland's 'human infrastructure' by supporting programs to retrain our workforce as the city transitions to a clean energy economy; and

BE IT FURTHER RESOLVED, that the City shall consult with its Tribal Government Partners, the State of Oregon, local governments, and other key stakeholder including labor, business, environment, neighborhoods and communities of color in advancing this policy; and

BE IT FURTHER RESOLVED, notwithstanding anything in this resolution, the Council will exercise its duty as a quasi-judicial land use decision making body in an impartial manner consistent with City Code and Oregon law.

BE IT FURTHER RESOLVED, this resolution is binding City policy.

entered the eights, and a three-minute quake is in the high eights. By four minutes, an earthquake has hit magnitude 9.0.

When Goldfinger looked at his watch, it was quarter to three. The conference was wrapping up for the day. He was thinking about sushi. The speaker at the lectern was wondering if he should carry on with his talk. The earthquake was not particularly strong. Then it ticked past the sixty-second mark, making it longer than the others that week. The shaking intensified. The seats in the conference room were small plastic desks with wheels. Goldfinger, who is tall and solidly built, thought, No way am I crouching under one of those for cover. At a minute and a half, everyone in the room got up and went outside.

It was March. There was a chill in the air, and snow flurries, but no snow on the ground. Nor, from the feel of it, was there ground on the ground. The earth snapped and popped and rippled. It was, Goldfinger thought, like driving through rocky terrain in a vehicle with no shocks, if both the vehicle and the terrain were also on a raft in high seas. The quake passed the two-minute mark. The trees, still hung with the

previous autumn's dead leaves, were making a strange rattling sound. The flagpole atop the building he and his colleagues had just vacated was whipping through an arc of forty degrees. The building itself was base-isolated, a seismic-safety technology in which the body of a structure rests on movable bearings rather than directly on its foundation. Goldfinger lurched over to take a look. The base was lurching, too, back and forth a foot at a time, digging a trench in the yard. He thought better of it, and lurched away. His watch swept past the three-minute mark and kept going.

Oh, shit, Goldfinger thought, although not in dread, at first: in amazement. For

Almost immediately, though, it became extremely uncool, because Goldfinger and every other seismologist standing outside in Kashiwa knew what was coming. One of them pulled out a cell phone and started streaming videos from the Japanese broadcasting station NHK, shot by helicopters that had flown out to sea soon after the shaking started. Thirty minutes after Goldfinger first stepped outside, he watched the tsunami roll in, in real time, on a two-inch screen.

In the end, the magnitude-9.0 Tohoku earthquake and subsequent tsunami killed more than eighteen thousand people, devastated northeast Japan, triggered the meltdown at the Fukushima power plant, and cost an estimated two hundred and twenty billion dollars. The shaking earlier in the week turned out to be the foreshocks of the largest earthquake in the nation's recorded history. But for Chris Goldfinger, a paleoseismologist at Oregon State University and one of the world's leading experts on a little-known fault line, the main quake was itself a kind of foreshock: a preview of another earthquake still to come.

Most people in the United States know just one fault line by name: the San Andreas, which runs nearly the length of California and is perpetually rumored to be on the verge of unleashing "the big one." That rumor is misleading, no matter what the San Andreas ever does. Every fault line has an upper limit to its potency, determined by its length and width, and by how far it can slip. For the San Andreas, one of the most extensively studied and best understood fault lines in the world, that upper limit is roughly an 8.2—a powerful earthquake, but, because the Richter scale is logarithmic, only six per cent as strong as the 2011 event in Japan.

in Seattle. Your left hand represents an oceanic plate called Juan de Fuca, ninety thousand square miles in size. The place where they meet is the Cascadia subduction zone. Now slide your left hand under your right one. That is what the Juan de Fuca plate is doing: slipping steadily beneath North America. When you try it, your right hand will slide up your left arm, as if you were pushing up your sleeve. That is what North America is not doing. It is stuck, wedged tight against the surface of the other plate.

Without moving your hands, curl your right knuckles up, so that they point toward the ceiling. Under pressure from Juan de Fuca, the stuck edge of North America is bulging upward and compressing eastward, at the rate of, respectively, three to four millimetres and thirty to forty millimetres a year. It can do so for quite some time, because, as continent stuff goes, it is young, made of rock that is still relatively elastic. (Rocks, like us, get stiffer as they age.) But it cannot do so indefinitely. There is a backstop—the craton, that ancient unbudgeable mass at the center of the continent—and, sooner or later, North America will rebound like a spring. If, on that occasion, only the southern

part of the Cascadia subduction zone gives way—your first two fingers, say—the magnitude of the resulting quake will be somewhere between 8.0 and 8.6. *That's* the big one. If the entire zone gives way at once, an event that seismologists call a full-margin rupture, the magnitude will be somewhere between 8.7 and 9.2. That's the very big one.

Flick your right fingers outward, forcefully, so that your hand flattens back down again. When the next very big earthquake hits, the northwest edge of the continent, from California to Canada and the continental shelf to the Cascades, will drop by as much as

Washington, Idaho, and Alaska, says, "Our operating assumption is that everything west of Interstate 5 will be toast."

In the Pacific Northwest, the area of impact will cover* some hundred and forty thousand square miles, including Seattle, Tacoma, Portland, Eugene, Salem (the capital city of Oregon), Olympia (the capital of Washington), and some seven million people. When the next full-margin rupture happens, that region will suffer the worst natural disaster in the history of North America. Roughly three thousand people died in San Francisco's 1906 earthquake. Almost two thousand died in Hurricane Katrina. Almost three hundred died in Hurricane Sandy. FEMA projects that nearly thirteen thousand people will die in the Cascadia earthquake and tsunami. Another twenty-seven thousand will be injured, and the agency expects that it will need to provide shelter for a million displaced people, and food and water for another two and a half million. "This is one time that I'm hoping all the science is wrong, and it won't happen for another thousand years," Murphy says.

In fact, the science is robust, and one of the chief scientists behind it is Chris Goldfinger. Thanks to work done by him and his colleagues, we now know that the odds of the big Cascadia earthquake happening in the next fifty years are roughly one in three. The odds of the very big one are roughly one in ten. Even those numbers do not fully reflect the danger—or, more to the point, how unprepared the Pacific Northwest is to face it. The truly worrisome figures in this story are these: Thirty years ago, no one knew that the Cascadia subduction zone had ever produced a major earthquake. Forty-five years ago, no one even knew it existed.

find: vast, cheap, temperate, fertile, and, to all appearances, remarkably benign.

A century and a half elapsed before anyone had any inkling that the Pacific Northwest was not a quiet place but a place in a long period of quiet. It took another fifty years to uncover and interpret the region's seismic history. Geology, as even geologists will tell you, is not normally the sexiest of disciplines; it hunkers down with earthly stuff while the glory accrues to the human and the cosmic—to genetics, neuroscience, physics. But, sooner or later, every field has its field day, and the discovery of the Cascadia subduction zone stands as one of the greatest scientific detective stories of our time.

The first clue came from geography. Almost all of the world's most powerful earthquakes occur in the Ring of Fire, the volcanically and seismically volatile swath of the Pacific that runs from New Zealand up through Indonesia and Japan, across the ocean to Alaska, and down the west coast of the Americas to Chile. Japan, 2011, magnitude 9.0; Indonesia, 2004, magnitude 9.1; Alaska, 1964, magnitude 9.2; Chile, 1960, magnitude 9.5—not until the late nineteen-sixties, with the rise of the theory of

plate tectonics, could geologists explain this pattern. The Ring of Fire, it turns out, is really a ring of subduction zones. Nearly all the earthquakes in the region are caused by continental plates getting stuck on oceanic plates—as North America is stuck on Juan de Fuca—and then getting abruptly unstuck. And nearly all the volcanoes are caused by the oceanic plates sliding deep beneath the continental ones, eventually reaching temperatures and pressures so extreme that they melt the rock above them.

The Pacific Northwest sits squarely within the Ring of Fire. Off its coast, an oceanic plate is slipping beneath a continental one. Inland, the Cascade volcanoes mark the line

REWIRED MY BRAIN

whether the Cascadia subduction zone had ever broken in its time there.

In the late nineteen-eighties, Brian Atwater, a geologist with the United States Geological Survey, and a graduate student named David Yamaguchi found the answer, and another major clue in the Cascadia puzzle. Their discovery is best illustrated in a place called the ghost forest, a grove of western red cedars on the banks of the Copalis River, near the Washington coast. When I paddled out to it last summer, with Atwater and Yamaguchi, it was easy to see how it got its name. The cedars are spread out across a low salt marsh on a wide northern bend in the river, long dead but still standing. Leafless, branchless, barkless, they are reduced to their trunks and worn to a smooth silver-gray, as if they had always carried their own tombstones inside them.

What killed the trees in the ghost forest was saltwater. It had long been assumed that they died slowly, as the sea level around them gradually rose and submerged their roots. But, by 1987, Atwater, who had found in soil layers evidence of sudden land subsidence along the Washington coast, suspected that that was backward—that the trees had died quickly when the ground beneath them plummeted. To find out, he teamed up with

Yamaguchi, a specialist in dendrochronology, the study of growth-ring patterns in trees. Yamaguchi took samples of the cedars and found that they had died simultaneously: in tree after tree, the final rings dated to the summer of 1699. Since trees do not grow in the winter, he and Atwater concluded that sometime between August of 1699 and May of 1700 an earthquake had caused the land to drop and killed the cedars. That time frame predated by more than a hundred years the written history of the Pacific Northwest—and so, by rights, the detective story should have ended there.

But it did not. If you travel five thousand miles due west from the ghost forest, you

REWIRED MY BRAIN

Finally, in a 1996 article in *Nature*, a seismologist named Kenji Satake and three colleagues, drawing on the work of Atwater and Yamaguchi, matched that orphan to its parent—and thereby filled in the blanks in the Cascadia story with uncanny specificity. At approximately nine o' clock at night on January 26, 1700, a magnitude-9.0 earthquake struck the Pacific Northwest, causing sudden land subsidence, drowning coastal forests, and, out in the ocean, lifting up a wave half the length of a continent. It took roughly fifteen minutes for the Eastern half of that wave to strike the Northwest coast. It took ten hours for the other half to cross the ocean. It reached Japan on January 27, 1700: by the local calendar, the eighth day of the twelfth month of the twelfth year of Genroku.

Briefly Review

Once scientists had reconstructed the 1700 earthquake, certain previously overlooked accounts also came to seem like clues. In 1964, Chief Louis Nookmis, of the Huu-ay-aht First Nation, in British Columbia, told a story, passed down through seven

Read more great writing

THE JAPANESE FRIED-RICE OMELETTE THAT REWIRED MY BRAIN

On average, the midpoint of that range was 1701.

It does not speak well of European-Americans that such stories counted as evidence for a proposition only after that proposition had been proved. Still, the reconstruction of the Cascadia earthquake of 1700 is one of those rare natural puzzles whose pieces fit together as tectonic plates do not: perfectly. It is wonderful science. It was wonderful *for* science. And it was terrible news for the millions of inhabitants of the Pacific Northwest. As Goldfinger put it, "In the late eighties and early nineties, the paradigm shifted to 'uh-oh.' "

Goldfinger told me this in his lab at Oregon State, a low prefab building that a passing English major might reasonably mistake for the maintenance department. Inside the lab is a walk-in freezer. Inside the freezer are floor-to-ceiling racks filled with cryptically labelled tubes, four inches in diameter and five feet long. Each tube contains a core sample of the seafloor. Each sample contains the history, written in seafloorese, of the past ten thousand years. During subduction-zone earthquakes, torrents of land

rush off the continental slope, leaving a permanent deposit on the bottom of the ocean. By counting the number and the size of deposits in each sample, then comparing their extent and consistency along the length of the Cascadia subduction zone, Goldfinger and his colleagues were able to determine how much of the zone has ruptured, how often, and how drastically.

Thanks to that work, we now know that the Pacific Northwest has experienced forty-one subduction-zone earthquakes in the past ten thousand years. If you divide ten thousand by forty-one, you get two hundred and forty-three, which is Cascadia's

OMELETTE THAT
REWIRED MY BRAIN

what the region was prepared to withstand. The same will hold true in the Pacific Northwest—but here the discrepancy is enormous. "The science part is fun," Goldfinger says. "And I love doing it. But the gap between what we know and what we should do about it is getting bigger and bigger, and the action really needs to turn to responding. Otherwise, we're going to be hammered. I've been through one of these massive earthquakes in the most seismically prepared nation on earth. If that was Portland"—Goldfinger finished the sentence with a shake of his head before he finished it with words. "Let's just say I would rather not be here."

The first sign that the Cascadia earthquake has begun will be a compressional wave, radiating outward from the fault line. Compressional waves are fast-moving, high-frequency waves, audible to dogs and certain other animals but experienced by humans only as a sudden jolt. They are not very harmful, but they are potentially very useful, since they travel fast enough to be detected by sensors thirty to ninety seconds ahead of other seismic waves. That is enough time for earthquake early-warning systems, such as those in use throughout Japan, to automatically perform a variety of

lifesaving functions: shutting down railways and power plants, opening elevators and firehouse doors, alerting hospitals to halt surgeries, and triggering alarms so that the general public can take cover. The Pacific Northwest has no early-warning system. When the Cascadia earthquake begins, there will be, instead, a cacophony of barking dogs and a long, suspended, what-was-that moment before the surface waves arrive. Surface waves are slower, lower-frequency waves that move the ground both up and down and side to side: the shaking, starting in earnest.

Soon after that shaking begins, the electrical grid will fail, likely everywhere west of the

EDITING DONALD TRUMP

KITCHEN NOTES

THE JAPANESE FRIED-RICE
OMELETTE THAT
REWIRED MY BRAIN

foundations, together with the rest of the Northwest, jolt westward. Unmoored on the undulating ground, the homes will begin to collapse.

Across the region, other, larger structures will also start to fail. Until 1974, the state of Oregon had no seismic code, and few places in the Pacific Northwest had one appropriate to a magnitude-9.0 earthquake until 1994. The vast majority of buildings in the region were constructed before then. Ian Madin, who directs the Oregon Department of Geology and Mineral Industries (DOGAMI), estimates that seventy-five per cent of all structures in the state are not designed to withstand a major Cascadia quake. FEMA calculates that, across the region, something on the order of a million buildings—more than three thousand of them schools—will collapse or be compromised in the earthquake. So will half of all highway bridges, fifteen of the seventeen bridges spanning Portland's two rivers, and two-thirds of railways and airports; also, one-third of all fire stations, half of all police stations, and two-thirds of all hospitals.

Certain disasters stem from many small problems conspiring to cause one very large problem. For want of a nail, the war was lost; for fifteen independently insignificant errors, the jetliner was lost. Subduction-zone earthquakes operate on the opposite principle: one enormous problem causes many other enormous problems. The shaking from the Cascadia quake will set off landslides throughout the region—up to thirty thousand of them in Seattle alone, the city's emergency-management office estimates. It will also induce a process called liquefaction, whereby seemingly solid ground starts behaving like a liquid, to the detriment of anything on top of it. Fifteen per cent of Seattle is built on liquefiable land, including seventeen day-care centers and the homes

begin.

Among natural disasters, tsunamis may be the closest to being completely unsurvivable. The only likely way to outlive one is not to be there when it happens: to steer clear of the vulnerable area in the first place, or get yourself to high ground as fast as possible. For the seventy-one thousand people who live in Cascadia's inundation zone, that will mean evacuating in the narrow window after one disaster ends and before another begins. They will be notified to do so only by the earthquake itself—"a vibrate-alert system," Kevin Cupples, the city planner for the town of Seaside, Oregon, jokes—and they are urged to leave on foot, since the earthquake will render roads impassable. Depending on location, they will have between ten and thirty minutes to get out. That time line does not allow for finding a flashlight, tending to an earthquake injury, hesitating amid the ruins of a home, searching for loved ones, or being a Good Samaritan. "When that tsunami is coming, you run," Jay Wilson, the chair of the Oregon Seismic Safety Policy Advisory Commission (OSSPAC), says. "You protect yourself, you don't turn around, you don't go back to save anybody. You run for your life."

The time to save people from a tsunami is before it happens, but the region has not yet taken serious steps toward doing so. Hotels and businesses are not required to post evacuation routes or to provide employees with evacuation training. In Oregon, it has been illegal since 1995 to build hospitals, schools, firehouses, and police stations in the inundation zone, but those which are already in it can stay, and any other new construction is permissible: energy facilities, hotels, retirement homes. In those cases, builders are required only to consult with DOGAMI about evacuation plans. "So you come in and sit down," Ian Madin says. "And I say, 'That's a stupid idea.' And you say, 'Thanks. Now we've consulted.' "

beaches are the hardest place to evacuate from."

Those who cannot get out of the inundation zone under their own power will quickly be overtaken by a greater one. A grown man is knocked over by ankle-deep water moving at 6.7 miles an hour. The tsunami will be moving more than twice that fast when it arrives. Its height will vary with the contours of the coast, from twenty feet to more than a hundred feet. It will not look like a Hokusai-style wave, rising up from the surface of the sea and breaking from above. It will look like the whole ocean, elevated, overtaking land. Nor will it be made only of water—not once it reaches the shore. It will be a five-story deluge of pickup trucks and doorframes and cinder blocks and fishing boats and utility poles and everything else that once constituted the coastal towns of the Pacific Northwest.

To see the full scale of the devastation when that tsunami recedes, you would need to be in the international space station. The inundation zone will be scoured of structures from California to Canada. The earthquake will have wrought its worst havoc west of

the Cascades but caused damage as far away as Sacramento, California—as distant from the worst-hit areas as Fort Wayne, Indiana, is from New York. FEMA expects to coördinate search-and-rescue operations across a hundred thousand square miles and in the waters off four hundred and fifty-three miles of coastline. As for casualties: the figures I cited earlier—twenty-seven thousand injured, almost thirteen thousand dead—are based on the agency's official planning scenario, which has the earthquake striking at 9:41 A.M. on February 6th. If, instead, it strikes in the summer, when the beaches are full, those numbers could be off by a horrifying margin.

PERSONAL HISTORY

EDITING DONALD TRUMP

KITCHEN NOTES

THE JAPANESE FRIED-RICE
OMELETTE THAT
REWIRED MY BRAIN

How much all this will cost is anyone's guess; FEMA puts every number on its relief-and-recovery plan except a price. But whatever the ultimate figure—and even though U.S. taxpayers will cover seventy-five to a hundred per cent of the damage, as happens in declared disasters—the economy of the Pacific Northwest will collapse. Crippled by a lack of basic services, businesses will fail or move away. Many residents will flee as well. OSSPAC predicts a mass-displacement event and a long-term population downturn. Chris Goldfinger didn't want to be there when it happened. But, by many metrics, it will be as bad or worse to be there afterward.

On the face of it, earthquakes seem to present us with problems of space: the way we live along fault lines, in brick buildings, in homes made valuable by their proximity to the sea. But, covertly, they also present us with problems of time. The earth is 4.5 billion years old, but we are a young species, relatively speaking, with an average individual allotment of three score years and ten. The brevity of our lives breeds a kind of temporal parochialism—an ignorance of or an indifference to those planetary gears which turn more slowly than our own.

This problem is bidirectional. The Cascadia subduction zone remained hidden from us for so long because we could not see deep enough into the past. It poses a danger to us today because we have not thought deeply enough about the future. That is no longer a problem of information; we now understand very well what the Cascadia fault line will someday do. Nor is it a problem of imagination. If you are so inclined, you can watch an earthquake destroy much of the West Coast this summer in Brad Peyton's "San Andreas," while, in neighboring theatres, the world threatens to succumb to Armageddon by other means: viruses, robots, resource scarcity, zombies, aliens, plague. As those movies attest, we excel at imagining future scenarios, including awful ones.

profoundly vulnerable to natural disaster.

The last person I met with in the Pacific Northwest was Doug Dougherty, the superintendent of schools for Seaside, which lies almost entirely within the tsunami-inundation zone. Of the four schools that Dougherty oversees, with a total student population of sixteen hundred, one is relatively safe. The others sit five to fifteen feet above sea level. When the tsunami comes, they will be as much as forty-five feet below it.

In 2009, Dougherty told me, he found some land for sale outside the inundation zone, and proposed building a new K-12 campus there. Four years later, to foot the hundred-and-twenty-eight-million-dollar bill, the district put up a bond measure. The tax increase for residents amounted to two dollars and sixteen cents per thousand dollars of property value. The measure failed by sixty-two per cent. Dougherty tried seeking help from Oregon's congressional delegation but came up empty. The state makes money available for seismic upgrades, but buildings within the inundation zone cannot apply. At present, all Dougherty can do is make sure that his students know how to evacuate.

Some of them, however, will not be able to do so. At an elementary school in the community of Gearhart, the children will be trapped. "They can't make it out from that school," Dougherty said. "They have no place to go." On one side lies the ocean; on the other, a wide, roadless bog. When the tsunami comes, the only place to go in Gearhart is a small ridge just behind the school. At its tallest, it is forty-five feet high—lower than the expected wave in a full-margin earthquake. For now, the route to the ridge is marked by signs that say "Temporary Tsunami Assembly Area." I asked Dougherty about the state's long-range plan. "There is no long-range plan," he said.

Port of Portland Commodity Flow Forecast

Final Project Presentation

presented to

Port of Portland and Stakeholders

presented by

Cambridge Systematics, Inc.

Michael J. Fischer

March 31, 2015

Transportation leadership you can trust.

CAMBRIDGE SYSTEMATICS

Agenda

- Macro-Economic Context
- Data Methodology
- Summary of Base Year Data
- Summary of Future Year Data
- Summary of Written Tasks

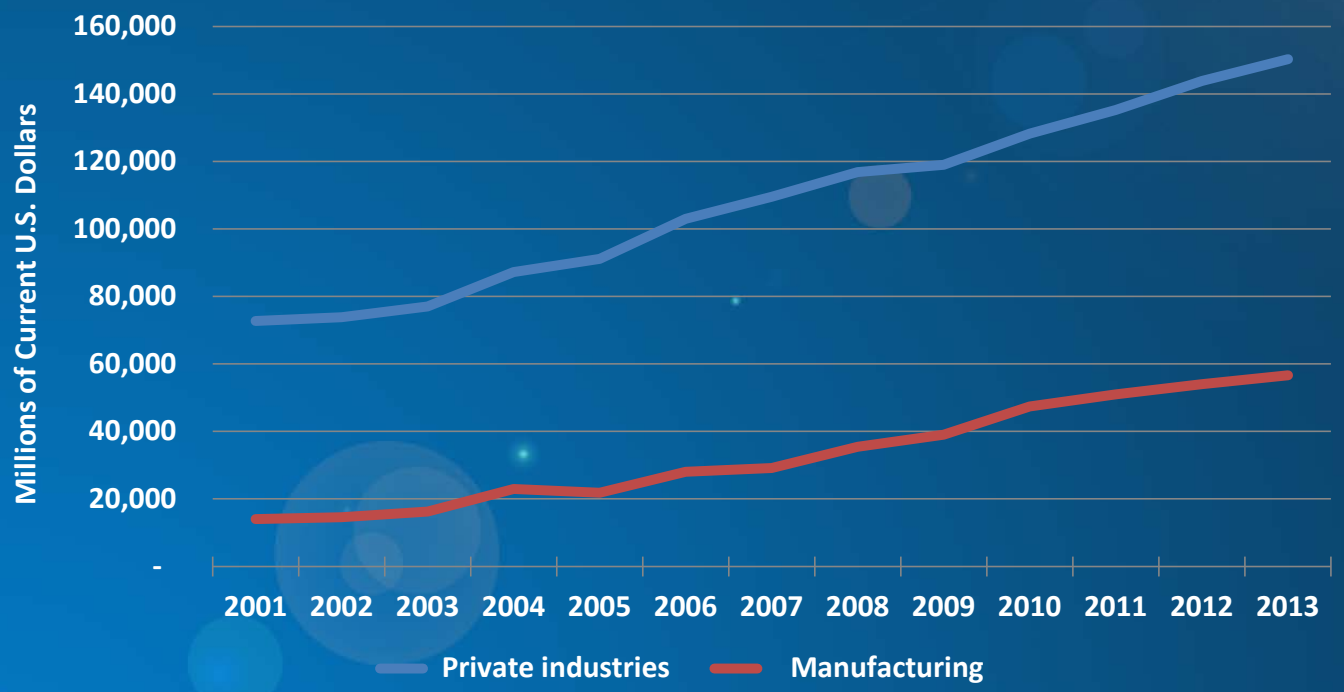
CAMBRIDGE SYSTEMATICS

Macro-economic Context

Portland's Economy is Supported by Three Goods Movement Functions

International Trade. This is done primarily through the Port of Portland and Port of Vancouver, including marine terminals and the Portland International Airport. It provides access to Pacific Rim trading partners.

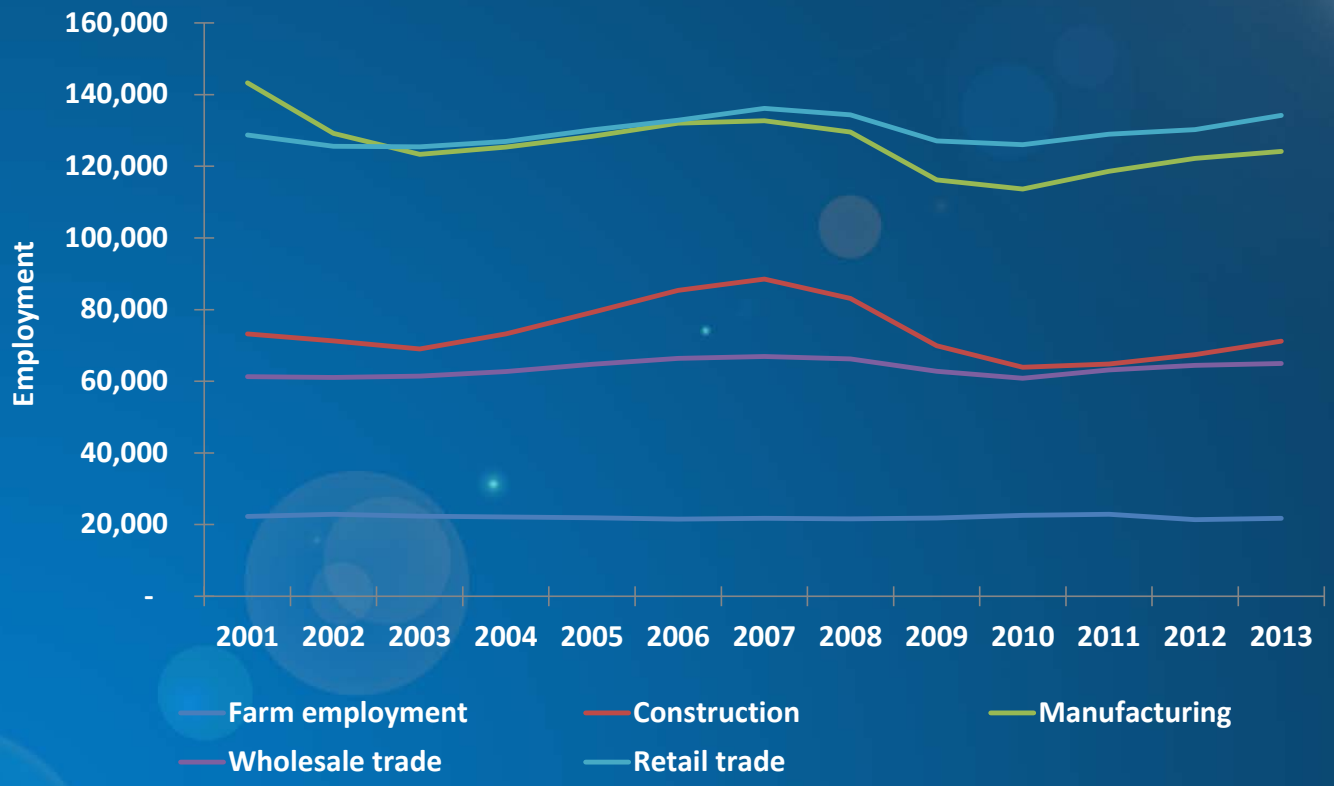
Domestic Trade. Local consumer base relies on industries across the country. The region also supports population centers in other domestic regions. Warehouse and DCs support this function.



Local Deliveries. As a large population center, the region relies on local goods movement to provide consumer products, food, and parcels to residents and businesses.

Commodity flows associated with the study area reflect all three goods movement functions.

CAMBRIDGE SYSTEMATICS



GDP of Industries in Portland Region

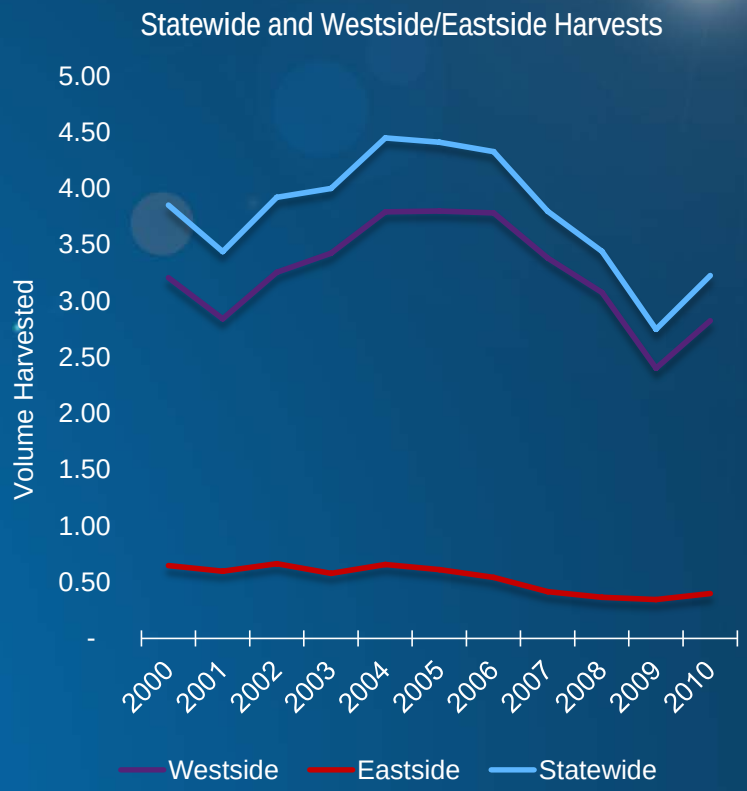
Source: Bureau of Economic Analysis.

CAMBRIDGE SYSTEMATICS

Employment of Industries in Portland Region

Source: Bureau of Economic Analysis.

CAMBRIDGE SYSTEMATICS



Portland's Key Industries Have Changed Overtime

1. Forest Products. Traditionally most important in the region. Currently experiencing domestic declines, but increased overseas import.
2. Manufacturing. High-tech electronics is becoming a highly significant sector.
3. Agriculture. Traditionally a very important industry in the region. Significant shares of agriculture products are exported to Asia.
4. Energy. Energy dependence in the region is shifting from hydroelectric power to other renewable energy sources and natural gas, which creates changes in demand in the future both in terms of commodities and mode.
5. Waste and Scrap. Dramatic increases of exports to China in past decade. Waste and scrap is believed to be the most important industry in the U.S. currently.

CAMBRIDGE SYSTEMATICS

Forest Products Industry

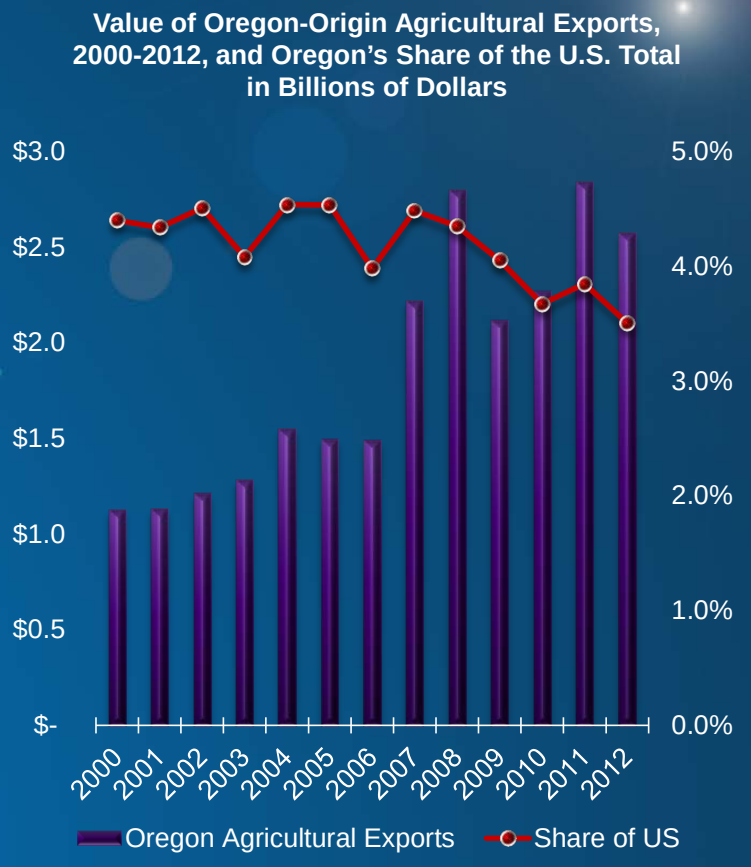
- In 2010, Oregon lumber and wood production is the highest in the country. It also is a mid-ranking state in terms of paper production.
- Most forest products comes from West Oregon (Lane and Davis Counties).
- Timber production and jobs in these industries has declined, due to reduction of logging on Federal lands.
- The movement of forest products is dependent on U.S. housing and construction markets, and increasingly on exports to China.

Source: Oregon Department of Forestry.

CAMBRIDGE SYSTEMATICS

Manufacturing – Hi-Tech

- Hi-tech manufacturing drives growth in manufacturing activities in Portland, especially from Intel's semi-conductor production.
- Oregon has the highest concentration of manufacturing in the country based on relative contribution to GDP
- Large recent capital investments means even more high-tech manufacturing activity in the future.

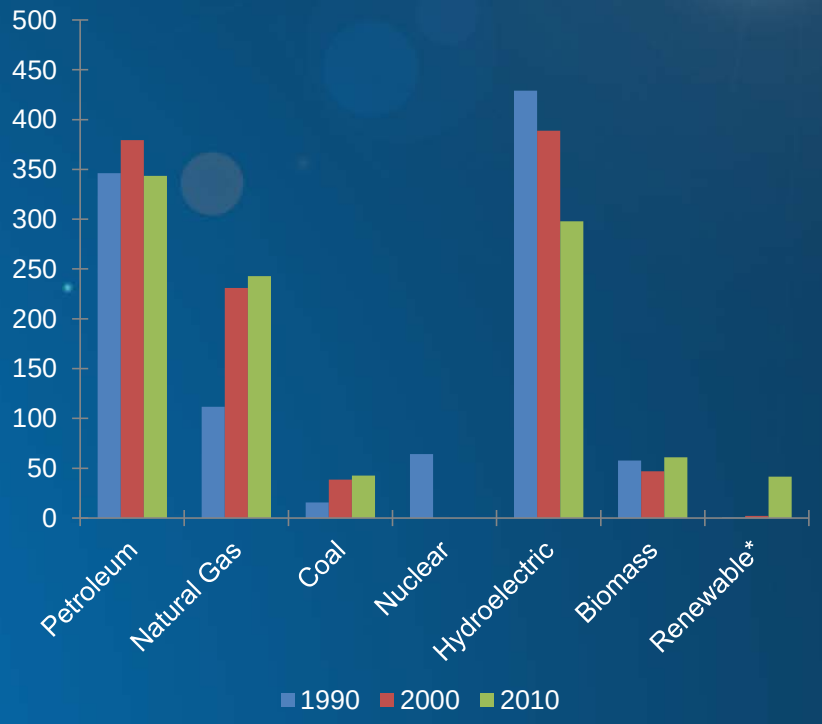


Oregon GDP in Computers and Electronics and Oregon's Share of the U.S. Total in Billions of Dollars

Source: Bureau of Economic Analysis.

Agriculture

- Oregon's main crops include wheat, hay, nursery products, apples. Wheat farms are concentrated in Umatilla County.
- Oregon agriculture has been rising steadily, but is eroding in terms of total U.S. shares.
- Oregon-origin exports account for 4% total U.S. exports, mostly destined to Asia.
- Food production also is important in Oregon, growing by 17 percent between 2000 and 2010. However, It remained stagnant since 2005.



Source: WISERTrade.

Energy

- Oregon energy consumption changed considerably since 2000, where energy consumption actually declined even though population increased.
- About one-third of electricity comes from hydro power, and as the hydroelectricity has declined in use, it is replaced by renewable and natural gas.

Oregon Energy Consumption by Source, 1990, 2000, and 2010 in Trillions of BTUs

Source: U.S. EIA.

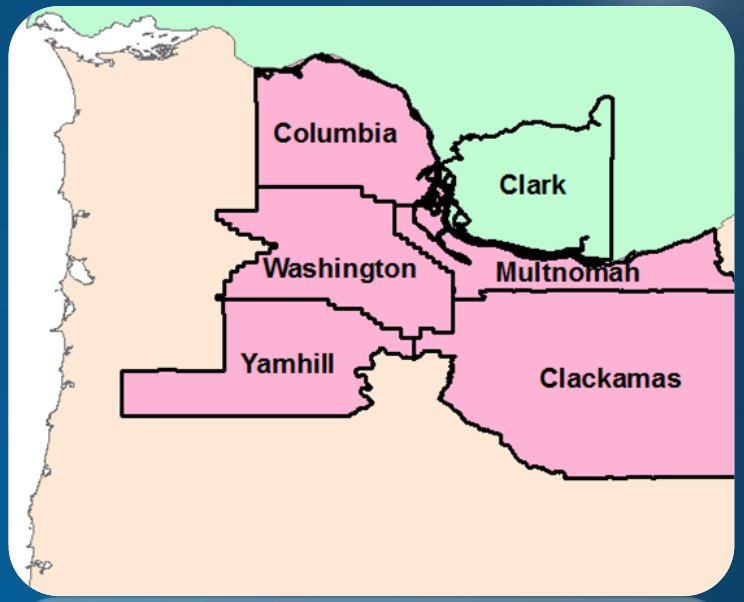
CAMBRIDGE SYSTEMATICS

Waste and Scrap

- A fast growing export sector in recent decades due to demand in China for:
  - » Waste scrap metal
  - » Waste paper/cardboard
  - » Waste plastics
- Shredded scrap material comes via rail and truck to the Port of Vancouver. The tonnage of the shredded scrap material has increase dramatically in recent years.
- In the future, though continued demand are expected from China, the market can be volatile.

CAMBRIDGE SYSTEMATICS

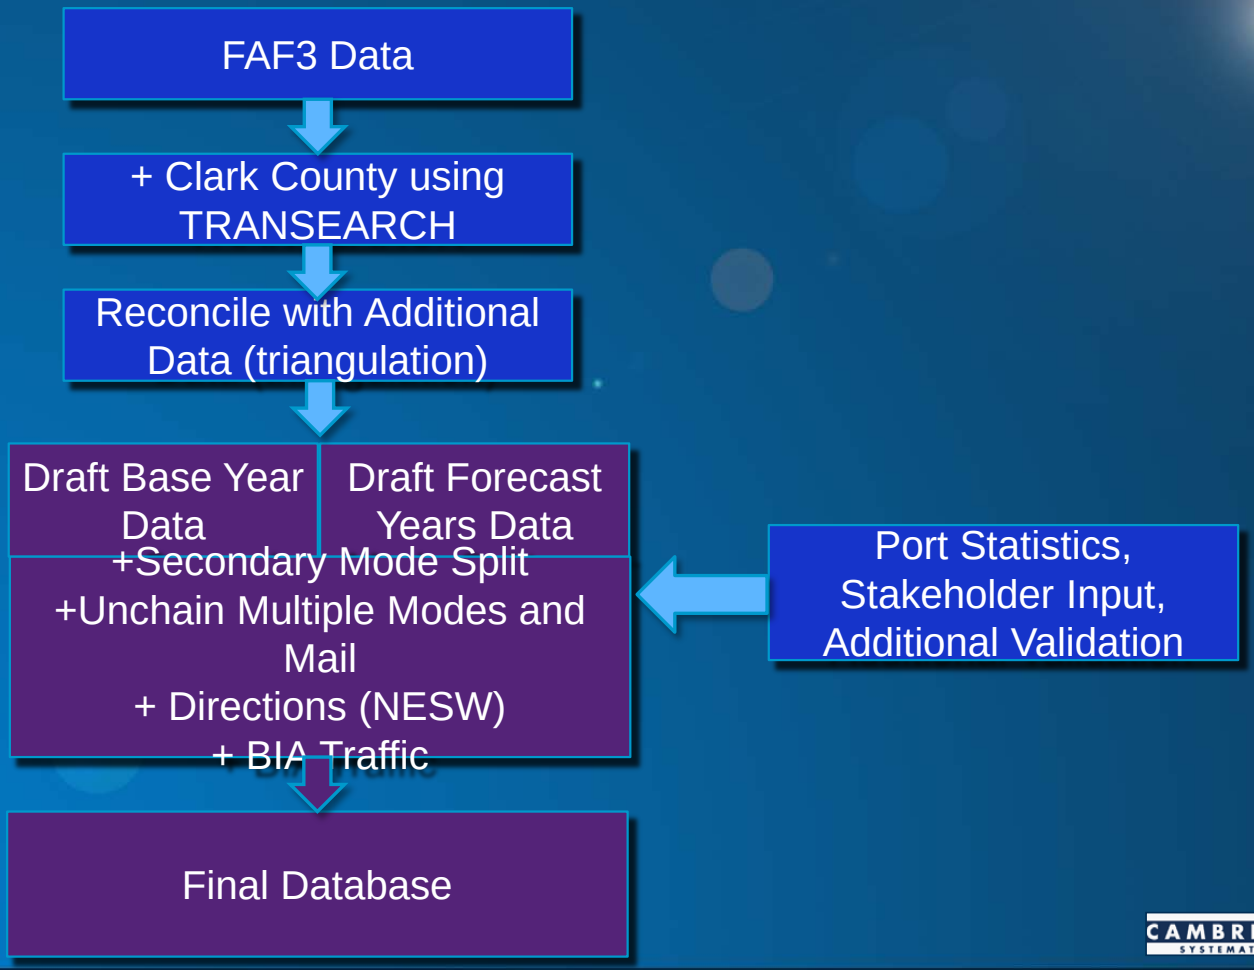
Data Methodology



Overview of the Project

Overall Purpose

Develop a commodity flow database with future forecast for the Portland-Vancouver Region using baseline FAF data.



Study Area

Consists of the Counties of Columbia, Washington, Multnomah, Yamhill and Clackamas in Oregon, and Clark in Washington.

CAMBRIDGE SYSTEMATICS

Overall Methodology

CAMBRIDGE SYSTEMATICS

Secondary Mode Split (for International Movements)

Goal: Split foreign ocean modes and air modes into domestic modes.
- Results in double-counting, but can toggle on/off depending on purpose.

CAMBRIDGE SYSTEMATICS

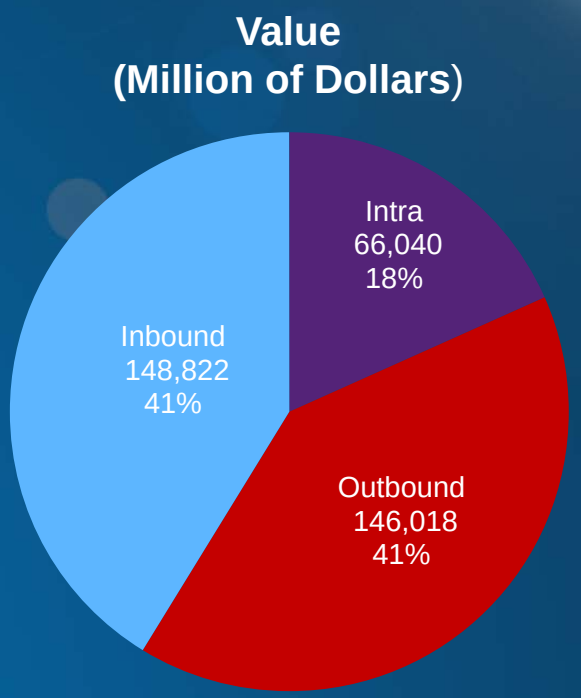
Summary of Base Year Data (2007)



Adjustments to Base Year Volumes

- Auto imports. Flows were reassigned so that total rail volumes matched the ports' statistics, with destination assigned in proportion to the volumes in the 2007 Carload Waybill Sample.
- Waste/Scrap. Base year calculated and adjusted using local municipal and industrial waste and scrap material volumes.
- Multiple other commodity groups checked with calculations from local data sources (such as pipeline flows using Kinder Morgan data). Original FAF3 volumes retains after comparison.

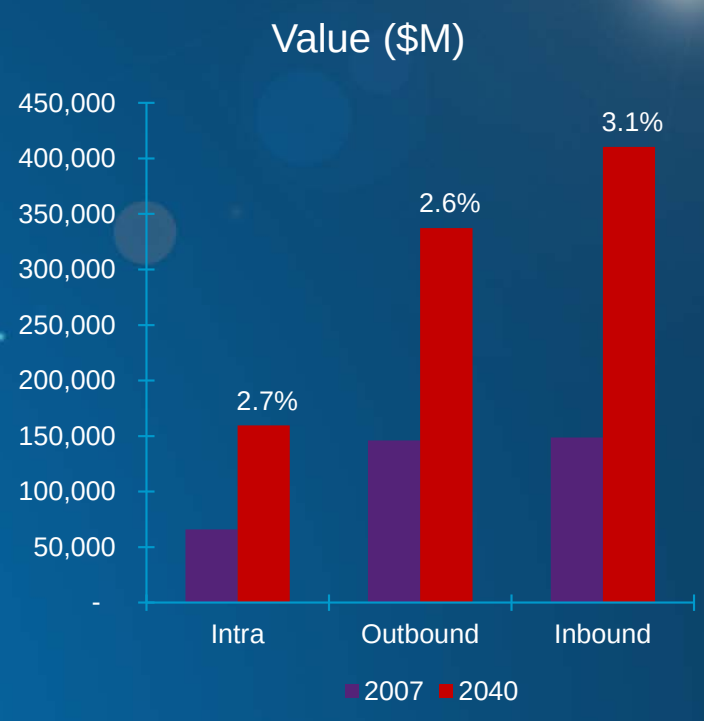
Future Year Data



Adjustments to Future Volumes

- Cereal Grain. Existing FAF forecasts for originated grain could not be supported. Grain tons were forecasted using IHS production forecasts.
- Auto imports. Flows were reassigned so that total rail volumes matched the ports' statistics, with destination assigned in proportion to the volumes in the 2007 Carload Waybill Sample.
- Non-metallic mineral products. FAF3 growth is unrealistically high. Growth rates adjusted using HIS forecast rates based on the most recent County Business Forecasts.
- Precision Instruments. FAF3 growth unrealistically high. Growth rates adjusted based on most recent version of County Business Forecasts.

CAMBRIDGE SYSTEMATICS

Summary of Written Tasks

Task F and H: Factors Specific to Top Commodity Groups for Growth and Mode

- Cereal Grains. Rail Congestion and barge congestion will have biggest impact on growth. Product likely to continue to move on rail.
- Waste and Scrap. Biggest driver of export will be price on the international market. Metallic scrap usually arrive by multiple modes to be exported by vessel. Non-metallic scrap arrives in trucks usually to be exported in containers. Shifts in modes can occur depending on demand.
- Non-Metallic Mineral Products. Domestic oil and gas production will drive imports of such products as barite. This will likely to continue move on rail, depending on rail pricing. Diversion of short haul movements to truck is also likely.
- Gasoline and Fuels. Future volume will be determined by success/failure of domestic extraction and refining of oil, and growth of alternative fuels (e.g., natural gas).

CAMBRIDGE SYSTEMATICS

Task F and H: Factors Specific to Top Commodity Groups (Cont'd)

- Precision Instrument. This time sensitive commodity can be affected by delays on roadways and rail. Air transportation can be increasingly utilized in the future in addition to road and rail.
- Machinery. Movement will grow at the pace of local and U.S. economy but can be affected by outsourcing/reshoring of production. Traditionally break-bulk moved by truck, it can be increasingly moved on intermodal rail.
- Electronics. Volumes will growth with the economy, as well as outsourcing/reshoring trends. Intermodal trucking/rail will continue, with potential increases in air shares for more time sensitive electronics.
- Motorized Vehicles. Future imports will largely be driven by domestic demand, while exports by foreign demand. Trucking/rail will continue as dominant mode of transpo

Task G: Trends/Changed in Transportation Technologies

1. Conversion of shipment from pipeline to rail (e.g., crude by rail)
2. Increase of LTL shipments of fast moving consumer goods
3. Increase in transloading of imported goods from international containers to domestic containers (40ft to 53ft containers)
4. Increased exportation of minerals and bulk products such as copper ore, LNG, and coal
5. Conversion of fuel used in freight from diesel to LNG
6. Adoption of electric vehicles for freight movements
7. Continued concern of freight movement security
8. Continued pressure to reduce health/environmental impacts from freight
9. Environmental pressure to increase fuel mileage in all vehicles

CAMBRIDGE SYSTEMATICS

Task I. Strength and Weakness of the Portland Region

Strengths	Weaknesses
• Natural advantage of Columbia River to assist in moving bulk products • Port of Portland's capacity and transfer of bulk products • Solid base and good incentive of attracting high value manufacturers • Class I and shortlines offer good modal alternative for BCOs • Port of Vancouver pipeline facility, heavy lift cranes, and other specialized facilities enable movement of gasoline, clean energy products, and other niche products.	• Increasing highway and local congestion • Limited direct airfreight service at PDX • Modal choice restricted for products sources from remote areas (e.g. ag products) • Lack of highway redundancy • Cumbersome OSOW permitting process • Few roads across coastal range, especially affecting fish and seafood
Opportunities	**Threats**
• Clustering of hi-tech sectors provide synergies and attract economy of scale and human capital. • Large dry cargo market can create possibility to attract further service if ag products, footwear/apparel shippers can cluster with hi-tech to form a strong cargo base.	• Dwindling containerized ocean carrier service can reduce competitiveness • Scarcity of industrial land for logistics • Failure to replace the Columbia River Crossing I-5 bridge that affects reliability and mobility

CAMBRIDGE SYSTEMATICS

Task J: Global Trends that Can Affect Freight Flows

- Re-shoring of Manufacturing to the U.S.
- BCOs distribution strategy shift from “push” to “pull” supply chains, and the increase of ecommerce
- Increase use of Mega Vessels
- Changing Asian demand for raw materials
- Changing demand for recycled products

CAMBRIDGE SYSTEMATICS

Task K: Potential Methodologies for Transshipment

1. TRANSEARCH approach to estimating warehouse and distribution center commodity flows as applied to the Portland – Vancouver regional commodity flow database

2. Transload secondary trip estimation methodology for the
   San Pedro Bay ports' PortTAM

3. CMAP mesoscale supply chain model

working for clean rivers

The Bureau of Environmental Services works with Portland residents and businesses to protect water quality, public health, and the environment through wastewater collection and treatment, sewer construction and maintenance, stormwater management, and stream and watershed restoration.

PHOTO COURTESY OF TRIMET

The Streamlining Agreement benefits the City of Portland and other local governments as well. The streamlining team worked with TriMet on permits for the Tilikum Light Rail Bridge across the Willamette River (above) and helped Multnomah County with permits for replacing the Sellwood Bridge.

City of Portland Streamlining Agreement

Building a collaborative process that encourages efficient and effective communication among multiple government agencies and City of Portland project teams to secure timely, responsive and non-conflicting decisions from agencies overseeing environmental permits and other authorizations

Early in 2003, Portland entered into an agreement with NOAA Fisheries, the U.S. Army Corps of Engineers (Corps) and the U.S. Fish and Wildlife Service (USFWS) to streamline stream restoration, capital improvement and other city projects that trigger Endangered Species Act requirements. It was the nation's first streamlining agreement between federal agencies and a municipal government.

The agreement brought into focus the many regulations that affect the city's work and the need for better coordination with more state and federal regulatory programs. As a result, the agreement expanded to include Oregon's state departments of Lands (DSL), Environmental Quality (DEQ) and Fish and Wildlife (ODFW) and the city's Bureau of Development Services (BDS).

The Streamlining Agreement has served Portland well. It improves working relationships with city project managers and permitting agencies, speeds project reviews, and helps keep projects on schedule and on budget. The program has issued more than 168 federal, state and local environmental permits since 2003 for nearly 60 city projects.

At a Glance

The streamlining agreement:

- Ensures timely construction and implementation of city projects
- Improves coordination, communication and agreement on permit applications and consultations
- Ensures permitted activities protect both listed and non-listed species
- Creates opportunities for overlapping jurisdictions to collaborate on key shared decisions

OCTOBER 2014

City of Portland Streamlining Agreement

Many Projects Benefit from Streamlining

The Streamlining Agreement has benefited several Portland city bureaus and other local governments. The team helped Portland Fire & Rescue gain permits for its new Station 21 at the Hawthorne Bridge and the Bureau of Transportation replace the North Vancouver Avenue Bridge. Other examples include:

Streamlining Team Members

TEAM CHAIR

Mike Reed, Water Resources Program Manager and fisheries biologist with Environmental Services

CITY OF PORTLAND

- Bureau of Development Services (BDS)

STATE AGENCIES

- Department of Environmental Quality (DEQ)
- Department of Fish and Wildlife (ODFW)
- Department of State Lands (DSL)

FEDERAL AGENCIES

- U.S. Army Corps of Engineers (Corps)
- National Marine Fisheries Service (NMFS)
- U.S. Fish and Wildlife Service (USFWS)

City bureaus and local governments that have worked with the streamlining team include:

- Fire & Rescue
- Water
- Transportation
- Environmental Services
- TriMet
- Parks & Recreation
- Portland Development Commission
- Planning and Sustainability

Portland Water Bureau

The Water Bureau worked with the streamlining team on several projects addressing pipe construction and habitat conservation efforts in the Bull Run watershed, including:

Sandy River Conduit Crossing Project

This project involved burying water pipes below river and stream crossings to reduce their vulnerability to natural and man-made hazards. The Department of Homeland Security provided funding.

Sandy River and the Bull Run Habitat Conservation Plan

This project constructed a fish ladder in Alder Creek, a tributary to the middle Sandy River, to improve fish passage for coho and steelhead at an impassable waterfall.

Post-project reviews found the streamlining process created a forum to provide information and obtain feedback, allowed minor design adjustments that minimized impacts to resources, and recommended the continued use of the process—especially for large, complex projects.

PHOTOS COURTESY OF THE WATER BUREAU

Projects included burying pipes to reduce vulnerability like these crossing the Sandy River on a 115- year-old steel truss bridge.

The fish ladder on Alder Creek improves fish passage.

"Pre-application meetings give the Corps and other agencies time to voice their concerns with project designs and discuss permit issues at an early step of the project. It is much easier to address and avoid issues earlier rather than later and try to force a project fit."

James A. Holm, U.S. Army Corps of Engineers

TriMet/Federal Transit Administration

Tilikum (Portland-Milwaukie) Light Rail Bridge Project

The 7.3-mile light rail extension to Milwaukie includes a new bridge over the Willamette River and crossings over Crystal Springs, Johnson Creek and four other streams along its route. The crossings created nearshore impacts from in-water piers and abutments requiring mitigation of the lost shallow-water habitat. Streamlining team member agencies reviewed and permitted projects to restore beaches and banks and replace a Crystal Springs Creek culvert to improve fish passage.

Multiple meetings with staff from TriMet, Environmental Services, Portland Parks & Recreation and the streamlining team helped ensure the project designs met agency concerns and expectations.

"The City of Portland's streamlining team meetings are very useful and important from our agency's perspective. The sooner that we can provide guidance in the planning process the better. Early interaction and communication will result in a more effective permitting process."

Michael V. McCabe, formerly of the Oregon Department of State Lands

Bureau of Environmental Services

Guilds Lake/Willamette River Sanitary Sewer Pressure Line Repair Project

In 2004, Environmental Services discovered that erosion had exposed two parallel sanitary sewer lines – one 20-inch line and one 30-inch line – at the bottom of the Willamette River. The bureau had to protect the pipes to avoid a line break that would release raw sewage into the river. The pipes are located in the Portland Harbor Superfund site and were in an area where the DEQ planned to construct a sediment cap. Funding for sediment cap construction was due to expire in 2005.

Early communication between the agencies and project team and the level of trust and commitment by the streamlining team helped the project receive all federal, state and local permits in about two months, which for such a complex project was a very short time. Agencies recognized the urgency of the situation and the city's project manager did an excellent job communicating and incorporating project design features to address multiple regulatory concerns and issues.

PROGRAM HISTORY AND MILESTONES

2001
Portland Mayor Vera Katz introduces her vision for a partnership with federal agencies to help the city address multiple regulatory requirements in a more coordinated, efficient manner.

2002
The city and federal agencies agree to participate in a streamlining process for Endangered Species Act (ESA) Section 7 consultations.

FEBRUARY 2003
City of Portland, the Corps, NMFS and USFWS sign an agreement to streamline ESA Section 7 consultations.

FEBRUARY 2006
Oregon Governor Ted Kulongoski and **Portland Mayor Tom Potter** invite **State** agencies to participate.

NOVEMBER 2006
Portland's **Bureau of Development Services** joins the streamlining team.

SEPTEMBER 2009
Five-year status report presented to **Mayor Sam Adams and City Council**. Participants agree to continue the program.

APRIL 2013
State Land Board presents the streamlining team with the **2012 Land Board Partnership Award**.

JUNE 2014
The **Hatfield School of Government's Center for Public Studies** conducts a third-party review of the streamlining team process and endorses the city's streamlining program.

Center for Public Service endorses City of Portland Streamlining Process

In 2014, the Hatfield School of Government's Center for Public Service (CPS) assessed the permit streamlining program. CPS reviewed program reports and documents; met with the team's chair; and interviewed team members, city project managers, consultants and city leaders about the program.

The assessment found the streamlining process:

- Fosters constructive relationships (among the most important benefits of the process)
- Builds trust through collaborative relationships between city project managers and regulators
- Ensures compliance with city, state and federal environmental regulations
- Builds and maintains consistency in messaging and decision-making
- Leads to final project designs that meet expectations and concerns
- Reduces permit processing time

The Hatfield School of Government Center for Public Service assessment of the streamlining team process found there were time and cost savings through process efficiency, consistent regulatory decisions and opportunities for constructive relationships with regulators.

LOOKING AHEAD

The Hatfield School of Government's Center for Public Service has endorsed the Streamlining Agreement and recommended that the streamlining team:

- Continue the collaborative and voluntary nature of the process, the consistency and efficiency of the team process, and continue building relationships
- Develop outreach to inform senior leaders of participating agencies about the value of the process
- Continue to assess and improve the streamlining process
- Explore exporting the process to other jurisdictions

The full report is available by contacting Streamlining Team Chair Mike Reed.

City of Portland Streamlining Team received 2012 Land Board Partnership Award

Citing ten years of collaborative work, the State Land Board honored the streamlining team on April 9, 2013 with the 2012 Land Board Partnership Award, which recognizes exemplary partnerships with the board and Department of State Lands.

Governor John Kitzhaber, chair of the Land Board, praised the Streamlining Team members for their "**...cooperative, multi-agency approach to waterway permitting. Their work results in a more streamlined process, less time spent on resolving issues, and better outcomes for applicants and the regulatory agencies.**"

At the award ceremony: *(from left to right) State Treasurer Ted Wheeler, Secretary of State Kate Brown, James Holm (Corps), Kathy Roberts (USFWS), Mike McCabe (DSL), Governor John Kitzhaber, Mike Reed (BES, Chair), Liz Ruther (ODFW), Christy Fellas (NMFS), Ben Meyer (NMFS), Corey Saxon (DEQ).*

Task 3 – Updated Compliance Scenarios

Final Report

August 2014

Prepared for
Oregon Department of Environmental Quality
811 SW 6th Avenue
Portland, OR 97204-1390

Prepared by
ICF International
75 E. Santa Clara St. Suite 300
San Jose, CA 95113
408.216.2800

ICF conducted this work under contract with the Oregon Department of Environmental Quality. The fuel volumes presented in this document are meant to be illustrative of compliance with a proposed Clean Fuels Program in Oregon. ICF developed the compliance scenarios in a manner consistent with our scope of work with Oregon DEQ, and as we do in all of our work, we strive to provide information and projections consistent with standard practices in a professional manner. These compliance scenarios, however, should not be confused with ICF market forecasts. These compliance scenarios reflect the fuel volumes that could be delivered to Oregon to comply with a Clean Fuels Program based on our understanding of transportation fuel availability today and projected transportation fuel availability. ICF makes no warranties express or implied (including without limitation any warranties or merchantability or fitness for a particular purpose), as to this material. Specifically but without limitation, ICF makes no warranty or guarantee regarding the accuracy of these scenarios or that such work products will be accepted by any legal or regulatory body.

Executive Summary

The clean fuel standard in Oregon, implemented by the Clean Fuels Program, requires a 10% reduction in carbon intensity from the gasoline and diesel baselines over a ten year period. In addition to carbon intensity reduction, the Clean Fuels Program helps Oregon reduce its consumption of traditional petroleum fuels. Potential fuels that could be used to achieve the standard are ethanol, biodiesel, hydrogen, electricity, natural gas, propane, and biogas. The Clean Fuels Program is designed as a performance-based standard using flexible market-based mechanisms that allow regulated parties to select the most cost-effective pathways to achieve compliance. In general, fuels that have a lower carbon intensity than gasoline or diesel generate credits. Regulated parties, such as refiners, have the option of producing or blending low carbon fuels, or purchasing credits from other fuel providers, including, but not limited to biofuel producers, natural gas infrastructure providers, electric utilities, and hydrogen producers.

As part of Oregon Department of Environmental Quality's (DEQ) original rulemaking and advisory committee process in 2010, technical analysis was performed by TIAX LLC to develop an Oregon specific business-as-usual (BAU) and compliance scenarios for a Clean Fuels Standard. As part of the previous analysis, assumptions were made around the composition of the vehicle fleet, carbon intensities, and availability of low carbon fuels for compliance both in Oregon and out-of-state. Four years later there is a greater understanding of the vehicles and fuels that could be available and new regulations and developments that will affect Oregon's fleet composition and fuel consumption.

This report is the final phase of the process to update the Clean Fuels Program compliance scenarios. The previous report detailed the updated BAU case and this report describes in detail the methodology used to develop the four compliance scenarios, available fuels and technologies and the resulting compliance scenarios. Compliance scenarios for the Clean Fuels Standard are compared against the updated BAU to determine incremental fuels required to achieve the scenarios.

ICF, in consultation with Oregon DEQ, developed four compliance scenarios based on two fuel scenarios (alternative vehicle technologies vs biofuel blending) and two different diesel baselines (B2 vs B5). Table 1 below shows the compliance scenario matrix.

Table 1. Compliance Scenarios

Compliance Scenarios	Scenario 1 – Advanced Vehicle Technology	Scenario 2 – Higher Biofuel Blending
B2 Diesel Baseline (2010)	1 – B2	2 – B2
B5 Diesel Baseline (2015)	1 – B5	2 – B5

The key highlights of the CFP compliance scenarios include:

- **Over-compliance in the early years of the program (2016-2021) is critical**. Credits can be banked and traded later and do not lose their value. Banking credits when the standard is lower reduces compliance costs and eases compliance in later years.
- **The Clean Fuels Standard can be achieved through a diverse fuel supply.** All of the scenarios required a combination of ethanol, biodiesel and renewable diesel from various feedstocks, electricity, natural gas, renewable natural gas, and propane for compliance. In addition, none of the analyzed compliance scenarios required the use of cellulosic ethanol.
- **Eight (8) years of overlap between the post-2017 Zero Emission Vehicle (ZEV) Program eases the burden of compliance**. The ZEV Program generates almost 15% of the cumulative credits needed over the compliance period. California only overlaps three (3) years with the post-2017 ZEV Program which limits the contribution electric and fuel cell vehicles can have towards compliance in their LCFS.
- **A B5 baseline compared to a B2 baseline results in greater greenhouse gas (GHG) emission reductions**. The B5 baseline scenarios generate more deficits than the B2 baseline scenarios and therefore require more credits for compliance. This results in an increased consumption of biodiesel and renewable diesel and lower cumulative GHG emissions over the compliance period.
- **Renewable natural gas is a key fuel for Clean Fuels Standard compliance**. In the advanced technology scenarios, renewable natural gas generated just as many credits as electricity and about one-third the amount credits generated from ethanol or biodiesel. In addition, Oregon has significant in-state potential for renewable natural gas production.
- **Renewable Diesel, even only in small volumes, is needed for compliance**. Renewable diesel does not require additional distribution or refueling infrastructure and there are no blend limitations.

Page 5868

1 Introduction

The clean fuel standard in Oregon, implemented by the Clean Fuels Program (CFP), requires a 10% reduction in carbon intensity from the gasoline and diesel baselines over a ten year period. In addition to carbon intensity reduction, the Clean Fuels Program helps Oregon reduce its consumption of traditional petroleum fuels. Potential fuels that could be used to achieve the standards are ethanol, biodiesel, hydrogen, electricity, natural gas, propane, and biogas. Task 3 developed updated compliance scenarios. Compliance scenarios for the Clean Fuels Standard are being compared against the updated BAU to determine incremental fuels required to achieve the scenarios.

As part of Oregon DEQ's original rulemaking and advisory committee process in 2010, technical analysis was performed by TIAX LLC to develop an Oregon specific BAU and compliance scenarios for a Clean Fuels Standard. The VISION model was used to quantify the amount of fuels, infrastructure, and investment required for the BAU scenario. VISION is a fleet sales and turnover model developed by Argonne National Laboratory that can be used to quantify future energy consumption and GHG emissions based on overall fleet characteristics and composition. It is important to understand the fleet composition when considering alternative fuel consumption. Many alternative fuels including E85 (blended ethanol and gasoline with 85% by volume ethanol), electricity and natural gas require new vehicles to be purchased or converted and maximum consumption of these fuels is constrained by the population of these vehicles within the fleet.

As part of the previous analysis, assumptions were made around the composition of the vehicle fleet, carbon intensities, and availability of low carbon fuels for compliance both in Oregon and out-of-state. Four years later there is a greater understanding of the vehicles and fuels that could be available and new regulations and developments that will affect Oregon's fleet composition and fuel consumption. The latest available version of the VISION model, "VISION 2013 AEO Base Case,"[1] was used to develop the updated BAU scenario and the compliance scenarios. After completing BAU case, ICF and DEQ agreed on the assumptions to update the compliance scenarios. The following document details the methodology for developing the compliance scenarios.

[1] http://www.transportation.anl.gov/modeling_simulation/VISION/

2 Methodology: Scenario Development

ICF developed four (4) Clean Fuels Program compliance scenarios based upon input and discussion with Oregon DEQ. The following subsections review the methodology for developing the compliance scenarios and compliance schedules.

2.1 Compliance Scenarios and Clean Fuels Compliance Schedules

Compliance Scenarios

From a broad perspective, there are two ways to deploy alternative fuels that will help comply with a Clean Fuels Program. Firstly, biofuels can be blended into conventional gasoline or diesel for consumption in the existing vehicle fleet. Secondly, advanced vehicle technologies can be deployed, which consume alternative fuels such as natural gas, electricity, or hydrogen. Compliance with a Clean Fuels Program will require a diverse mix of all of these alternative fuels. Due to constraints on how quickly the vehicle fleet can be turned over, biofuel blending will likely be a major form of compliance until advanced vehicle technologies are deployed in significant numbers.

ICF developed two fuel scenarios – Scenario 1 and Scenario 2 – to capture the potential market responses to achieve compliance with a Clean Fuels Program. Scenario 1 reflects a market that is more dependent on advanced vehicle technologies than Scenario 2 and puts less pressure on advanced biofuels and biofuel blending for compliance. ICF will account for a variety of market developments in the compliance scenarios including the immediate availability of lower carbon biofuels such as biodiesel from waste greases, and animal fats; renewable diesel from tallow; and ethanol from sorghum and lower carbon intensity corn. Although cellulosic biofuels have been produced at a slower-than-expected rate, these lower carbon biofuels are available to California in significant quantities today and supply is forecasted to increase dramatically over the next several years.

Apart from biofuels, increasing natural gas supplies and lower fuel pricing than diesel have renewed interest in natural gas in the transportation sector. The use of low carbon biomethane (also referred to biogas and renewable natural gas) from waste sources including landfills and wastewater treatment plants in natural gas vehicles is projected to be a major compliance pathway. Biomethane is currently consumed in large volumes in California for LCFS compliance and EPA has qualified biomethane from landfills and other sources to generate cellulosic renewable identification numbers (RINs).

The Oregon Renewable Fuel Standard biodiesel blend mandate was 2% by volume (B2) in 2010 and increased to 5% (B5) in April 2011. The previous Clean Fuels Program analysis included a B2 diesel baseline. ICF will analyze the effects of compliance with a B2 compared to a B5 diesel baseline for both Scenarios as shown in the table below. Before DEQ selects a baseline and compliance schedule for the regulation, it is important to understand the implications. A B2 diesel is consistent with when the regulation was conceived in 2009 and analysis was performed in 2010 and allows for built-in credit generation from the B2 to B5 blend levels that are currently mandated. A B5 diesel baseline is consistent with the regulatory landscape in 2015 when the compliance schedule would begin in 2016.

Table 2. Compliance Scenarios

Compliance Scenarios	Scenario 1 – Advanced Vehicle Technology	Scenario 2 – Higher Biofuel Blending
B2 Diesel Baseline (2010)	1 – B2	2 – B2
B5 Diesel Baseline (2015)	1 – B5	2 – B5

Development of Compliance Schedules

The Oregon Clean Fuels Program is proposing using a similar percent reduction compliance schedule for the 10 year period as the California LCFS. To develop the actual numerical compliance schedule carbon intensities, ICF needed to develop baseline carbon intensity values for gasoline containing 10% by volume ethanol (E10), B2 and B5. Table 3 below shows the development of the baseline carbon intensities for E10, B2 and B5. Table 4 and Figure 1 show the compliance schedule for E10, B2 and B5 using the baseline carbon intensities in Table 3.

Table 3. Baseline Carbon Intensity Calculation

Baseline Fuels	Carbon Intensities (gCO2e/MJ)	Biofuel by Volume (%)	Biofuel by Energy (%)	Baseline Carbon Intensity (gCO2e/MJ)
Gasoline Pool – E10	Gasoline Blendstock – 89.40 Midwest Corn Ethanol – 88.02	10%	6.7%	89.31
Diesel Pool – B2	ULSD – 89.00 Biodiesel – 47.70[2]	2.27%	2.1%	88.13
Diesel Pool – B5	ULSD – 89.00 Biodiesel – 47.70[2]	5%	4.6%	87.09

[2] Weighted average of soybean, canola and used oil biodiesel based on individual carbon intensities of 50.19, 68.91 and 10.28 gCO2e/MJ and 2013 reported consumption volumes for the first six months of 13.66 million gallons, 4.37 million gallons and 3.39 million gallons for soybean, canola and used oil biodiesel, respectively.

Table 4. Gasoline and Diesel Compliance Schedules

Compliance Year	Percent Reductions	Gasoline Compliance Schedule	B2 Baseline Diesel Compliance Schedule	B5 Baseline Diesel Compliance Schedule
2015	-	89.31	88.13	87.09
2016	0.25%	89.08	87.91	86.87
2017	0.50%	88.86	87.69	86.65
2018	1.0%	88.41	87.25	86.22
2019	1.50%	87.97	86.81	85.78
2020	2.50%	87.08	85.93	84.91
2021	3.50%	86.18	85.05	84.04
2022	5.00%	84.84	83.73	82.73
2023	6.50%	83.50	82.40	81.43
2024	8.0%	82.16	81.08	80.12
2025	10.0%	80.38	79.32	78.38

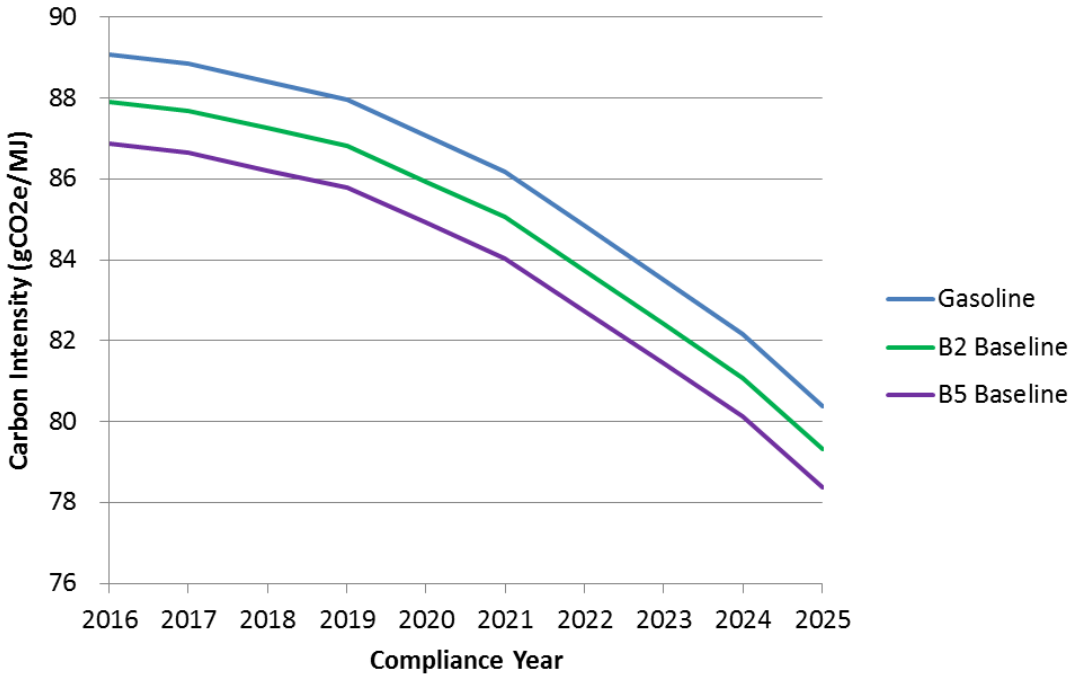

Figure 1. Gasoline and Diesel Compliance Schedules

2.2 Compliance Options Considered

ICF considered a variety of low carbon fuels to develop representative CFP compliance scenarios. Furthermore, to determine the balance of deficits and credits in each compliance scenario, ICF made various assumptions regarding how vehicles and fuels will be used in the near-term future towards CFP compliance. These are distinguished between fuels that substitute for gasoline (the gasoline pool) and fuels that substitute for diesel (the diesel pool).

Fuels that Substitute for Gasoline

ICF assumed that ethanol would continue to be blended into gasoline at a rate of 10 percent by volume, consistent with today's reformulated gasoline requirements. ICF limited the blending of ethanol with gasoline at a maximum of 15 percent by volume based on EPA's recently issued waiver for E15 in vehicle model years (MY) 2001 or newer. In addition, ICF included the potential of E85 consumption in flex-fuel vehicles (FFVs) if significant low carbon ethanol consumption is required for compliance. Although there is no E15 consumed in Oregon today – and very little generally in the United States – E15 could be consumed in meaningful quantities in Oregon as a result of drivers such as LCFS and the RFS2.

ICF considered the following pathways for ethanol production:

- **Corn, MW**: Corn from conventional processes is typically sourced from the Midwest. Corn has been and continues to be the most common feedstock for ethanol consumed in Oregon. Nearly 200 million gallons of corn ethanol are currently consumed in Oregon to meet the state's E10 requirement.
- **Corn, Boardman, OR**: The Boardman, OR ethanol facility currently produces 26 million gallons of corn ethanol per year. We assumed the same pathway carbon intensity from the 2010 plus the proposed CARB indirect land use change (ILUC) values.
- **Corn, low carbon intensity**: There is significant potential to lower the carbon intensity of corn ethanol through a variety of measures. For the purposes of this report, ICF assumed a lower limit of 46 g/MJ for what we term low carbon intensity corn ethanol (not including ILUC). There has already been a shift towards more efficient corn ethanol production as a result of the California LCFS, with many new lower carbon pathways submitted to and approved by CARB. The MW corn carbon intensity will exceed the gasoline standard in 2019 and ICF assumes by 2019 only ethanol meeting the standard will be consumed within Oregon with low carbon intensity corn will make up the balance of ethanol consumed in Oregon to meet the state's E10 requirement.
- **Corn, Sorghum**: There is a shift occurring towards lower carbon intensity feedstocks for ethanol production including grain and sweet sorghum as a result of the California LCFS. Based on the volumes of current applications submitted to CARB, ICF assumes that upwards of 100 million gallons per year of sorghum or other low carbon intensity feedstock ethanol will be available to Oregon by 2019 when the MW corn carbon intensity exceeds the gasoline standard.
- **Sugarcane**: Most sugarcane ethanol is produced in Brazil and shipped via tanker to the United States. In some cases, hydrous ethanol is shipped to a country in the Caribbean Basin Initiative (CBI); the excess water is subsequently removed and the anhydrous ethanol is shipped to the US. This step was more common when the US had a tariff on sugarcane ethanol imported directly from Brazil; the interim step allowed importers to avoid paying the tariff. For the sake of reference, the United

LUBA No. 2020-009
Page 5873

States imported 500 million gallons of sugarcane ethanol in 2012. ICF assumes that up to 50 million gallons per year of sugarcane ethanol could be consumed in Oregon.

- **Cellulosic**: Cellulosic ethanol refers generally to ethanol produced from wood, grasses, or other lignocelluosic materials.

Although ethanol from various feedstocks is the primary substitute for gasoline today, ICF also considered the following fuels that substitute for gasoline:

- **Electricity** used in plug -in electric vehicles (PEVs), including plug-in hybrid electric vehicles (PHEVs) and battery electric vehicles (BEVs), stands to play an important role towards compliance, particularly in later years of the regulation as the Zero Emission Vehicle (ZEV) Program takes full effect. In each of the compliance scenarios, a minimum number of PEVs was deployed to be consistent with business as usual case. For Scenario 1, ICF also considered the potential for all PHEVs in the BAU to be PHEV40s and not a split between PHEV10 and PHEV40.
- **Natural gas** has significant potential to displace gasoline consumption in medium-duty and light heavy-duty vehicles.
- **Biogas** has the potential to displace natural gas consumption and create significant reductions in carbon intensity. It is assumed that up to 47 million diesel gallon equivalents of biogas, comparable to Oregon in-state feedstock potential, could be consumed.

The table below shows the carbon intensity values used for fuels that substitute for gasoline. Unless otherwise noted, the carbon intensity values were taken directly from 2010 analysis with updates for CARB proposed ILUC values tables.

Page 5874

Table 5. Carbon Intensity Values for Fuels that Substitute for Gasoline

Fuel / Feedstock	Pathway Carbon Intensity (gCO2e/MJ)	ILUC (gCO2e/MJ)[a]	Updated CI (gCO2e/MJ)
Ethanol, MW Corn	64.82	23.20	88.02
Ethanol, Boardman	56.99	23.20	80.19
Ethanol, Low CI Corn	46.00	23.20	69.20
Ethanol, Sorghum	46.00	23.20	69.20
Ethanol, Sugarcane	26.44	26.50	52.94
Ethanol, Cellulosic[b]	18.22	2.5	20.72
Natural Gas (CNG/LNG) and Propane[c]	71.41	-	71.41
Biogas, multiple sources[d]	25.00	-	25.00
Electricity, marginal [e]	45.58	-	45.58

[a] ILUC values are proposed CARB values presented on March 11, 2014

[b] The average of previous Oregon pathways for ethanol from farmed trees and wheatstraw

[c] Assumes propane is mainly from natural gas liquids

[d] Representative of California LCFS applications for biogas used as CNG or LNG

[e] Includes the energy economy ratio (EER) of 3.4 for electric vehicles

Fuels that Substitute for Diesel

The fuel volumes in the compliance scenarios represent a combination of ICF research and previous project experience which includes input provided by the National Biodiesel Board (NBB). In the development of the compliance scenarios, we considered the following feedstocks for biodiesel:

- **Soybean oil**: Soybean oil is the largest single feedstock for biodiesel production in the United States. It is a well-established crop with a robust commodity market. While most soybeans are grown in the Midwest and a significant amount of biodiesel production capacity exists in the Midwest, Oregon biodiesel capacity can also utilize soybean oil. Soybean oil biodiesel is used as the balance biodiesel to make up necessary volumes to achieve desired blend levels.
- **Waste Grease/Used Oil**: Waste grease is a significant feedstock at Oregon production facilities. As a waste feedstock, waste grease has a low carbon intensity. The production process for biodiesel from waste grease is generally more energy intensive than for vegetable oils because there is generally a higher free fatty acid content. This requires an additional acid-catalyzed esterification reaction, thereby increasing the energy inputs. For the compliance scenarios, waste grease is assumed to remain constant at 15.8% of all biodiesel consumed based on the first 6 months of data from 2013.
- **Canola oil**: Canola oil is similar to soybean oil as a feedstock; it is more prominent feedstock in the European Union (referred to there as rapeseed). In North America, canola production historically exists primarily in Canada and northern states of the US and is a significant feedstock for Oregon

LUBA No. 2020-009
Page 5875

based biodiesel production. For the compliance scenarios, canola oil is assumed to remain constant at 20.4% of all biodiesel consumed based on the first 6 months of data from 2013.

- **Corn oil**: Corn oil is a byproduct of corn ethanol production and generally requires retrofitting an ethanol plant. It is a feedstock with significant growth potential for the biodiesel industry. Corn oil extraction is a relatively new commodity for the majority of ethanol production facilities, but represents another high-value co-product. Anecdotal evidence indicates that the majority of corn ethanol facilities in the US will have installed equipment to extract corn oil by the end of 2013. Corn oil biodiesel will be used as needed for the compliance scenarios.

ICF also considered the following alternative fuels:

- **Renewable diesel**: Like biodiesel, there are multiple feedstocks that can be used to produce renewable diesel, including palm oil, canola (or rapeseed) oil, jatropha oil, camelina oil, soy oil, waste greases, and animal fats (i.e., tallow). ICF considered renewable diesel produced from tallow and waste oil; this pathway is largely based on the availability of renewable diesel produced by Neste Oil in its Singapore production plant using its renewable diesel production process. A conservative assumption was made that maximum renewable diesel would be an average statewide 2% blend with a maximum of 10 million gallons per year from tallow and the balance from waste oil.
- **Natural gas**: ICF considered the potential for natural gas – compressed, liquefied, and biogas – in heavy-duty applications such as short-, medium-, and long-haul trucks, refuse haulers, and transit buses. It is assumed that up to 47 million diesel gallon equivalents of biogas, comparable to Oregon in-state feedstock potential, could be consumed. For Scenario 1, it is assumed that medium and heavy duty CNG vehicle sales increase to the point where 10% of diesel pool fuel consumption in 2025 is a combination of natural gas, biogas and LPG.
- **Propane** has potential to displace diesel consumption in medium-duty and light heavy-duty vehicles in niche applications. It is assumed that propane consumption will reach a maximum of 1% of total natural gas consumption. Since it is assumed that fossil fuel natural gas and propane have the same carbon intensity, the quantities of each fuel summing to the total are fungible.
- **Hybrid-Electric Vehicles (HEVs)**: HEVs do not consume alternative fuels; they do reduce the quantity of diesel consumed. In Scenario 1, the assumption is made that HEVs achieve 10% sales penetration in the medium- and heavy-duty markets. The BAU case and Scenario 2 do not included medium- and heavy-duty HEVs.

The table below includes the carbon intensity values used to determine the balance of deficits and credits in each scenario. Unless otherwise noted, the carbon intensity values were taken directly from 2010 analysis with updates for CARB proposed ILUC values tables.

LUBA No. 2020-009
Page 5876

Table 6. Carbon Intensity Values for Fuels that Substitute for Diesel

Fuel / Feedstock	Pathway Carbon Intensity (gCO2e/MJ)	ILUC (gCO2e/MJ)[a]	Updated CI (gCO2e/MJ)
Biodiesel, soy oil	19.99	30.20	50.19
Biodiesel, waste grease	10.28	-	10.28
Biodiesel, corn oil	4.00	-	4.00
Biodiesel, canola oil	27.31	41.60	68.91
Renewable diesel, tallow	16.85	-	16.85
Renewable diesel, waste oil	10.28	-	10.28
Natural Gas and Propane [b]	79.34	-	79.34
Biogas, landfill [c]	27.78	-	27.78

[a] ILUC values are proposed CARB values presented on March 11, 2014

[b] Assumes propane is mainly from natural gas liquids; includes the EER of 0.9 for spark ignition CNG vehicles

[c] Representative of California LCFS applications for biogas used as CNG or LNG; includes the EER of 0.9 for spark ignition CNG vehicles

3 Overview of Compliance Scenarios

Based on the alternative fuels available for each compliance scenario and two diesel baselines described in Section 2, ICF developed four (4) different scenarios that achieve compliance with the Clean Fuels Program by balancing the cumulative deficits and credits over the 10 year compliance period.

Table 7. Overview of Clean Fuels Program Compliance Scenarios

Scenario	Ethanol	Biodiesel (BD) / Renewable Diesel (RD)	Natural Gas	Advanced Vehicles (PEVs / MD-HD HEVs)
Scenario 1-B2	Maintained E10 blend rate 50 million gallons per year (MGPY) of sugarcane ethanol for all years 100 MGPY of sorghum and balance ethanol required from low CI corn in 2019 when MW corn greater than standard	Maintained BD blend at 5% and canola/soy/used oil ratios RD at 1% in 2021 and increases to 2% by 2025; between 5-10 MGPY from tallow, balance waste oil	Natural gas vehicle market share increased till 10% diesel pool consumption is natural gas (18% market share in 2025) By 2019, 50% of natural gas from biogas (46 MGPY in 2025)	All PHEVs are PHEV40 MD-HD HEV sales increased to 10% market share by 2025
Scenario 1-B5	Same as Scenario 1-B2	BD blend to 6% in 2023 and 7% in 2025; maintained canola/soy/used oil RD 2% from 2016-2025 with 10 MGPY from tallow and balance waste oil	Same as Scenario 1-B2	Same as Scenario 1-B2
Scenario 2-B2	Same as Scenario 1-B2	Biodiesel blend to 6% in 2021 up to 8.9% in 2025; maintained canola/soy/used oil RD 2% from 2016-2025 with 10 MGPY from tallow and balance waste oil	By 2019, 100% of natural gas from biogas (12 MGPY in 2025)	Same as BAU
Scenario 2-B5	Same as Scenario 1-B2	BD blend to 6% in 2019 up to 10% in 2021; maintained canola/soy/used oil till 2020, capped canola at 10 MGPY and (2020) and waste oil at 30 MGPY (2023) RD 2% from 2016-2025 with 10 MGPY from tallow and balance waste oil	Same as Scenario 2-B2	Same as BAU
Assumptions for All Scenarios	Maximum ethanol blend is E15 FFVs 85% of miles on E85 Maximums for ethanol: Sorghum-100 MGPY; Low CI Corn-150 MGPY; Sugarcane- 50 MGPY			Achieves ZEV compliance BAU vehicle populations: 90,000 BEVs in 2025; 61,000 PHEV10 in 2025; 62,000 PHEV40 in 2025

3.1 Compliance Scenarios 1-B2 and 1-B5

Summary Overview of Compliance Scenarios 1-B2 and 1-B5

Figure 2 and Figure 3 on the following page show the annual credits and deficits generated for Scenarios 1-B2 and 1-B5. Each colored stacked bar represents credits generated from low carbon fuels; the blue line represents the deficits from forecasted gasoline blendstock and ultra-low sulfur diesel (ULSD) consumption. When the bars in years 2016-2021 exceed the blue line, annual credits exceed annual deficits and banked credits are generated for future compliance. When the bars fall short of the blue line in years 2022-2025, banked credits are required to meet annual compliance. The stacked bars are grouped by biofuels for blending at the bottom and advanced vehicle technologies at the top. Table 8 and Table 9 below show the annual deficits and credits generated and cumulative (banked) credits.

Table 8. Credits and Deficits: Banking in Scenario 1-B2

Fuel		2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Deficits (Millions)	Gasoline	-0.05	-0.08	-0.14	-0.20	-0.32	-0.43	-0.59	-0.75	-0.89	-1.08
	Diesel	-0.11	-0.13	-0.18	-0.22	-0.31	-0.40	-0.53	-0.65	-0.78	-0.93
Credits (Millions)	Gasoline Subs	0.22	0.23	0.25	0.57	0.60	0.63	0.64	0.66	0.68	0.68
	Diesel Subs	0.21	0.22	0.24	0.29	0.32	0.41	0.43	0.48	0.49	0.53
Balance		0.28	0.24	0.17	0.44	0.28	0.20	-0.05	-0.26	-0.49	-0.79
Banked (Net)		0.28	0.51	0.68	1.12	1.40	1.60	1.55	1.29	0.80	0.00

Table 9. Credits and Deficits: Banking in Scenario 1-B5

Fuel		2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Deficits (Millions)	Gasoline	-0.05	-0.08	-0.14	-0.20	-0.32	-0.43	-0.59	-0.75	-0.89	-1.08
	Diesel	-0.21	-0.23	-0.28	-0.32	-0.41	-0.50	-0.62	-0.74	-0.85	-1.00
Credits (Millions)	Gasoline Subs	0.22	0.23	0.25	0.57	0.60	0.63	0.64	0.66	0.68	0.68
	Diesel Subs	0.33	0.34	0.36	0.42	0.44	0.46	0.49	0.54	0.56	0.59
Balance		0.30	0.26	0.19	0.46	0.31	0.16	-0.09	-0.29	-0.50	-0.81
Banked (Net)		0.30	0.56	0.75	1.22	1.53	1.69	1.60	1.31	0.81	0.00

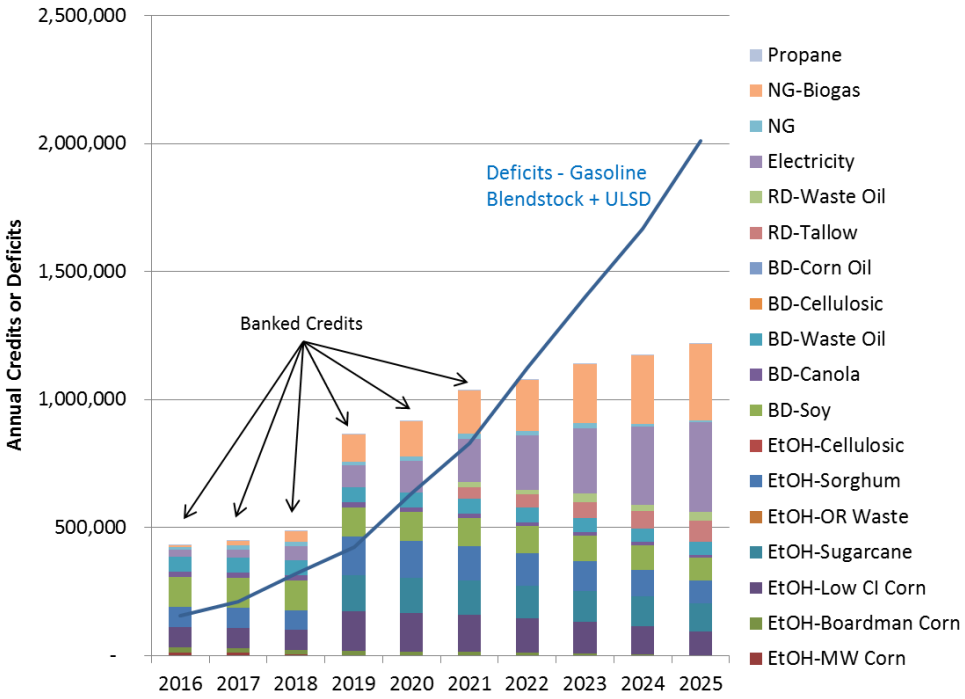

Figure 2. Balance of Credits and Deficits in Scenario 1-B2

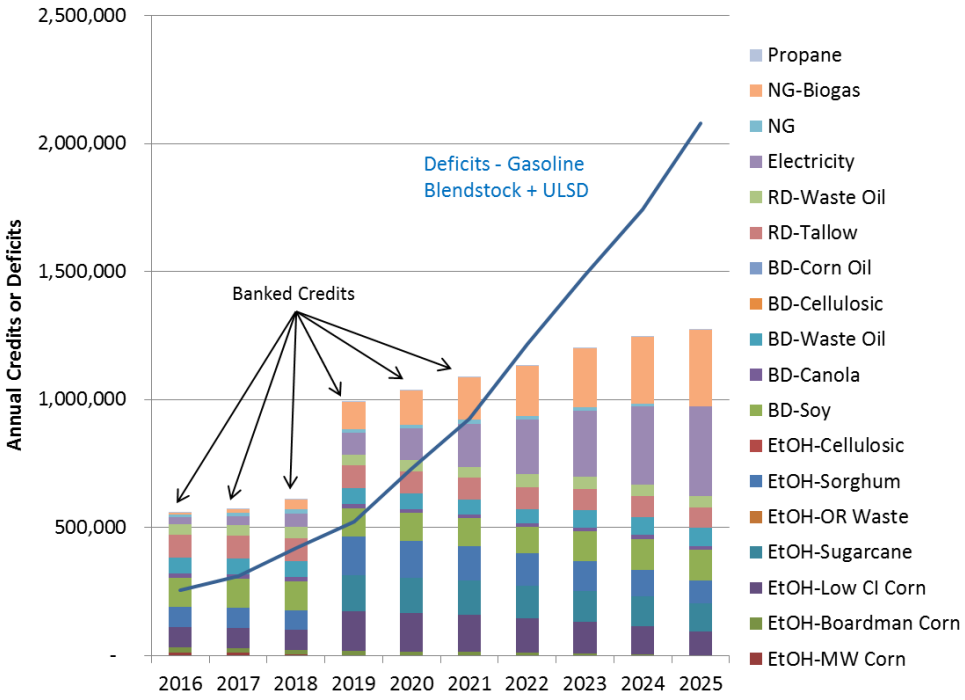

Figure 3. Balance of Credits and Deficits in Scenario 1-B5

In Scenario 1-B2, gasoline and diesel generate a similar number of deficits while in Scenario 1-B5 diesel generates almost 1 million more deficits than gasoline.

Fleet Changes from the BAU

Two fleet changes occurred between the BAU and Scenario 1 (both 1-B2 and 1-B5). In the light-duty fleet, all PHEVs are PHEV40s compare to the 50/50 split between PHEV10 and PHEV40 in the BAU. Figure 4 below shows the Scenario 1 light-duty vehicle fleet.

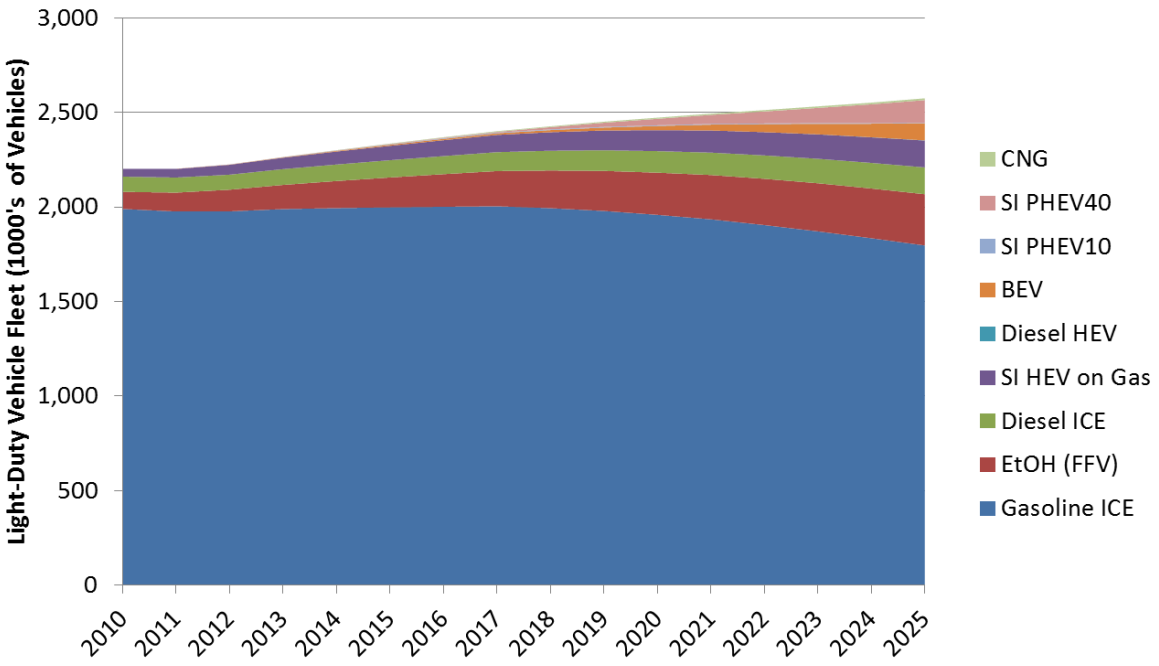

Figure 4. Scenario 1 Light-Duty Vehicle Fleet

The medium- and heavy-duty market shares for HEVs and natural gas/LPG vehicles were increased in Scenario 1 over the BAU case. The natural gas vehicle market shares were increased to achieve 10% diesel pool fuel consumption from natural gas/LPG. This assumption resulted in 18% market share of natural gas/LPG vehicles in 2025. The medium- and heavy-duty market shares for HEVs were increased to 10% by 2025. Figure 5 below shows the resulting Scenario 1 medium- and heavy-duty vehicle fleet.

LUBA No. 2020-009
Page 5882

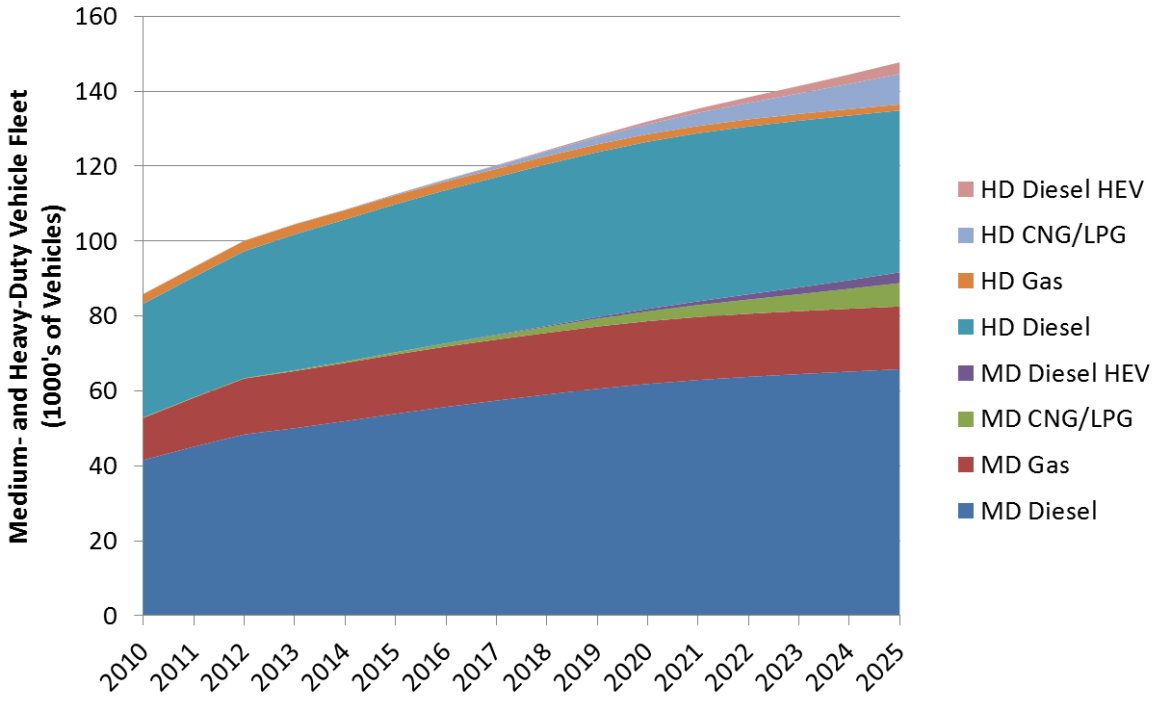

Figure 5. Scenario 1 Medium- and Heavy-Duty Fleet

Ethanol and Biofuels that Substitute for Gasoline

Table 10 below identifies the volumes of ethanol, broken down by feedstock, for both Scenarios 1-B2 and 1-B5. The ethanol volumes and feedstocks between 1-B2 and 1-B5 are identical.

Table 10. Ethanol Volumes (in million gallons) in Scenario 1

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Corn, MW	135.14	142.19	147.62	0	0	0	0	0	0	0
Corn, Boardman	26	26	26	26	26	26	26	26	26	26
Low CI Corn	50	50	50	102.18	104.72	106.05	106.86	106.38	104.56	102.26
Sugarcane	0	0	0	50	50	50	50	50	50	50
Sorghum	50	50	50	100	100	100	100	100	100	100
Total	261.14	268.19	273.62	278.18	280.72	282.05	282.86	282.38	280.56	278.26
% EtOH in Gasoline	10%	10%	10%	10%	10%	10%	10%	10%	10%	10%

Scenarios 1-B2 and 1-B5 consume very similar volumes of ethanol to the BAU case since all cases maintain a 10% ethanol blend. Scenarios 1-B2 and 1-B5 cease to consume MW corn ethanol by 2019 since the carbon intensity of MW Corn exceeds the standard in that year and every subsequent year.

Biodiesel

Table 11 and Table 12 below show the volumes of biodiesel, by feedstock, consumed in Scenarios 1-B2 and 1-B5.

Table 11. Biodiesel Volumes (in million gallons) in Scenario 1-B2

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Soy	24.48	24.77	24.98	25.09	25.05	24.98	24.91	24.71	24.42	24.13
Canola	7.83	7.93	7.99	8.02	8.01	7.99	7.97	7.90	7.81	7.72
Waste Oil	6.07	6.14	6.20	6.22	6.21	6.20	6.18	6.13	6.06	5.98

Table 12. Biodiesel Volumes (in million gallons) in Scenario 1-B5

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Soy	24.50	24.80	25.01	25.12	25.08	24.99	24.92	29.68	31.79	33.83
Canola	7.84	7.93	8.00	8.03	8.02	8.00	7.97	9.49	10.17	10.82
Waste Oil	6.08	6.15	6.20	6.23	6.22	6.20	6.18	7.36	7.88	8.39
Total	38.42	38.89	39.21	39.38	39.32	39.19	39.08	46.54	49.84	53.04
% BD in ULSD	5%	5%	5%	5%	5%	5%	5%	6%	6.5%	7%

Scenario 1-B5 requires an increase from statewide average B5 to 6% biodiesel in 2023 and up to 7% in 2020. This results in a cumulative increase of over 35 million gallons of biodiesel between 2023 and 2025.

Renewable Diesel

Table 13 and Table 14 below show the volumes of renewable diesel, by feedstock, consumed in Scenarios 1-B2 and 1-B5.

Table 13. Renewable Diesel Volumes (in million gallons) in Scenario 1-B2

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Tallow	0	0	0	0	0	5	6	7	8	10
Waste Oil	0	0	0	0	0	2.19	1.89	3.67	2.54	3.89
Total	0	0	0	0	0	7.19	7.89	10.67	10.54	13.89
% RD in ULSD	0%	0%	0%	0%	0%	1%	1.1%	1.5%	1.5%	2%

Table 14. Renewable Diesel Volumes (in million gallons) in Scenario 1-B5

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Tallow	10	10	10	10	10	10	10	10	10	10
Waste Oil	4.11	4.28	4.40	4.46	4.44	4.39	5.48	5.36	5.18	5.01
Total	14.11	14.28	14.40	14.46	14.44	14.39	15.48	15.36	15.18	15.01
% RD in ULSD	2%	2%	2%	2%	2%	2%	2%	2%	2%	2%

Scenario 1-B5 requires an increase to 2% renewable diesel throughout the program while Scenario 1-B2 only requires small volumes in the later years. This results in a cumulative increase of almost 100 million gallons of renewable diesel during the 10 year compliance period of the program.

Natural Gas/LPG

Table 15 below shows the natural gas/LPG and biogas consumption in million DGE where market share was increased to achieve 10% diesel pool consumption of natural gas/LPG/biogas in 2025. The vehicle penetrations and assumptions were the same for natural gas/LPG/biogas in Scenarios 1-B2 and 1-B5.

Table 15. Natural Gas/LGP Consumption (in million DGE) in Scenarios 1-B2 and 1-B5

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Natural Gas/LPG	8.11	11.79	15.25	14.11	18.52	23.26	28.28	33.80	39.94	46.62
Biogas	0.90	2.08	5.08	14.11	18.52	23.26	28.28	33.80	39.94	46.62
Total	9.01	13.87	20.34	28.22	37.04	46.53	56.55	67.61	79.87	93.24

Electricity

Table 16 below shows the electricity consumption from BEVs and PHEVs in million GGE.

Table 16. Electricity Consumption (in million GGE) in Scenarios 1-B2 and 1-B5

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Total	1.51	1.85	3.17	4.99	7.39	10.24	13.40	16.87	20.76	25.12

3.2 Compliance Scenarios 2-B2 and 2-B5

Summary Overview of Compliance Scenarios 2-B2 and 2-B5

Figure 6 and Figure 7 on the following page show the annual credits and deficits generated for Scenarios 2-B2 and 2-B5. Each colored stacked bar represents credits generated from low carbon fuels; the blue line represents the deficits from forecasted gasoline blendstock and ultra-low sulfur diesel (ULSD) consumption. When the bars in years 2016-2021 exceed the blue line, annual credits exceed annual deficits and banked credits are generated for future compliance. When the bars fall short of the blue line in years 2022-2025, banked credits are required to meet annual compliance. The stacked bars are grouped by biofuels for blending at the bottom and advanced vehicle technologies at the top. Table 17 and Table 18 below show the annual deficits and credits generated and cumulative (banked) credits.

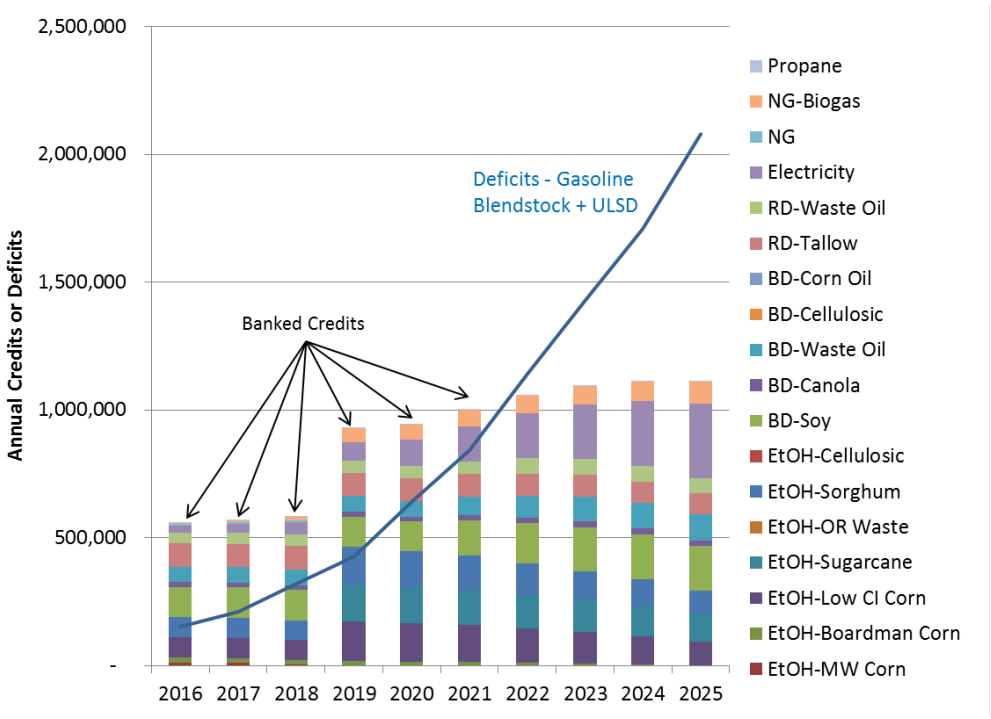

Figure 6. Balance of Credits and Deficits in Scenario 2-B2

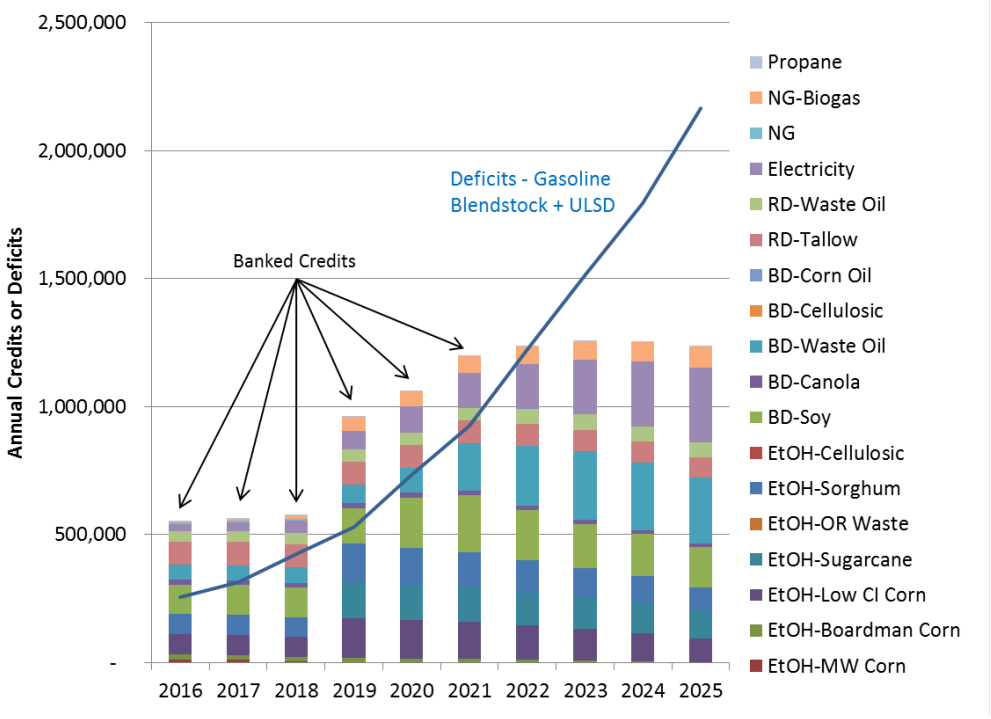

Figure 7. Balance of Credits and Deficits in Scenario 2-B5

Table 17. Credits and Deficits: Banking in Scenario 2-B2

Fuel		2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Deficits (Millions)	Gasoline	-0.05	-0.08	-0.14	-0.20	-0.32	-0.43	-0.60	-0.75	-0.90	-1.09
	Diesel	-0.11	-0.13	-0.18	-0.23	-0.32	-0.41	-0.54	-0.68	-0.81	-0.99
Credits (Millions)	Gasoline Subs	0.22	0.23	0.24	0.56	0.58	0.60	0.61	0.62	0.63	0.63
	Diesel Subs	0.33	0.34	0.34	0.36	0.36	0.40	0.44	0.47	0.48	0.49
Balance		0.40	0.36	0.26	0.50	0.31	0.16	-0.09	-0.34	-0.60	-0.97
Banked (Net)		0.40	0.76	1.03	1.53	1.83	1.99	1.91	1.57	0.97	0.00

Table 18. Credits and Deficits: Banking in Scenario 2-B5

Fuel		2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Deficits (Millions)	Gasoline	-0.05	-0.08	-0.14	-0.20	-0.32	-0.43	-0.60	-0.75	-0.90	-1.09
	Diesel	-0.21	-0.24	-0.28	-0.33	-0.41	-0.49	-0.63	-0.76	-0.90	-1.08
Credits (Millions)	Gasoline Subs	0.22	0.23	0.24	0.56	0.58	0.60	0.61	0.62	0.63	0.63
	Diesel Subs	0.33	0.33	0.34	0.39	0.48	0.59	0.62	0.63	0.62	0.61
Balance		0.29	0.25	0.15	0.43	0.33	0.27	0.01	-0.26	-0.54	-0.93
Banked (Net)		0.29	0.54	0.69	1.12	1.45	1.72	1.73	1.47	0.93	0.00

In Scenario 2-B2, gasoline and diesel generate similar numbers of deficits while in Scenario 2-B5, diesel generates almost 1 million more deficits than gasoline.

Fleet Changes from the BAU

There are no fleet changes between Scenarios 2-B2 and 2-B5 and the BAU.

Ethanol and Biofuels that Substitute for Gasoline

Table 19 below identifies the volumes of ethanol, broken down by feedstock, for both Scenarios 2-B2 and 2-B5. The ethanol volumes and feedstocks between 2-B2 and 2-B5 are identical.

Table 19. Ethanol Volumes (in million gallons) in Scenario 2

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Corn, MW	135.15	142.21	147.72	0	0	0	0	0	0	0
Corn, Boardman	26	26	26	26	26	26	26	26	26	26
Low CI Corn	50	50	50	102.36	104.99	106.44	107.36	107.02	105.34	103.18
Sugarcane	0	0	0	50	50	50	50	50	50	50
Sorghum	50	50	50	100	100	100	100	100	100	100
Total	261.15	268.21	273.72	278.36	280.99	282.44	283.36	283.02	281.34	279.18
% EtOH in Gasoline	10%	10%	10%	10%	10%	10%	10%	10%	10%	10%

Scenarios 2-B2 and 2-B5 consume the same volumes of ethanol to the BAU case since all cases maintain a 10% ethanol blend. Scenarios 2-B2 and 2-B5 cease to consume MW corn ethanol by 2019 since the carbon intensity of MW Corn exceeds the compliance in that year and every subsequent year. By 2025, there is a slight increase in ethanol consumption over Scenarios 1-B2 and 1-B5 since they include only PHEV40s and not PHEV10s which results in a slight increase in E10 consumption.

Biodiesel

Table 20 and Table 21 below show the volumes of biodiesel, by feedstock, consumed in Scenarios 2-B2 and 2-B5.

Table 20. Biodiesel Volumes (in million gallons) in Scenario 2-B2

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Soy	24.64	25.06	25.43	25.75	25.96	31.41	37.01	42.55	45.39	48.30
Canola	7.88	8.01	8.13	8.24	8.30	10.05	11.84	13.61	14.52	15.45
Waste Oil	6.11	6.21	6.31	6.39	6.44	7.79	9.18	10.55	11.26	11.98
Total	38.63	39.28	39.87	40.37	40.70	49.25	58.02	66.71	71.17	75.73
% BD in ULSD	5%	5%	5%	5%	5%	6%	7%	8%	8.5%	9%

Table 21. Biodiesel Volumes (in million gallons) in Scenario 2-B5

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Soy	24.64	25.06	25.43	30.92	44.94	52.33	47.47	43.51	43.83	44.21
Canola	7.88	8.01	8.13	9.89	10	10	10	10	10	10
Waste Oil	6.11	6.21	6.31	7.67	10.32	20	25.6	30	30	30
Total	38.63	39.28	39.87	48.48	65.27	82.33	83.07	83.51	83.83	84.21
% BD in ULSD	5%	5%	5%	6%	8%	10%	10%	10%	10%	10%

Scenario 2-B2 requires an increase from statewide average B5 to 6% biodiesel in 2021 and up to 9% in 2020 and Scenario 2-B5 requires an increase from B5 to B6 in 2019 and up to 10% in 2021. This results in a cumulative increase of almost 130 million gallons of biodiesel between Scenarios 2-B5 and 2-B2.

Renewable Diesel

Table 22 below shows the volumes of renewable diesel, by feedstock, consumed in Scenarios 2-B2 and 2-B5.

Table 22. Renewable Diesel Volumes (in million gallons) in Scenario 2-B2 and 2-B5

Feedstocks	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Tallow	10	10	10	10	10	10	10	10	10	10
Waste Oil	4.18	4.42	4.64	4.82	4.94	5.07	6.41	6.51	6.58	6.66
Total	14.18	14.42	14.64	14.82	14.94	15.07	16.41	16.51	16.58	16.66
% RD in ULSD	2%	2%	2%	2%	2%	2%	2%	2%	2%	2%

Scenarios 2-B2 and 2-B5 increase to 2% renewable diesel throughout the program resulting in 154 million gallons of renewable diesel consumption throughout the program.

Natural Gas/LPG

Table 23 below shows the natural gas/LPG and biogas consumption in million DGE where market share was increased to achieve 10% diesel pool consumption of natural gas/LPG/biogas in 2025. The vehicle penetrations and assumptions were the same for natural gas/LPG/biogas in Scenarios 2-B2 and 2-B5.

Table 23. Natural Gas/LGP Consumption (in million DGE) in Scenarios 2-B2 and 2-B5

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Natural Gas/LPG	4.51	5.38	6.20	6.99	7.77	8.52	9.36	10.13	10.94	12.22
Biogas	4.06	4.57	4.65	0.07	0.08	0.09	0.09	0.10	0.11	0.12
Total	0.45	0.81	1.55	6.92	7.70	8.43	9.27	10.03	10.83	12.10

Electricity

Table 24 below shows the electricity consumption from BEVs and PHEVs in million GGE.

Table 24. Electricity Consumption (in million GGE) in Scenarios 2-B2 and 2-B5

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
Total	1.51	1.85	2.80	4.20	6.12	8.44	11.07	13.97	17.24	20.93

The fleet change between Scenario 1 and 2 where all PHEVs are PEHV40 resulted in 4.2 million GGE of increased electricity consumption in 2025 in Scenario 1.

3.3 Greenhouse Gas Reductions

Table 25 shows the annual GHG emissions in million metric tons from transportation fuels from 2015 to 2025. Table 26 shows the percent GHG reductions annually from 2016 to 2025 and cumulatively over the compliance period from 2016 to 2025.

Table 25. Annual GHG Emissions (million metric tons)

Scenario	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025
BAU	23.93	24.12	24.22	24.24	24.22	24.10	23.96	23.81	23.62	23.39	23.19
1-B2	23.92	23.95	24.04	24.03	23.64	23.48	23.21	23.00	22.71	22.41	22.09
1-B5	23.92	23.82	23.90	23.90	23.50	23.34	23.14	22.94	22.63	22.32	22.01
2-B2	23.92	23.83	23.92	23.94	23.58	23.45	23.26	23.06	22.81	22.56	22.32
2-B5	23.92	23.83	23.92	23.94	23.53	23.31	23.03	22.85	22.62	22.39	22.18

LUBA No. 2020-009
Page 5891

Table 26. GHG Emissions Reductions from the BAU (Percent)

Scenario	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2016-2015
1-B2	0.7%	0.7%	0.9%	2.4%	2.6%	3.1%	3.4%	3.8%	4.2%	4.7%	**2.6%**
1-B5	1.3%	1.3%	1.4%	2.9%	3.2%	3.4%	3.7%	4.2%	4.6%	5.1%	**3.1%**
2-B2	1.2%	1.2%	1.3%	2.6%	2.7%	2.9%	3.2%	3.4%	3.6%	3.7%	**2.6%**
2-B5	1.2%	1.2%	1.3%	2.8%	3.3%	3.9%	4.1%	4.2%	4.3%	4.4%	**3.0%**

The reductions in Table 26 are compared to the BAU (which includes the ZEV Program and increased light-duty fuel economy standards) and only represent those reductions that would be directly attributed to the Clean Fuels Program. As expected, the scenarios with the B5 baseline achieved more cumulative reductions than the B2 scenarios. Additionally, both of the B2 baseline scenarios and the B5 baseline scenarios achieved similar cumulative reductions which were expected since the compliance period was looking to achieve the same carbon intensity reductions. The advanced vehicle technology scenarios are reducing more emissions annually at the end of the program compared to the blending scenarios due to displacing diesel with natural gas and biogas and reducing consumption of diesel from medium- and heavy-duty hybrids.

The Oregon Resilience Plan

Reducing Risk and Improving Recovery for the Next Cascadia Earthquake and Tsunami

Report to the
77th Legislative Assembly

from
Oregon Seismic Safety Policy
Advisory Commission (OSSPAC)

Salem, Oregon
February 2013

Cover Page graphic is designed by Deb Schueller with Oregon Department of Geology and Mineral Industries (DOGAMI)

2012-2013 Oregon Seismic Safety Policy Advisory Commission (OSSPAC) Members

CHAIR: Kent Yu - Structural Engineer Stakeholder, Degenkolb Engineers
VICE CHAIR: Jay Wilson - Public Member, Clackamas County Emergency Management
Deborah Boone - Representative, Legislative Assembly
Greg Ek-Collins - Oregon Department of Transportation
Carl Farrington - Multifamily Housing Stakeholder
Fred Girod - Senator, Legislative Assembly
David Holton - American Red Cross*
Francisco Ianni - American Red Cross
Ian Madin - Department of Geology and Mineral Industries
Michael Mumaw - Local Government Stakeholder, Emergency Manager, City of Beaverton
Jay Raskin - Public Member, Ecola Architects
Althea Rizzo - Oregon Emergency Management
Richard Rogers - Building Codes Division
Stephen Lucker - Department of Land Conservation & Development
Susan Steward – Building Owners Stakeholder, BOMA
Mark Tyler - Schools Stakeholder
Bryce Ward – Banking Stakeholder, ECONorthwest
Stan Watters – Utilities Stakeholder, Port of Portland
Gerry Williams - Public Member, Construction & Engineering Management Research, Inc.

Bev Hall – OSSPAC Secretary, Oregon Emergency Management

*Retired from the commission in June 2012.

Project Team and Acknowledgments

On behalf of my fellow OSSPAC Commissioners, I want to thank several individuals whose vision and support have made our resilience planning work possible. First and foremost, we thank our colleague Rep. Deborah Boone, who introduced House Resolution 3 and won the unanimous support of her colleagues on April 18, 2011. We are also grateful to Governor John Kitzhaber, who encouraged OSSPAC's efforts on resilience, and to President Barack Obama's Senior Director for Resilience Richard Reed, who took the time to express his support for the preparation of Oregon's resilience plan.

We are very grateful to members of the project Steering Committee, who have offered their advice, counsel, and support at every stage of our work: **Jay Wilson** (Vice Chair)**, Ian Madin, Dr. Althea Rizzo, and Stan Watters**.

We appreciate the commitment of our Advisory Panel, whose members participated in meetings on January 26th, 2012 and October 5th, 2012 and have made themselves available for informal consultation over the past year: **Prof. Scott Ashford, Sen. Lee Beyer, Sen. Peter Courtney, Ed Dennis, JR Gonzalez, Prof. Chris Goldfinger, Dave Harlan, Onno Husing, Bruce Johnson, Dr. Leon Kempner, Jr., Prof. Andre LeDuc, Dr. Vicki McConnell, Dr. Jean O'Connor, Cameron Smith, Jeffrey Soulages, Yumei Wang, Edward Wolf, and Dr. Nate Wood**. In particular, we want to thank Dr. Vicki McConnell, Yumei Wang and Edward Wolf for their guidance and support.

We owe the creation of the *Oregon Resilience Plan* to diligent efforts by our eight Task Groups and the capable leadership and project management performed by our Task Group leaders, who may not have fully realized the magnitude of the project when they agreed to serve:

Earthquake and Tsunami Scenario Task Group: ***Ian Madin*** (Chair), Bill Burns, Art Frankel, Chris Goldfinger, Matthew Mabey, George Priest, Yumei Wang, and Ivan Wong.

Business and Work Force Task Group: ***Susan Steward*** (Co-Chair), ***Gerry Williams*** (Co-Chair), Lori Chamberlain, Patrick Estenes, Kelley Okolita, Patrick Slabe, Bert Sorio, Jeffrey Soulages, Rick Van Dyke, and Bryce Ward.

Coastal Communities Task Group: ***Jay Wilson*** (Co-Chair), ***Jay Raskin*** (Co-Chair), Jacque Betz, Rep. Deborah Boone, Josh Bruce, Charlie Davis, Sue Graves, Dave Harlan, Jeffrey Hepler, Maggie Kirby, Sen. Jeff Kruse, Margo Lalich, Jack Lenox, Gary Milliman, Sam Steidel, Wayne Stinson, and Laren Woolley.

Critical Buildings Task Group: ***Ed Quesenberry*** (Co-Chair), ***Trent Nagele*** (Co-Chair), Andre Barbosa, David Bugni, Ed Dennis, Kimberly Dills, Shane Downing, Shelly Duquette, Jennifer Eggers, Joe Gehlen, Tonya Halog, Robert Johnson, Kevin Kaplan, Amit Kumar, Dominic Matteri, Anne Monnier, Willy Paul, Josh Richards, Tim Rippey, Richard Rogers, Terry Shugrue, Jason Thompson, Mark Tobin, Jim Weston, Michael Wieber, and Edward Wolf.

Transportation Task Group: ***Bruce Johnson*** (Chair), Martin Callery, Lieutenant Meredith Condon, Chris Corich, Peter Duskica, Greg Ek-Collins, Herb Florer, Doug Grafe, Elsie Hamner, Chuck Hutto, Doug Kirkpatrick, Jeff Langstrom, Lee Lazaro, Mark Libby, Matt Maass, Nason McCullough, Bob Melbo, Curran Mohney, Lucy Moore, Nancy Murphy, Albert Nako, David Neys, David Olongiagh, Jeff Olson, Jon Oshel, Tom Peterson, Craig Shike, Craig Totten, Tom Wharton, John Wilson, and Holly Winston.

Energy Task Group: ***JR Gonzalez*** (Co-Chair), ***Stan Watters*** (Co-Chair), Heide Caswell, Rick Carter, Brian Doherty, Michael Dougherty, Del Draper, Dave Ford, Debbie Guerra, Teresa Hagins, Marion Haynes, Leon Kempner, Jr., Brian Knight, Lori Koho, Christy Munro, Bruce Paskett, Robbie Roberts, Dave Stuckey, Jack Vranish, Yumei Wang, Tashiana Wanger, and Grant M. Yoshihara.

Information and Communications Task Group: ***Mike Mumaw*** (Chair), Rick Carter, Michael Dougherty, Walter Duddington, JR Gonzalez, Alexis Kwasinki, Devon Lumbard, Kelley Stember, Alex Tang, Yumei Wang, Stan Watters, and Geoffery Williams.

Water and Waste Water Task Group: ***Mike Stuhr*** (Co-Chair), ***Mark Knudson*** (Co-Chair), Don Ballantyne, Steve Behrandt, James Bela, Andy Braun, Scott Burns, Mel Damewood, Jim Doane, Michael Doane, Tom Hickmann, Gary Irwin, Gwynn Johnson, Jeff Leighton, Arturo Leon, Ian Madin, Jim Male, Jim Newell, Bob Patterson, Sherry Patterson, Todd Perimon, Brad Phelps, Jeff Rubin, Rob Schab, Ken Schlegel, Brian Stahl, and Jeffrey H. Winchester.

Dr. Kyra L. Nourse compiled and edited the *Oregon Resilience Plan*, with assistance from my OSSPAC colleagues Dr. Althea Rizzo, Jay Wilson, Ian Madin, Bev Hall and from Edward Wolf. We are grateful to FEMA for financial support, through a grant administered by Oregon Emergency Management, for the technical editing of the plan.

The Port of Portland hosted our workshops on January 26, 2012 and October 5, 2012 in its headquarter building. We want to thank Michelle Walker for her planning and coordination to make the workshops successful. Cascadia Region Earthquake Workgroup (CREW) provided their endorsement for our resilience planning efforts, and also helped sponsor our January 26, 2012 workshop. We want to thank Cale Ash (then President of CREW) and John Schelling (Washington State Emergency Management) for their participation and for sharing their resilience planning experience with us.

On a personal note, I wish to thank my colleagues at Degenkolb Engineers, particularly Chris Poland in San Francisco and Stacy Bartoletti in Seattle, for their inspiration on resilience, and colleagues in our Portland office including Liz Francis and Karla Richards who helped me to manage my resilience plan responsibilities without leaving my other professional obligations too far behind.

Finally, I want to acknowledge the leadership of OSSPAC's Vice Chair Jay Wilson, who has in every respect been a full partner in the vision and execution of the *Oregon Resilience Plan*, and who is a great champion for resilience.

Many other individuals have generously shared their expertise and perspective with us during the creation of this plan. OSSPAC bears the sole responsibility for any errors or omissions it contains.

Foreword

"If we cannot control the volatile tides of change, we can learn to build better boats."

—Andrew Zolli and Ann Marie Healy, *Resilience: Why Things Bounce Back* (2012)

For more than 300 years, a massive geological fault off America's northwest coast has lain dormant. Well into that interval, Meriwether Lewis and William Clark journeyed to the mouth of the Columbia River and returned to Washington, D.C. to tell the new United States about what came to be known as the Oregon Country. Tens of thousands of settlers crossed the Oregon Trail to establish communities throughout the Willamette Valley, in coastal valleys, and beside natural harbors. With the provisional government established in 1843 followed by statehood in 1859, the modern history of Oregon began. Industries rose and fell, cities and towns grew . . . and still the fault lay silent.

Not until the 1980s did scientists recognize the Cascadia subduction zone as an active fault that poses a major geological hazard to Oregon. A decade later, the state's building codes were updated to address this newly revealed earthquake threat to the built environment.

Since that time, scientists have documented a long history of earthquakes and tsunamis on the Cascadia subduction zone, and state and local officials have urged Oregonians to prepare for the next one. In 1999, the state's Department of Geology and Mineral Industries published a preliminary statewide damage and loss study identifying the dire consequences of a Cascadia earthquake and tsunami for Oregon's infrastructure and for public safety.

One official who took that warning seriously was Senator Peter Courtney, Oregon's unchallenged champion of earthquake safety and advocate for measures to protect students who attend unsafe schools. His legislative efforts over more than a decade launched a statewide assessment of schools and emergency response facilities, and established a state grant program to help fund seismic upgrades to hazardous schools and other critical facilities. Other than California, no state has done as much—yet the hazard surpasses the commitments Oregon has made to date.

In early 2011, we suggested in the pages of *The Oregonian* that Oregon should take new steps to make itself resilient to a big earthquake. Less than two months later, the Tohoku earthquake and tsunami disaster in Japan provided the occasion for Representative Deborah Boone to introduce a House Resolution calling on Oregon to plan for the impacts of a Cascadia earthquake and tsunami here.

House Resolution 3 directed Oregon Seismic Safety Policy Advisory Commission to lead the planning effort. Chairman Kent Yu, Ph.D., has skillfully guided more than 150 volunteer professionals, including noted experts, to develop a landmark report on Oregon's priorities to survive and bounce back from a magnitude 9.0 Cascadia earthquake and tsunami.

The authors of this *Oregon Resilience Plan* set out to help Oregonians know what to expect from the state's infrastructure should that disaster strike this year, and to propose the level of infrastructure reliability that a resilient state should provide. The plan's recommendations highlight ways to close the gap that separates expected and desired performance.

Business leaders engaged in this resilience planning effort have indicated that in a major disaster, interruptions of infrastructure services lasting longer than two weeks will put their enterprises at risk. Yet, under present conditions, we can expect some interruptions to last much longer, in some cases from 18 to 36 months or more. The state, in tandem with the private sector, has much to do to improve the reliability of basic services. Citizens, too, need to plan to be self-sufficient for far longer than the 72-hour period commonly advised for disaster preparedness.

The most recent Cascadia earthquake struck at around 9:00 p.m. on a late January evening; the next could shake a mid-July morning when hundreds of thousands of Oregonians and visitors are enjoying coastal beaches and towns. No one can predict the next time the Cascadia fault will rupture, and *today* is just as likely as fifty years from now. If we begin now, it is possible to prevent that natural disaster from causing a statewide catastrophe. Now is the time to have a plan. Now is the time to close Oregon's resilience gap.

The Oregon Resilience Plan maps a path of policy and investment priorities for the next fifty years. The recommendations offer Oregon's Legislative Assembly and Governor immediate steps to begin a journey along that path. The plan and its recommendations build on the solid foundation laid over the past quarter century by some of Oregon's top scientists, engineers, and policymakers.

As we wrote two years ago, adopting and implementing such a plan can show "Oregon at its best, tackling a risk with imagination and resourcefulness while sharing the knowledge gained."

Executive Summary

Very large earthquakes will occur in Oregon's future, and our state's infrastructure will remain poorly prepared to meet the threat unless we take action now to start building the necessary resilience. This is the central finding of the *Oregon Resilience Plan* requested by Oregon's 76th Legislative Assembly.

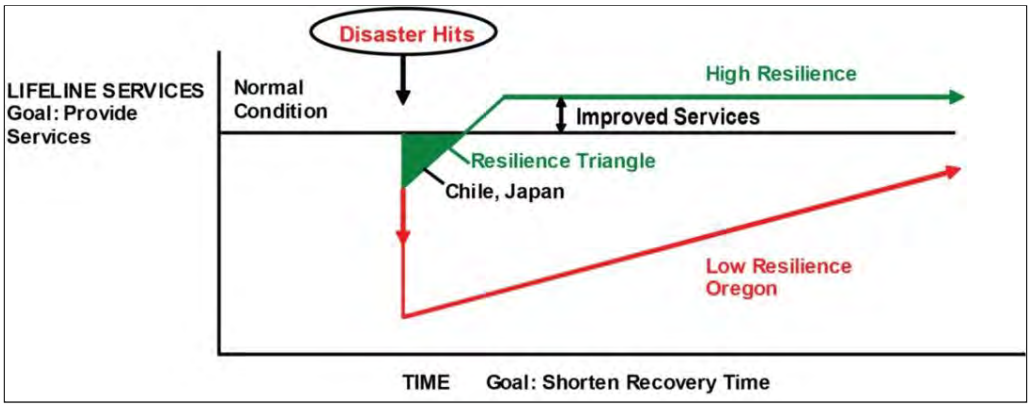
Impact zones for the magnitude 9.0 Cascadia earthquake scenario. Damage will be extreme in the Tsunami zone, heavy in the Coastal zone, moderate in the Valley zone, and light in the Eastern zone.

About the Plan

House Resolution 3, adopted in April 2011, directed the Oregon Seismic Safety Policy Advisory Commission (OSSPAC) "to lead and coordinate preparation of an Oregon Resilience Plan that reviews policy options, summarizes relevant reports and studies by state agencies, and makes recommendations on policy direction to protect lives and keep commerce flowing during and after a Cascadia earthquake and tsunami." OSSPAC assembled eight task groups, comprising volunteer subject-matter experts from government, universities, the private sector, and the general public. An Advisory Group of public- and private-sector leaders oversaw the Task Groups' work, assembled in the portfolio of chapters that make up the plan.

OSSPAC offered the following definition of the seismic resilience goal:

> "Oregon citizens will not only be protected from life-threatening physical harm, but because of risk reduction measures and pre-disaster planning, communities will recover more quickly and with less continuing vulnerability following a Cascadia subduction zone earthquake and tsunami."

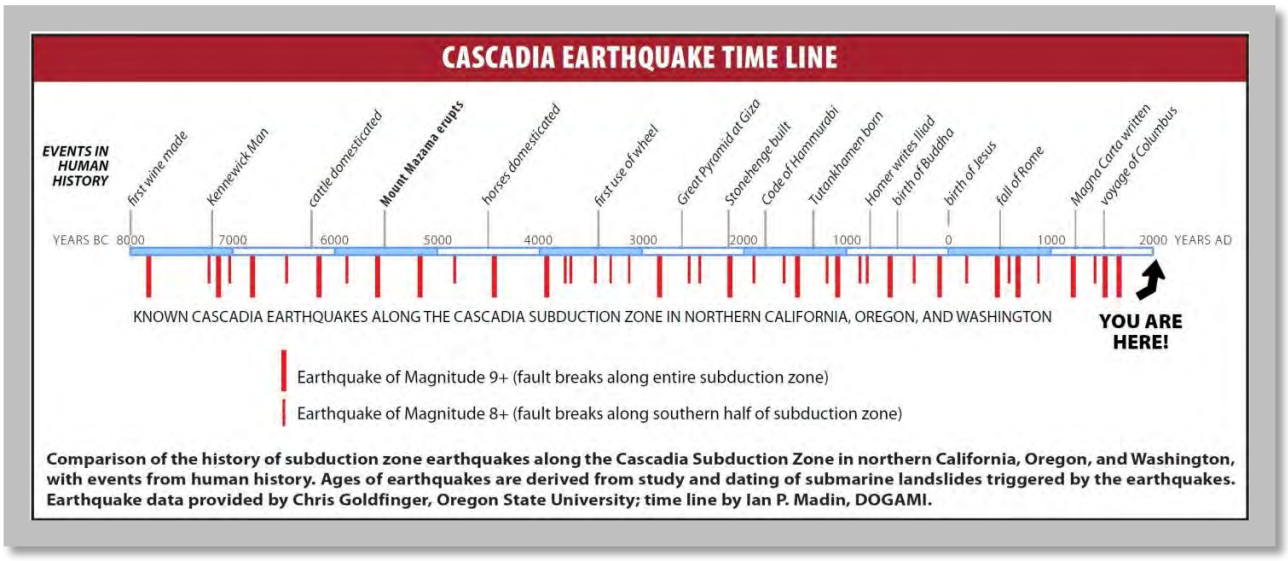


Each group was charged with three tasks for four affected zones (tsunami, coastal/earthquake only, valley, and central/eastern Oregon):

1. Determine the **likely impacts** of a magnitude 9.0 Cascadia earthquake and tsunami on its assigned sector, and estimate the time required to restore functions in that sector if the earthquake were to strike under present conditions;

2. Define **acceptable timeframes** to restore functions after a future Cascadia earthquake to fulfill expected resilient performance; and

3. Recommend **changes in practice and policies** that, if implemented during the next 50 years, will allow Oregon to reach the desired resilience targets.

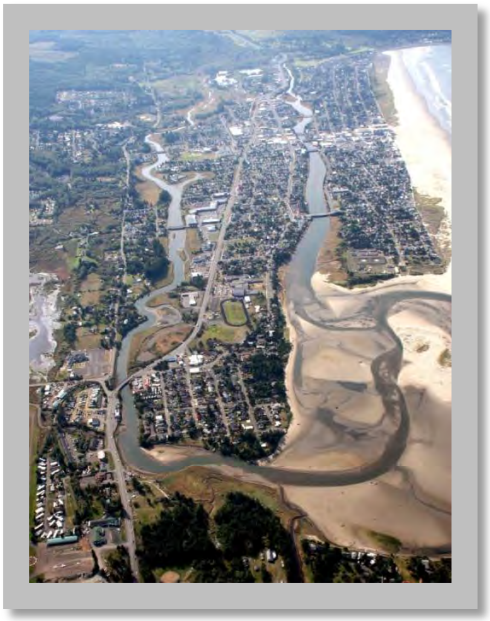


The purpose of the analysis is to identify steps needed to eliminate the gap separating current performance from resilient performance, and to initiate that work through capital investment, new incentives, and policy changes so that the inevitable natural disaster of a Cascadia earthquake and tsunami will not deliver a catastrophic blow to Oregon's economy and communities.

The basic principle of the resilience triangle is that the smaller the triangle, the higher the resilience. Higher resilience requires minimal reductions in critical lifeline services after a disaster, speedy recovery of those services, and an overall improved service level as a result of rebuilding damaged systems and implementing better systems. The resilience triangle diagram indicates that Chile and Japan have high levels of earthquake resilience. At the current stage, Oregon's infrastructure has low resilience and is expected to have significant loss of sector services and a slow recovery time. Source: Resilience Triangle by Wang, Bartlett, and Miles (2012)

Overview of the Task Groups

The **Cascadia Earthquake Scenario Task Group** (Chapter One) reviewed current scientific research to develop a detailed description of the likely physical effects of a great (magnitude 9.0) Cascadia subduction zone earthquake and tsunami, providing a scenario that other task groups used to assess impacts on their respective sectors.



This timeline compares the 10,000-year-long history of Cascadia earthquakes to events in human history.

The **Business and Workforce Continuity Task Group** (Chapter Two) sought to assess the workplace integrity, workforce mobility, and building systems performance – along with customer viability – needed to allow Oregon's businesses to remain in operation following a Cascadia earthquake and tsunami and to drive a self-sustaining economic recovery.

The **Coastal Communities Task Group** (Chapter Three) addressed the unique risks faced by Oregon's coast, the region of the state that will experience a devastating combination of tsunami inundation and physical damage from extreme ground shaking due to proximity to the subduction zone fault.

Critical Facilities in the Tsunami Zone – Minamisanriku, March 14, 2011. Because their hospital, emergency operation center, and other government and community service facilities were located in the tsunami inundation zone, the surviving community lost nearly all of its capacity to respond and implement recovery efforts. Source: Asia Air Survey Co., Ltd.

Tsunami Vulnerability: City of Seaside with 83% of its population, 89% of its employees and almost 100% of its critical facilities in the tsunami inundation zone. Source: Horning Geosciences

The **Critical and Essential Buildings Task Group** (Chapter Four) examined the main classes of public and private structures considered critical to resilience in the event of a scenario earthquake, and sought to characterize the gap between expected seismic performance (current state) and desired seismic resilience (target state). The group also assessed buildings deemed vital to community resilience, and addressed the special challenges posed by unreinforced masonry (URM) and non-ductile concrete structures.

Many of existing public and private buildings such as the State Capitol Building were built prior to our knowledge of the Cascadia subduction earthquake. They are not seismically safe, and pose significant life-safety threat to the building occupants. Photo Source: http://en.wikipedia.org/wiki/File:Oregon_State_Capitol_1.jpg

The **Transportation Task Group** (Chapter Five) assessed the seismic integrity of Oregon's multi-modal transportation system, including bridges and highways, rail, airports, water ports, and public transit systems, examined the special considerations pertaining to the Columbia and Willamette River navigation channels, and characterized the work deemed necessary to restore and maintain transportation lifelines after a Cascadia earthquake and tsunami. The group's scope included interdependence of transportation networks with other lifeline systems.

The approach (foreground) to the 1966 Astoria-Megler Bridge that spans the Columbia River has major structural deficiencies that could lead to a collapse following an earthquake. Damaged bridge sections could block waterway access to the Critical Energy Infrastructure Hub. (DOGAMI photo)

The **Energy Task Group** (Chapter Six) investigated the seismic deficiencies of Oregon's energy storage and transmission infrastructure, with a special emphasis on the vulnerability of the state's critical energy infrastructure (CEI) hub, a six-mile stretch of the lower Willamette River where key liquid fuel and natural gas storage and transmission facilities and electricity transmission facilities are concentrated.

Left: Site map of the Critical Energy Infrastructure (CEI) Hub on the western bank of the Lower Willamette River area in NW Portland, Oregon. The CEI Hub, outlined in red, stretches for six miles. (Google Earth) Right: Oil terminals in the CEI Hub. (DOGAMI photo)

The **Information and Communications Task Group** (Chapter Seven) examined the inherent vulnerabilities of Oregon's information and communications systems and the consequences of service disruptions for the resilience of other sectors and systems. The group explored the implications of co-location of communications infrastructure with other vulnerable physical infrastructure (*e.g.,* bridges), and specified the conditions needed to accomplish phased restoration of service following a Cascadia earthquake and tsunami.

Left: These high voltage electrical transmission towers are built on a river bank in the Critical Energy Infrastructure (CEI) Hub susceptible to lateral spreading. (DOGAMI photo) Right: Structural damage to a high voltage transmission tower located at a river crossing in 2010 Chile earthquake (ASCE Technical Council on Lifeline Earthquake Engineering – TCLEE)

The **Water and Wastewater Task Group** (Chapter Eight) reviewed vulnerabilities of the pipelines, treatment plants, and pump stations that make up Oregon's water and wastewater systems, and discussed the interventions needed to increase the resilience of under-engineered and antiquated infrastructure at potential failure points. The group proposed a phased approach to restoration of water services after a Cascadia earthquake and tsunami, beginning with a backbone water and wastewater system capable of supplying critical community needs.

Key Findings

Oregon is far from resilient to the impacts of a great Cascadia earthquake and tsunami today. Available studies estimate fatalities ranging from 1,250 to more than 10,000 due to the combined effects of earthquake and tsunami, tens of thousands of buildings destroyed or damaged so extensively that they will require months to years of repair, tens of thousands of displaced households, more than $30 billion in direct and indirect economic losses (close to one-fifth of Oregon's gross state product), and more than one million dump truck loads of debris.

A particular vulnerability is Oregon's liquid fuel supply. Oregon depends on liquid fuels transported into the state from Washington State, which is also vulnerable to a Cascadia earthquake and tsunami. Once here, fuels are stored temporarily at Oregon's critical energy infrastructure hub, a six-mile stretch of the

lower Willamette River where industrial facilities occupy liquefiable riverside soils. Disrupting the transportation, storage, and distribution of liquid fuels would rapidly disrupt most, if not all, sectors of the economy critical to emergency response and economic recovery.

Business continuity planning typically assumes a period of two weeks to be the longest disruption of essential services (*i.e.*, utilities, communications, etc.) that a business can withstand, and service disruptions lasting for one month or longer can be enough to force a business to close, relocate, or leave the state entirely. Analysis in the *Oregon Resilience Plan* reveals the following timeframes for service recovery under present conditions:

Critical Service	Zone	Estimated Time to Restore Service
Electricity	Valley	1 to 3 months
Electricity	Coast	3 to 6 months
Police and fire stations	Valley	2 to 4 months
Drinking water and sewer	Valley	1 month to 1 year
Drinking water and sewer	Coast	1 to 3 years
Top-priority highways (partial restoration)	Valley	6 to 12 months
Healthcare facilities	Valley	18 months
Healthcare facilities	Coast	3 years

Resilience gaps of this magnitude reveal a harsh truth: a policy of business as usual implies a post-earthquake future that could consist of decades of economic and population decline – in effect, a "lost generation" that will devastate our state and ripple beyond Oregon to affect the regional and national economy.

- After the February 27, 2010 M8.8 Maule Earthquake, Chile was able to restore 90% communication services and 95% power supply within two weeks, and re-start commercial flights after ten days.
- After the March 11, 2011 M9.0 Tohoku Earthquake, Japan was able to restore more than 90% power supply in ten days, 90% telephone lines in two weeks, and 90% cellular base stations in 19 days.

Recommendations

Based on the findings in this *Oregon Resilience Plan*, OSSPAC recommends that Oregon start now on a sustained program to reduce our vulnerability and shorten our recovery time to achieve resilience before the next Cascadia earthquake inevitably strikes our state.

OSSPAC urges systematic efforts to assess Oregon's buildings, lifelines, and social systems, and to develop a sustained program of replacement, retrofit, and redesign to make Oregon resilient.

Sector-by-sector findings and detailed recommendations are presented in each chapter of the *Oregon Resilience Plan*. Overarching priorities, illustrated with examples selected from the chapters, include new efforts to:

1. Undertake **comprehensive assessments** of the key structures and systems that underpin Oregon's economy, including

    a. Completing a statewide inventory of critical buildings (those needed for emergency response and the provision of basic services to communities) in both public and private sectors (Chapter Four);
    b. Completing an updated inventory of the local agency, transit, port, and rail assets that assure access to school buildings and hospitals and could be used during emergencies (Chapter Five);
    c. Charging the Oregon Public Utility Commission to define criteria for seismic vulnerability assessments that will be applied by operating companies in the energy and information and communications sectors (Chapters Six and Seven); and
    d. Requiring all water and wastewater agencies to complete a seismic risk assessment and mitigation plan as part of periodic updates to facility plans (Chapter Eight).

2. Launch a sustained **program of capital investment** in Oregon's public structures, including

    a. Fully funding Oregon's Seismic Rehabilitation Grants Program for K-12 schools, community colleges, and emergency response facilities (Chapters Two and Four);
    b. Seismically upgrading lifeline transportation routes into and out of major business centers statewide by 2030 (Chapter Five); and
    c. Establishing a State Resilience Office to provide leadership, resources, advocacy, and expertise in implementing statewide resilience plans (Chapter Four).

3. Craft a **package of incentives** to engage Oregon's private sector in efforts to advance seismic resilience, including

    a. Developing a seismic rating system for new buildings to incentivize construction of buildings more resilient than building code compliance requires and to communicate seismic risk to the public (Chapters Two and Four);
    b. Tasking the Oregon Public Utilities Commission to provide oversight for seismic preparedness of the energy providers currently under its jurisdiction (Chapter Six); and

c. Working with the hospitality industry to develop plans to assist visitors following a major earthquake and tsunami and to plan strategies to rebuild the tourism industry (Chapter Three).

4. **Update Oregon's public policies**, including

   a. Revising individual preparedness communications to specify preparation from the old standard of 72 hours to a minimum of two weeks, and possibly more (Chapters Two and Three);
   b. Developing a policy and standards for installation of temporary bridges following earthquake disruption (Chapter Five); and
   c. Adopting a two-tiered ratings system that indicates the number of hours/days that a citizen in a community can expect to wait before major relief arrives, and the number of days/months that a citizen can expect to wait before the community itself achieves 90 percent restoration of roads and municipal services (Chapter Two).

These and other recommendations may be refined and implemented via a combination of new legislation, regulations, administrative rules, budget priorities, and in consultation with private sector leaders as appropriate.

Looking Ahead

This *Oregon Resilience Plan* emphasizes the resilient physical infrastructure needed to support business and community continuity. The policy recommendations presented here, if implemented over the next 50 years, will enhance our infrastructure resilience, help preserve our communities, and protect our state economy.

This is a timeframe much longer than typical of government planning efforts. To affirm Oregon's commitment, OSSPAC needs to work with the Joint Ways & Means Committee of Oregon's Legislative Assembly to track and report on progress toward seismic resilience at the beginning of each legislative session, to keep the 50-year goal in view.

Local Oregon communities can use the framework and gap-analysis methodology developed by the *Oregon Resilience Plan* to conduct more refined assessments that consider local seismic and tsunami hazards, and develop community-specific recommendations to meet their response and recovery needs.

A Cascadia earthquake and tsunami will affect both Oregon and Washington. Both states share common challenges, among them the interstate bridges and the Columbia River navigation channel as well as the regional power grid and liquid fuel supply. In particular, Oregon gets almost one hundred percent of its liquid fuel from suppliers in Washington, delivered via pipeline and river. We believe that it would be beneficial for both states to work together at a regional level to address the common challenge of resilience to a region-wide seismic event.

OSSPAC recommends expanding future resilience planning efforts to include:

1. Community-level planning
2. Human resilience
3. Civic infrastructure
4. Joint regional planning with Washington State

With resilient physical infrastructure, a healthy population, and functioning government and civic infrastructure to provide services to those in need, Oregon will be ready to withstand a Cascadia earthquake and tsunami, and to expedite response and recovery efforts quickly.

NOTE: This Executive Summary selects from the large number of detailed recommendations in the chapters of the *Oregon Resilience Plan*. The full report is available online at the Oregon Office of Emergency Management website: http://www.oregon.gov/OMD/OEM/Pages/index.aspx

1. Cascadia: Oregon's Greatest Natural Threat

Introduction

When, not if, the next great Cascadia subduction zone earthquake strikes the Pacific Northwest, Oregon will face the greatest challenge in its history. Oregon's buildings, transportation network, utilities, and population are simply not prepared for such an event. Were it to occur today, thousands of Oregonians would die, and economic losses would be at least $32 billion. In their current state, our buildings and lifelines (transportation, energy, telecommunications, and water/wastewater systems) would be damaged so severely that it would take three months to a year to restore full service in the western valleys, more than a year in the hardest-hit coastal areas, and many years in the coastal communities inundated by the tsunami. Experience from past disasters has shown that businesses will move or fail if services cannot be restored in one month; so Oregon faces a very real threat of permanent population loss and long-term economic decline.

We cannot avoid the future earthquake, but we can choose either a future in which the earthquake results in grim damage and losses and a society diminished for a generation, or a future in which the earthquake is a manageable disaster without lasting impact. We need to start preparing now by assessing the vulnerability of our buildings, lifelines, and social systems, and then developing and implementing a sustained program of replacement, retrofit, and redesign to make Oregon resilient to the next great earthquake. We know how to engineer buildings, roads, and power lines to withstand this earthquake; the hard part will be to find the will, commitment, and persistence needed to transform our state.

The Oregon legislature recognized the scale of this problem when it passed House Resolution 3 in 2011 (see Appendix I for details of House Resolution 3), noting the likely impact of a Cascadia earthquake and the need for a plan to move the state towards resilience to that event. The Oregon Seismic Safety Policy Advisory Commission (OSSPAC) was charged with developing a resilience plan, which is described in this report. The report summarizes the science of Cascadia subduction zone earthquakes and estimates their impacts; it then provides detailed analysis of the current vulnerability of our buildings and business community, and our transportation, energy, communication, and water/wastewater systems. The report defines the performance targets that each sector must meet to achieve adequate resilience, and provides detailed recommendations for the actions required to meet those targets over the next 50 years.

How OSSPAC Developed This Plan

House Resolution 3 passed by the 2011 legislature directed OSSPAC to "lead and coordinate preparation of an Oregon Resilience Plan that reviews policy options, summarizes relevant reports and studies by state agencies and makes recommendations on policy direction to protect lives and keep commerce

flowing during and after a Cascadia earthquake and tsunami". To meet this challenge OSSPAC first defined what resilience would mean for Oregon:

Oregon citizens will not only be protected from life-threatening physical harm, but because of risk reduction measures and pre-disaster planning, communities will recover more quickly and with less continuing vulnerability following a Cascadia subduction zone earthquake and tsunami.

OSSPAC identified existing and ongoing earthquake resilience planning from San Francisco, California (SPUR, 2009) and the State of Washington (Washington Seismic Safety Committee, 2012) as good models to follow. These studies outlined an approach that included estimating the current earthquake vulnerability of systems and structures, defining the performance standards that structures and systems would need to meet over fifty years in order to be sufficiently resilient, and then identifying changes in practice and policy that would help attain those performance standards. One difference for the Oregon Resilience Plan was that it needed to encompass the entire state unlike the City of San Francisco study, and that it focused on the Cascadia earthquake threat, unlike the Washington study which considered multiple earthquake scenarios.

To complete the plan without funding and on a one-year schedule, OSSPAC chose to tap into volunteer expertise from Oregon's academic, professional, governmental and public communities. Over one hundred volunteer experts drawn from a broad section of Oregon society were organized into eight work groups to survey the following parts of the problem:

- Cascadia Earthquake Scenario
- Business and Workforce
- Coastal Communities
- Critical and Essential Buildings
- Energy
- Transportation
- Information and Communications
- Water and Wastewater

The purpose of the task group assigned to the Cascadia Earthquake Scenario was to develop a detailed description of the likely physical effects throughout Oregon of a major Cascadia subduction earthquake so that the other groups could assess the impact on their respective sectors. Each of the remaining seven groups focused on one of the sectors of society or parts of the built environment listed above. The Coastal Task Group was included to recognize the unique risk along the coast: this region will experience a combination of tsunami damage and damage from extreme shaking.

Each group was charged with three primary tasks: First, determine the likely impact of the scenario earthquake on the assigned sector and estimate the time required to restore functions in that sector if

the earthquake were to happen under current conditions. Second, define performance targets for the sector. The targets represent the desired timeframes for restoring functions in a future Cascadia earthquake—in other words, the timeframes within which functions must be restored if Oregon is to be resilient. Finally, provide a series of recommendations to OSSPAC for changes in practice and policy that, if implemented, would ensure that Oregon reaches the desired resilience targets over the next 50 years.

The products from the various task groups were reviewed by an advisory group of subject matter experts to ensure that the material was accurate, complete, and up-to-date. OSSPAC then reviewed the recommendations and selected and endorsed those that the commission felt offered the most effective way to achieve resilience to a great Cascadia disaster.

Great Earthquakes on the Cascadia Subduction Zone

For the last twenty-five years, the scientific community has been aware of the possibility that a great earthquake caused by the Cascadia subduction zone could strike the Pacific Northwest. Now, after decades of research and recent great earthquakes in Sumatra, Chile, and Japan, awareness of this threat is widespread in Oregon, and we know enough to paint a picture of what Oregon might look like after such an earthquake. Oregon is a geologic mirror image of northern Japan (see Figure 1.1). In both places, the Pacific Ocean floor is sliding beneath the adjacent continents along giant faults called subduction zones. The scientific understanding of the Cascadia threat makes it clear that very large earthquakes will occur in Oregon's future, and that our societal and physical structures are poorly prepared to meet the threat unless we take action now to start building the necessary resilience.

What Are Subduction Zone Earthquakes?

The surface of the earth is broken into dozens of tectonic plates—continent-sized slabs of rigid rock that slowly slide across the more pliant mantle of the earth beneath. Moving at speeds of a few inches per year, the plates can pull apart, slide past each other, or collide head on. Where an oceanic and a continental plate collide, a subduction zone forms, as one plate is forced beneath the other, deep into the softer rock of the mantle. A great arc of subduction zones surrounds the Pacific Ocean, producing what geologists call the "Ring of Fire." In Japan, the ocean floor of the Pacific Plate moves towards the west, sliding beneath the Eurasian Plate that supports the islands of Japan. The Pacific Northwest is a geologic mirror image of Japan, with the Pacific Ocean floor moving towards the east, sliding beneath Oregon, Washington, and Northern California along a 600-mile fault called the Cascadia subduction zone.

In Japan, there has never been any doubt that great subduction earthquakes are possible: Japan's long written history has recorded many such events, with the 2011 Tohoku earthquake being the most recent and one of the most powerful and destructive. In that earthquake, a section of the Pacific Ocean floor measuring 300 miles long and 125 miles wide lurched as much as 100 feet down the subduction zone, causing a great magnitude 9.0 earthquake. The eastern edge of the Eurasian Plate, which had been slowly bending for centuries under the relentless pressure of subduction, snapped back during the

earthquake, displacing trillions of tons of seawater and triggering a catastrophic tsunami. The release of the bent Eurasian Plate caused land along the coast of Japan to permanently sink several feet, and the strong shaking from the earthquake caused widespread landslides on steep slopes (both on land and undersea) and widespread liquefaction of soft sediments on land.

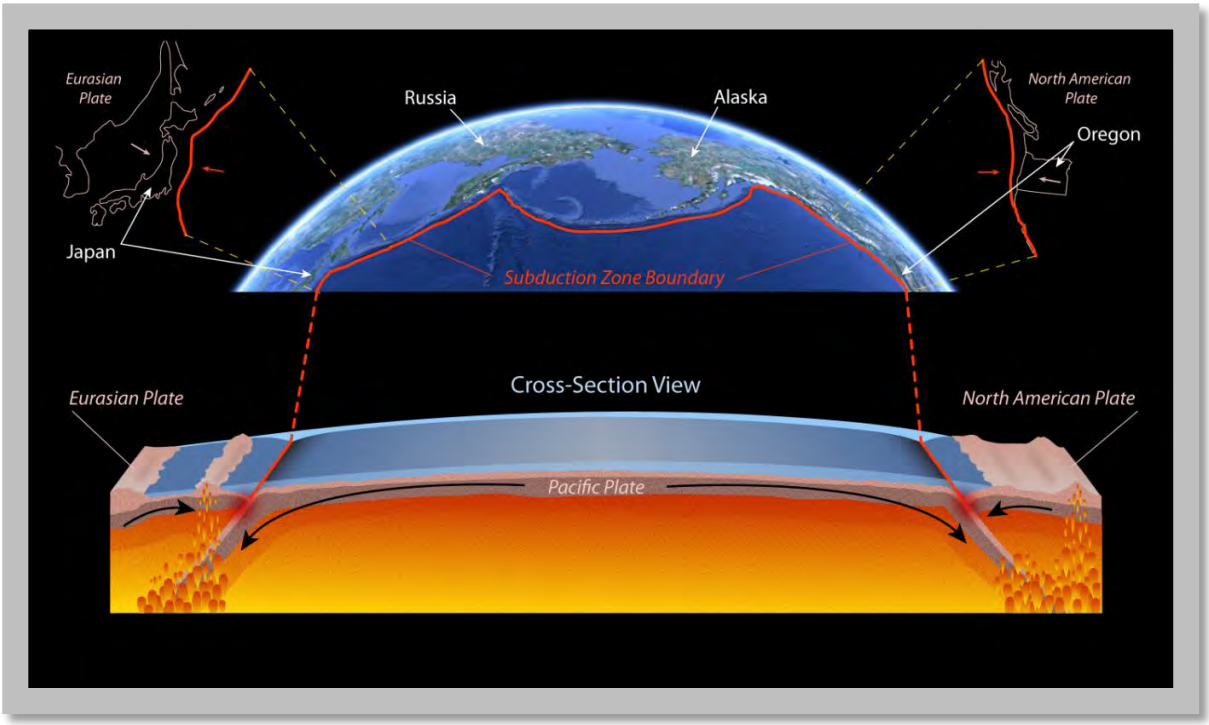


Figure 1.1: Oregon is a geologic mirror-image of Northern Japan. In both places, the Pacific Ocean floor is sliding beneath the adjacent continents along giant faults called subduction zones (Source: Graphic by Dan Coe, DOGAMI).

In 1984, when seismologists first proposed that Cascadia might produce similar earthquakes, there was considerable doubt. Research since then has confirmed that Cascadia has a long history of great subduction earthquakes and that energy for the next great earthquake is currently building along the fault. Geologic studies (see Figure 1.2) have uncovered evidence of the coastal subsidence, tsunamis, landslides, and liquefaction that were produced by past Cascadia earthquakes, and ultra-sensitive GPS measurements show that the Oregon coast is moving eastward a few inches per year along with the Pacific Ocean floor, motion that will be abruptly reversed during the next great subduction earthquake. There is no scientific doubt that another great subduction earthquake will strike the Pacific Northwest; the questions now are how soon, how large, and how destructive that earthquake will be.

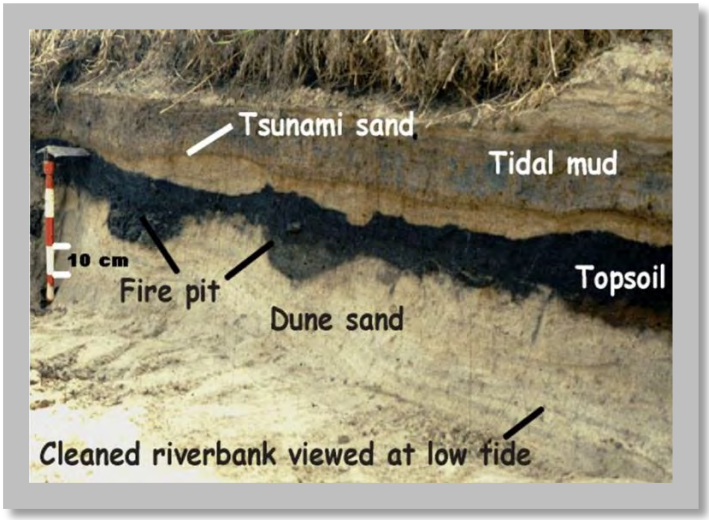

Figure 1.2: This photo (Source: Brian Atwater, USGS) shows a riverbank from the Salmon River estuary where Native American firepots were found in a forest soil that subsided in the 1700 AD earthquake and was buried by tsunami sand and tidal mud.

Geologists have assembled a ten thousand year record of past Cascadia earthquakes (see Figure 1.3) by studying sediments in coastal marshes and on the ocean floor. This record shows that past earthquakes have occurred at highly variable intervals and can range widely in size and in which parts of the Pacific Northwest they affect. About half of the past earthquakes have been very large (estimated magnitude 8.3 to 8.6) and centered on the southern Oregon coast, while the other half have been great (estimated magnitude 8.7 to 9.3) and extending from northern California to British Columbia. The most recent event occurred on January 26, 1700 AD, and was a great earthquake with a magnitude of 9.0. The time interval between previous earthquakes has varied from a few decades to many centuries, but most of the past intervals have been shorter than the 313 years since the last event. It is simply not scientifically feasible to predict, or even estimate, when the next Cascadia earthquake will occur, but the calculated odds that a Cascadia earthquake will occur in the next 50 years range from 7-15 percent for a great earthquake affecting the entire Pacific Northwest to about 37 percent for a very large earthquake affecting southern Oregon and northern California. The likelihood of a M 9 Cascadia earthquake during our lifetimes and the consequences of such an earthquake are both so great that it is prudent to consider this type of earthquake when designing new structures or retrofit of existing structures, evaluating the seismic safety of existing structures, or planning emergency response and preparedness.

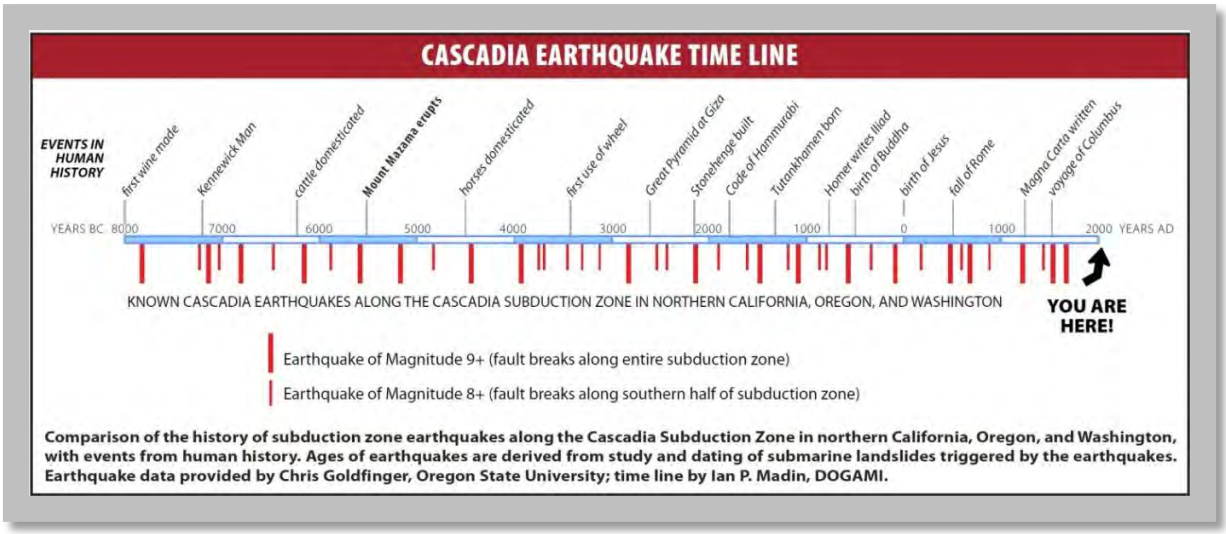

Figure 1.3: This timeline compares the 10,000-year-long history of Cascadia earthquakes to events in human history.

Resilience Plan Earthquake Scenario

For the purpose of this resilience planning effort, we chose to look at the effects of a great earthquake of magnitude 9.0, because it is a very real possibility that would affect all of Oregon and is directly comparable to the 2011 Tohoku earthquake, the effects of which are all too well known. Using the latest models from the United States Geological Survey (USGS), we simulated the strong shaking that is likely to occur during the region's next magnitude 9.0 event. The simulated shaking map was then used to estimate the amount of ground failure due to liquefaction and landsliding that would result from such an earthquake. For the tsunami, we used a model of the inundation from a magnitude 9.0 event. This model, which was produced by the Oregon Department of Geology and Mineral Industries (DOGAMI), was applied to maps of the coast to show which areas and facilities would be inundated. The tsunami models also provided estimates of the permanent coastal subsidence that would accompany the earthquake and tsunami. These maps of simulated earthquake effects were used to evaluate the likely performance of Oregon's critical buildings and infrastructure.

The simulation shows that Oregon would experience shaking very similar to the shaking that northern Japan endured in 2011. As indicated in Figure 1.4, areas along Oregon's coast would experience severe to violent shaking, while cities along the I-5 corridor would experience strong or very strong shaking. East of the Cascades, shaking would be light to moderate. In all areas, the strong shaking would last from two to four minutes.

This expected pattern of damage led OSSPAC to evaluate the state in four distinct zones (see Figure 1.5):

- The Tsunami Zone, where severe shaking and tsunami inundation would cause near total damage, and threaten the lives of thousands of residents.

- The Coastal Zone, where severe shaking and damage to transportation systems would severely disrupt and isolate communities and where the major challenge after the earthquake would be to keep the population sheltered, fed and healthy.
- The Valley Zone, where widespread moderate damage would severely disrupt daily life and commerce and where restoring services to business and residents would be the main priority.
- The Eastern zone where light damage would allow rapid restoration of services and functions, and where communities would become critical hubs for the movement of response recovery and restoration personnel and materials for the rest of the state.

The results of the ground failure simulation (see Figure 1.6) suggest that large areas of western Oregon would be severely affected. Strong shaking causes ground failure in two ways. Along rivers, lakes, and the coast, where there are deposits of loose water-saturated sand, shaking causes the sand to liquefy, and the weakened soil readily settles or spreads. On steep slopes with weak soil and rock, or in areas of existing landslides, the shaking can cause new or renewed landslide movement, with very damaging results. Ground failure can cause severe damage to buildings and is particularly damaging to lifelines, which by their nature must often cross wide areas of affected ground.

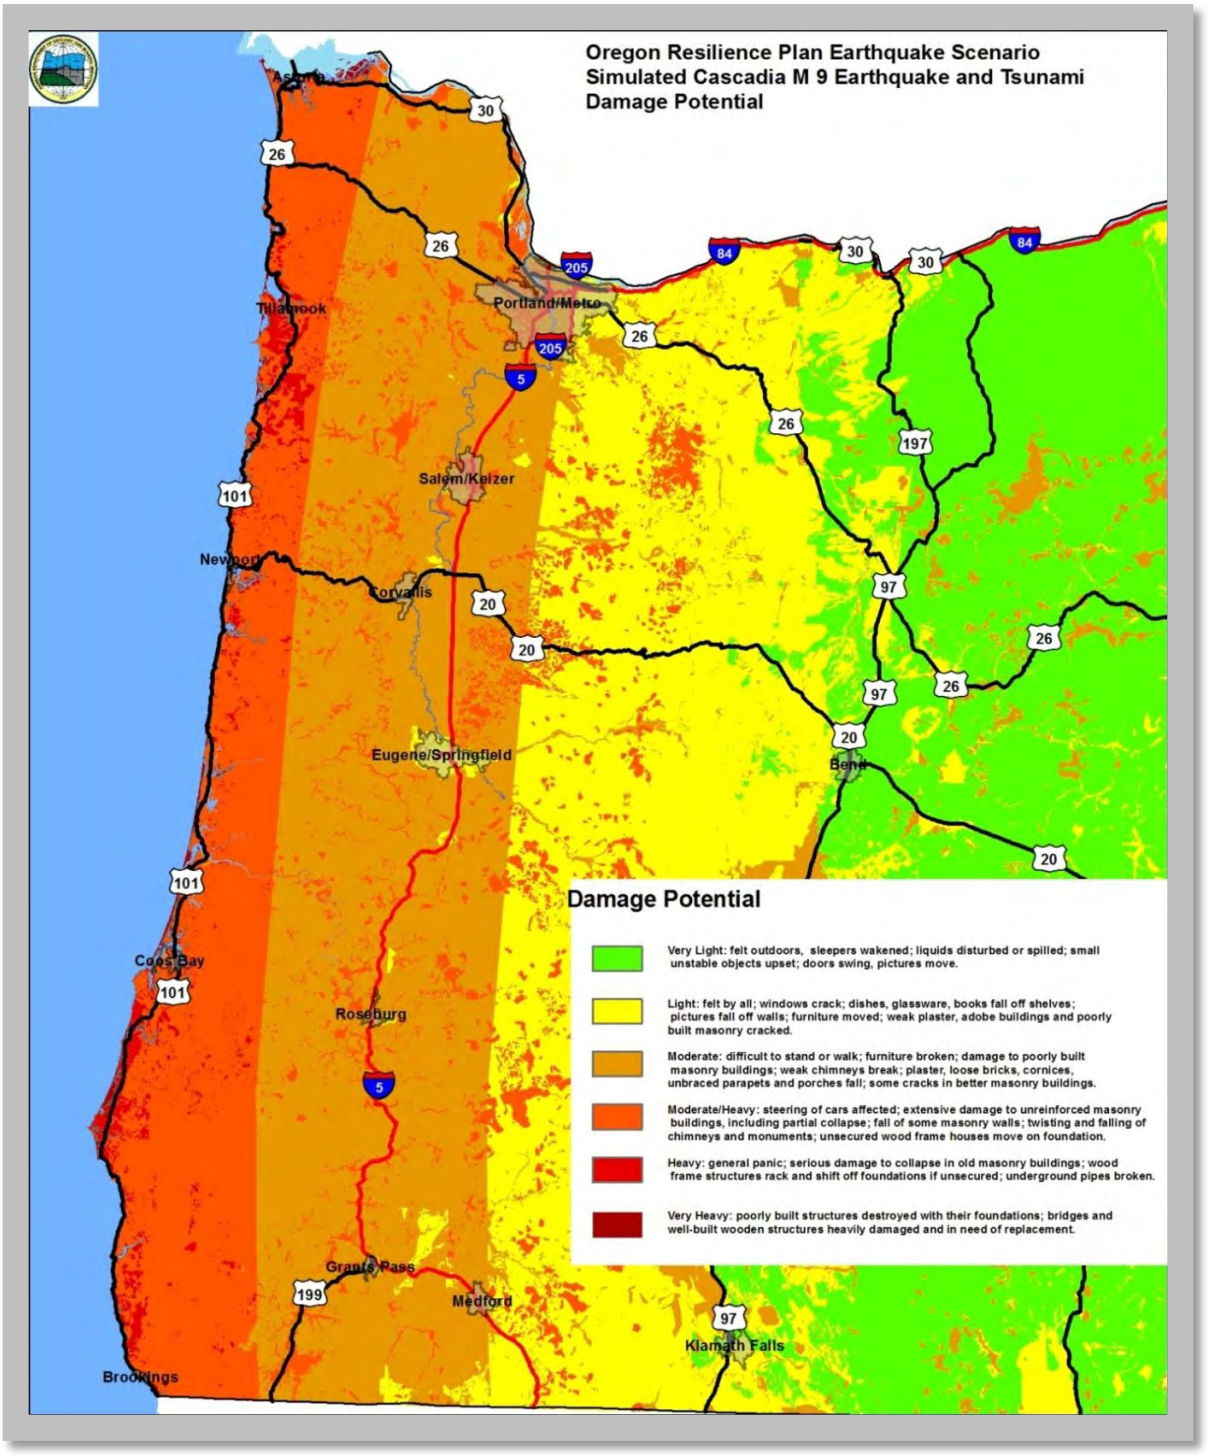

Figure 1.4: Simulated shaking for the magnitude 9.0 Cascadia scenario.

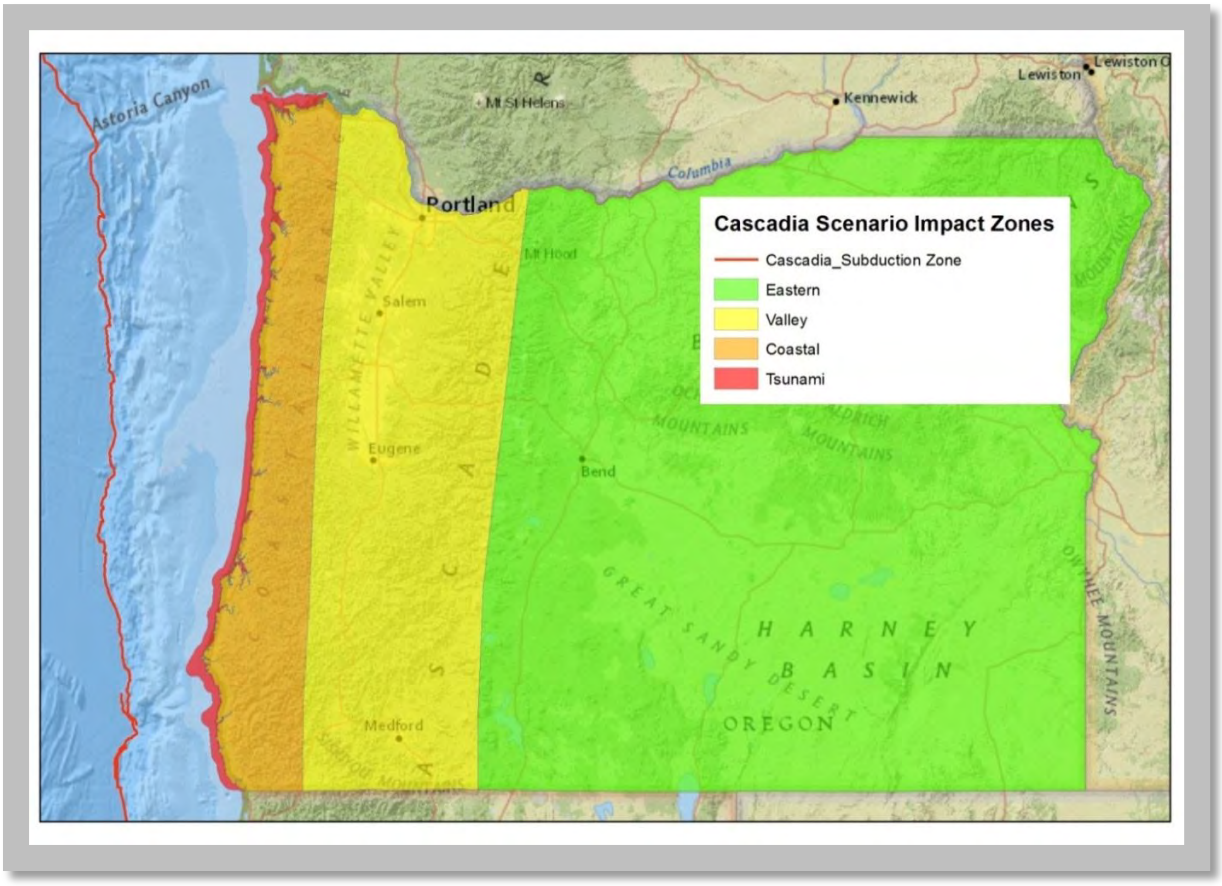

Figure 1.5: Impact zones for the magnitude 9.0 Cascadia earthquake scenario. Damage will be extreme in the Tsunami zone, heavy in the Coastal zone, moderate in the Valley zone, and light in the Eastern zone.

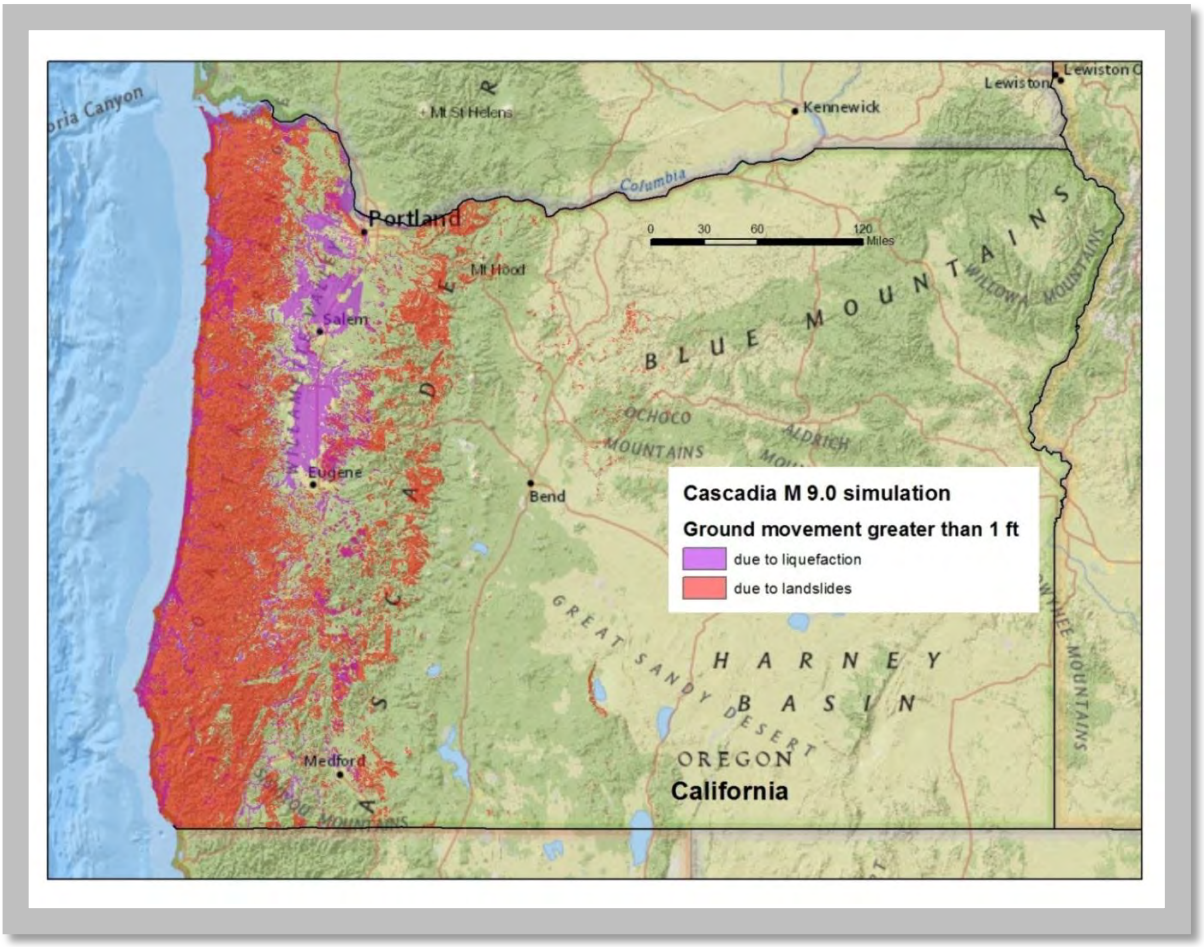

Figure 1.6: Ground failure and movement for the magnitude 9.0 Cascadia earthquake scenario. Colored areas could experience more than one foot of ground movement due to earthquake-induced landslides in steep areas and liquefaction failure in lowlands. Both forms of ground failure can cause severe damage.

The amount of tsunami inundation that would be experienced along the coast due to the scenario magnitude 9.0 earthquake is quite variable and depends on local topography. Large parts of many low-lying communities, such as Warrenton, Seaside, Rockaway Beach, and Neskowin (see Figure 1.7), will be inundated.

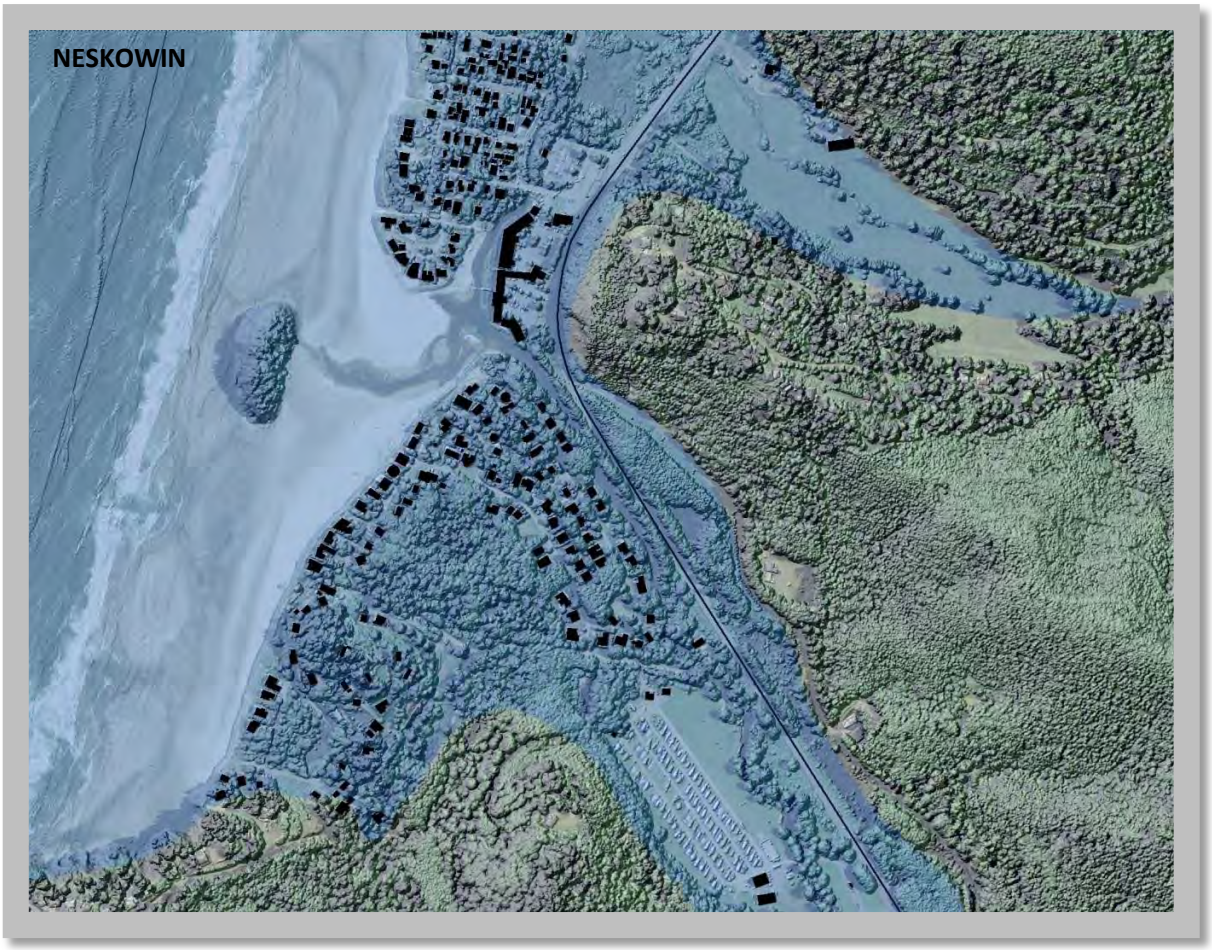

Figure 1.7: Estimated inundation of Neskowin due to the tsunami from the scenario magnitude 9.0 Cascadia earthquake. This tsunami map is based on the SB 379 regulatory inundation line.

The same large scale bending of the tectonic plates that causes the tsunami will also cause immediate and permanent subsidence in many parts of the coast. As indicated in Figure 1.8, the amount that the land will drop varies from place to place, with as much as 5 to 6 feet possible near Astoria, and even more possible at Brookings.

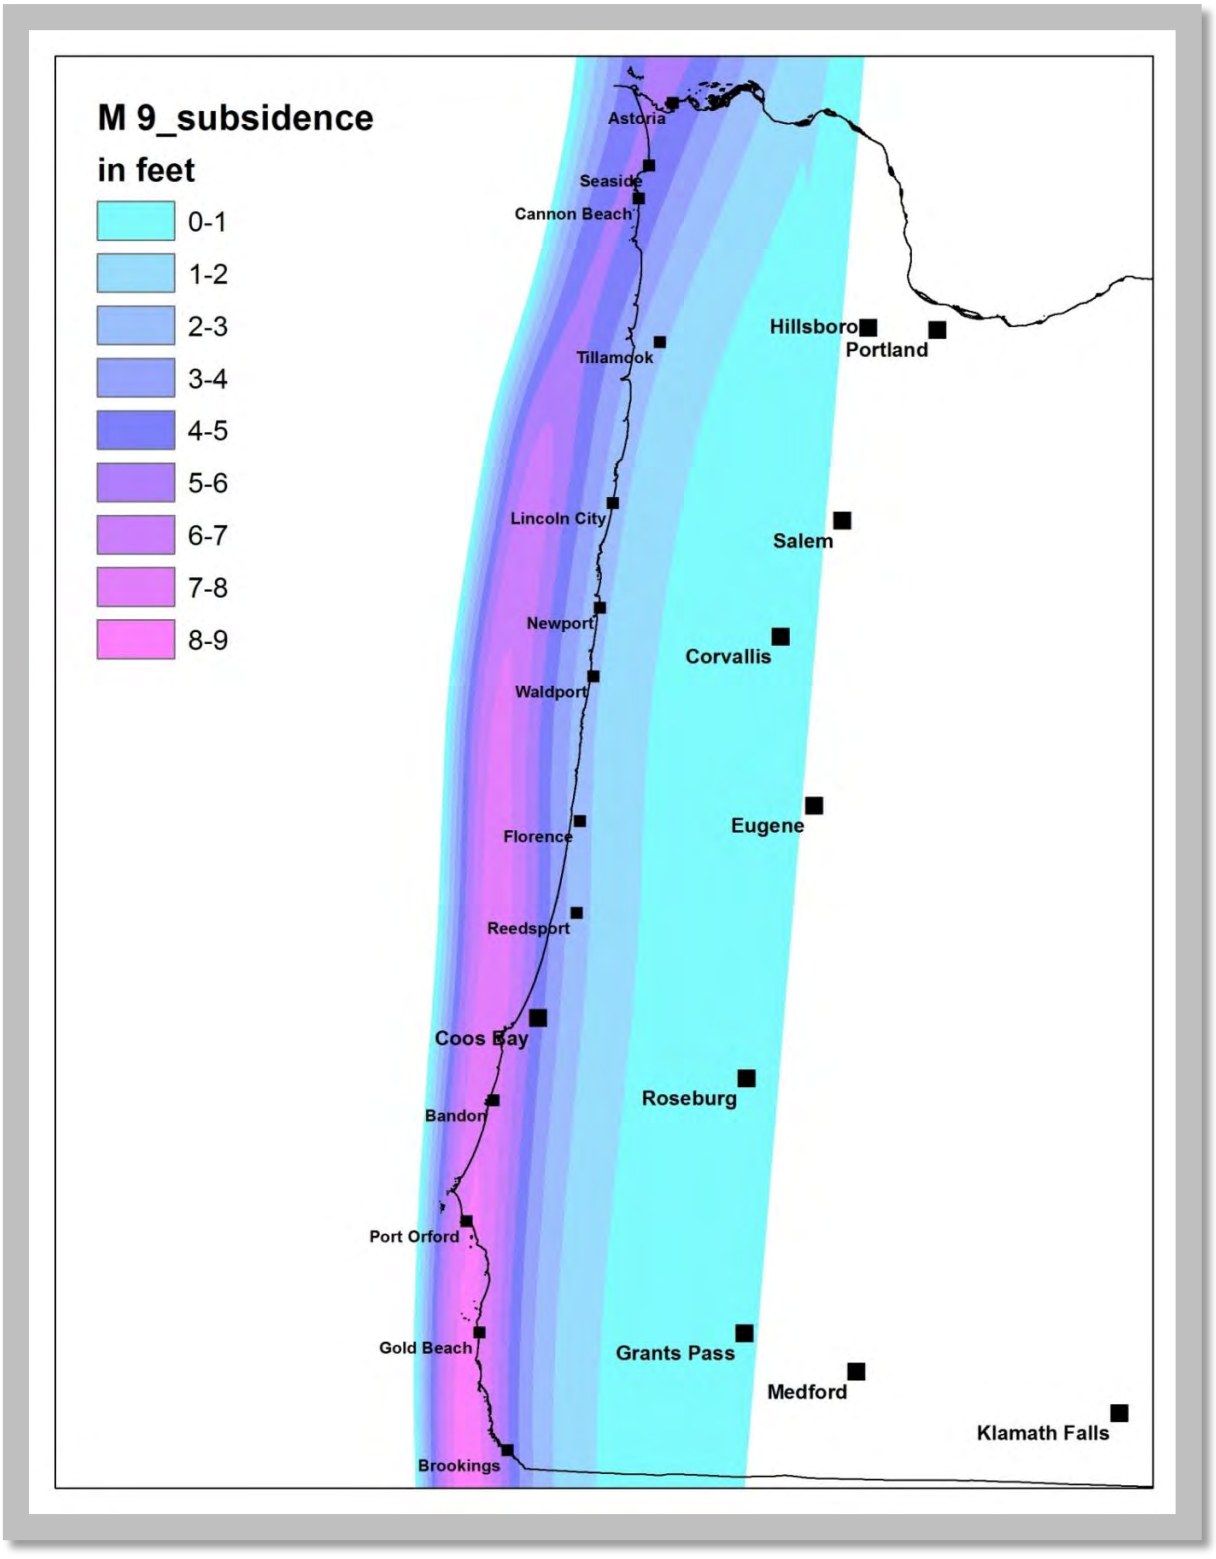

Figure 1.8: Estimated permanent land subsidence from the scenario magnitude 9.0 earthquake for the Oregon Coast. Subsidence would occur during the earthquake.

Oregon's Infrastructure and Risk

The estimated impacts of a Cascadia subduction earthquake in Oregon are catastrophic. This is partly due to the sheer size and power of a magnitude 9.0 earthquake, but it is also the result of the inherent vulnerability of our buildings and lifelines. In 1974, Oregon adopted a statewide building code that mandated some seismic resistance for new construction. Prior to that date, the majority of buildings in Oregon had been designed without regard to earthquake forces. In 1993, Oregon's building codes were changed to require designs that would accommodate shaking from a Cascadia subduction zone earthquake, almost doubling the earthquake forces used in earlier codes. This means that the majority of buildings in Oregon have not been designed to resist the shaking from a magnitude 9.0 Cascadia earthquake. This widespread vulnerability of Oregon's buildings is grimly illustrated in the *Statewide Seismic Needs Assessment* completed by the Oregon Department of Geology and Mineral Industries (DOGAMI) in 2007. This study surveyed public schools and public safety buildings (police and fire stations, hospitals, and emergency operation centers) in Oregon and assessed their potential for collapse in a major earthquake. Almost half of the 2,193 public school buildings examined had a high or very high potential for collapse, as did almost a quarter of the public safety buildings. Of the 2,567 highway bridges in the Oregon Department of Transportation (ODOT) system, 982 were built without seismic considerations, and of the rest, only 409 were designed specifically with consideration of Cascadia subduction zone earthquakes. The list goes on: old, brittle iron water pipes in the Portland water system, century-old bridges over the Willamette River, and highways and power transmission lines that traverse landslide-prone terrain. The core of our vulnerability to a Cascadia earthquake is not the earthquake alone, but the inadequacy of our built environment.

The experience of the Tohoku earthquake shows that few structures are likely to survive in the tsunami inundation zone. In Oregon, the USGS estimates that almost 1,900 businesses employing nearly 15,000 people are located in the scenario inundation zone. The inundation zone also contains almost 10,500 housing units with a total population of just over 22,000. This exposure to the extreme hazard posed by the tsunami is unavoidable.

Another major factor that amplifies the effects of a Cascadia earthquake is the interdependency of our lifeline systems, coupled with the wide geographic spread of a Cascadia disaster. Unlike a severe storm, a Cascadia subduction earthquake would simultaneously damage power, natural gas, and petroleum lines, roads and bridges, water and sewer systems, critical buildings, and communications over large parts of three states (i.e., California, Oregon and Washington). Restoration of communication service would require that electric power be restored, which would require that roads and bridges be repaired, which in turn would require that the petroleum delivery and distribution system be repaired. These interdependencies between lifeline systems would be made even more difficult by the broad geographic extent of the damage. The nearest undamaged urban areas from which assistance could be organized would be Spokane, Washington, Boise, Idaho, and Redding, California. Virtually all of the resources required for the recovery of lifeline systems would have to come from outside the affected states.

Estimated Impacts

The scenario Cascadia earthquake would be an unprecedented catastrophe for Oregon and for the United States. It would impact every aspect of life for all Oregonians and for the residents of northern California, Washington, and British Columbia. The effects of a Cascadia subduction earthquake will be greatest on the coast, which is right next to the subduction zone fault, and will diminish as one goes inland. This, in combination with Oregon's mountainous geography, divides the state into four impact zones: within the tsunami zone, damage will be nearly complete. In the coastal zone, shaking will be severe, liquefaction and landsliding will be widespread and severe, and damage will be severe. In the valley zone, shaking will be strong, liquefaction and landsliding will be common but less severe, and moderate damage will be widespread. In the eastern zone, shaking will be mild, landslides and liquefaction sporadic, and damage generally light.

The impacts of a great subduction earthquake on Oregon are impossible to predict accurately, but several studies have estimated damage and casualties, and those estimates give a sense for how far-reaching a disaster the next great earthquake will be. Estimated consequences include:

- Earthquake deaths ranging from 650 to 5,000, with another 600 to 5,000 deaths due to the tsunami.
- 24,000 buildings completely destroyed, and another 85,000 with extensive damage requiring months to years of repair.
- Approximately $32 billion in economic losses.
- 27,600 displaced households.
- Almost 10 million tons of debris (1 million dump truck loads).

These high levels of damage and loss reflect both the great size of the earthquake and the fact that many buildings, roads, bridges, and utility networks were designed before Oregon's building codes and practices recognized any significant earthquake threats, and most were designed before codes began to take great subduction earthquakes into account. Lifeline systems, such as highways and pipelines, are particularly vulnerable to ground failure, which will be widespread in the next great earthquake. As a result, the vulnerability analyses done for this plan are grim. For example, if the earthquake were to happen tomorrow, the estimated time to restore function would be:

- One to three years to restore drinking water and sewer service in the coastal zone.
- One month to one year to restore water and sewer in the valley zone.
- Six to twelve months to restore partial function of the top-priority highways in the valley zone.
- Two to four months to restore police and fire stations in the valley zone.
- Eighteen months to restore healthcare facilities in the valley zone, three years or more in the coastal zone.

- One to three months to restore electricity service in the valley zone.
- Three to six months to restore electricity service in the coastal zone.

These estimates of the time it will take to restore the functions necessary to maintain our population and economy are sobering, particularly when coupled with the likelihood that businesses will start to leave the state if services are not restored within one month. If we pursue a policy of "business as usual," our future after the next Cascadia earthquake will include decades-worth of declining economy and population. We can only avoid this future and achieve resilience by starting now on a sustained program to reduce our vulnerability and decrease our recovery time before the next earthquake inevitably occurs.

Recommendations

The Cascadia Scenario workgroup prepared a description of the likely effects of a magnitude 9 subduction earthquake for the other workgroups to use in their evaluations. The scenario used the best currently available data, and well-established methods, but still provides an estimate that has a lot of uncertainty and little detail. For an improved understanding of the threat posed by Cascadia earthquakes, we recommend that the state:

- ► Support Oregon universities and state agencies to carry out research into the effects of future Cascadia subduction earthquakes and tsunamis on Oregon's landscape, population, buildings and lifelines;
- ► Support Oregon universities and state agencies in preparing more detailed and accurate estimates of damage and loss in Oregon from future Cascadia subduction earthquakes and tsunamis; and
- ► Provide ready access to the best available Cascadia earthquake information for emergency responders and planners, architects and engineers, and the general public.
- ► In order to ensure that design of future structures, retrofit of existing structures, seismic vulnerability evaluations and preparedness planning will provide adequate resilience, we also recommend that all of these efforts use, as a minimum, the ground motion parameters provided by the most current version of the International Building Code, which reflect the most current USGS seismic hazard maps.

2. Business and Workforce Continuity

Introduction

We know from experience of previous disasters such as hurricanes and earthquakes that a large proportion of the businesses affected by these natural cataclysms will not survive. Nevertheless, it is our mission to make Oregon's businesses and workforce more resilient against the threat posed by a megathrust Cascadia earthquake. The key to business survivability begins with the survivability of the buildings that house the businesses (see Figure 2.1). Few businesses can survive without a domicile for more than a month. Experience tells us that if a business cannot reoccupy its offices within a month, it will either relocate, or dissolve.

Reoccupation of a business's workspace depends on three principal factors: the building's structure must be safe; the workforce must be able to get to the workplace; and, the building's mechanical and utility systems must be up and running. In addition, it is essential that the business's customers survive the catastrophe. This is of particular concern when a business's customers are other businesses that may be housed in buildings that do not survive. A 2011 Cascadia earthquake study by the Federal Emergency Management Agency estimated that only about 20 percent of the buildings in the Metro Region would escape damage, while 80 percent would suffer damage ranging from slight damage to a complete loss (see Figure 2.2).

Statewide, about 27 percent of commercial buildings would survive without damage and about 22 percent would suffer slight damage. The remaining buildings, which would suffer moderate (31%) or extensive (16%) damage, or be completely destroyed (4%), will not be immediately inhabitable for commercial purposes.

Evaluation of the Scenario Earthquake's Economic Impact

A magnitude 9.0 Cascadia subduction earthquake has the potential to inflict tens (and maybe even hundreds) of billions of dollars in damage to existing property and infrastructure, but the costs of the event are not limited to these billions of dollars in replacement costs. While damaged infrastructure is removed, repaired, or replaced, normal economic activity will be interrupted. Some firms may be forced to shut down or move. Some people may migrate out of the state. These spillover disruptions may permanently change the trajectory of the regional economy, imposing damages that dwarf those inflicted directly by the event.

Preparing now and creating a more resilient Oregon is essential to reducing these costs and preserving the health of our communities and our economy. Resilience will reduce the deaths and injuries that such an event will inevitably cause. Resilience will minimize the damage to our homes and office buildings, to our roads and bridges, to our energy and telecommunications transmission systems, and to our water and wastewater systems. In short, resilience will minimize the disruptions to our economy, our community, and ourselves.

Every large natural disaster is unpredictable, not only in its timing, but in its effects. We cannot say precisely how large the damages associated with a Cascadia event will be, nor forecast in detail what will be damaged, nor foresee how the loss of buildings, roads, utility infrastructure, and other elements will ripple through the economy. As best, we can draw on economic theory and the experiences from previous disasters to assess the potential effects of such an event.

HOW DO NATURAL DISASTERS AFFECT REGIONAL ECONOMIES?

Fundamentally, natural disasters break things. They break houses and buildings. They break roads and bridges. They break pipelines and transmission lines. They break water pipes and treatment plants. When things break, people and the economy suffer.

Direct Damage

What disasters break is expensive to repair. Economists use the term *direct damage* to refer to damage that disasters inflict on buildings, infrastructure, inventories, natural resources, and people (Pelling, Oezerdem, and Barakat, 2002). When news articles report that a disaster inflicted $300 billion in damages, they are reporting an estimate of the direct damage inflicted by the event. They are reporting the expected amount of money needed to replace what has been lost.

Indirect Damage

When things break, they can no longer be used to support economic activity. If key port infrastructure breaks, the port must shut down. If a bridge breaks, workers may not be able to get to work and firms may not be able to ship or receive goods. If the internet or telecommunications networks fail, firms may lose customers. If oil spills into rivers, river dependent industries, such as fishing or recreation, may be disrupted. Economists use the term *indirect damage* to refer to the loss of economic activity that results from the inability to use what breaks (Pelling, Oezerdem, and Barakat, 2002).

Figure 2.3: Branford, Conn., August 31, 2011 -- A gas station on Route 95 is closed due to loss of power from Hurricane Irene. (Source: Jocelyn Augustino/FEMA)

Thus, the benefits of greater resilience can be assessed along two lines: First, greater resilience means fewer things break, so Oregonians will need to spend less money on cleaning up, repairing, or replacing

what has been lost. Second, when fewer things break, there is less potential for extensive interruption of the economy (see Figure 2.3).

GREATER RESILIENCE MEANS LESS DIRECT DAMAGE FROM THE EVENT

Spending on resilience today means spending less on recovery later. For an event as large as a magnitude 9.0 Cascadia subduction zone earthquake, such avoided costs may be substantial. For instance, the recent earthquake in Sendai, Japan inflicted approximately $300 billion in damage, the 1995 Kobe earthquake inflicted $200 billion in damage, hurricane Katrina inflicted approximately $160 billion in damage, and the 1994 Northridge earthquake inflicted nearly $100 billion in damage (see *The Economist* online, 2011. "Natural Disasters: Counting the Costs"). For context, Katrina's direct damages equaled nearly two-thirds of total personal income in Louisiana and Mississippi in 2006 and the Northridge quake inflicted damages equal to approximately 25 percent of the Los Angeles metro area's personal income in 1994 (US Bureau of Economic Analysis, Regional Economic Accounts). By extension, if a Cascadia earthquake only inflicts damage proportionate to Hurricane Katrina, it might cost Oregon approximately $100 billion to repair what was lost.[1]

Ultimately, we cannot know precisely how much damage an earthquake in Oregon will inflict. The precise amount of initial damage will depend on the magnitude of the earthquake, the value of property and infrastructure in Oregon, and what we do to protect our property and infrastructure before the event occurs. We do know that recovery is unlikely to come cheaply.

While some (and hopefully much) of the money required to fund recovery will come from outside the region (for example, from insurance payments or the federal government), recovery will still require substantial local resources from both the private and public sectors. Money spent repairing something the region already had is money that cannot be spent pursuing other priorities. Furthermore, some of what Oregon will lose to the earthquake cannot be replaced. The direct damage estimates described above do not include damages to human health and other hard-to-value items, such as historical or culturally significant items.

GREATER RESILIENCE MEANS FEWER INTERRUPTIONS OF NORMAL ECONOMIC ACTIVITY

Disasters Depress Normal Economic Activity

Ultimately, the direct costs of a Cascadia subduction zone earthquake are likely to pale in comparison to the indirect costs. The interruption of normal economic activity could generate costs so substantial that the region may never fully recover.

In 2011, Oregon's economy produced nearly $195 billion in goods and services (US Bureau of Economic Analysis, Regional Economic Accounts). The state's firms and agencies employed over 2.2 million people who earned over $104 billion in compensation (Bureau of Economic Analysis, Regional Economic Accounts). While these workers produced goods and services in a wide variety of industries (including

[1] Oregon's 2011 total personal income was $145 billion.

agriculture, logging, wood products manufacturing, computer and electronics manufacturing, metals manufacturing, company management, and tourism), every industry depends on various factors that could be disrupted by a Cascadia event.

For a regional economy to operate smoothly, several conditions must be met:

(1) Raw materials (food, water, energy, information, and other commodities) and imported goods and services must be available and able to reach households and firms.

(2) Households must be able to provide workers to firms (and government) and they must be able to consume the goods and services that are made available by local producers. In other words, households must have their basic needs satisfied, and they must have the resources to consume.

(3) Firms must be able to combine raw materials, workers, and equipment to transform the available inputs into finished products.

(4) Finished products must be available to customers, inside and outside of the region.

These basic relationships are illustrated in Figure 2.4; however, a severe natural disaster would likely affect each of these areas and break the key infrastructure that connects them. For example, a severe natural disaster could:

(1) Directly damage raw materials or inventories of imported goods.

(2) Damage the roads, bridges, pipes, or utility lines used to transport such goods to households and firms.

(3) Damage houses and households and limit both their ability to provide workers to firms and their ability to consume goods and services produced by local firms.

(4) Damage the buildings and equipment owned by firms, making production impossible.

(5) Damage the infrastructure used to transport finished products to customers (households or other firms).

If any of these (or many other possible) impacts occur, Oregon's economic output will suffer. Oregon's employers simply cannot produce and sell their goods and services if they lack the space in which to carry out production, if inputs cannot reach them, or if their outputs cannot get to their customers. When firms cannot produce and sell their goods and services, they stop contributing to the regional economy, and they may be unable to survive if the interruption lasts too long.

Firms may also struggle due to disruptions in consumption. Seventy percent of Oregon's workers work in industries that primarily serve customers in Oregon (that is, they work in the local as opposed to the traded sector). (For additional information about the distinctions between the traded and local sectors,

see Ward, Thoma, Moore, and Tapogna, 2012). Local sector firms will suffer if Oregonians (both households and firms) do not have money to spend, either because they have lost their sources of income or because they are spending their incomes on repairing or replacing what was lost. Local sector firms could also suffer if people or firms chose to leave the region entirely. Thus, even if local sector workers and firms are fully capable of continuing to produce, they could suffer because their customers have disappeared.

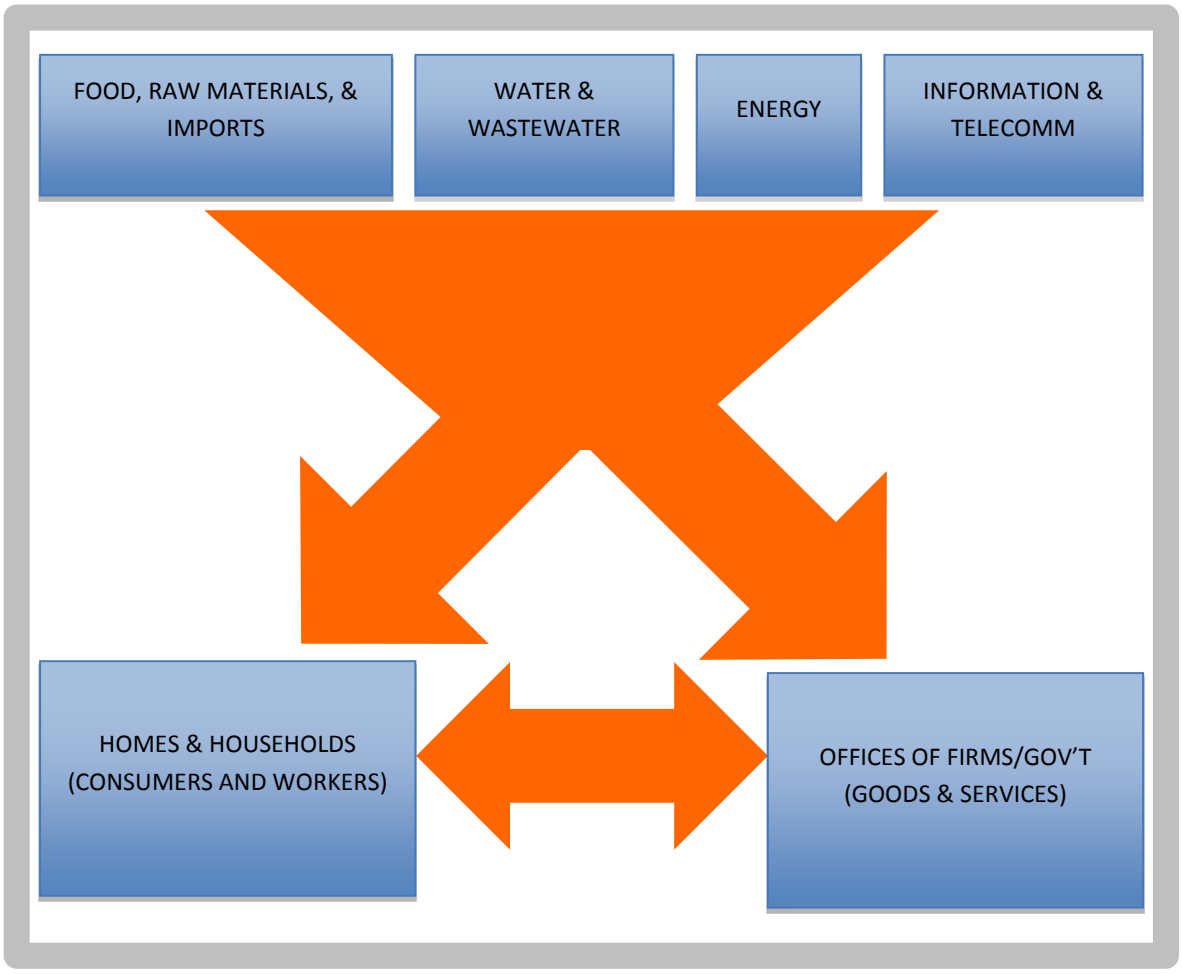

Figure 2.4: Core Economic Relationships That May Be Affected By Natural Disasters

A Disaster's Indirect Effects Are Felt over Both the Short and the Long Run

When people imagine the economic effects of a natural disaster, they typically imagine the disruptions that occur in the immediate aftermath of the event. Economists refer to these initial disruptions as the

short-run effects of the disaster[2] (Cavallo and Noy, 2010). During this period (which may last a few years), normal economic activity may be severely inhibited as resources are diverted toward cleanup and recovery efforts. The literature that examines the short-run effects of natural disasters finds that the event will depress economic outcomes for a few years, but that areas with "a better educated population, better governance, and more direct access to reconstruction resources will fare better in the disaster's aftermath" (see Noy, 2011).

Unfortunately, the effects of a natural disaster may not be limited to the time it takes to clean up and rebuild. Disasters may permanently shift the trajectory of the economy. In other words, the disaster may have long-run effects.[3]

Some economists argue that economies are resilient and generally return to "as before" conditions within a few years[4] (see DuPont and Noy, 2012). However, recent evidence suggests that disasters may have larger long-run consequences than previously thought (see DuPont and Noy, 2012; Lynham, Noy, and Page, 2012; and Coffman and Noy, 2012). Specifically, economist Ilan Noy and various co-authors have examined the long-run regional effects of the 1995 Kobe earthquake, the 1960 tsunami in Hilo, Hawaii, and the 1992 hurricane in Kauai, Hawaii (DuPont and Noy, 2012; Coffman and Noy, 2012; Lynham, Noy, and Page, 2012). In each case, these studies found that the disaster caused outcomes to deteriorate from what they likely would have been in the absence of the disaster; however, how the disaster adversely affected long-run outcomes differs across these three events.

Kobe (DuPont and Noy, 2012): The Kobe earthquake inflicted nearly $200 billion in damage (in 2010 dollars). The quake severely damaged Kobe's port–a significant source of local economic activity–as well as 80 percent of its shoe factories, 50 percent of its sake breweries, and half of its markets. While many sectors recovered to pre-earthquake levels, several sectors of Kobe's economy remain significantly below these levels. Port capacity recovered to 98 percent of pre-earthquake levels, but the number of ships handled peaked at 87.7 percent of pre-earthquake levels. Mining and manufacturing activity has only reached 81.3 percent of pre-earthquake levels. Shoe production remains at 60 percent of pre-earthquake levels. Sake breweries ship less than 50 percent of their pre-earthquake levels. Department store sales remain at only 75 percent of pre-earthquake levels.

While such changes could reflect other trends and not the influence of the earthquake, a careful analysis, which compared Kobe and its surrounding areas to parts of Japan not severely affected by the earthquake – finds evidence that the earthquake had lasting effects on local output. While output per

[2] The short run effects are generally those that occur within the first three years of the event, and long run effects are generally those occurring beyond five years.

[3] Economic theory does not provide a clear expectation for the direction or magnitude of long run effects. Cavallo et al. (2010) summarize the competing theories.

[4] This position was effectively summarized by John Stuart Mill in 1872 when he stated, "…what has so often excited wonder, the great rapidity with which countries recover from a state of devastation; the disappearance, in a short time, of all traces of the mischiefs done by earthquakes, floods, hurricanes, and the ravages of war. An enemy lays waste to a country . . . and yet in a few years after, everything is much as it was before."(Mill, 1872). Many economists espoused similar sentiments in the wake of the recent 2010 Tohoku earthquake.

capita initially spiked with recovery efforts, it fell as recovery efforts waned. In 2010, output per person was 13 percent lower than it likely would have been in the absence of the earthquake. For context, if Oregon were to experience a 13 percent decline in output per capita, output would fall by over $6,200 per person, and Oregon's output per capita would fall from 9th to 23rd among all states.

Hilo (Lynham, Noy, and Page, 2012): In 1960, a tsunami generated by the magnitude 9.5 Valdivia earthquake in Chile (the largest earthquake ever recorded) struck Hilo, Hawaii. This tsunami killed 61 people and inundated 600 acres, completely destroying half of the buildings in the inundation zone. An analysis that compared the affected area to other Hawaiian islands that were not significantly affected by the tsunami found that, 15 years after the event, Hilo was short of people, firms, and jobs.

Fifteen years after the tsunami, Hilo's population was nine percent below the levels it likely would have achieved in the absence of the tsunami. The total number of establishments remained depressed and unemployment remained elevated–33 percent higher than expected. Finally, sugar, the island's most important industry, remained depressed following the tsunami.

Kauai (Coffman and Noy, 2012): In 1992, Hurricane Iniki struck Kauai (but largely missed the other Hawaiian islands). While the hurricane did not cause significant mortality, it did severely damage local infrastructure. The loss of infrastructure appears to have had significant long-term consequences. Twenty years after the event, population and employment on Kauai remain well below (15 percent) the levels expected in the absence of the hurricane.

Combined, these three studies suggest that disasters can substantially disrupt long-run economic performance. Thus, greater resilience may help Oregon avoid large long-run consequences such as severe losses to output per capita (such as occurred in Kobe) or population and employment (such as occurred in Hilo and Kauai). This is not inconsistent with how regional economists expect regions to respond to non-natural economic disasters. Frequently, when regional economies suffer adverse regional shocks, the economy shrinks and then grows from the new lower base at the same rate as before—never catching up to where it would have been in the absence of the shock (Blanchard, Katz, Hall, and Eichengreen, 1992).

Figure 2.5: Carrollton, New Orleans, LA, 9-17-05 -- Small business owners are planning on returning to New Orleans. After three weeks many areas are still without power and utilities. (Source: MARVIN NAUMAN/FEMA photo)

Natural Disasters Do Not Uniformly Affect Residents

The above discussion focuses on the effects of natural disasters on aggregate measures of economic activity (such as output per capita) but ignores potentially important distributional consequences of disasters. Even if the disaster produced no adverse effect on aggregate outcomes, the avoided distributional effects may be sufficient to justify investments in greater resilience. Disasters affect incumbent residents and they are the ones whose homes are damaged, whose jobs may be lost, and whose businesses may close. Even if the economy recovers, those who benefit from the recovery may be different from those who lost during the destruction. Evidence shows that poorer residents are particularly likely to suffer following a natural disaster because they lack access to resources to help them absorb the adverse shock (Sawada and Shimizutani, 2008).

RESILIENCE AND REGIONAL ECONOMIES

In sum, greater resilience may benefit Oregonians in three major ways. First, greater resilience means less stuff will break, so Oregonians will spend less money later removing, repairing, or replacing items damaged by the event. Second, less breakage means smaller interruptions to normal economic activities in both the short and long run. Finally, greater resilience means fewer losses to the incumbent residents–particularly the poor who suffer the most when disasters strike.

While we cannot say with certainty how large such benefits may be, experiences with previous disasters suggest that the adverse consequences of disasters (and thus the benefits of greater resilience) may be large. Direct damages may reach into the hundreds of billions of dollars (amounts equal to half or more of Oregon's annual output). If damages are similar in magnitude to those inflicted by Hurricane Katrina, Oregonians will need to work for almost a year (at normal levels) to replace what the disaster destroys. Indirect damages are very difficult to estimate. When the disaster breaks things, what is broken can no longer be used to support the economy. As a result, the damage inflicted by the disaster may ripple through the economy reducing population, output, income, and employment over both the short and long run (Figure 2.5). Several recent case studies suggest that, in the 15 years following a major disaster, outcomes (population, employment, or income) fall 10-15 percent below levels they might otherwise have reached in the absence of the disaster.

Business Workforce Interdependency

Businesses and the business workforce do not exist in a vacuum. Without a government and a system of laws and enforcement of commercial instruments (such as contracts), a strong banking system to provide access to capital, and a transportation network to bring in and distribute raw materials and manufactured goods, businesses cannot thrive. Even businesses whose products are "intellectual capital," such as consultants, and personal services companies such as barbers or physical therapists, require strong information, communications, and municipal utility infrastructure to function successfully.

Figure 2.6 depicts some of the interdependencies of business, government, the public (both workforce and customers), banking, transportation, public and private infrastructure, and the healthcare sector. This figure is specifically intended to reflect the relationships following a major catastrophe and to serve as a guide for recovery. With the possible exception of the healthcare sector, the relationships depicted are also applicable to the interdependency of everyday commerce. The one notable omission is the education sector, which is a subset of both government (public schools) and business (private schools). Schools are likely to become major refugee and triage centers in the immediate aftermath of a Cascadia earthquake and tsunami, but from the standpoint of business recovery, schools are primarily important as a place where workers' children can spend their days, thus freeing up parents to return to work.

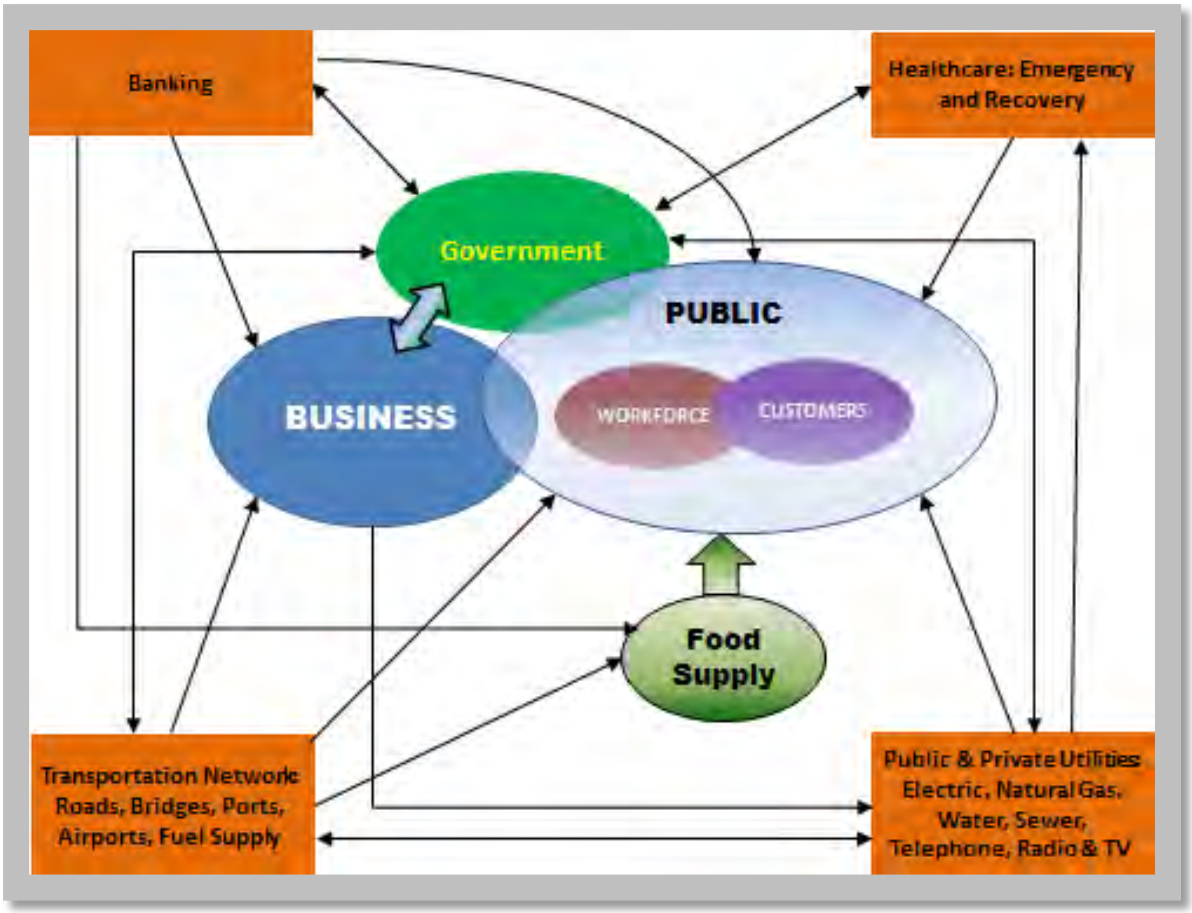

Figure 2.6: Business Workforce Interdependency

Some relationships, such as business interdependency with the healthcare sector are imputed through the business/workforce/public-to-healthcare relationship. In other words, to the extent that businesses rely on a healthy workforce and customers, who in turn rely on the healthcare sector for health-related services, the business sector relies on the healthcare sector through a sort of transitive property.

Recommendations

- **Rehabilitate or Replace vulnerable Oregon public schools**
  - *Finding*: The Department of Geology and Mineral Industries 2007 report assessed more than 1,100 public education buildings in Oregon at a high or very high risk of collapse in a major seismic event. Parents cannot return to work after a major seismic event if their children are unable to attend school.

- *Action Needed*: The State of Oregon shall establish (in addition to the General Obligation bond-funded Seismic Rehabilitation Grants Program) a statewide sinking or reserve fund, outside of the Oregon Emergency Management department budget, to fully fund the Seismic Rehabilitation Grant Program for public education facilities.

GOVERNMENT

Government, in addition to enforcing contracts and other commercial instruments, also provides security so that businesses can operate free from fear of being looted or robbed. Government's security mission also extends to the public (see Figure 2.7). In the aftermath of Hurricane Katrina, looting of non-essential[5] items by some members of the public was well documented. Some shop owners resorted to defending their property with personal firearms. Similar acts were documented when Hurricane Andrew devastated South Florida in 1992 and caused some homeowners to be without power for weeks.[6]

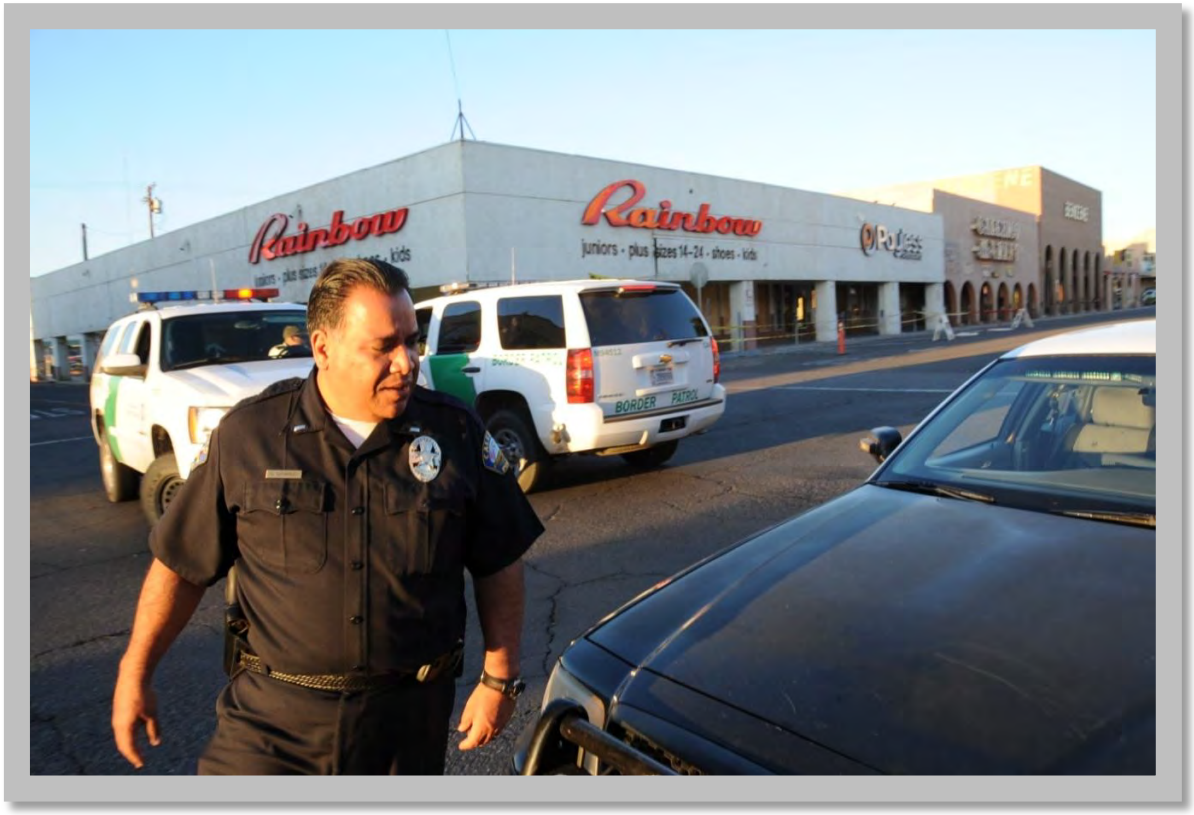

Figure 2.7: Calexico, Calif., April 6, 2010 -- Calexico Police Lt. Gonzalo Gerrado and US Border Patrol agents patrol the damaged businesses and public facilities to mitigate looting and theft. A magnitude 7.2 earthquake rocked the city on Easter leaving many facilities, roads, and public buildings closed, broken, and exposed. (Source: Adam DuBrowa/FEMA)

[5] By "non-essential" we mean non-food, or non-food preparation items such as gas or charcoal grilles, fuel, and so on. Looting of entertainment devices, such as TV's and X-Boxes, furniture, and so on were well documented, as was the lack of police presence in the immediate aftermath of the hurricane.

[6] Within Miami-Dade County more than 25,500 homes were actually destroyed and another 100,000 plus were damaged.

Hurricane damage and devastation differs from the expected impacts of a Cascadia subduction zone earthquake in that much of the damage resulting from hurricanes such as Katrina and Andrew is to smaller wood frame buildings, a type of construction typically used for single-family homes. After Katrina, for example, much of the central business core of New Orleans either survived or was quickly re-inhabitable, but much of the housing stock was destroyed. Similarly, Hurricane Andrew destroyed 63,000 homes leaving 175,000 to 250,000 people homeless (Dorschner 1992). We expect most wood-frame homes to survive a Cascadia earthquake, but we expect power and the other private and public utilities to be down in some neighborhoods for several weeks or months.

Security in the central business districts of the state is likely to be more easily accomplished than in some residential neighborhoods. The main commercial areas of the state – Portland, Eugene-Springfield, Salem, and to some extent, Albany, Corvallis, Grants Pass, and Medford – are relatively small compared to the residential areas of the cities and their suburbs. For example, in the City of Portland, the downtown commercial core[7] makes up less than seven tenths of one percent of Portland's 145.4 square miles (376.6 square KM) of area. The remaining area is largely residential neighborhoods, local or neighborhood commercial areas[8], parks and industrial areas (principally in northwest, north and northeast Portland). Keeping the neighborhoods secure is expected to be a major challenge for the Portland Police Bureau and, more likely than not, National Guard troops.

Continuity of government following a Cascadia event will depend on the immediate functionality of critical and essential facilities, such as police, fire, emergency operations and critical care centers.

Recommendations

- **Assess seismic performance of critical and essential public buildings**
  - *Finding*: The seismic vulnerability of critical and essential public buildings throughout Oregon has not been fully assessed.
  - *Action Needed*: The State of Oregon shall direct local jurisdictions to determine the seismic resilience of all critical and essential public buildings.

[7] The commercial core here is the area west of the Willamette River extending to the I-405 freeway, about 13 city blocks, and south from Union Station to Portland State University and I-405. This area also includes the RiverPlace and Pearl District neighborhoods and the Old Town/China Town Districts.

[8] These commercial districts include the Hawthorne District, the Broadway District, the Albina District, the Lloyd District, The Goose Hollow, Multnomah Village, Interstate Avenue, MLK, St. Johns, and so on. These areas include a significant inventory of mostly service businesses, restaurants, theaters, and in the case of the Lloyd District, a major shopping mall.

FOOD SUPPLY

Given that businesses cannot survive without their workforces or their customers, and given that people cannot survive for long without food, the food supply is inexorably linked to the survival of businesses. It is unlikely that a large proportion of the population currently stores more than a few days' worth of food—and probably stores even less water—in their homes. It is almost certain that a Cascadia subduction zone earthquake will cause all private and public utilities to fail; this means there will be no municipal water or sewer service, no electricity, no telephone, and no television, radio, or internet. Without power, local grocery stores will be unable to keep frozen foods frozen or fresh meats and dairy cold enough to prevent spoiling. It is likely that most of the food in the grocery stores will be distributed (as opposed to sold) to the public because the store's registers will not work without power and there would be no sense in letting frozen foods, meats, and dairy products spoil in the store.

Because stores are routinely resupplied several times each week, the amount of food actually held in an individual store is probably no more than what is required to supply the surrounding neighborhood for a few days. In particular, fresh fruits, vegetables, and dairy products are typically replenished several times a week, so the quantities kept in stock are not large. With supplies already limited, a related concern is that people will hoard food out of fear that stores will run out completely. In the near term, such hoarding will exacerbate the erosion of the food supply.

Figure 2.8: Brooklyn, N.Y., Dec. 4, 2012 -- Local Red Hook business, Cornell Paper and Box Company, continues cleanup of boxes at the warehouse that was flooded during Hurricane Sandy. (Source: Jocelyn Augustino/FEMA)

Once the food supply at local grocery stores is exhausted, the government will have to set up food distribution centers to support the population until local grocery stores regain electrical power and municipal services and can be resupplied. That resupply activity also requires the transportation and distribution network to be functioning (see Figure 2.8). Transportation lifelines have to be open for trucks to deliver the food, and truckers have to know where the lifeline routes are located and which bridges have been seismically braced and are safe to use following the earthquake. The transportation of supplies by truck is further dependent on the fuel supply. Currently, Oregon's liquid fuel supply is severely constrained. The main liquid fuel depot in the Portland Metro area is a "tank farm" located in Northwest Portland, adjacent to Highway 30, built on soils that are highly susceptible to liquefaction.

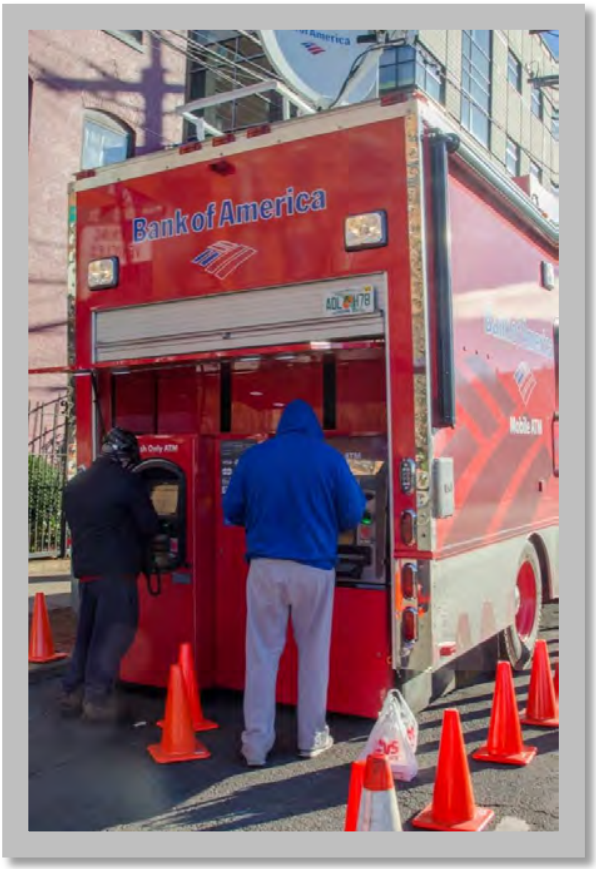

Figure 2.9: Hoboken, N.J., Nov. 3, 2012 -- Bank of America and other banks have set up mobile ATMs for survivors of Hurricane Sandy to get cash to spend at stores that are open for cash customers. (Source: Photo by Liz Roll/FEMA)

Finally, the resupply of food is dependent on a functioning banking system. All commercial transactions at grocery stores involve a debit or credit card issued from a bank (or the Oregon Trail cards issued by the state), a check (which is nearly always scanned to prevent fraud), or cash. Even after electrical power is restored and communications between stores and banks re-established, the banks themselves have to be functioning in order to assure the stores that transactions will result in actual payment (see Figure 2.9). Even cash purchases will require banks to have cash to distribute, and the banks' own information systems have to be functioning in order for them to distribute cash to their customers via bank teller or ATM network.

Recommendations

► **Strengthen transportation lifelines**

- *Finding*: Transportation has been identified as a major linkage in the business recovery chain. Inability to access office buildings due to failed bridges will have a devastating effect on business recovery efforts.

- *Action Needed*: The Oregon Department of Transportation (ODOT) shall identify and repair major lifeline routes in and out of major business centers statewide. Prioritize and seismically upgrade these lifelines by 2030. The state must also arrange for alternate modes of transportation in and out of the major population areas in Oregon.

PUBLIC & PRIVATE UTILITIES, INFRASTRUCTURE AND TRANSPORTATION

In Figure 2.6 above, the transportation network is shown as a separate sector from the utilities and infrastructure sector, but these sectors have strong interdependencies. Utilities cannot be repaired if roads and bridges are impassable. Likewise, the communication infrastructure is interdependent with the transportation network. If communications systems are down, repair crews have no way of knowing where they are needed most.

It is axiomatic that workers need a functioning transportation system in order to get to the workplace; one only needs to look at rush hour traffic, on a bad day, across the Interstate Bridge linking Vancouver, Washington and Portland, Oregon to observe an example of how the transportation network affects the workplace. On December 14, 2007, the City of Portland allowed contractors working on separate projects[9] to close all but one lane of SW 4th and SW 6th Avenue on or near SW Harrison Street, near the southern end of downtown. All traffic traveling north through the downtown core from the I-405 freeway, Barbur Boulevard, and SW 1st Avenue[10] were squeezed down to two traffic lanes on 4th and 6th Avenues and two northbound lanes of Naito Parkway. The result was gridlock, with cars taking more than an hour to move through downtown.[11] What happened that night, similar to many other December nights that year, illustrates what can be expected following a Cascadia earthquake, with many roads impassable and many bridges closed. The challenge of getting the workforce home after a Cascadia event that occurs during the workday may be dwarfed by the challenge of getting the workforce back to work.

The Willamette River bisects all of Oregon's major commercial centers: Portland, Salem, Eugene, Corvallis, and Albany. In Portland, nine bridges—the St. Johns, Fremont, Broadway, Steel, Burnside, Morrison, Hawthorne, Ross Island, and Sellwood—were all built before modern seismic codes were in force. Multnomah County bridge engineers have stated that they do not expect their bridges to collapse into the river; however none are expected to be passable prior to inspection in the event of a Cascadia earthquake. What this means is that many of the workers in the downtown core of Portland will not be able to get home if they live east of the river. The west side Highway 26 tunnels, built in the 1960s, may not be passable following a Cascadia earthquake. Highway 26 is a major transportation artery between Portland and its west side suburbs (though the tunnels can be circumvented via SW Jefferson Street).

[9] On SW 4th Avenue it was the Cyan Apartment Project and on SW 6th it was the Portland State University Student Recreation Center.
[10] SW 1st Avenue's northbound lane ends at SW Harrison and traffic heading north has to either go east to Naito Parkway or west to SW 4th, SW 2nd Avenue (and 3rd) was abandoned when the South Auditorium Urban Renewal Development was built in the 1960's.
[11] A snowstorm at the time contributed to traffic slowing, but this condition would mirror the problems we would face in the aftermath of a Cascadia earthquake.

Figure 2.10: Sea Bright, N.J., Jan. 25, 2013 -- Some businesses have permanently relocated to higher ground after being destroyed by Hurricane Sandy. (Source: Photo by Liz Roll/FEMA)

Before a business can reopen following a Cascadia earthquake, the building it occupies has to be certified to be structurally safe, it has to be served by municipal and private utilities, and the communications infrastructure must be operating. A business that cannot reopen within a month of a major earthquake or other disaster resulting in extended service disruption will likely never reopen at its previous location (see Figure 2.10). Potable water, sewage systems, heating (natural gas or electric), and ventilating systems must be operable before workers can reoccupy a business. To a lesser extent, but nevertheless important in our ever more technologically oriented business environment, the communications infrastructure must be re-established before businesses can be re-established. These requirements set the performance benchmarks for the transportation and utility infrastructure sectors.

Recommendations

► **Improve seismic performance of infrastructure for rapid community recovery**

- *Finding*: Business and community cannot recover within two to four weeks due to inadequate seismic performance of infrastructure.

- *Action Needed*: Upgrade existing infrastructure and increase seismic design standards for new infrastructure over the next 50 years to enable business and community recovery within two to four weeks.

Considerations for Different Sectors

As with all state economies, there are multiple business sectors in Oregon, and a Cascadia earthquake will affect each differently. A manufacturer, for example, could sustain significant damage to machines and equipment used to make products and suffer from the lack of raw materials in the immediate aftermath of the earthquake prior to repair of roads and bridges. In addition, even if the manufacturer is able to resume production quickly, the firm may not be able to ship products to market because the transportation system may not be available.

Service providers come in all shapes and sizes, from small consulting practices to large medical clinics. These will be affected differently by a Cascadia earthquake depending on the service they provide and the customer base. Companies that provide consulting services within the locality or region may not have a customer base for some time into the recovery. Others, like doctors' offices for example, will be pressed into service during the immediate recovery period and most likely for some months. However, it is also unknown how those services will be reimbursed or how liability for "bad outcomes" will be dealt with. It is our assessment that small service businesses like sundry shops will not survive in the central business cores that suffer significant damage, particularly those businesses dependent on sales to building occupants who may not return to their place of employment for some time (see Figure 2.11).

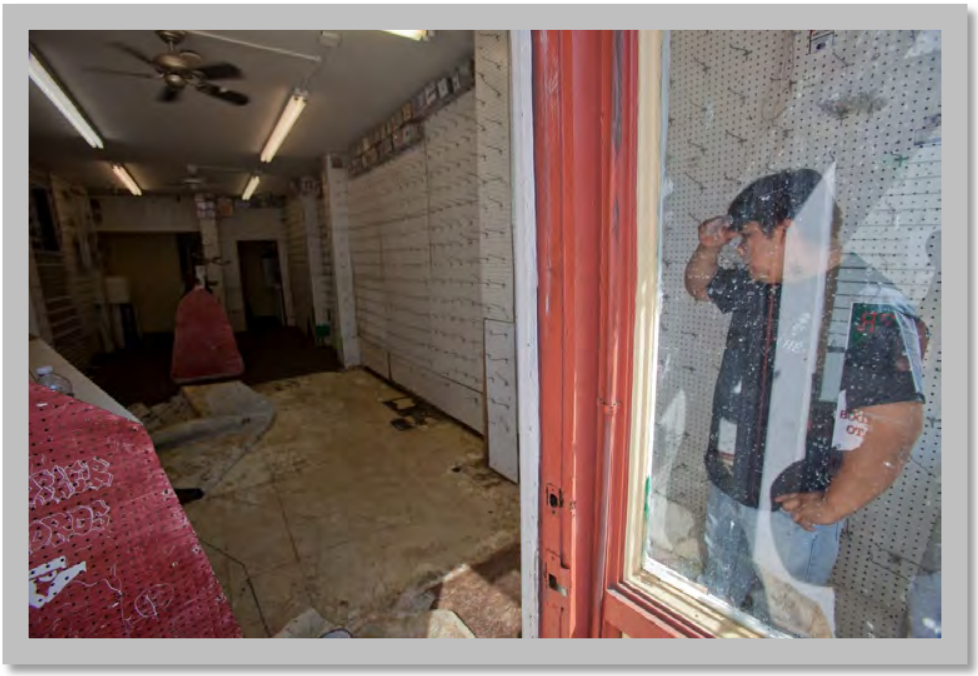

Figure 2.11: Bound Brook, N.J., August 30, 2011 -- Business owner, Brijo Garcia returns to clean up his internet store after Hurricane Irene swept through the Bound Brook area. (Source: Andrea Booher/FEMA)

Even though the goal is to have businesses up and running in two to four weeks, it seems unlikely that most customers will be making anything beyond the most essential purchases. Clothing stores, tailors, and other retail stores will suffer a prolonged period of depressed sales. These types of businesses should prepare for a Cascadia earthquake by building capital sufficient to help the business endure a prolonged disruption.

Some retail businesses, such as home repair,[12] plumbing supply, hardware, lumberyards and so on, will likely see their sales skyrocket during the immediate aftermath of a Cascadia earthquake. One problem facing homeowners who suffer earthquake-related damage to their homes will be finding construction contractors to repair the damage (assuming they cannot repair it on their own). Hurricane Andrew in 1992 drew hundreds of contractors to South Florida from as far away as Portland, Oregon. Many of the contractors in South Florida were there to repair roofs damaged in the Hurricane's high winds; an earthquake will cause different types of structural damage that will require more sophisticated contractors and likely require the services of structural engineers (see Figure 2.12). However, the potential exists for unlicensed contractors to enter the region affected by a Cascadia earthquake, and local building officials and the police will have to be aware of this potential problem.

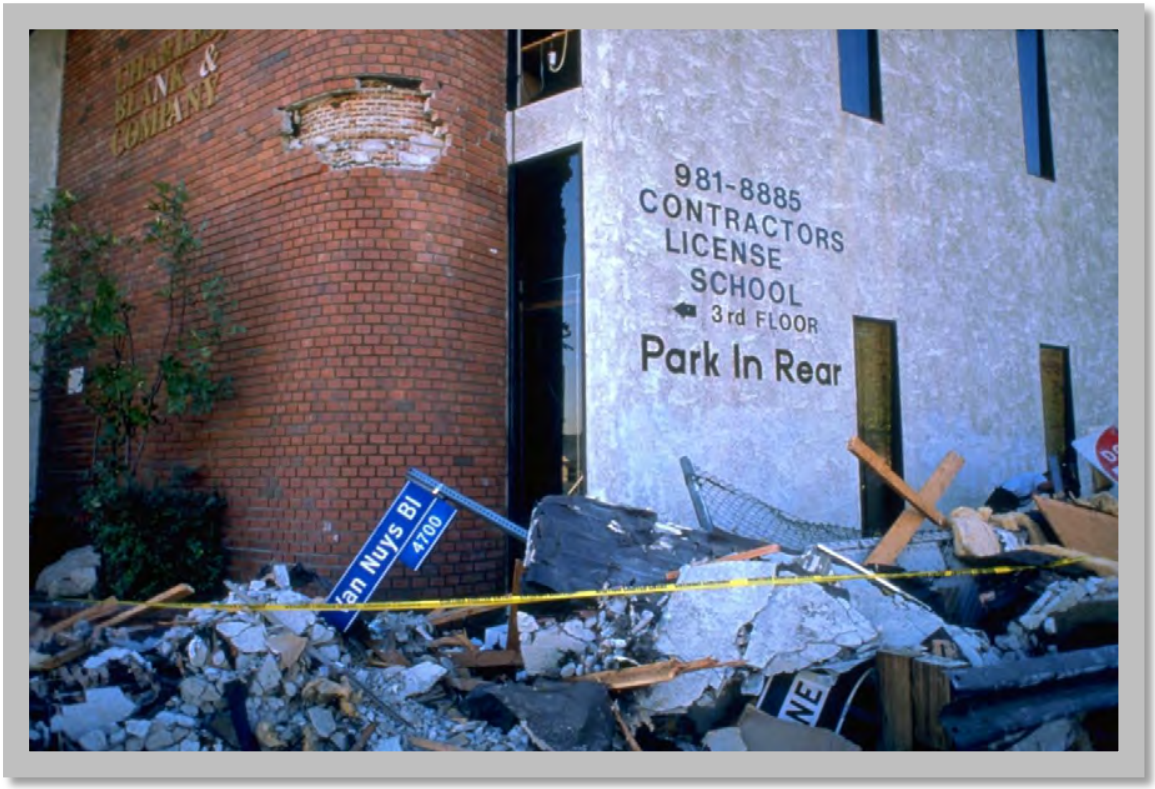

Figure 2.12: Northridge Earthquake, Calif., January 17, 1994 -- Approximately 114,000 residential and commercial structures were damaged and 72 deaths were attributed to the earthquake. Damage costs were estimated at $25 billion. (Source: FEMA News Photo)

[12] Companies like Home Depot and Lowes, for example

Businesses that offer services outside the affected region[13] are likely to be the least affected by a Cascadia earthquake. The demand for their services may not suffer, and their recovery will be more closely linked to the public infrastructure recovery discussed above. Once they can reoccupy their buildings or offices, they will be able to resume work.

A large portion of Oregon's Willamette Valley remains in agricultural production. Other than damage to equipment, many of these types of businesses will suffer minimal impact to their operations from a Cascadia earthquake. The notable exceptions are agricultural businesses located at or near the Oregon Coast. Some of these businesses suffered significant losses in the 2007 flooding and windstorms; losses from a major tsunami are likely to be much greater. For further discussion of the special challenges facing coastal enterprises, see Chapter Three.

Recommendations

- **Plan for business continuity**
  - *Finding*: Although there are numerous resources for business continuity planning, we are unaware of evidence that the majority of businesses in Oregon have a business continuity plan.
  - *Action Needed*: Assess hazards that could impact business; develop business continuity/ continuity of operations plan; partner with public sector to assess public/private building stock pre-event and help with post-event recovery. Business and building owners should be encouraged to review their business continuity plans and level of seismic vulnerability with respect to the Cascadia earthquake and to seismically upgrade their buildings. Employees must be trained to be their own first responders.

- **Expand emergency operation efforts to support private business for rapid resumption**
  - *Finding:* To date, the State has not included the private sector in its Emergency Operation Centers (EOC).
  - *Action Needed:* Encourage all Emergency Operation Centers to pursue public/private partnerships to enhance communication and coordination with the private sector after a major seismic event.

Cascadia Earthquake Aftermath

In the initial aftermath of a Cascadia earthquake, escaping the building safely will be the highest priority for businesses and their workers (Figure 2.13). Making workplaces safe before the event, as discussed in the previous section, will increase the chances that building occupants can exit unharmed. Several considerations need to be addressed by businesses in preparing for the immediate aftermath of a Cascadia subduction zone earthquake.

[13] Examples of these types of firms would be attorneys with overseas clients, accounting firms, architects and engineers that have a significant amount of their business outside the region, software developers, advertising agencies, and so on.

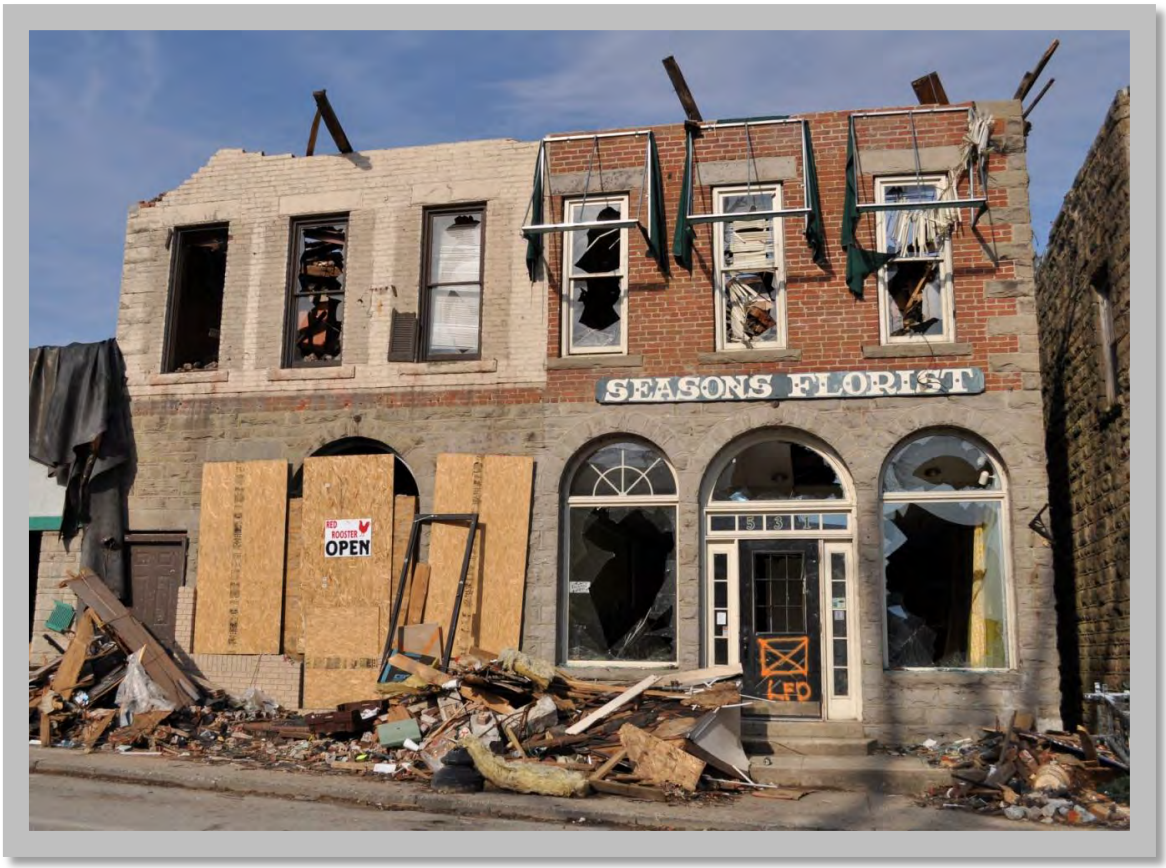

Figure 2.13: West Liberty, Ky., March 19, 2012 -- Destroyed buildings, many with historical significance, line the streets of downtown West Liberty. FEMA is working with Commonwealth and local officials to remove debris and demolish buildings that cannot be saved. (Source: Photo by Marilee Caliendo/FEMA)

If a Cascadia earthquake occurs during the workday (a one in three chance), workers will be in their offices or industrial plants during the event. In areas of the state where the Willamette River bisects the cities—Portland, Salem, Albany, Corvallis/Lebanon, and Eugene/Springfield—it is possible that a large number of workers will be trapped on the "wrong side" of the river. This will be a particular concern in Portland, where none of the ten bridges that currently carry automobile traffic is likely to be cleared by local officials to allow auto traffic for up to 72 hours, even if the bridge appears to have sustained no damage. The most recently constructed Willamette River bridge in Portland is the Fremont Bridge, built in 1976. Some renovations have been performed on the Broadway, Morrison, and Hawthorne Bridges in recent years, but the Multnomah County Bridge Division maintains that these upgrades have only brought the bridges up to level where those bridges were reinforced so that they will not collapse. The Sellwood Bridge is currently being reconstructed to modern seismic standards by Multnomah County and a new light rail bridge is currently being constructed by Tri-Met between the State-owned Marquam and Ross Island Bridges. The Marquam Bridge was opened in October 1964, and has had some seismic strengthening done since, but it is not expected to be immediately usable following a Cascadia earthquake, and may require some repairs before re-opening. The Ross Island Bridge is second only to

the existing Sellwood Bridge as the most unsafe bridge crossing the Willamette River in Portland due to unstable foundation on the east side, and is unlikely to be usable following a Cascadia earthquake.

It is likely that many of the workers in Portland's downtown core who live on the east side of the Willamette River would be forced to shelter in their office buildings, if those structures are safe enough for that purpose. In absence of that, local downtown parks and open spaces would be natural shelter and triage sites.

Buildings that do survive and are capable of sheltering-in workers will face significant challenges related to building security and liability. Most large buildings in downtown Portland have a large number of tenants, and it is unlikely that any one person in a building knows all of the building occupants by sight. This means that there is a distinct possibility that someone who does not work a particular building may end up sheltering-in there. Building owners will have to provide first for the security of their tenants.

Figure 2.14: Mt. Olive, N.J., Nov. 12, 2012 -- After almost two weeks without power in the town of Mt. Olive, shop owners want to let people know the power has been restored and the mall is open for business. (Source: Photo by Sharon Karr)

A second concern for building owners is health and sanitary conditions (Figure 2.14). It is unlikely that water and sewer systems will work in the immediate aftermath of a Cascadia earthquake. Persons sheltering in a downtown office building will not be able to use or will have limited use of its

bathrooms.[14] Sheltering –in is probably only going to be acceptable for one night, and only if an earthquake strikes in the mid to late afternoon on a short rainy or snowing winter day. If an earthquake strikes during a summer workday, when daylight extends well past 9 PM, it is likely that most workers will try to find some way to get home, even those who work on the opposite side of the river from where they live. Nevertheless, businesses in Oregon's river-bisected cities need to plan for the possibility that people could have to shelter-in for several days, even if that possibility seems remote.

Recommendations

- **Communicate gaps between current and target relief and resilience ratings**
  - *Finding*: The impact of a Cascadia earthquake and tsunami will be severe, especially for coastal communities. Earthquake ground shaking will damage buildings and infrastructure and disrupt lifelines. In addition, there will be near total destruction in the tsunami inundation areas that will result in large displacements of residents and visitors. Based on current expected levels of service disruption, the standard recommendation for the public to be prepared for 72 hours should be revised to at least two weeks or longer.

  - *Action Needed*: With an overall goal to increase awareness, a dual ratings system is proposed to give citizens information about the status of emergency preparedness and resilience efforts in their communities.

    - Adoption of a two-level ratings system. The first level would indicate the time period that citizens should anticipate relying on emergency supplies. The second level would indicate the time anticipated necessary for 90 percent restoration of roads and services.
    - The rating system should follow the four zones proposed by the Oregon Resilience Plan: tsunami zone, coastal earthquake only, valley, and eastern zone. Standards and methodology need be developed for the system to be consistent across zones, and applicable at the community level.

Cascadia Earthquake Business Planning

BUSINESS STRATEGIES RELATED TO BUILDING STRUCTURES

One of the primary goals of pursuing disaster resilience in Oregon is to expedite building re-occupancy and restore public/private services such as transportation and power back to a 90% level within two to four weeks. Following a damaging earthquake the buildings occupied by businesses will need to be evaluated for the extent of damage and level of occupancy using the three-tiered Applied Technology Council (ATC)-20 methodology (see Figure 2.15):

[14] Even flush valve toilets will function by gravity, and it is possible that some facilities can remain open for urination, but without water service, actual flushing to push fecal matter down the toilet will not happen, and toilet facilities will quickly become clogged and unsanitary.

- Green-Tagged: Structures that survived the earthquake and are immediately available for occupancy (as noted above, statewide this is about 27 percent of all commercial buildings).

- Yellow-Tagged: Structures that survived with limited access but require structural repair prior to re-occupancy (about 67 percent of all commercial buildings fall into this category). The time to re-occupy will depend on several factors including location, damage to infrastructure in the surrounding area, and the extent of damage to the building.

- Red-Tagged: Structures that have collapsed or are otherwise unsafe for occupancy due to damage (in the case of collapse, the building and its contents would be a complete loss). About 5 percent of all commercial buildings will fall into this category.

For pre-earthquake business planning with respect to business operations[15]:

Businesses in Green-Tagged buildings will need to have municipal and public utilities restored to the building within two to four weeks or tenant businesses may move their operations elsewhere, at least temporarily. Building owner-occupied businesses are probably less likely to relocate, but still will find it hard to survive much more than one month of inactivity due to their inability to get to their buildings. In addition, building owner-occupied businesses, particularly small businesses, probably have a large share of their net worth tied up in their buildings. This means that they are disproportionately likely to suffer losses from fire, or from burglary and looting, following a Cascadia earthquake. For businesses in Green-Tagged buildings, the business strategy following a Cascadia earthquake would be to back up intellectual capital off-site, and retrieve important documents or equipment following the event, as soon as it is safe to re-enter the building. Of course, this will be limited to the things that can be carried out by hand. If possible, a business may need to plan to set up shop temporarily in a building, such as a residence, which has not been damaged and is situated in a location the key business personnel can reach, continue minimal business operations if possible, and monitor reconstruction of transportation, infrastructure and utilities so that the business can re-occupy the building as soon as practicable.

For businesses in Yellow-Tagged buildings, restoring municipal services is less critical because it is likely to take several months to a year before these buildings will be structurally repaired to the extent required to allow reoccupation. Business strategy in these buildings will be to move to another location as soon as they can access the building and move business-related intellectual capital and equipment out. This will likely have to occur within one month for the reasons cited above, and moving will require at least some transportation lifelines to be open.

[15] Here we separate "Business Operations Strategy" from other Business responsibilities such as making the business as safe as possible and caring for workers housed in the business's building.

Figure 2.15: Northridge Earthquake, Califonira, January 17, 1994 – Post-earthquake damage assessment teams coordinate between inspections to business buildings. (Source: Photo by Andrea Booher/FEMA News Photo)

For businesses in Red-Tagged buildings, restoring municipal services is irrelevant because the buildings and their contents will be a complete loss. Following earthquakes in California, businesses located in Red-Tagged buildings were not allowed to re-enter to retrieve equipment or intellectual capital, even if they agreed to hold the government harmless should the building collapse when they were inside. Businesses that occupy buildings unlikely to survive a seismic event in a condition that can be reoccupied need to have their intellectual capital backed up off-site and should be insured against a seismic event.

Recommendations

► **Institutionalize post-earthquake assessment inspection process**

- *Finding*: The State of Oregon has only a passive approach to training and registering certified structural inspectors and certified plan examiners as Applied Technology Council (ATC)-20 post-earthquake damage assessment inspectors and no formal process for deployment.

- *Action Needed*: State shall sponsor annual ATC-20 trainings at no cost to qualified engineers and certified plan examiners and indemnify all trained ATC-20 inspectors. The state must negotiate mutual aid agreements with professional associations and our neighboring states to increase ATC-20 certification and disaster response capacity.

► **Develop seismic rating system for buildings to promote resilience**

- *Finding*: Oregon does not have a seismic rating system for the expected performance of buildings subject to earthquake ground motions.

- *Action Needed*: State should develop a seismic rating system modeled after Structural Engineers Association of Northern California rating system. The objective of this system is (1) to make buildings more resilient and usable after a Cascadia event and (2) to help communicate seismic risk to the general public.

► **Incentivize seismic upgrade of existing buildings**

- *Finding:* The majority of buildings in Oregon were built before the code change of 1994 and thus do not meet current seismic building code standards. Seismic upgrading of these buildings is expensive and is typically only done when there is a change-in-use of the building, or when the buildings are substantially modified. If only a small portion of these buildings will be seismically upgraded over the next fifty years, then the potential loss of the business and workforce housing in these buildings will seriously impact the recovery of the economy following the Cascadia earthquake.

- *Action Needed:* The State should consider incentives and other options to encourage building owners to seismically upgrade their buildings.

► **Reduce community vulnerability from unreinforced masonry (URM) buildings/non-ductile concrete buildings**

- *Finding*: The Historic Preservation League of Oregon (HPLO) estimates there are between 5,000 and 10,000 unreinforced masonry (URM) buildings in Oregon.

- *Action Needed*: State shall adopt the findings and recommendations in the 2012 HPLO Special Report, *Resilient Masonry Buildings*, and extend the recommendations to all non-ductile concrete buildings.

BUSINESS STRATEGIES FOR COASTAL COMMUNITIES

The Oregon Coast can anticipate that a Cascadia subduction zone earthquake offshore will generate a tsunami similar to the March 2011 Tohoku earthquake in Japan. The Department of Geology and Mineral Industries has published numerous inundation maps that show whole communities including, for example, downtown areas of Cannon Beach and Seaside as being prone to complete inundation. Likewise, low-lying areas including Lincoln City, Neskowin, Rockaway, Tillamook, and Bandon will be inundated. Businesses in these tsunami inundation zones will be wiped out even more completely than businesses housed in Red-Tagged Buildings discussed above.

Figure 2.16: New Orleans, La., October 9, 2005 - This souvenir shop is open for business in New Orleans despite the sidewalk being blocked by crushed vehicles and debris leftover from Hurricanes Katrina and Rita. (Source: Robert Kaufmann/FEMA)

Businesses located in tsunami inundation zones should consider the business strategies outlined for businesses housed in Red-Tagged buildings. A high proportion of the businesses in Oregon's coastal communities cater to the tourist industry (see Figure 2.16). Most of these firms are small (or very small) businesses that would not be expected to survive following a tsunami. Even if a business had sufficient capital to relocate, it is unlikely that the tourist industry will recover rapidly enough to support business start-up. Local authorities may need to keep tourists out of the inundation zones, for safety reasons, for months or years after a tsunami.

In the event of a tsunami similar to the Tohoku event, coastal business owners' first concern will be personal survival, not business survival. Oregon's coastal communities face resilience challenges so unique that they are addressed in detail in Chapter Three.

3. Coastal Communities

Because the coast will suffer the worst consequences of this inevitable Pacific Northwest catastrophe, we emphasize the following main actions in the next 50 years:

- Protecting lives requires consistent and relentless education and outreach based on up-to-date physical and social science.
- Investing in hazard mitigation is necessary to reduce, relocate, and avoid exposure of vital community assets to tsunami devastation.
- Strengthening of critical facilities in the earthquake-only zone must occur so that they will be available when communities need them most.
- Planning for reconstruction and recovery must be done now to provide a strategic vision for restoring the economy and livability of the Oregon coast.

Introduction

Of the Oregon Resilience Plan's eight task groups, the Coastal Task Group was the only one focused geographically on a single sub-region of the state. This group looked at the resilience of the coastal counties in the face of both the Cascadia earthquake and the resulting tsunami. To facilitate this assessment, the group divided the coastal area into the tsunami zone and the remaining earthquake-only zone. The group also recognized that almost all coastal communities have a necessary relationship with the Pacific Ocean or a connected marine environment, such as a bay or estuary. This proximity not only defines these communities, but is the basis of much of their economies, whether they are dependent on a port, recreation, or tourism. Tourism has the additional effect of bringing large numbers of second-homeowners and visitors to the coast, which means that coastal areas have a variable daily population that equals or exceeds the resident population.

The coastal region's built environment, including roads, bridges, and ports, is nestled into the coastline's natural environments of estuaries, wetlands, headlands, mountains, and beaches. It is this dependent relationship with the Pacific Ocean that creates so much of the inherent vulnerability that we now face with a Cascadia earthquake and tsunami (see Figure 3.1).

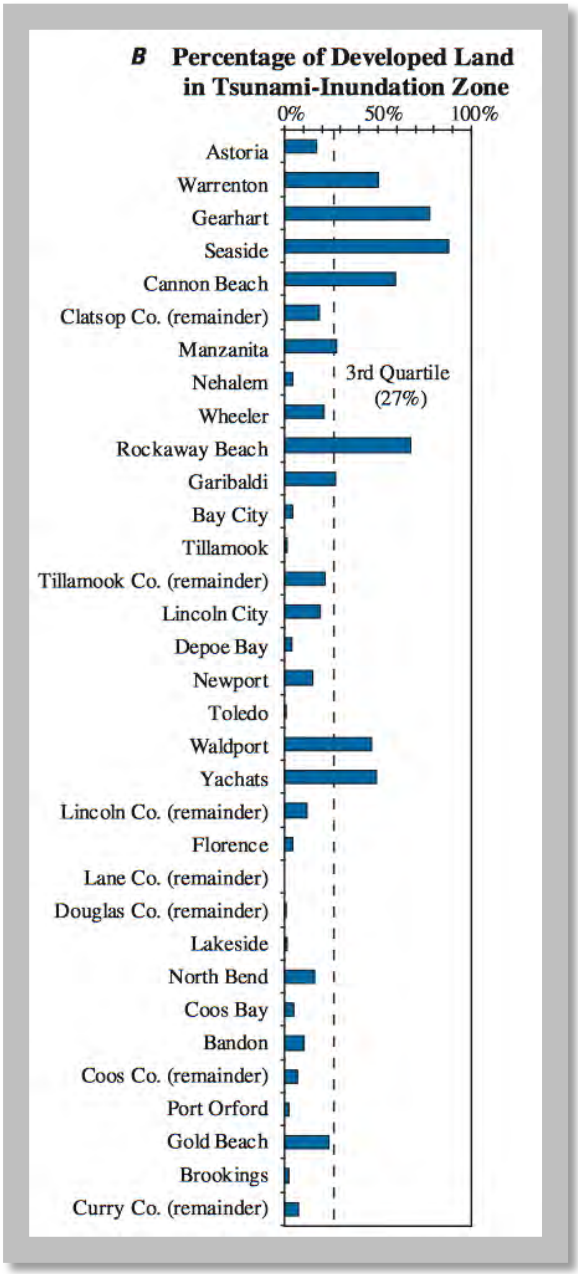
All of these communities will be affected by the earthquake. The vulnerabilities of these communities to the tsunami vary, with the northern coastal communities of Cannon Beach, Seaside, and Warrenton having the most concentrated exposure to inundation. The Coastal Task Group focused its attention on land use planning and other social factors and relied on the results and conclusions of the other task groups, which were sector based.

The tsunami creates a greater challenge for coastal communities. It is both more destructive than the earthquake and will make mitigation and reconstruction efforts more difficult. Achieving (within a 50 year timeframe) the goal of restoring 90 percent of service within two to four weeks of the earthquake and tsunami will be a greater challenge for the coast than it will be for the rest of the state.

Figure 3.1: Tsunami Vulnerability: City of Seaside with 83% of its population, 89% of its employees and almost 100% of its critical facilities in the tsunami inundation zone. (Source: Horning Geosciences)

Earthquake and Tsunami Zones

The coastal area covers the majority of the seven coastal counties of Clatsop, Tillamook, Lincoln, Lane, Douglas, Coos, and Curry, reaching up to the summit of the Coast Range. The Coastal Task Group divided the coastal area into two zones: the tsunami inundation zone and the earthquake-only zone. The relationship between these two zones will define the local and regional capacity for resilience in the context of the Cascadia event. The post-disaster welfare of the earthquake-only zone of each community is dependent on which critical and essential facilities are located inside the tsunami inundation zone. Each coastal community's capacity to respond, direct relief efforts, and begin recovery will depend on how much it relies on its tsunami-affected area (see Figure 3.2). Communities that have not successfully relocated or created redundancies for important facilities, such as emergency service facilities, energy and water facilities, and vital businesses, will have a severely diminished response and recovery capacity.



TSUNAMI ZONE

The tsunami zone is defined by inundation mapping, which was produced by the Oregon Department of Geology and Mineral Industries (DOGAMI), primarily based on the earlier mapping defining the state's tsunami inundation line and established by Senate Bill 379 in 1995. DOGAMI is currently finishing up a more accurate tsunami inundation mapping study that will be finished in 2014. Due to its proximity to the fault, the tsunami zone will be subject to among the strongest earthquake motions to be generated during a Cascadia subduction event. It will then be subject to multiple tsunami inundations generated by the earthquake, inundations which will continue for up to 24 hours after the earthquake. The tsunami will further damage buildings, bridges, roads, and utility infrastructure, and will obliterate nearly all wood frame buildings. Even steel and reinforced concrete buildings that survive the earthquake and tsunami may be damaged beyond repair. The existing utilities will be severely damaged or destroyed. The tsunami zone will also have areas of coastal subsidence—places that had been dry land above the tidal zone before the earthquake, but that, having sunk three to six feet during the earthquake, are afterwards inundated daily during high tides or seasonally by variable high tides.

The vulnerability of coastal communities to tsunami hazards varies, with the most concentrated exposure being on the northern Oregon coast (as indicated in Figure 3.3). Within the tsunami inundation zone, practically all of the 22,000 permanent residents—along with an equal or greater number of second-homeowners—who survive the tsunami will be instantly displaced (Wood, 2007). The visitor population presents a great challenge, because visitors tend to congregate in the tsunami inundation zone and have the least knowledge of where and how to evacuate. Moreover, those that survive will put extreme pressure on local relief efforts, which must provide for their initial welfare.

Figure 3.2: Critical Facilities in the Tsunami Zone – Minamisanriku, March 14, 2011. Because their hospital, emergency operation center, and other government and community service facilities were located in the tsunami inundation zone, the surviving community lost nearly all of its capacity to respond and implement recovery efforts. (Source: Asia Air Survey Co., Ltd.)

Numbers in Tsunami Inundation Zone	
Residents	22,000
Households	10,000
Percent of coastal counties	4%
Employees	14,800
Businesses	1,800
Percent of coastal counties	6%
Oregon State Parks – Coastal (Annual average daily attendance)	53,700

Figure and numbers from Nate Wood Variations in City Exposure and Sensitivity to Tsunami Hazards in Oregon, USGS 2007

Figure 3.3: Oregon Coast Tsunami Exposure of People and Places. Wood, Nathan: 2007, Variations in City Exposure and Sensitivity to Tsunami Hazards in Oregon. (Source: US Geological Survey)

EARTHQUAKE-ONLY ZONE

The earthquake-only zone is the area outside of the tsunami zone. It includes portions of communities that will have tsunami inundations in their lowland areas, and communities that are completely outside of the inundation zone. Again, the proximity to the fault means that damage to roads and infrastructure from the magnitude 9.0 earthquake scenario will be greater here than in the valley. Minutes of strong ground shaking will concentrate damage in areas subject to ground failures such as liquefaction, lateral spreading, differential settlement, and landslides. The coast and Coast Range are particularly at risk from these effects of the earthquake.

Well-built wood frame buildings will withstand the shaking fairly well. Unreinforced masonry (URM) and under-reinforced concrete buildings will suffer significant damage. Unfortunately, this includes a number of government buildings and essential facilities in the coastal zone. Because subduction zone earthquakes generate long-period seismic waves and because the duration of the shaking is so long, certain structures, such as bridges, may resonate, amplifying shaking impacts.

Following the Cascadia Event

Following the Cascadia event, the coastal communities will be cut off from the rest of state and from each other. The coastal area's transportation system, electrical power transmission and distribution grid, and natural gas service will be fragmented and offline, with long-term setbacks to water and wastewater services. Reliable communications will be similarly affected. Because so many of these connecting systems are single lines with little or no redundancy, any break or damage requiring repair or replacement will compromise the service capacity of the entire line.

The loss of roads and bridges that run north and south will make travel up and down the coast and into the valley difficult, if not impossible, due to the lack of alternate routes in many areas. Reestablishing the roads and utility infrastructure will be a challenge, and the difficulties will be exacerbated in the tsunami inundation area by its more complete destruction. Even businesses outside of the tsunami inundation may not recover from the likely collapse of a tourist-based economy during the phased and complicated recovery and reconstruction period.

Based on the resilience targets provided by the Transportation, Energy, Communications, and Water/Wastewater task groups, current timelines for the restoration of services to 90-percent-operational levels will take a minimum of one to three years, and often over three years in the earthquake-only zone. Restoration in the tsunami zone will take even longer than that (see Figure 3.4). The most critical infrastructure is the road and highway system. Without functioning road systems, none of the infrastructure can be accessed to begin repairs.

The tsunami will also create an enormous amount of debris that needs to be gathered, sorted, and managed. The recent experience of Japan, with a similar mountainous coastline, has shown that debris management competes with shelter and reconstruction needs for the same flat land that is often in the inundation zone.

Figure 3.4: Hurricane Katrina Storm Surge – Electric Facility. Replacement of coastal power infrastructure based on 2012 capabilities may take one to three years for the Earthquake-only zone. (Source: FEMA.gov)

PREPAREDNESS AND POST DISASTER RELIEF

Emergency preparedness education and training helps people react appropriately during a disaster. Preparedness can also provide the foundation for initial disaster relief efforts at the personal, household, and community levels. Surviving the earthquake and then evacuating the tsunami zone is just the beginning of achieving life safety in the following hours, days, and even weeks (see Figure 3.5). Properly anticipating and managing relief efforts will have a significant impact on resilience.

Relief efforts need to consider other populations in addition to residents. The coast attracts a large number of second-homeowners and visitors. Data from the 2007 United States Geological Survey (USGS) study by Wood (2007) showed that the resident population in the coast's tsunami inundation area numbered around 22,000. Not included in this count was the population of second-homeowners and visitors, which in many coastal communities equals or exceeds the number of full-time residents. To arrive at a general estimate of the number of visitors to the coast, Wood looked at the number of visitors to Oregon's coastal state parks and found that the annual average daily attendance is 53,700 people. This is more than double the number of permanent residents at risk, and it does not include hotel visitors. The visiting population is generally located in the tsunami inundation zone and typically has low levels of knowledge about tsunami hazards and evacuation routes. The large population of visitors will also be difficult to house and feed adequately following the earthquake and tsunami. An essential task during the relief period will be transporting these people from the coastal areas to their own homes or to shelters further inland. Reducing the loss of life among residents and visitors is critical to insuring that people will come back to help with reconstruction and recovery.

Recommendations

► **Improve earthquake/tsunami education efforts.**

- Teach an earthquake/tsunami curriculum to Oregon's school children.
- Provide information about Cascadia earthquakes and tsunami in all hotels, motels, and short-term rentals. This should include information about tsunami evacuation routes.
- Require that all businesses over a certain size and located in tsunami inundation zones have tsunami evacuation plans.

► **Improve tsunami evacuation efforts.**

- Create tsunami evacuation modeling for each coastal community as a base level to estimate the likely fatality level. Models can be used to test improvements in evacuation measures and determine whether the improvements will reduce fatality levels.
- Improve tsunami evacuation measures by further developing existing evacuation routes, creating new evacuation routes, bettering education and signage about evacuation routes, and creating vertical evacuation structures or buildings.

► **Improve relief efforts to account for residents in the tsunami inundation areas and the visitor population.**

- Develop plans to provide shelter, water, and food for residents and visitors.
- Develop plans for getting visitors back to their own homes.

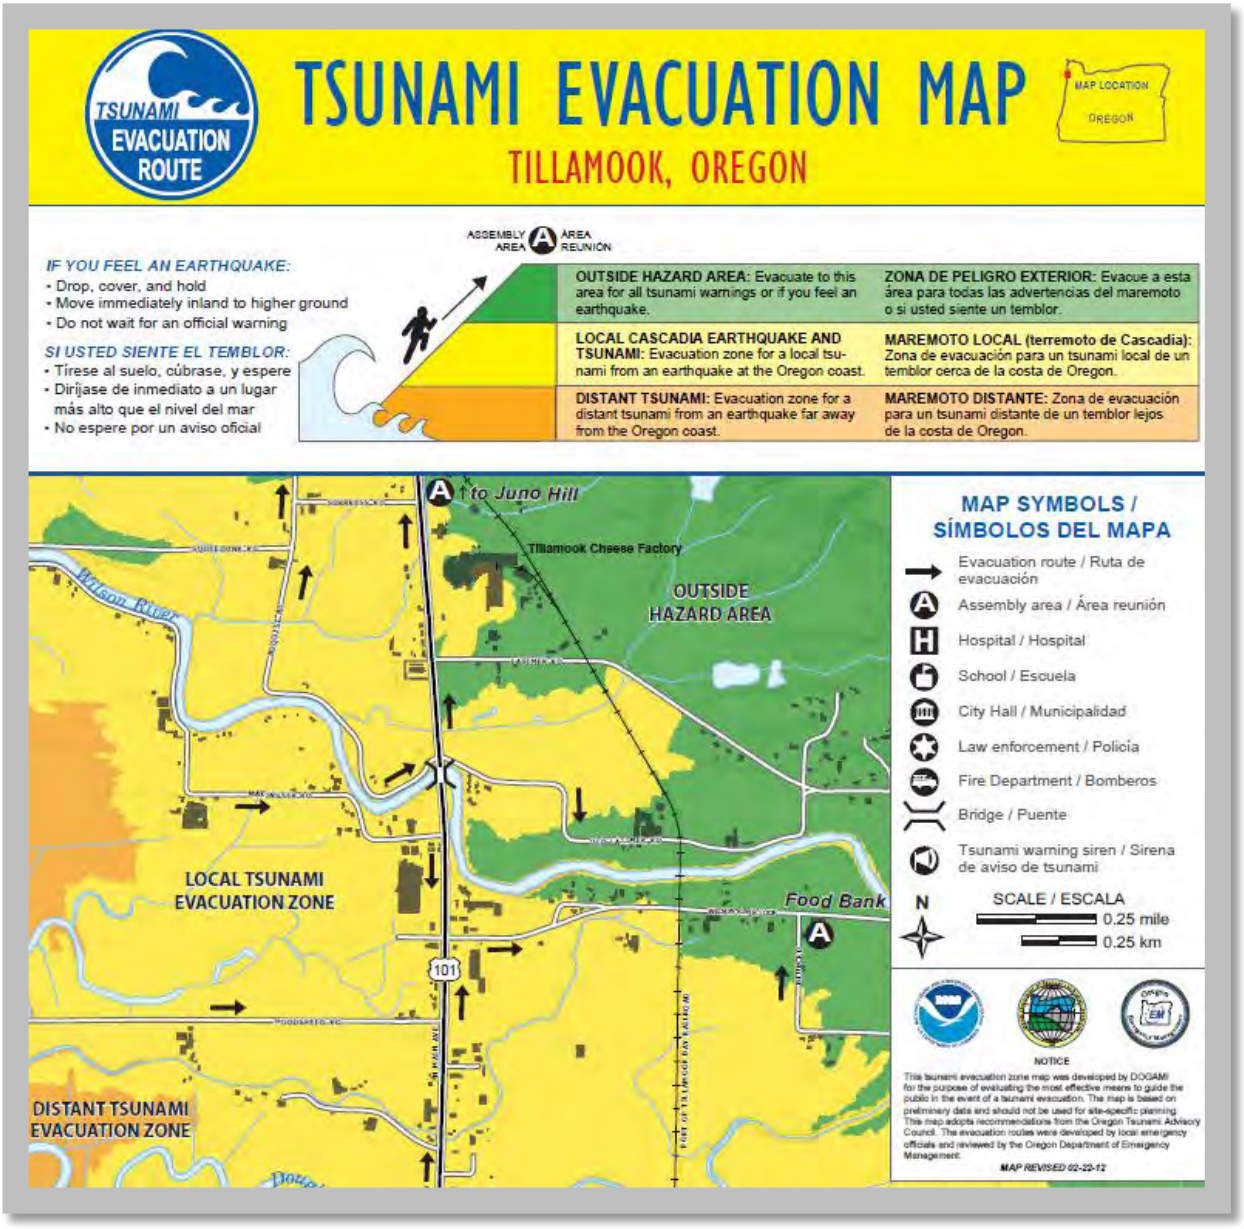


Figure 3.5: Tsunami Evacuation Map for the City of Tillamook, Oregon. (Source: Oregon Department of Geology and Mineral Industries, 2012)

Coastal Zone Targets

The goal for the coastal zone—like that of the other zones of the state—is 90-percent recovery in a two- to four-week period. This goal is based on the amount of stress businesses can take before they go out of business or relocate. While this goal should be the target for all of Oregon, it will be difficult to achieve in both the tsunami zone and the earthquake-only zone of the coast, with the tsunami zone presenting particularly significant obstacles. Consequently, it will likely either take longer to achieve this goal on the coast than it will in the other regions of the state, or it will require the application of substantial resources. Some coastal communities will have to reconstruct their economic districts—either substantially or completely. Alternate strategies need to be considered, and the expectations of coastal residents and businesses must be addressed with the realities of the state of preparedness.

PROTECTING BUILDINGS AND INFRASTRUCTURE

The first obstacle is the anticipated level of destruction of buildings and infrastructure within the tsunami zone. The solutions to protecting them include:

- Creating tsunami resistant seawalls. This solution has been tried in Japan, and it works provided that the wall is designed for the earthquake/tsunami that actually occurs. The failure of these structures in the 2011 Tohoku earthquake and tsunami was primarily due to their having been designed for a smaller event. They are very costly and would cut off the communities from the ocean, disrupting the main economic basis of many coastal communities. Moreover, this solution does not address such things as port facilities, which need direct access to the ocean.
- Constructing tsunami resistant buildings and infrastructure. This type of solution is typically used for port facilities, roads and bridges, and other essential buildings or infrastructure. It is very expensive and would be done in critical cases where other options do not exist. This solution does not address existing buildings and infrastructure.
- Relocating. While it is theoretically possible to relocate communities, in reality this rarely happens, even following major earthquakes and tsunamis. A more likely scenario is relocating essential buildings and functions outside of the tsunami zone as a mitigation strategy. In this way, police stations, fire stations, government offices, hospitals, public works, and similar critical facilities can, over time, be shifted outside of the tsunami zone. In addition, some thought can be given to the relocation of businesses and residences.

As Wood's study shows, the vulnerabilities of communities within the tsunami zone vary, so the solutions must vary accordingly (Wood 2007). Mitigation proposals should be developed that include actual mitigation projects—such as relocation—as well as more land-use related solutions that look at rebuilding communities after the earthquake and tsunami so that they are tsunami-ready for future events.

The target goal in earthquake-only areas of the coast also presents challenges. First, much of the essential infrastructure runs through both the tsunami zone and the non-tsunami earthquake zone.

Second, the geology of the coast means that there will be high levels of damage to these systems. Because these areas are lightly populated compared to the urban areas of the valley, strengthening them will tend to be a lower priority (from an economic standpoint) than projects that target the valley.

Recommendations

- **Use relocation strategies to meet target goals on a community basis as part of overall mitigation planning.**
- **Use tsunami resistant buildings as vertical evacuation structures to insure the safety of people in the inundation zone where other options are limited.**
- **Use tsunami resistant infrastructure for critical transportation, port facilities, and utilities.**
- **Ensure that critical transportation links to the valley and along the coast survive the earthquake so that coastal communities are not cut off from relief and recovery efforts.**

Government/Essential Facility Continuity

Given the high level of destruction in the tsunami zone, it is important that government buildings, essential facilities, and schools continue in operation following the earthquake and tsunami. Experience from the Tohoku earthquake/tsunami in Japan and other natural disasters in the U.S. and other countries has shown that where government continuity has been disrupted, post-disaster recovery times have been greatly increased. In addition to continuity of governments within the coastal zones, the capacity to communicate with state government offices must be firmly established.

Recommendations

- **Upgrade, or replace with buildings that meet or exceed current seismic codes, all government buildings, schools, and essential facilities located in the earthquake-only zone.**
- **Make all government buildings, schools, and essential facilities located within tsunami zones more resilient by adopting one of the following strategies:**
  - Relocate the facility outside of the tsunami zone.
  - Build the facility with reinforced concrete to resist tsunami loads. (If such a strategy is adopted, consider using the facility as a tsunami vertical evacuation refuge (TVER).

- Upgrade the facility to meet seismic life-safety standards, and create a backup facility outside of the tsunami zone.

Land Use

This resilience planning effort encourages a comprehensive, risk-based approach to reducing exposure and vulnerability to all natural hazards that potentially affect our coastal communities. Options and recommendations within this section should be helpful in assisting communities move forward in these important efforts. However, if a community needs to relocate a specific facility (for example, a hospital, fire station, police station, emergency response center, or school) in the short term to reduce tsunami risk, then utilizing a more strategic approach may be necessary and appropriate.

The need for pre-disaster relocation of government buildings, schools, and essential facilities has the potential to raise land-use issues. In some communities, such as Cannon Beach and Seaside, existing business areas may become part of new tidal zones after a Cascadia subduction earthquake as a result of subsidence. In some situations, such as the Seaside School District's relocation effort, sufficient existing land is not available inside the urban growth boundary for relocation, so it is necessary to collaborate with stakeholders to look at other appropriate sites. In other cases, such as the Waldport High School project, relocation can be accommodated within the existing urban growth boundary. In the Waldport case, it was necessary to maintain the vacated site as open space due to the requirements of FEMA funding, which assisted substantially in the relocation effort. FEMA funding can be very helpful in the development and implementation of community relocation strategies; however, there are situations in which these funds are not available or maintaining vacated sites as open space is not workable for a community. In these cases, transitioning to a more resilient community may dictate that the vacated site not be removed from the community's tax base, but instead be considered for (and used to help fund) the development of low-risk uses or uses which include appropriate and adequate protection or mitigation for seismic and tsunami risks.

The economies of most coastal communities are based on their proximity to the ocean. Ports, by their very nature, will always be in tsunami zones. Similarly, towns such as Cannon Beach and Seaside exist due to their close proximity to the ocean. Rethinking how ports can return and tourism can rebound following a Cascadia event will require an inspired strategy on the part of coastal communities and the state. (It should be noted that Oregon's coastal ports were built to support fishing and logging, and in many places, these industries are no longer the economic motors they were when the port facilities were built.) In addition, future development within the tsunami zone should seek to reduce risk. One hopeful sign is that 50 percent of growth since 2000 and 2010 census in coastal communities has been outside the tsunami zone (Personal communication with Wood, 2012).

SENATE BILL 379 TSUNAMI INUNDATION ZONE

In the mid 1990's, Senate Bill 379 directed the Department of Geology and Mineral Industries (DOGAMI) and its board to adopt a tsunami inundation line, and established requirements and restrictions for

certain development within the identified inundation zone. These requirements are found within ORS 455.446-447 and are administered within the Oregon Building Code. DOGAMI is currently remapping the Oregon coast for tsunami hazards. This new analysis is more comprehensive and uses updated methodology developed as a result of analysis of recent tsunami events and further Cascadia earthquake and tsunami research. The DOGAMI Board will soon review this new work to determine how this information should be used for purposes of administering the development restrictions of ORS 455.446-447. This updated mapping, and associated requirements as indicated, will be important considerations for local governments' comprehensive planning efforts and the development of implementation measures as required by Oregon Statewide Planning Goal 7, 17 and 18 (see http://www.oregon.gov/lcd/pages/goals.aspx for details).

OREGON DEPARTMENT OF LAND CONSERVATION AND DEVELOPMENT (DLCD) AND ITS COASTAL MANAGEMENT PROGRAM (OCMP)

Statewide Planning Goal 7 requires local governments to adopt comprehensive plans (inventories, policies, and implementing measures) to reduce risk to people and property from natural hazards and to address concerns about life safety, lifelines, economic viability, and infrastructure. Natural hazards include earthquakes and related hazards, tsunamis, and coastal erosion. DLCD is the agency charged with the responsibility of assisting local governments and local communities in addressing and planning for these hazards.

DLCD is charged with working with DOGAMI and local governments to address the implications of the updated tsunami inundation zone mapping for community development and comprehensive planning. This includes assisting local governments to develop adequate adaptation planning responses in anticipation of a major tsunami event. As part of this effort, DLCD has clarified specific policies that identify the tools that communities can use when adjustments to urban growth boundaries are required, or comprehensive long-term resilience planning is needed. These include:

- Urban growth boundary adjustments to address tsunami risk. Urban growth boundary expansions may be needed to allow for relocation of some community facilities due to tsunami hazard risks—if land is not suitable within the boundary. These would be strategic measures for a single purpose and would be subject to existing urban growth boundary requirements.
- Urban reserves. Communities may use a more comprehensive risk-based approach to reducing exposure and vulnerability to all natural hazards that may affect a community. This approach would be a longer-term effort and would help in situations where land-use zones would no longer be tenable or desirable following the event. Urban reserve work could include planning areas outside the urban growth boundary in preparation for pre- and post-disaster land-use efforts. This comprehensive approach could also help define what associated rezoning efforts would be needed inside the urban growth boundary.
- Community land use tsunami preparation. DLCD has placed a priority on supporting community land use tsunami preparation and on providing tools to help communities become more

resilient to this catastrophic hazard. In order to provide this assistance, the DLCD will partner with a qualified consultant to develop an array of best practices and tools which are tailored to the comprehensive plans of coastal local governments and statewide planning goals. This work will require comprehensive research, creative thinking, and compilation of an extensive set of resilience options, including a range of both land use incentive and regulation tools. This effort anticipates the development of a set of comprehensive tsunami resilience tools, which include such things as a tsunami hazard overlay zone and other land use related tsunami resilience provisions.

Recommendations

- **Encourage coastal communities to adopt the latest version of tsunami maps and analysis and to include these within local comprehensive plans.**
- **Work with local communities to develop comprehensive plans and policies related to becoming more resilient to tsunamis; such plans and polices should direct and authorize associated implementation actions.**
- **Encourage communities to develop a tsunami hazard overlay zone and other tsunami resilience provisions related to land use, which could be adopted and used within local land use codes.**
  - The code language could include options for incentives, requirements, and best practices for assisting communities to become more resilient to tsunamis.
  - Guidance materials could include options such as incentives and regulations related to allowed uses in inundation zone areas, tsunami evacuation route requirements, use requirements for vacated areas, and mitigation measures for development within inundation areas.
- **Support local government consideration of ORS 455.446-447 requirements (as potentially amended) for minimum requirements within local comprehensive plans and implementing ordinances.**
- **Support local government efforts to apply best practices and the tools developed by the Oregon Department of Land Conservation and Development (DLCD), when revising coastal communities' comprehensive plans to increase resilience to Cascadia type events.**
- **Support local governments as they review their respective urban growth boundaries to identify key community facilities which may need to be relocated to address substantial tsunami risk. Work with communities to develop local land use policies and strategies to address future relocation of these facilities.**
- **Encourage communities to consider strategies to increase the tsunami resilience of those parts of the community that cannot be relocated.**

- These strategies could include such things as the development of structures of such size and bulk that, if appropriate for the area, a vertical evacuation structure could be included as the top component.
- These strategies may need to include revision of zoning codes to allow suitable building height provisions for these structures.

Reconstruction

LARGE-SCALE DEBRIS REMOVAL

Requirements and plans for the removal of debris must be developed on a county and community level per discussion with U.S. Army Corps of Engineers before the Cascadia event. Given the terrain of the Oregon coast, available land for such purposes will be at a premium, and the need to dispose of debris may conflict with other vital needs during relief and recovery efforts. Moreover, both the debris and its removal will have long-lasting environmental impacts. Planning for recycling and reuse of this debris must be put into place before the event to reduce landfill and environmental impacts.

The U.S. Army Corps of Engineers has indicated that local governments should identify land for response and recovery efforts as part of their planning work *before* a Cascadia subduction zone event. This essential planning will expedite debris removal activities after the earthquake and tsunami. In addition, a viable transportation system must be put in place in order for the Corps of Engineers to get the necessary heavy equipment into place. Local jurisdictions can facilitate this effort by making arrangements in advance with existing local heavy equipment operators. These plans need to include both staging areas for the heavy equipment and areas for collection and sorting of the debris.

It should be noted that there are no landfill areas on the coast, and the local transfer station areas will be quickly overloaded following the event.

Recommendations

- ► **Develop and implement debris management programs for the recovery period following a Cascadia subduction zone earthquake and tsunami.**
- ► **Look at alternative strategies to reduce environmental impacts of debris for coastal communities.**
- ► **Develop a tool box of creative methods to recycle and reuse debris.**

COASTAL ECONOMIC RESILIENCE

Tourism

The impact of the earthquake and tsunami on coastal businesses will be severe and long-lasting. The impact on tourism will be felt with the loss of substantial numbers of buildings and businesses. Even those that remain will not have basic services, and the road system will be down, so that even if these services could be provided locally, there would be no way for visitors to travel into the area. The state park system will be damaged, and there will be changes in the beaches and estuaries as the tides re-equilibrate to the subsidence along the coast. Recreational opportunities will become limited. In addition, the positive image that people have of the Oregon coast will be damaged if there are widespread fatalities.

Plans should be developed for reestablishing tourism following the disaster (Figure 3.6). These arrangements should include coordinated recovery plans to provide an adequate workforce so that the number of visitors will not put a strain on the surviving infrastructure. Following the disaster, visitors must be protected and provided for in such a way that they understand that the coastal communities did all they could to assist them and that this understanding leads visitors to feel an attachment to the coastal communities and a desire to help them rebuild.

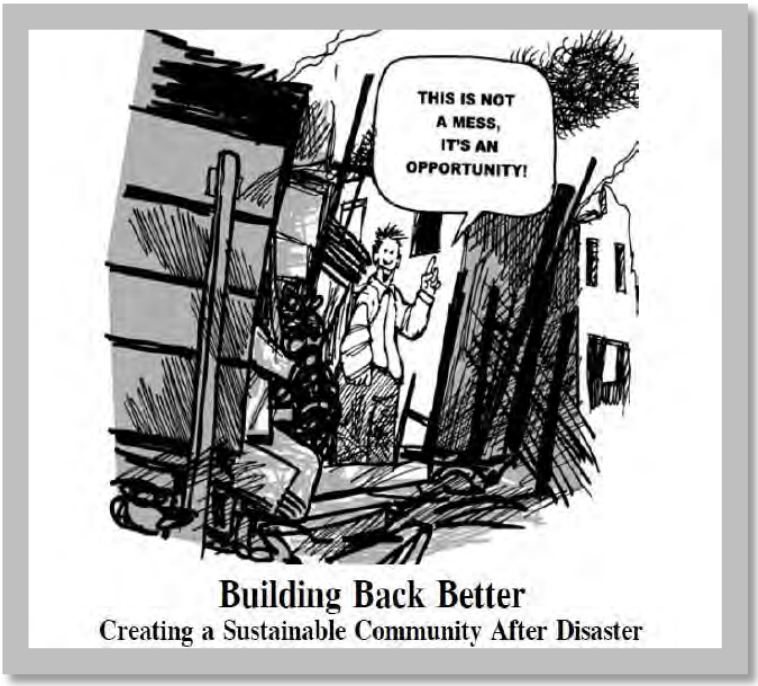

Figure 3.6: Building Back Better
(Source: www.colorado.edu/hazards)

Other Industries

- The logging industry will sustain major damage to its logging road system and will have difficulty transporting its products to market.
- The ports will sustain major damage so that goods and services will not be able to enter or leave until the ports are repaired.
- The fishing fleets may be severely damaged if they are in port when the tsunami arrives.

The Local Population

Even businesses that are not involved in tourism will be impacted by the loss of residents from the tsunami zones; and residents in earthquake-only zones will be forced to leave the area due to loss of jobs and loss of access to schools and medical facilities (see Figure 3.7). Many of the retirees who bring substantial money into the coastal communities may opt to relocate out of the area, putting further strain on coastal communities. The loss of the workforce will make it difficult for the businesses that remain to find sufficient help. For governments seeking to replace damaged infrastructure, the resulting reduction in the tax base will make recovery efforts more difficult. This problem will also hamper the efforts of the utilities providers, as demand for services will substantially decrease.

Recommendations

- **Require the state to do an assessment to determine an accurate level of coastal business operation following the Cascadia subduction zone event as a base case for recovery efforts.**
- **Require the Oregon Tourism Commission to work with the coastal hospitality industry and communities to develop plans for taking care of visitors following the Cascadia event and plan strategies for rebuilding the tourism industry after the event.**
- **Modify the use of room taxes to develop funding for mitigation efforts directly related to the evacuation of visitors to high ground, the provision of relief for visitors, and the development of mitigation and post-disaster recovery efforts. This could also include the creation of emergency funds.**
- **Develop economic incentives for recycling/reuse of post-disaster debris.**
- **Develop re-insurance or group insurance for the coastal zone to provide lower cost insurance to help with recovery efforts.**

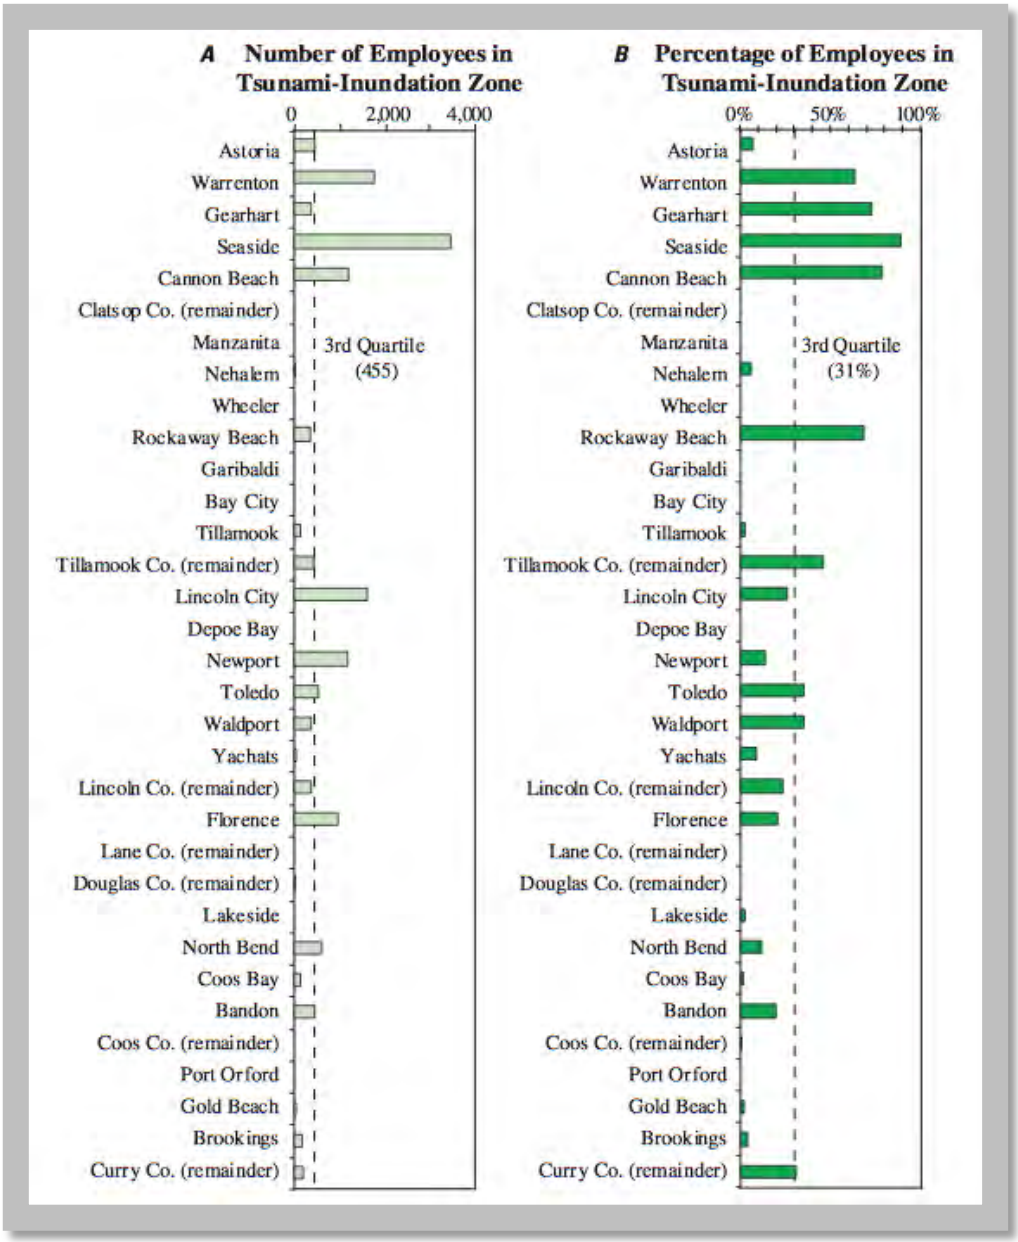

Figure 3.7: Number and Percentage of Employees in the Tsunami Inundation Zone. Wood, Nathan: 2007, Variations in City Exposure and Sensitivity to Tsunami Hazards in Oregon. (Source: US Geological Survey)

Disaster Resilience and Sustainability

Mitigation will be a primary tool in the creation of disaster resilience within Oregon's coastal areas. Solutions that are currently thought of as *sustainable development* should be studied as part of these mitigation and post-disaster recovery plans (see Figure 3.8). One of the main reasons that Japan and Chile got back up and running from their most recent earthquakes (i.e., the 2010 M8.8 Maule Earthquake and the 2011 M9.0 Tohoku Earthquake) was that they have redundant service systems. Sustainable solutions can help provide this redundancy. Given the expected problems of energy delivery following a Cascadia event, coastal communities should explore alternatives to the statewide utility grid and, to the extent possible, work towards greater self-sufficiency. Current localized energy generation options include:

- Wave, wind, and solar as models for economic growth, improved emergency self-reliance, and less dependency on a tourism-based economy.
- The proposed energy generation plant, if it is accepted, for a Coos Bay LNG facility. This plant could have value after a Cascadia subduction zone event if it is located outside of the tsunami zone.
- Investment early in infrastructure redundancy and alternative local sources of energy for areas that will someday need to be rebuilt and relocated due to catastrophic earthquake and tsunami damage. Such investment can have dual benefits: minimizing disaster-related downtime and encouraging sustainable community development. *(Example:* The Smart Grid concept http://www.smartgrid.gov/ to invest in alternative local/regional electricity generation and distribution.)

Figure 3.8: Disaster Resilience is a Critical Component of Community Sustainability. (Source: Public Entity Risk Institute)

HAZARD MITIGATION: PRE-DISASTER RISK REDUCTION

Natural hazard mitigation plans are required at the state, county, and city levels in order for these jurisdictions to be eligible for post-disaster FEMA grants. These plans acknowledge local and regional natural hazards and assess the related vulnerability of the community to determine the community's acceptable level of risk.

A tiered approach to mitigation should be developed:

- Top tier mitigation efforts should prioritize strengthening life-safety capacity during a worst-case-scenario event. Examples include finishing all mapping, hardening evacuation routes, increasing capacity to aid visitors, improving consistent signage, designating earthquake-resistant shelters, and stocking community emergency provisions sufficient to last for one month. This would also include strengthening existing critical facilities that are already outside of the tsunami zone.
- Tier two mitigation efforts should be to relocate critical infrastructure outside of the tsunami zone so that it is operational or repairable immediately following a Cascadia subduction zone event and is therefore able to provide emergency services (rather than being destroyed, abandoned, and useless).

Coastal hazard mitigation plans should have action items that are specific to a Cascadia subduction zone event. Such action items should call for prioritized mitigation projects to improve life safety and avoid damage or reduce exposure from the tsunami and earthquake.

PLANNING FOR RECONSTRUCTION AND RECOVERY

For legacy facilities that are too problematic to relocate, such as electric substations or wastewater treatment plants, pre-disaster recovery planning will allow community decision makers to outline goals, objectives, and strategies for realizing the more resilient and sustainable public and private sector arrangements that are to be implemented during post-disaster long-term recovery. There has been some concern expressed by utility providers about how these improvements will impact ratepayers.

Economic resilience must really address the number of local businesses that are located in the tsunami zone and the extent to which these businesses depend on services that are in (or move through) the tsunami zone. The tourism-based businesses that survive may have reduced demand following the Cascadia subduction zone event, but lodging, food, and commercial businesses can provide invaluable benefits to their communities by maintaining the capacity to operate.

Example: Timebank Concept from Lyttelton, New Zealand. *This isolated coastal community is using a concept they started called Timebank as a way to barter professional, skilled, and volunteer services to do earthquake recovery for community projects. This is a great model (at the small-community scale) for sharing the community's internal resources and a very practical model for Oregon's highly self-reliant coastal communities, especially those with a strong sense of place. (http://www.lyttelton.net.nz/earthquake/lyttelton-timebank)*

Recovery planning now is really about rebuilding for the *subsequent* Cascadia subduction zone event. While it may not provide any risk-reduction benefits now, it will substantially minimize uncertainty, deliberation, conflict, and delay by getting a very complicated and bureaucratic process moving forward in accordance with whatever vision the community adopts. The great importance of this recovery visioning process was revealed during a tsunami recovery workshop at Cannon Beach in 2006 (see http://csc.uoregon.edu/opdr/recovery/cannonbeachpilot). Coos, Curry, Douglas and Lane counties have already participated in a recovery planning process for southwestern Oregon. This process was facilitated by the Oregon Partnership for Disaster Resilience and funded by FEMA.

Having witnessed other subduction zone events during the past eight years (2004 Indian Ocean, 2009 American Samoa, 2010 Chile, and 2011 Japan)—events that are similar to what is expected from a Cascadia subduction zone earthquake and tsunami—Oregon's coastal communities are taking stronger steps towards planning for this inevitability. With the imperative of the Oregon Resilience Plan, it is critical that limited federal, state, and local capital be wisely invested in a manner that looks forward to sustainable objectives, with an emphasis on local resources, rather than doubling down on older systems that have heavy dependencies on services delivered from out of the area.

Relief and Resilience Ratings

The initial analysis of the current state of preparedness that was done to establish baselines for resilience targets has confirmed that our levels of preparedness are low (see Figure 3.9). This analysis has also revealed the timeframes within which people in Oregon can expect relief efforts to reach them following a Cascadia subduction zone earthquake and tsunami. Relief efforts of any size will clearly need to come from outside of the area, but the transportation systems—whether travel is by highway, air, or sea—are expected to be severely impacted. The difficulties associated with delivering aid are most acute for the coastal zone, but they could also be an issue for rural areas in the valley.

Information about the likely timeframes involved in delivering aid should be disseminated to citizens and communities to allow them to plan accordingly. The standard recommendation is for people to prepare to be self-sufficient for 72 hours following a natural disaster of this kind. This standard should be raised (see Figures 3.10 and 3.11). In the tsunami zone, preparation involves evacuating to high ground. Because homes and businesses will be lost, the preparation of residents also needs to include survival kits containing some sort of shelter (protection from the elements), food and water, and any other items that the individual will need while living in temporary shelters, whether located on the coast or in other areas). Visitors in the tsunami zone will not have made these preparations and will be relying on the help of residents and communities. People in the earthquake-only zone are expected to fare better, because they will likely still have their homes—although a certain percentage of those homes will be so damaged by the earthquake that they can no longer be occupied.

Coastal communities are beginning to make preparations. For example, several communities are creating stockpiles of emergency supplies outside of the tsunami zone. Communities and citizens need

some level of transparency in order to keep track of their own level of preparation for emergency response and progress towards achieving resilience.

Recommendations

- **Adopt a two-tiered rating system that gives (1) the number of hours/days that a citizen in a community can expect to wait before major relief arrives and (2) the number of days/months that a citizen can expect to wait before the community itself achieves 90-percent restoration of roads and services.**
  - The rating system should adopt the zones established by the resilience report: tsunami zone, coastal earthquake-only zone, valley zone, and eastern zone.
  - Standards and methodology must be developed to ensure that the rating system is consistent.
  - Communities and counties should use these standards and methodology to develop standards for cities and unincorporated areas.

The goal of this two-tiered rating system is to provide information at any given time about what citizens should expect, and to serve both as the basis for a community's resilience targets and as a means of measuring how close the community is to meeting them. Because the resilience report sets a 50-year target for achieving statewide resilience, a mechanism is needed to track progress and provide pressure to meet the target.

	RELIEF	RESILIENCE
Eastern	72 hours	1 to 3 years
Valley	72 hours	1 to 3 years
Coast (Earthquake Only)	1-2 Weeks	3 years +
Tsunami Zone	1-2 Weeks	3 years +

Figure 3.9: Existing Relief/Resilience Ratings

	RELIEF	RESILIENCE
Eastern	72 hours	2 weeks
Valley	72 hours	2 to 4 weeks
Coast (Earthquake Only)	72 hours	2 to 4 weeks
Tsunami Zone	72 hours	2-4 weeks

	Tier 3										60%
	Other										60%

50 Year Targets

Minimal: (A minimum level of service is restored, primarily for the use of emergency responders, repair crews, and vehicles transporting food and other critical supplies.)

Functional: (Although service is not yet restored to full capacity, it is sufficient to get the economy moving again—e.g. some truck/freight traffic can be accommodated. There may be fewer lanes in use, some weight restrictions, and lower speed limits.)

Operational: (Restoration is up to 90% of capacity: A full level of service has been restored and is sufficient to allow people to commute to school and to work.)

60% - ESTIMATED TIME FOR RECOVERY TO 60% OPERATIONAL

90% - ESTIMATED TIME FOR RECOVERY TO 90% OPERATIONAL

Disaster Resilience in Action:

- Waldport High School is the first FEMA tsunami acquisition project in the country. Lincoln County School District secured a bond to rebuild a new high school on the hill above the city.
- As of December 19, 2012, the Seaside School Board approved a resolution to authorize the superintendent to hire an architect to begin designing a new school campus, which would be constructed above the tsunami inundation zone. A long-anticipated bond measure to support this effort is expected to be on the ballot in May 2013.
- As of December 12, 2012, the Cannon Beach City Council agreed to acquire 55 acres to expand the city limits for a new school site above the tsunami inundation zone.

4. Critical and Essential Buildings

Introduction

Building safety and functionality will be critical both during and after a magnitude 9.0 Cascadia subduction zone seismic event. Oregon's buildings must be able to withstand the intense ground shaking without devastating loss of life, damage to infrastructure, or significant disruption to our communities and economy. Because of this, the Critical Buildings Task Group was assigned the task of reviewing the status of buildings in critical sectors and considering how they may be affected by a Cascadia subduction zone event. Buildings in these critical sectors include those that are necessary for the immediate response to the event—such as emergency operations centers, hospitals, police and fire stations, and emergency shelters—and buildings that are necessary for the provision of basic services to communities as they begin to restore functions and return to normal life—for example, schools, housing, certain retail stores, and banks. The group reviewed one additional building category: vulnerable buildings. These are unreinforced masonry and non-ductile concrete structures that have shown time and again in past earthquakes that they pose a very significant and direct threat to life safety.

While the task group acknowledges that there are many other buildings and sectors that could also be considered vital to resilience, the group decided to limit the study to those buildings that we believe are most critical to resilience in the case of an earthquake scenario. Buildings and structures that are directly associated with and critical to the functionality of communications, utilities, ports, water supply, wastewater, and fuel storage have been evaluated separately by other task groups; the assessments and recommendations of these task groups are provided elsewhere in this report.

To assess the overall seismic resilience of critical and essential buildings in the state of Oregon, the work group considered the gap between the building-performance goal needed for seismic resilience (target state) and the expected seismic performance of the buildings as they are today (current state). Most of the building sectors that are critical to the response to a seismic event are recognized by the current building code. Oregon's current seismic design standard for new buildings, the Oregon Structural Specialty Code (OSSC), classifies buildings according to four distinct occupancy categories based on their relative importance to life safety in the event of a natural disaster (see Figure 4.1). Occupancy Categories III and IV are structures that have large assembly areas (such as schools), or that are deemed essential to emergency response (such as hospitals, police and fire stations, and emergency operations centers). Buildings that fall under these Category III or IV classifications were obvious components of the Critical Buildings data set used in our evaluation. Under current code, occupancy category type III buildings are designed for a 25-percent higher seismic load than Category I and II buildings. Category IV buildings are designed for a 50-percent higher load.

Our group also looked beyond the building code to buildings that have functions that we believe are vital to the seismic resilience of the state as a whole. Supermarkets, pharmacies, some big-box retail stores, and banks comprise a subset of buildings that will be relied upon heavily following a disaster. The importance of having an ample supply of basic provisions—such as food, water, medical supplies, and money—in affected areas after a natural disaster has been underscored by many previous events, including Hurricane Katrina and the 2011 Tohoku earthquake and tsunami in Japan. If buildings that house these resources are not seismically resilient, the ability of the community to recover after the event will be adversely affected. For these reasons, the community's large retail buildings and bank buildings have been classified as critical buildings in this study.

TABLE 1604.5
OCCUPANCY CATEGORY OF BUILDINGS AND OTHER STRUCTURES

OCCUPANCY CATEGORY	NATURE OF OCCUPANCY
I	Buildings and other structures that represent a low hazard to human life in the event of failure, including but not limited to: • Agricultural facilities. • Certain temporary facilities. • Minor storage facilities.
II	Buildings and other structures except those listed in Occupancy Categories I, III and IV
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: • Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300. • Buildings and other structures containing elementary school, secondary school or day care facilities with an occupant load greater than 250. • Buildings and other structures containing adult education facilities, such as colleges and universities, with an occupant load greater than 500. • Group I-2 occupancies with an occupant load of 50 or more resident patients but not having surgery or emergency treatment facilities. • Group I-3 occupancies. • Any other occupancy with an occupant load greater than 5,000[a]. • Power-generating stations, water treatment facilities for potable water, waste water treatment facilities and other public utility facilities not included in Occupancy Category IV. • Buildings and other structures not included in Occupancy Category IV containing sufficient quantities of toxic or explosive substances to be dangerous to the public if released.
IV	Buildings and other structures designated as essential facilities, including but not limited to: • Group I-2 occupancies having surgery or emergency treatment facilities. • Fire, rescue, ambulance and police stations and emergency vehicle garages. • Designated earthquake, hurricane or other emergency shelters. • Designated emergency preparedness, communications and operations centers and other facilities required for emergency response. • Power-generating stations and other public utility facilities required as emergency backup facilities for Occupancy Category IV structures. • Structures containing highly toxic materials as defined by Section 307 where the quantity of the material exceeds the maximum allowable quantities of Table 307.1(2). • Aviation control towers, air traffic control centers and emergency aircraft hangars. • Buildings and other structures having critical national defense functions. • Water storage facilities and pump structures required to maintain water pressure for fire suppression.

a. For purposes of occupant load calculation, occupancies required by Table 1004.1.1 to use gross floor area calculations shall be permitted to use net floor areas to determine the total occupant load.

Figure 4.1: Oregon Structural Specialty Code, Table 1604.5

Past earthquakes have brought to light the dangerous nature of unreinforced masonry (URM) and non-ductile concrete structures. Because of their tendency to sustain excessive damage or even collapse in

moderate earthquakes, these buildings pose the greatest threat to life safety of any other building type in the state of Oregon. This, along with the fact that URM and non-ductile concrete buildings can be found in all occupancy categories, was the main reason that our task group included these vulnerable buildings in our study of critical buildings.

Building Data and Analysis

After identifying the building sectors, the task group went on to identify data sources for the existing building stock that could be used for assessment of the buildings' seismic resilience. Two sources were used:

- The *2007 Statewide Seismic Needs Assessment: Implementation of Oregon 2005 Senate Bill 2 Relating to Public Safety, Earthquakes, and Seismic Rehabilitation of Public Buildings* (Open File Report 07-020) prepared by the Oregon Department of Geology and Mineral Industries (DOGAMI), hereafter referred to as the 2007 SSNA.
- The Hazus Earthquake Model developed by the Department of Homeland Security and FEMA, hereafter referred to as FEMA Hazus.

The 2007 SSNA is an assessment of existing hospitals, police and fire stations, emergency operations centers, and K-12 schools throughout Oregon. This assessment was conducted using a rapid screening method developed by FEMA to identify potential seismic hazards. The report provides evaluations of each facility, which were visited by screeners to establish a Rapid Visual Screening (RVS) score based on the FEMA 154 methodology. The data was compiled by DOGAMI, and the resulting scores were then reviewed by the structural engineers in our task group, who, in the case of emergency operation centers, police stations, fire stations, and acute care hospitals, reviewed the screening for every building and converted the RVS scores to *expected recovery* scores. These scores were then placed into the overall *Critical Building Target States of Recovery Matrix* shown in Figure 4.2. A similar procedure was also used for schools, but because of the number of school buildings, only about 10 percent of the total school building stock was reviewed directly. Additionally, the task group took into consideration tsunami inundation, liquefaction, and landslides, which were not a part of the DOGAMI study.

To assess residential buildings, community retail centers, banks, critical government facilities, and vulnerable buildings, data for expected damage estimates based on a Cascadia subduction zone event were extracted from the FEMA Hazus model, and an analysis was performed to develop *expected recovery* scores, which were then added to the overall matrix shown in Figure 4.3. Unlike the 2007 SSNA data, which looked at each individual building, the FEMA Hazus model utilizes a complex series of statistical analyses to predict damage estimates. This involves making predictions about the quantity, size, and construction of buildings in various sectors based on census data, and then calculating an expected performance for these buildings using additional statistical models. While this is a useful tool for looking at large populations of buildings, the outcomes do not correlate directly to any specific buildings. Because more detailed reports were not available, this data was used to establish *expected*

recovery scores; these are subject to a larger variation in expected results and should not be viewed with same level of reliability as those in Figure 4.2. Recovery scores developed from the 2007 SSNA report have been separated from the scores developed through the use of FEMA Hazus due to the differences between the two sources.

Target States of Recovery

With recovery scores established, the next step was to determine the recovery state that should be targeted in planning the path to statewide seismic resilience. The recovery state is the average time that should be needed to repair a building in a given sector and restore most of its functionality. For the Phase 1 target states, which are measured in hours, there is not much differentiation in the building performance, though it should be realized that just evaluating buildings, particularly in the areas most severely affected, may take several days. Buildings with Phase 2 response times are expected to require some repairs, but generally should not sustain major damage to the primary structures. Phase 3 buildings are expected to sustain significant damage, likely requiring many months to a year or more to repair. The worst building performance—expected of structures in the 18 month and 36+ month categories—will likely be at, or near, a complete loss. Many buildings can be reconstructed in 18 months with sufficient resources; the remaining collapsed buildings will likely require 36+ months.

The determination of target states was based mostly on assessing the relative importance of each of the occupancy types to the response and recovery effort after the seismic event. Buildings that house first responders or provide emergency functions are the most vital to the response effort and will need to be functional immediately after the seismic event occurs. Schools in the affected areas need to provide a level of life-safety protection for the children and adults in them during the earthquake, but could be out of service for up to 60 days without significant impacts on resilience. The exceptions are those schools designated as emergency shelters for displaced citizens after the event occurs. The availability of food, water, medical supplies, and money will also be critical to the speed of recovery of the communities affected by the seismic event. Consequently, retail centers, pharmacies, and banks will have to be able to return to normal operation in a reasonable amount of time. All of these considerations informed the development of the *target recovery* scores for each building class that are reflected in Figures 4.2 and 4.3. Note that a specific target state was not determined for vulnerable buildings. This is because the use and function of these structures varies widely. Instead, the recovery state should either match the building's occupancy category, if the building is used for a critical function, or upgrade criteria should be established based on the needs of the facility—but these criteria should not be less than life safety.

With both expected and target recovery states identified and tabulated for each building class by seismic region, the gaps between expected and target building performance can easily be seen.

Target State **X Estimated Current State**

Figure 4.3: Target States of Recovery For Oregon's Buildings Based on FEMA HAZUS Loss Estimations

While the gaps between the target state and the estimated current state may appear large, it was our task to look beyond them and formulate a 50-year plan for closing these gaps. The Critical Buildings Task Group has therefore developed an extensive list of recommended actions that, if followed, provide a framework for achieving this objective. These recommendations, along with a proposed implementation timeline, can be found in the *Conclusions and Recommendations* section at the end of this chapter. As the building stock continues to age and the likelihood of the next Cascadia subduction zone event continues to grow, the gaps that we have identified will only continue to get larger. We cannot underscore enough the importance of taking immediate action so that the movement to an acceptable level of seismic resilience in the most essential and vital buildings in our state can begin.

Assessment of Current Building Performance: A Sector by Sector Review

EMERGENCY OPERATIONS CENTERS, POLICE AND FIRE STATIONS

Introduction

In 2005, the Oregon Department of Geology and Mineral Industries (DOGAMI) published a report titled *Statewide Seismic Needs Assessment: Implementation of Oregon 2005 Senate Bill 2 Relating to Public Safety, Earthquakes, and Seismic Rehabilitation of Public Buildings, Report to the Seventy-Fourth Oregon Legislative Assembly*. This report catalogued the vast majority, if not all, of the emergency operations centers, police stations, and fire stations within Oregon. Of the sources of data collected, 82 emergency operations centers, 109 police stations (which includes city police, state police, and county sheriff), and 595 fire stations (which includes city and rural fire protection districts) provided enough information for the Critical Buildings Task Group to reasonably assess the state of seismic resilience of each of these buildings.

Most of the buildings considered by the task group are one- or two-stories tall and are constructed from reinforced masonry or wood. The median building age is approaching 40 years. Despite the good performance record of wood structures during earthquakes, the age of these buildings and the low level of seismic design used prior to 1995 places the older structures at risk. Additionally, a number of buildings located in the coastal region are at risk of earthquake-caused tsunami inundation or large ground displacements due to either liquefaction or landslides. A number of buildings in the valley region are also at risk of significant movement due to liquefaction or landslides resulting from an earthquake. All of these factors increase the level of risk for many buildings exposed to the effects produced by a Cascadia subduction zone event.

Estimated State of Recovery

The expected state of recovery of these buildings ranges from a few buildings remaining fully functional during and immediately following a Cascadia subduction zone event, to many other buildings requiring three or more years for repair before they are deemed fully functional or are demolished. Of particular concern are the buildings along the Oregon coast, where 82 percent of the emergency operations centers, 86 percent of the police stations, and 67 percent of the fire stations will most likely take 18 months or more to resume normal operations. The buildings within the valley zone are also problematic, with 27 percent of the emergency operations centers, 38 percent of the police stations, and 31 percent of the fire stations likely to sustain damage to the extent that 18 months or more will most likely be required to resume normal operations. Therefore, instead of being able to withstand and operate during and after a Cascadia subduction zone seismic event, which is what we should expect of buildings performing these vital life-safety functions, it is anticipated that a significant percentage of the buildings that house these types of essential services will not be functional for some time after the event. Of significant concern is the longer recovery time anticipated for many of the critical buildings that are located along the coast and in portions of the valley.

Target State of Recovery

The importance of emergency operations centers, police stations, and fire stations to the post-earthquake response and recovery is widely recognized. Building codes have required for some time that these facilities be designed to a higher standard, with the intent that they will remain operational after a major earthquake. The public also recognizes that these facilities are the centers for first response, and there is consequently a general expectation that they will remain functional after the disaster. For these reasons, the target state of recovery for these facilities must be *Event Occurs* as indicated in the recovery matrix, Figure 4.2.

Sector Specific Recommendations and Conclusions

To our knowledge, a mandatory program with a formal mechanism to identify deficient structures and require their upgrade with a firm timeline does not currently exist. ORS 455.400 requires seismic rehabilitation of publicly-operated emergency operations centers, police stations and fire stations by 2022, but with the caveat of being, "subject to available funding." As a result, it appears to have had only limited effect in this and other essential and critical building sectors. Typically, the impetus to evaluate these types of buildings to determine their seismic-resisting capability is motivated at the local level, often by the public agency itself. Once the evaluation has been completed, a determination can be made about whether a particular building or group of buildings requires seismic rehabilitation. The agency will then submit a request to the voters within that community to support a general obligation bond to accomplish the needed work. This was recently done within the city of Portland, where a general obligation bond was passed in 1998 to rehabilitate the city's fire stations (See Figure 4.4). The last fire station rehabilitation was completed in 2012.

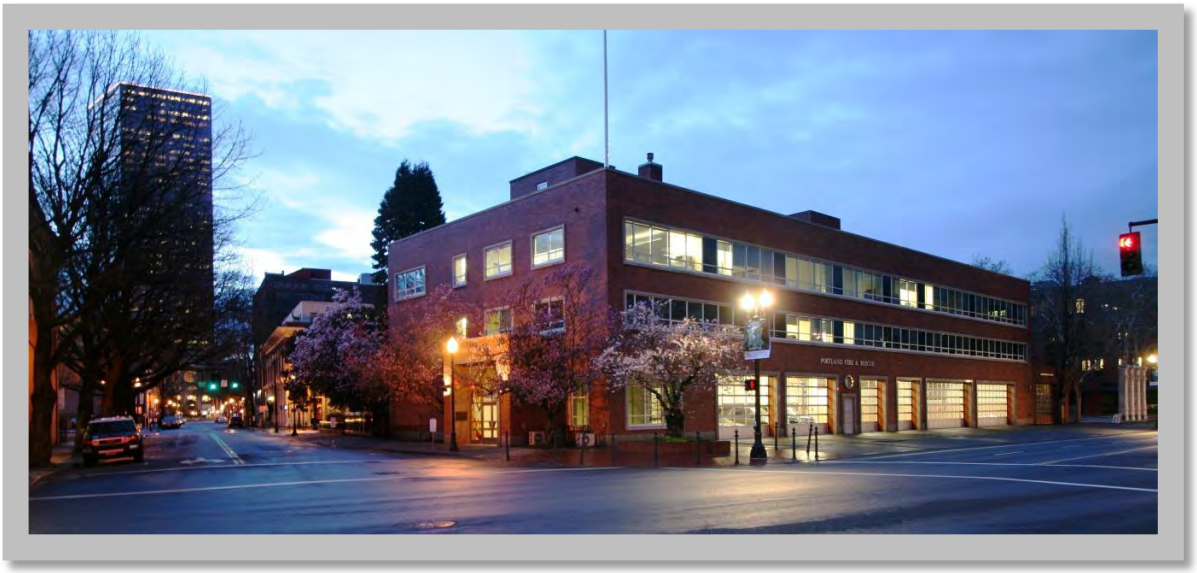

Figure 4.4: Some cities in Oregon have already started seismic rehabilitation program to strengthen the fire stations that are susceptible to serious damage in an earthquake. Fire Station #1, the largest in Portland, was retrofitted in 2009. It should now be in working order after an earthquake, serving downtown Portland. (Source: Peck Smiley Ettlin Architects)

Financing methods for the rehabilitation of public buildings are much more limited than the opportunities that exist for privately-owned buildings. As a result, general obligation bonds, or some variation thereof, are likely to be the primary method to finance the seismic upgrading of these critical facilities. Oregon Senate Bill 3 and 5 (2005) provided for the establishment and funding of a grant program for emergency services buildings to assist with upgrades of these facilities, but funding to date for this program has been limited. Public buildings ultimately must be financed, either substantially or completely, with public funds. This can only happen by implementing a broad program of education to inform the voters of the risks associated with these seismic hazards and the impact that those risks, if unmitigated, will have on their communities when the Cascadia subduction zone event occurs.

In addition to the types of public buildings discussed above, other types of critical government facilities exist, including, but not limited to, city halls, public safety answering points (PSAPs, usually termed 911 Centers), and jails. The 2007 SSNA report did not collect data on these types of facilities, and to our knowledge, no publicly-available data exists about them within Oregon, except for broad statistical data which can be inferred from the FEMA Hazus data discussed in the *Critical Government Facilities* section of this chapter (see below). Consequently, no specific, data-driven recommendations regarding the seismic resilience of these other critical government facilities have been provided as part of this report.

EDUCATION FACILITIES

Introduction

Public school facilities make up a special category of Oregon's public infrastructure. Oregon has 1,355 K-12 public schools organized in 197 school districts that are overseen by independent elected local school boards. Combined, these schools have a total of over 2,000 buildings of various structural types, sizes, and vintages, including numerous buildings that are more than a century old.

Schools are among the most heavily used public buildings in Oregon and one of a few classes of buildings whose occupants' presence is compulsory. In 2010, the Western States Seismic Policy Council (WSSPC) adopted a policy recommendation that states, "Children have the right to be safe in school buildings during earthquakes" (WSSPC, 2010). Based on the findings of the Critical Buildings Task Group, the state of Oregon is far from meeting this ideal of student safety today.

The 2007 Statewide Seismic Needs Assessment (SSNA) employed the FEMA 154 Rapid Visual Screening (RVS) methodology to characterize the structural performance of buildings by placing them into one of four broad categories of collapse potential. Of the full sample of 2,018 K-12 educational facilities assessed using the FEMA 154 methodology, 12 percent rated Very High, 35 percent rated High, 23 percent rated Moderate, and 30 percent rated Low collapse potential (Lewis, 2007). The assessment focused on school facilities constructed before 1994, although some more recent buildings were included. Of the buildings assessed, roughly 80 percent were built before Oregon first adopted a statewide building code in 1971, and 60 percent are more than 50 years old. The assessment revealed

that inadequate or non-existent seismic design is pervasive in every region of Oregon, and that seismic retrofit investment at the school district level has been limited.

Schools are typically large, complex buildings with plan irregularities that will be sources of poor seismic performance. Many schools are campuses that are comprised of multiple buildings of varying sizes and construction dates, and often varied construction materials. Primary, K-8, and high schools generally consist of one- or two-story wood-frame or concrete masonry unit (CMU) and concrete buildings with flexible roof diaphragms. One- to three-story lightly-reinforced concrete buildings braced by concrete shear walls, concrete tilt-up buildings, and unreinforced masonry (URM) buildings are also common.

Figure 4.5: The previous Molalla High School building, a three-story unreinforced masonry structure, was damaged from the M5 .6 Scotts Mills, Oregon earthquake in 1993. It happened during spring break, when the school was empty, which prevented serious injuries. The district took the opportunity to forecast future needs and decided not to rebuild at the same location. Molalla High School is now housed on a larger campus with a stronger, more spacious building. Many URM schools and other buildings in Oregon could suffer a similar fate in future earthquakes. Communities can act now to plan how and when to rehabilitate or replace these aging, potentially dangerous facilities. (Source: DOGAMI)

The building stock of Oregon's K-12 schools possesses seismic vulnerabilities that are common to the specific building types of which it consists. Unreinforced masonry (URM) buildings historically perform poorly in seismic events and are the most dangerous existing building type in the school building stock (See Figure 4.5). Many 1930s-era multistory schools rely on lightly-reinforced concrete shear walls that are historically poor performers as well. Wood framed schools should perform well provided they are well constructed, even though many of them pre-date building codes. These wood buildings may possess deficiencies, including weak or missing roof-to-wall connections, and weak or missing anchorage of walls to foundations—all of which could contribute to poor seismic performance. Concrete tilt-up buildings have also proven to perform poorly in earthquakes. Newer tilt-up buildings have been improved by code changes adopted following the 1994 Northridge earthquake in California, but older tilt-up buildings, and even CMU buildings, may remain vulnerable due to poor connections between heavy rigid walls and flexible roofs. Modular classrooms may also be vulnerable, because they may have insufficient connections to their foundations. In addition, many schools contain unsecured and inadequately braced nonstructural components that may present falling hazards during a seismic event (See Figure 4.6).

Figure 4.6: Pendant light fixtures failed in this elementary school library during the 1983 M6.5 Coalinga, California earthquake. If the room had been occupied, this could have caused injuries. Bracing nonstructural elements in homes, schools, and offices can often be done easily and relatively inexpensively. (Source: NOAA/NGDC, Earthquake Engineering Research Institute)

Estimated State of Recovery

The 2,377 educational facility records in the 2007 SSNA were too numerous to be analyzed individually by members of the educational facilities subgroup. Our analysis and results are based on a random sample of approximately 300 records (224 primary school buildings and 79 secondary school buildings) that were selected as representative of the broader data set. We classified the building records into the appropriate geographic seismic zone (coast, valley, and eastern) and verified that we had assembled an adequate sample size for each zone.

Our analysis revealed that in a Cascadia subduction zone earthquake scenario, pervasive structural vulnerabilities would likely result in recovery durations of 18 months or longer for primary and secondary schools in the seismic zones of the coast and valley. Primary and secondary schools in the eastern seismic zone are expected to have recovery times of 60 days or less, mainly due to the minimal level of ground motion expected in that geographical area.

Target States of Recovery

Giving consideration to the prioritized needs of the entire community for resilience and recovery, returning children to school within 30 days is preferred. However, it was also the opinion of the task group that a disruption of the public education system for up to 60 days could be tolerated without having a major impact on communities and students. This determination was based on several considerations:

- School buildings will not initially be as critical to the recovery as most other critical buildings included in our study. The exception to this would be those schools that are needed as emergency shelters, and as such, should have a target state of recovery of 72 hours.
- Teacher/employee contracts can be adjusted to accommodate a 2 month stoppage of work more readily than employee contracts in many private businesses.
- Temporary facilities, including portable buildings and large buildings that are undamaged after the event, can be employed to serve some of the more immediate needs of education until full recovery is achieved.

Discussion and Sector Specific Recommendations

Oregon's K-12 educational facilities have been the focus of seismic rehabilitation policy efforts for more than a decade. In 2001, legislation (ORS 455.400) directed that, subject to available funding, K-12 educational facilities with seismic deficiencies should be rehabilitated to a life-safety performance level by 2032. In 2002, Oregon voters adopted ballot measures amending Oregon's constitution with Articles XI-M and XI-N, provisions that allow the state to issue general obligation bonds for the purpose of seismic retrofits to existing schools and emergency response facilities. In 2005, a series of bills (Senate Bills 2, 3, 4, and 5) directed DOGAMI to organize and conduct the *Statewide Seismic Needs Assessment*,

directed Oregon Emergency Management to establish a seismic rehabilitation grants program, and allowed the Department of Administrative Services and the Oregon State Treasurer to issue bonds to finance seismic rehabilitation.

In 2007, Senate Bill 1 provided funding to establish and staff the seismic rehabilitation grants program. The first opportunity to authorize a bond sale for an inaugural round of seismic retrofit grants came in the 2009-2011 biennium. The legislative assembly authorized $30 million for seismic grants, divided equally between the program for K-12 schools and the companion program for emergency response facilities. The first round of K-12 grants directed $5.6 million to projects at twelve schools in eight school districts in the spring of 2010. As the recession deepened, the governor chose to rescind $7.5 million of the original authorization for the program, limiting additional granting during 2009-2011. Three additional seismic grants were awarded to K-12 schools (including two URM buildings) in early 2011. These grants marked the end of the first funded cycle of the program.

On the final day of the 2011 legislative session, the legislature authorized $7.5 million in new seismic grants for K-12 schools during the 2011-2013 biennium. These grants, announced in Fall 2011 and funded by a bond sale in July 2012, directed $7.2 million to seven K-12 schools. To date, the Seismic Rehabilitation Grants Program has funded retrofit projects at 22 schools, about 2 percent of the need documented by the *Statewide Seismic Needs Assessment*.

During the short 2012 session of the legislative assembly, legislators passed Senate Bill 1566. The bill directs the state's Department of Education, which communicates with parents about student achievement and school performance via an annual report card, to inform the public in that report that a database of seismic ratings exists and to provide a web link to the ratings. Further, the bill asks school districts to advise DOGAMI when they rebuild or renovate schools, so that the state can share information about the upgrades. The first reports submitted by individual school districts are now posted on the DOGAMI website, although the agency has no funding to integrate information from the reports in an update of the statewide database itself.

Given both the limited impact that existing policies have had on restoring resilience in Oregon's schools and the uneven success that Oregon school districts have had passing local capital bond measures for school rehabilitation and construction in recent years, an evaluation of Oregon's approach to characterizing and addressing the seismic vulnerability of school facilities is in order. Past outreach using the results of the *Statewide Seismic Needs Assessment* has emphasized the threat to life safety and the possibility of mass casualties in collapsed school buildings. By contrast, the gap analysis we have performed as part of this resilience study focuses on quantifying the state's ability to resume public education after a region-wide Cascadia subduction zone earthquake, given what is known about the condition of the state's school facilities. With the anticipated level of damage to those facilities, the disruption of public education could extend considerably beyond a full school year, particularly in the coast and valley regions—a factor that could impede Oregon's economic and social recovery for years after the Cascadia subduction zone earthquake.

HEALTHCARE FACILITIES

Introduction

There are 60, mostly privately-owned, healthcare facilities within the state of Oregon, with the majority of the buildings being over 40 years old. Each healthcare facility is comprised of either a single building or multiple buildings that form a campus. Roughly 180 structures within all of the 60 healthcare facilities serve critical healthcare functions. There are additional buildings within each healthcare facility's campus that have not been included in this study because they do not serve acute care needs and are not considered essential.

In essential healthcare buildings, the most prevalent construction material is concrete, with approximately 70 percent of concrete structures relying on concrete shear walls to resist lateral loads and the remaining structures relying on concrete moment frames. The second most prevalent construction material is steel: approximately an equal distribution using steel braced frames and steel moment frames to resist lateral loads. Reinforced masonry and wood are seen more often in the smaller structures located in the coastal or eastern zones.

The most notable structural lateral-system vulnerabilities found within healthcare facilities are the non-ductile concrete and non-ductile steel frame buildings. These building structures were typically constructed before the increased seismic risk in Oregon was well understood in the early 1990's, and before substantial code changes were made to require more robust connections that are better able to resist seismic forces.

Independent of the type of lateral system, two very notable structural irregularities that typically create problems were found in many of the healthcare buildings. The first is a horizontal irregularity in the footprint of the building. Seismically, the most reliable shape for a floor plan of a building is a square or a rectangle. The least reliable shapes are T, E, L, and X configurations or variations of these. In association with these irregular shapes, many problems occur at parts of the structure called *reentrant* or *interior* corners, which do not occur in a rectangular floor plan. The second notable structural irregularity is a vertical irregularity, which occurs when the building steps back in plane as the floor levels increase.

Historically, performance of healthcare facilities around the world has been extensively affected by nonstructural damage. The ability of a healthcare facility to function is greatly dependent on the nonstructural items within that facility. The building's structure may perform very well during the expected earthquake, but the hospital might not be functional after such an event due to nonstructural damage alone. Nonstructural vulnerabilities typically includes lack of proper anchorage of mechanical, electrical, and medical equipment and lack of proper bracing of ceilings, pipes, ductwork, electrical elements, medical gas such as oxygen, and other critical service lines. Healthcare facilities are often campuses made up of multiple buildings, which include those that provide healthcare and often a central utility plant (CUP) or a central building that contains a large number of pieces of essential equipment (such as boilers and air handling units) that support the rest of the campus. Although this

central building may not provide healthcare directly, it is considered a vulnerability, because damage to its structure and contents can have a great impact on the entire campus' utilities and ability to function.

Estimated State of Recovery

Currently, essential healthcare facilities in Oregon are not expected to perform well during a Cascadia subduction zone seismic event. The facilities on the coast and in the valley will likely take over three years to recover to an operational state. Some facilities in eastern Oregon will take approximately 30 days to recover to an operational state.

Target State of Recovery

Essential healthcare facilities are critical for the life safety of the entire population and must be capable of surviving the expected Cascadia subduction zone seismic event. This survival requires that the buildings remain completely functional during the event and be available to respond to emergency needs immediately following the earthquake and any aftershocks that may occur. For these reasons, the target state of recovery for these facilities must be *Event Occurs* as shown in the Recovery Matrix.

Sector Specific Recommendations

As outlined in the 2011 Oregon Revised Statutes (ORS 672.107), *significant structures* must be designed under direct supervision of a licensed structural engineer. Hospitals and other major medical facilities that have surgery and emergency treatment areas are considered *significant structures* or *essential facilities* according to ORS 455.447. Standby power generating equipment for essential facilities is also considered *essential* and is covered under ORS 672.107. However, buildings that contain the balance of equipment required to keep these vital facilities functional are not considered *essential*, and therefore are typically designed to a lesser seismic standard. In order for critical healthcare facilities to be truly resilient, all buildings that provide mechanical, electrical, and plumbing service to the buildings must be designed to the same standard. This shift will require revisions to the building code and an expanded definition of *essential facility*.

In 2001, legislation (ORS 455.400) directed that, subject to available funding, acute inpatient care facilities that are determined to pose an "undue risk to life" should be rehabilitated to a life-safety performance level by 2022. Currently, to our knowledge, most of the deficient acute care facilities in the state have not been upgraded in accordance with this legislation. By having the "subject to available funding clause" in the statute language, the legislation does not provide a mandate and therefore is not proving to be effective in addressing the problem. A more effective mandate should include specific measures that would give private healthcare systems incentives, whether tax credits or some other vehicle, to make seismic improvements.

A facility's buildings and internal infrastructure are not the only factors to take into consideration when assessing the facility's ability to operate without interruption after the expected Cascadia subduction zone seismic event. Healthcare facilities are also dependent on the city for their water, on distribution-center buildings for supplies, and on roadways for the delivery of supplies, to name only a few things.

Healthcare facilities do not have control over any of these components. It is therefore recommended that healthcare facilities maintain a minimum thirty-day supply of all items that come from external sources; this should include water, fuel, and medical supplies.

EMERGENCY SHELTERING

Shelter as an essential part of disaster recovery and resilience, and the need for it is great. Many facilities throughout the state are listed as designated emergency shelters by local jurisdictions and the state Office of Emergency Management. The most common buildings on these lists are schools and churches, followed by other miscellaneous buildings (including community centers) that have the capacity to hold large numbers of occupants. The expected and target states of recovery for school buildings can be found in the *Education Facilities* section of this chapter (above). As with all building sectors, the performance of churches and other facilities in a Cascadia subduction zone event will be a function of the building's vintage, construction type, and geographical location. In general, the expected and target states for churches should, at a minimum, match those of school facilities with similar construction.

Discussion of recommendations for buildings designated as emergency shelters can be found in the *Conclusions and Recommendations* section at the end of this chapter.

CRITICAL GOVERNMENT FACILITIES

Introduction

Critical government facilities are those buildings that are necessary to the continuing operation of essential services following a significant event. The most obvious of these—police stations, fire stations, and emergency operations centers (EOC)—are addressed separately in this report. Other services, however, which may include some limited administrative functions and essential health services, and certain structures, such as correctional facilities and even the maintenance buildings that are needed for repairing roads and utilities following the earthquake, are also necessary. Compiling a specific list of these services and their associated facilities was beyond the scope of this report—but in many ways, such a list was not necessary to get a general overview of how these facilities may perform.

Estimated State of Recovery

Data for general government facilities was available from the FEMA Hazus damage estimates and was reviewed to determine the resilience scores included in the resilience matrix. The statistical analysis from Hazus was based on an estimated 2,357 government buildings located throughout the state—this estimate represents the total number of government buildings, not all of which are critical to statewide resilience. We assumed that both the non-critical buildings and the remaining critical buildings (those not included in the assessment of police, fire, and EOC facilities) will generally behave in a similar manner. We were therefore able to determine with reasonable certainty the level of performance that can be expected.

The construction types anticipated by Hazus statistics are primarily steel and concrete prior to 1950, with about 20 percent of the inventory being shared between wood and unreinforced masonry (URM). These construction types change for construction periods between 1950 and 1970. The post-1970 distribution still anticipates concrete and steel, as well as some wood, but much more prevalent is reinforced concrete masonry (CMU), which is now estimated to comprise about 25 percent of the building stock.

Figure 4.7: Several states have rehabilitated their state capitol buildings. The Utah State Capitol was seismically retrofitted with base isolation to protect visitors and occupants and preserve historic fabric in the building. (Source: State of Utah)

Target State of Recovery

The target states of recovery for these facilities will vary depending on the facility. An average target state was estimated to be 30 days, although the task group recognized that some buildings may need to be immediately serviceable (correctional institutions, for instance), while other critical functions may not be immediately needed and could wait several weeks before coming back into service. It will be necessary for the state and local governments to determine which functions are critical for resilience and then inventory and evaluate the associated facilities, before eventually prioritizing and upgrading the deficient structures.

RESIDENTIAL HOUSING

Introduction

Following an earthquake, people must have shelter—it is one of the basic elements required for resilience. In some cases, such as when a person's residence has been damaged and is not safe to occupy or when people are temporarily unable to reach their homes, this need may be met by emergency shelters. Emergency shelters, however, cannot provide for everyone. For a large segment of the population, primary residences must serve as shelters, although in many cases, they will be without power and running water. In the absence of such residential shelters, the humanitarian needs of the population following a large earthquake grow tremendously. Post-earthquake response can also be impeded if emergency responders must first devote time to finding shelter and safety for their own families before they are available to help others.

In the state of Oregon, single-family residential homes make up the largest portion of residences, and therefore, potential shelters. The U.S. Census data for 2010 place the number of residential dwelling units in Oregon at approximately 1.6 million. FEMA's Hazus program, which was used for this review, estimates that there are approximately 960,000 single-family homes; this is generally consistent with similar census estimates.

Construction of single-family homes is almost entirely of light wood framing. Historically, these buildings have generally performed well in seismic events. One- and two-story wood frame buildings are relatively light-weight compared to other structures, and will usually see larger forces from a design-level wind storm than from a significant earthquake, since seismic forces are (in part) a function of the structure's weight.

However, the details of a wood frame structure's construction have a lot to do with its ability to withstand earthquakes, and certain common vulnerabilities make these buildings susceptible to earthquake damage, particularly if they were built before 1976. One of the most common deficiencies is a lack of adequate anchorage between the upper wood frame structure and the concrete foundation or basement walls. Another common deficiency can result in the failure of cripple walls, which are short wood framed wall segments that typically extend from a foundation to the floor above. Frequently, these lack proper connections and can easily rotate in a manner similar to a hinge, allowing the building to shift laterally off of its foundation (see Figure 4.8). In older structures, unreinforced masonry chimneys can fall and cause additional structural damage.

Multifamily housing is also at risk. Depending on construction type and size, these buildings will typically have more seismic risk compared to single-family homes. Construction of multifamily buildings ranges from light wood frame construction, unreinforced masonry, to steel and concrete. The apartment buildings built of unreinforced masonry apartment buildings are particularly vulnerable.

Figure 4.8: This residential building shifted on its foundation after the 1989 M 7.1 Loma Prieta, California earthquake. (Source: NOAA/NGDC, C. Stover, U.S. Geological Survey)

Estimated State of Recovery

Using statistical data from FEMA's HAZUS program, the task group reviewed estimated damage data for single-family residences. The average estimated recovery duration for residences on the coast was less than 30 days, which may be low considering the intensity and duration of ground shaking that will likely result from a Cascadia subduction zone event in this area. In the valley, the estimated recovery duration is 72 hours, which again may underestimate the damage. The eastern zone is expected to have negligible damage (again based on the Hazus estimates). These results are compared with a target state of recovery of 30 days, which is based on the need for shelter as an essential part of disaster recovery and resilience.

The recovery time of multifamily housing was not reviewed by the task group. Recovery time for smaller light wood framed buildings will be similar to single family homes. Larger buildings of other construction types will have longer recovery times. The loss of low income multifamily housing will affect economic recovery.

Sector Specific Recommendations

Improving existing structures will require significant education of homeowners, who need to understand the risks, the potential costs, and the steps necessary to evaluate and correct deficiencies. Additionally, common structural deficiencies should be noted during home inspections at the time of purchase. It is

likely that homeowners will bear the majority of the expenses for upgrading deficient structures; however, financial incentives, such as tax credits and low interest loans, might be considered to encourage improvements if future evaluations, based on more complete data, show unacceptable damage estimates.

Outreach should seek to provide education and resources for homeowners. A number of such tools are already available, though not widely known. FEMA provides a number of publications on their website for homeowners, such as FEMA-530 Earthquake Safety Guide for Homeowners. The City of Portland has also created a guide, Brochure #12-*Residential Seismic Strengthening – Methods to Reduce Potential Earthquake Damage* and provided additional information on the Bureau of Development Services website at www.portlandoregon.gov/bds.

COMMUNITY RETAIL CENTERS AND BANKS

Introduction

There are thousands of community retail centers and banks within the state of Oregon. These types of facilities have been deemed critical buildings because of their importance to the post-disaster recovery of communities throughout the state. The most important of the many community retail buildings in the state are large supermarket and pharmacy chain stores, which have large inventories of supplies that will be in high demand following a disaster. Many of these large chains have remote storage and distribution centers that will be of equal importance for supplying goods to damaged communities. Banks also have an important role in Oregon's seismic resilience, as they will be critical to processing vital financial transactions for businesses and consumers as they recover from the disaster. Although many banks have emergency response plans in place, if the buildings they are housed in perform poorly during an earthquake, overall resilience will be compromised.

FEMA's Hazus analysis includes a wide variety of commercial buildings, including some overlap with other structures evaluated separately in this report using different analysis methods. However, part of this large group of commercial buildings includes wholesale and retail buildings and banks, which were reviewed to estimate the resilience of these structures. A specific estimate of building quantities for this subset was not available, but the statistical analysis considered their construction types, general age, and historical performance. The number of retail and bank buildings in each county was assumed to be proportional to the overall distribution of commercial buildings.

Structural Vulnerabilities

The construction types anticipated statistically by Hazus for retail buildings vary with the building's age. Prior to 1950, wood, steel, concrete, concrete masonry (CMU), and even unreinforced masonry (URM) were common. As construction practices changed, buildings shifted toward larger stores, and the post-1970 Hazus statistics reflect this, with greater use of CMU and concrete, including precast (or tilt-up) construction which began to see much wider use after 1970. Statistics for bank buildings also reflect

some similar shifts in construction, moving away from steel and unreinforced masonry after 1950 and toward more wood frame, CMU, and concrete construction.

Today, most big-box stores, supermarkets, distribution warehouses, and pharmacies are housed in concrete masonry (CMU) or tilt-up concrete structures with light-framed wood or steel roofs. Buildings of this type that were constructed prior to 1995 have historically not performed well in earthquakes. The seismic vulnerabilities of these buildings were highlighted in the aftermath of the 1994 Northridge earthquake. The most prominent structural failure in this building type has been the connection between the light framed roof and the relatively heavy exterior walls, which led to partial or full roof collapse (see Figure 4.9). Building code provisions for the design and construction of the roof/wall connections were enhanced following the Northridge earthquake, with requirements for a higher degree of resistance being incorporated in the 1997 UBC and subsequent building codes. As a result, buildings of this type that were built after approximately 1995 should have a higher degree of resilience than those built prior to that year.

Figure 4.9: Several tilt-up concrete panels of this construction material supply store in Concepcion fell away from the building, causing the roof framing to collapse after the M 8.8 February 27, 2010 Maule Chile earthquake. (Source: Kent Yu, Degenkolb Engineers)

Banks are different from big-box stores in that they are housed in a multitude of structures, including stand-alone one-story wood framed buildings, unreinforced masonry or non-ductile concrete buildings, and steel and concrete high-rise buildings. The seismic performance of these buildings will vary based on their location, vintage, and construction type; however, structural vulnerabilities are present to some degree in a large percentage of the existing building stock.

During an earthquake, many existing community retail and bank structures could also suffer extensive damage to nonstructural elements and components within the buildings. Nonstructural elements include, but are not limited to, mechanical, electrical, and plumbing systems and associated equipment, lighting fixtures, suspended ceiling and soffit systems, and unsecured storage racks and display shelving. These elements can be a falling hazard during a seismic event, impeding occupants from safely exiting the building, disrupting the operation of the facility, and extending the time it will take to restore the building to normal operation.

One unique aspect of retail and bank buildings is that they are almost exclusively privately owned. This makes establishing and enforcing building seismic upgrade requirements and mandates for these occupancies particularly difficult.

Estimated State of Recovery

The expected average time of recovery to normal operation for community retail big-box, supermarket, and pharmacy buildings after a Cascadian subduction zone seismic event is four months for Oregon's coastal region and 30 days for the valley region. The recovery duration for these types of buildings in eastern Oregon is expected to be nominal, mainly due to their distance from the earthquake source.

The recovery time for bank buildings after the Cascadia subduction zone seismic event is estimated at 60 days for Oregon's coastal region and 30 days for the valley region. As in the case of the community retail centers, the recovery duration for banks in eastern Oregon is expected to be nominal.

A critical aspect of the resilience of this building class is the degree to which the business' ancillary facilities, provided they are not located within the high seismic hazard zone, can provide support to and replacement of the functions of the damaged facilities. While this aspect was not considered in our analysis, it is possible that the actual impact of the Cascadia subduction zone event on the functionality of these buildings could be lessened if protocols are in place to replace their functions remotely. Additionally, it should be noted that the efficiency of the distribution of goods, services, and medical prescriptions to the general public has increased with the advent of one-stop-shop, big-box retailers that typically occupy newer tilt-up concrete or masonry (CMU) structures that have been designed and built to more stringent seismic code requirements. It is likely, however, that after the Cascadia subduction zone seismic event, the inventory in these facilities will be quickly depleted, so overall seismic resilience will depend upon the condition of ancillary facilities, including distribution warehouses, data centers, roads, bridges, and highways.

Target State of Recovery

The suggested statewide target state of recovery for community retail centers and banks is 30 days. This timeframe is primarily due to the importance of having goods, services, and medical prescriptions available to the general public after a significant seismic event. The assumption behind this target is that facilities in areas unaffected by the earthquake will be able to fill the needs of the public remotely until the damaged buildings can be repaired. This target state is also consistent with both the performance expectations behind code provisions for new buildings of this occupancy category and the recommendations of the Business Continuity Task Group that took part in the development of Oregon's resilience plan.

Sector Specific Recommendations

As community retail centers and banks are normally privately owned, the ability to mandate building upgrades with public funding is minimal. Therefore, seismic upgrades of deficient existing buildings will most likely need to be incentivized through tax credits or other similar means. Mandates, tax credits, and other incentives (whether singly or in combination) should also be developed to require or strongly encourage the building owners and tenants to properly brace and anchor deficient nonstructural elements within their buildings, as it is anticipated that nonstructural damage resulting from the Cascadia subduction zone earthquake will have a significant impact on the seismic resilience of these building types.

For the existing building stock in this sector, the redundancy of critical business continuity elements, such as distribution of goods and data, remote accessibility and support, and availability of personnel, should be assessed by each company. This redundancy is vital to achieving the 30-day target state of recovery over the entire state of Oregon.

Finally, improving awareness—both within businesses and among the general public—of the seismic vulnerabilities of the existing community retail centers and banks is critical to moving toward a more resilient Oregon. Developing a seismic resilience rating for existing retail and bank building stock could serve as an effective tool for these businesses as they select buildings to lease or prioritize buildings for upgrades. As part of this rating program, common seismic vulnerabilities could be explained in layman's terms, in an effort to improve public awareness and understanding of Oregon's current seismic resilience status.

VULNERABLE BUILDINGS

Introduction

For the purposes of this evaluation, vulnerable buildings are defined as unreinforced masonry (URM) and non-ductile concrete structures. These building types are classified as critical buildings in this study because they represent the most significant threat to life-safety and historically exhibit extremely poor performance in seismic events (see Figures 4.10 to 4.12). URM buildings are constructed with clay brick, hollow clay tiles, or concrete block, with little or no reinforcement. Most of these buildings in Oregon

were originally built prior to 1940, and the majority has undergone no seismic improvements since they were constructed. Non-ductile concrete buildings have been historically susceptible to extreme damage in moderate to severe seismic events and have very little steel reinforcement. These buildings range in age from 40 to 100 years and are generally one to five stories in height. These vulnerable buildings represent a building *type* rather than an occupancy *use* and, as such, they can be found in many occupancy uses, including essential facilities (such as fire and police stations), retail centers, restaurants, residential buildings, and commercial office buildings.

Figure 4.11: The fourth-story wall of this unreinforced masonry building on Bluxome Street in San Francisco collapsed onto the street, killing five people in their cars, during the M7.1 October 18, 1989 Loma Prieta, California earthquake. (Source: NOAA/NGDC, E.V. Leyendecker, U.S. Geological Survey)

Figure 4.12: This non-ductile concrete frame medical building collapsed during the 1994 M6.8 Northridge, California earthquake. (Source: NOAA/NGDC, J. Dewey, U.S. Geological Survey)

Estimated State of Recovery

Based on the limited information available for these types of buildings throughout the state (other than those that were already addressed in the other occupancy use categories discussed above), recovery timelines were estimated based on FEMA Hazus data provided by the Oregon Department of Geology and Mineral Industries (DOGAMI). Categories included URM buildings only; specific data was not available for non-ductile concrete structures. Hazus software operates through a geographic information system (GIS) to display earthquake hazard information, inventory data, and estimated losses, which approximate building damage from a particular seismic event. The Hazus data used for this study was based on a Cascadia subduction zone earthquake as well as the age and construction type of the buildings. In addition, the Hazus data assumes that all structures were designed prior to the incorporation of seismic provisions in the building code.

As expected, the data in Figure 4.3 indicates that most of these buildings will experience either significant structural damage or partial to total collapse. Accordingly, most of the vulnerable building stock in the coastal and valley regions will require major repairs or wholesale replacement. Buildings in eastern Oregon will experience ground shaking levels similar to or greater than those that URM buildings experienced during two previous Oregon earthquakes: Scotts Mills and Klamath Falls. Because the Cascadia subduction zone earthquake will likely be of much longer duration than these two previous events, it has the potential to cause even more damage. For this reason, the expected recovery duration for vulnerable buildings in eastern Oregon was determined to be 30 days.

It should be noted that these recovery times are based on a Cascadia subduction zone earthquake, which may not result in the highest possible ground shaking intensities in some parts of the valley and eastern Oregon, but would likely have a longer duration. Other hazards, such as soil liquefaction, landslides, and tsunamis, were considered in the projected states of recovery. DOGAMI's recent studies indicate that soil hazards exist in all three regions of the state, and many coastal regions are located in a tsunami inundation zone, which increases the vulnerability of these buildings.

Because hard data related to nonstructural components in vulnerable buildings was not readily available, the performance of these components was not a consideration in determining the recovery scores. It is likely, however, that the damage to the primary structure of these buildings will override that of nonstructural components in terms of effect on resilience.

Target State of Recovery

As mentioned above, vulnerable buildings can be found in many different building occupancy uses. Consequently, the reader should refer to the *Target State of Recovery* discussions in the occupancy-based sections of this chapter to develop an understanding of the gap between the projected and recommended performance of these buildings.

Codes, Past Legislation, and Funding Sources

A few jurisdictions have adopted code language mandating seismic upgrades for these types of buildings (primarily URMs) to varying degrees. For legislation, or funding sources, refer to each sector-specific section of this chapter and to the following recommendations.

Recommendations

Recommendations are provided below for Oregon's critical and vulnerable structures with the goal of achieving a resilient state. In making these recommendations, the task group recognized that not all buildings are critical and necessary to achieve resilience. Many buildings are expected to perform reasonably close to their target states in the eastern part of the state, where the seismic design category is low. Residential buildings are expected to perform reasonably well, although older homes need to be tied to their foundations and older multi-family buildings are at risk.

Leadership and resources are needed for adopting standards and policies, evaluating and inventorying buildings, and rehabilitating structures. Creating a State Resilience Office that could outline the steps required for creating seismic resilience, should be a priority. This Office can take into consideration the gaps between existing and target states of recovery and critical building functions. It can also coordinate with resiliency efforts in the other sectors (such as transportation, energy, etc.)

It is imperative, however, that implementation and funding for seismic resilience not be delayed while we wait for a full inventory, definition, and budgeting of the problem. More than enough is already known to begin making strides toward resilience. Whether the journey before us is a thousand miles or ten thousand miles, we should start moving forward now; additional inventories and studies should be made as we progress along the way.

IMMEDIATE ACTIONS

► **Establish a State Resilience Office**

- *Finding*: The State does not currently have person or office to provide the resources and leadership necessary for coordinating and implementing a statewide seismic resilience plan.
- *Recommended*: Establish and fund a State Resilience Office(r) to provide leadership, resources, advocacy, and expertise in implementing a statewide resilience plan.

► **Prioritize Education**

- *Finding*: There is a great need for education and awareness of the impact of a Cascadia subduction zone event, and how to prepare Oregon to be resilient to that impact.
- *Recommended*: Programs should be encouraged and implemented to provide a broad range of education, public awareness, and public relations regarding Cascadia subduction zone risks and State resilience.

► **Complete an Inventory of Critical Buildings**

- *Finding*: A complete statewide inventory of critical buildings does not exist, but is needed for future planning, assessment and upgrading of critical building structures.
- *Recommended*: An inventory, compiled within five years, should include an initial seismic screening of each building and updates to the existing inventory. More detailed evaluations should be completed for those buildings identified by the initial screening to be the most susceptible to damage from an earthquake.

► **Include Inspection in Emergency Response**

- *Finding*: There will be immediate demand for safety inspections of critical buildings (both public and private) following a Cascadia earthquake.
- *Recommended*: Strengthen the existing database of ATC-20 certified post-earthquake inspectors, establish procedures for their engagement and response following an event, and strengthen Good Samaritan laws to protect them. Expand database and training for ATC-45 of certified post flood and wind inspectors.

SUSTAINED ACTIONS

► **Prioritize Essential Facilities**

- *Finding*: The estimated current state of hospitals, Emergency Operation Centers, fire and police stations falls significantly short of the target state need for these facilities to be immediately available following the CSZ event.

- *Recommended*: Hospitals should be upgraded within 15 years of completing an inventory and seismic evaluations. Emergency Operation Centers, fire and police stations should be upgraded within 20 years if the building is a URM or non-ductile concrete structure, or 30 years if it is of other construction. Non-structural elements in these buildings should also be upgraded within the same timeframes, and ORS 455.400 should be strengthened and updated for consistency with these recommendations. Create publicly accessible database that shows annual seismic performance data for essential facilities.

► **Fully Fund the Seismic Retrofit of K-12 Schools**

- *Finding*: The current average estimated state of recovery for K-12 school facilities in the Coast and Valley regions of Oregon falls significantly short of the recommended target state, despite an existing statute directing seismic retrofit by January 1, 2032.

- *Recommended*: Fully fund state investment in seismic retrofit of schools; prioritize the replacement of structure types that present the greatest hazard to their occupants in a seismic event; promote ASCE- 31 (or equivalent) engineering assessment of existing school facilities; and update the state's database of public school facilities on a regular basis.

► **Expand the Passive Trigger Seismic Strengthening Program**

- *Finding:* The existing building code includes triggers that require building upgrade for a change of occupancy or increase in structural loads, but does not go far enough, allowing major building upgrades to deficient structures without requiring seismic strengthening.

- *Recommended:* Encourage local jurisdictions to adopt the triggers for seismic upgrade to include changes in the level of occupancy risk, major building renovations, and re-roof of URM and non-ductile concrete buildings. Give seismic upgrades the highest priority for non-conforming upgrades, and allow them to be phased over 10 years if needed.

► **Accelerate the Retirement or Full Upgrade of Vulnerable Buildings**

- *Finding:* Unreinforced Masonry (URM) and non-ductile concrete buildings are generally the most dangerous types of buildings in an earthquake, and should not be allowed to remain in service indefinitely unless they are fully upgraded.

- *Recommended:* Initially, the danger of URM and non-ductile concrete buildings should be disclosed at the time of building sale or lease. Through market pressures and upgrades triggered by other building repairs and changes, upgrades can be made to many of these structures.

► **Improve Plan Review and Construction Oversight**

- *Finding*: Structural plan reviews are often performed by individuals who would not otherwise be qualified to provide the design being reviewed. Special inspections and structural observations are not currently required by code for certain structure types and structural elements important for resilience.

- *Recommended*: Require a licensed design professional or structural engineer provide plan reviews for critical buildings (Cat. 3 & 4) reciprocal with the licensing required to provide the design. Strengthen state building code to expand Special Inspections and Structural Observations to include special inspections and structural observations for most commercial structures, critical non-structural components, and wall connections in tilt-up and CMU buildings with light framed roofs and floors.

► **Introduce an Earthquake Performance Rating System**

- *Finding*: Public knowledge of the seismic safety of the buildings they own, live in, and work in is often limited, or misinformed, especially in comparison with public awareness of other hazards.

- *Recommended*: Encourage and promote a voluntary, standardized rating system for the expected earthquake performance of buildings, similar to the LEED rating used for green buildings. The system should be easily understood and readily available to anyone with an interest or stake in the building.

► **Incorporate Resilience into Performance-Based Design**

- *Finding*: Many new buildings will be constructed over the next 50 years, but current code is only intended to protect the life safety of occupants, not ensure resilient performance.

- *Recommended*: Adopt incentives to encourage owners to build to performance standards that exceed the “code minimum." Support research aimed at better tools and criteria for performance based design.

► **Encourage seismic retrofit of existing homes and multi-family buildings.**

- *Finding:* Many residential homes built before 1976 have vulnerabilities to earthquakes and the damage may result in them being unusable or in need of costly repairs. Many older multi-family buildings are at risk as well.

- *Recommended:* Adopt seismic retrofit programs and incentives to encourage homeowners to tie their older homes to their foundations, and encourage the seismic retrofit of multi-family buildings.

5. Transportation

Introduction

Emergency response, access to critical buildings, the restoration of utilities, and the reopening of businesses all depend on the transportation network. The resilience of the transportation network is considered a key factor for re-establishing other lifelines after a major Cascadia subduction zone earthquake.

To assess the status of the various modes of transportation and determine appropriate levels of resilience, a task group consisting of representatives of each mode of transportation, including highways, rail, airports, water ports, and transit, along with representatives of local agencies, met in person monthly and worked extensively outside these meetings to develop and collect data and formulate a plan that will help increase the survivability of citizens and critical features of the built environment.

GOALS

The overall resilience goal for the transportation network is first to facilitate immediate emergency response, including permitting personnel to access critical areas and allowing the delivery of supplies, and second to restore general mobility within specified time periods for various areas of the state. In order to establish specific resilience goals in support of this larger objective, the task group assessed the transportation network in four geographical areas:

- The tsunami inundation zone along the coast (based on DOGAMI maps).
- The coastal zone (the area outside of the tsunami zone, from the Oregon coastline to the summit of the Coast Range).
- The Willamette Valley zone (from the summit of the Coast Range to the summit of the Cascades).
- The central Oregon zone (east of the Cascades summit).

In addition, the task group established resilience targets for transportation facilities. These targets align with a phased, three-tiered approach to the restoration of the transportation network. The main factors in forming this approach were the need to optimize post-earthquake response for our state and the need to establish priorities for making future investments to achieve the targets. Similar to the Oregon Seismic Lifeline Routes identification project, the task group prioritized highways into three tiers: Tier 1 is a small backbone system that allows access to all vulnerable regions, major population centers, and areas considered vital for rescue and recovery operations. Tier 2 is a larger network that provides access to most urban areas and restores major commercial operations. Tier 3 is a more complete transportation network.

Resilience targets were further established at three levels:

- **Minimal.** A minimum level of service is restored, primarily for the use of emergency responders, repair crews, and vehicles transporting food and other critical supplies.
- **Functional.** Although service is not yet restored to full capacity, it is sufficient to get the economy moving again—for example, some truck/freight traffic can be accommodated. There may be fewer lanes in use, some weight restrictions, and lower speed limits.
- **Operational.** Restoration is up to 90 percent of capacity: A full level of service has been restored and is sufficient to allow people to commute to school and to work.

THE TASK GROUP'S OBJECTIVES

In developing a resilience plan for transportation, the task group's objectives were to:

- Summarize the state of our knowledge about the seismic ground shaking and tsunami inundation risks of various transportation modes.
- Estimate the ability of each mode to recover following a major earthquake.
- Develop recommendations for strategically focused retrofit solutions. For example, one of the recommended solutions proposed in the plan includes a program of prioritized investments over a 50-year period to achieve the desired level of operation after a major Cascadia subduction zone event. (The plan considers all modes of transportation to maximize both access to and the utility of the network, while minimizing the level of investment.)

THE TRANSPORTATION SYSTEM'S ROLE IN STATEWIDE RESILIENCE

A resilient transportation network is critical for re-establishing other lifelines, such as water, electricity, fuel, communication, and natural gas, after the earthquake. For example, a resilient transportation system allows repair crews to access and reconnect water pipes and power lines more quickly, and it provides access to much needed fuel and supplies.

Given the transportation system's current state of vulnerability to ground shaking and tsunami inundation, initial damage from a Cascadia subduction zone earthquake is expected to be devastating to the parts of the system located along the coast and in western Oregon. The resulting lack of mobility will have direct impacts that severely limit rescue operations, inspection of critical infrastructure, restoration activities, and the state's ability to restore services leading to recovery. The widespread damage and lack of access to many parts of western Oregon will be partially mitigated by disaster preparedness planning, but that effort will be hampered by the lack of access to disaster areas after the event, which could limit the ability of emergency responders to save lives, facilitate evacuation, and manage critical infrastructure.

To collect and develop the information used for this report, the members of the Transportation Task Group consulted transportation providers and collected data on potential infrastructure damage and the

state of preparation and availability of trained, experienced personnel to manage transportation systems in the aftermath of a major earthquake. Keeping in mind that the core objective of the plan is to better support both immediate statewide post-earthquake/tsunami response and longer-term recovery and construction, the task group considered both emergency response actions and various ways to improve the resilience of the transportation network. This included strengthening or armoring existing systems, adding new facilities that will withstand seismic loads and motions, moving facilities out of tsunami inundation zones, and identifying alternate means to provide service. Resilient transportation systems planning must address all facets of the problem in order to provide for effective and efficient movement of goods and people after a large seismic event—an event that is expected to cause widespread damage to the built environment as well as significant reconfiguration of the natural environment.

THE TASK GROUP'S APPROACH

The task group's general approach in developing the transportation section of the Oregon's resilience plan was to use existing emergency operations or response plans and any existing programs for strengthening facilities and other assets within the various modes. The task group used existing plans for strengthening and armoring transportation systems. This chapter includes a section on each mode, covering response for life safety and recovery, and a section on strengthening and armoring options. The task group also considered the interdependencies among the various modes and the relevance of these interdependencies for response, recovery, and strengthening. Finally, a summary of known gaps in available data and a list of recommendations are provided to identify next steps in the transportation sector. These recommendations reflect the need to determine the most cost effective solutions to reduce interruptions in service and increase mobility immediately after an event and during long term recovery. An example of a fully developed assessment of a mode, including retrofitting recommendations and cost estimates, is provided in the 2012 Oregon Seismic Lifeline Routes identification project and ODOT Seismic Options Report.

Assessment of Transportation Performance

When a large earthquake is triggered within the Cascadia subduction zone, the result will be widespread disruption of the transportation system. This disruption will make rescue operations in many areas difficult, if not impossible, and will have an immediate, disruptive impact on the economy. The majority of bridges and other transportation infrastructure in western Oregon are susceptible to serious damage in a major seismic event, because they were built before modern seismic codes were in place. Dozens of unstable slopes and pre-existing deep slides are expected to fail under the extended three minutes or more of shaking that will accompany a large Cascadia event, further impacting our mobility by closing roads.

Modern seismic codes were developed in the late 1980s and early 1990s. The extended period of strong shaking from a Cascadia subduction zone event will damage many masonry and other structures built prior to modern seismic codes. Homes, hospitals, businesses, schools, and other critical structures that

have not been seismically retrofitted may collapse or be severely damaged, killing or injuring many people. The injured will need immediate attention, but may be stranded due to the lack of mobility.

Our knowledge of the locations of faults and the geological history of major events in Oregon is very recent. Although Oregon has low seismicity in comparison to California and Washington, there is potential for less frequent—but much larger and more damaging—earthquakes than the crustal earthquakes that have occurred regularly in those states. Oregon has not yet seen the effect of a large damaging earthquake, and ODOT has so far expended minimal resources on seismic retrofitting. As a result, much of Oregon's highway system will not be usable immediately after a major seismic event.

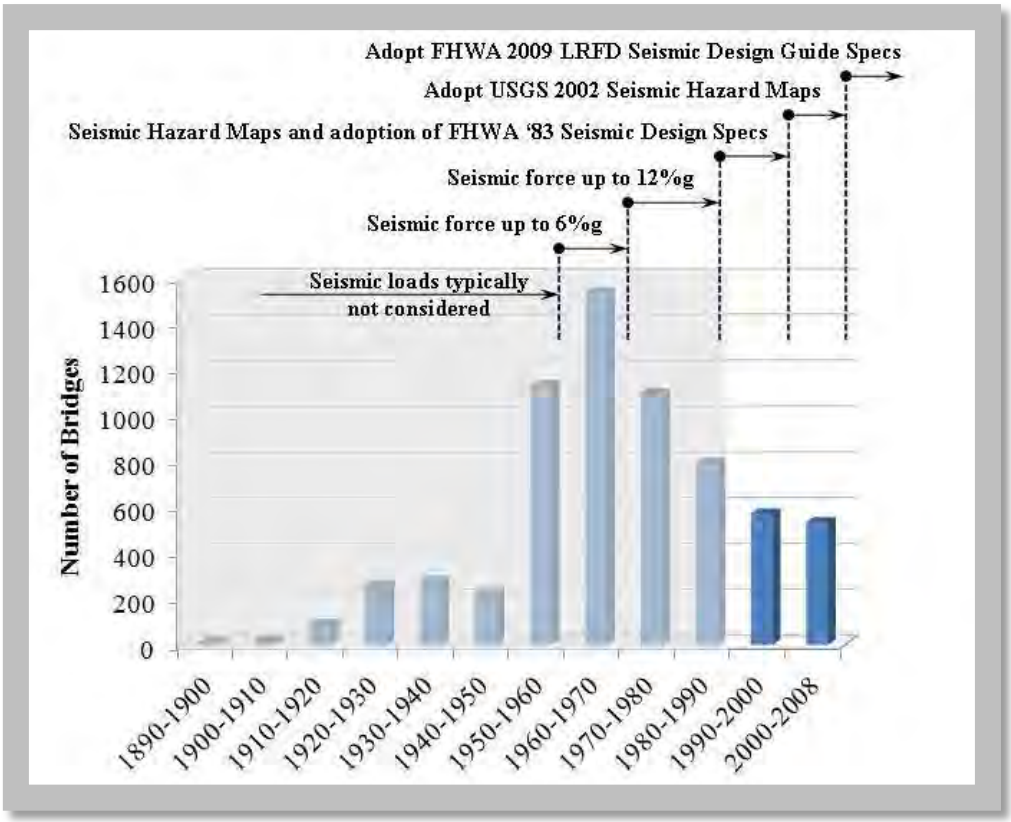
Because the impacts will be widespread, a Cascadia earthquake and tsunami have the potential to cause unparalleled economic and human catastrophe for the state of Oregon. The issue is *when* not *if* the state will have a major damaging seismic event. The question is whether we will be effectively prepared to rescue our citizens and recover economically without the use of a continuous connected transportation system. Aftershocks and movement of historic slides will complicate rescue and extend recovery times.

The task group recognized that failure of a major dam would lead to additional impacts to transportation that were not explicitly considered in our study. Like much of our other infrastructure, it is assumed that most of the power generation and flood control dams in Oregon were constructed prior to consideration of modern seismic provisions. Well-constructed dams have fared well in other subduction zone events, however, so failure may not be likely in Oregon. Damage to spillway gates, on the other hand, may lead to unexpected water release, and the resultant flooding would compound damage from a Cascadia subduction zone event.

Highway Transportation

Because most of Oregon's highways were constructed before design codes considered the potential Cascadia subduction zone effects, many bridges and unstable slopes are vulnerable to severe damage. The chart below shows the age-related vulnerability of Oregon's bridges.

Resilience targets for mobility on highways vary from zone to zone and from tier to tier within the same zone. For example, a Tier 1 route in central Oregon is expected to be resilient within three days, whereas a Tier 3 route may take up to four weeks. Similarly, a Tier 1 route within the coastal zone is expected to become resilient within seven days, whereas a Tier 3 may take up to three months or more. The detailed range of targets is shown in the tables titled *Oregon Transportation Resilience Status* in Figure 5.22.



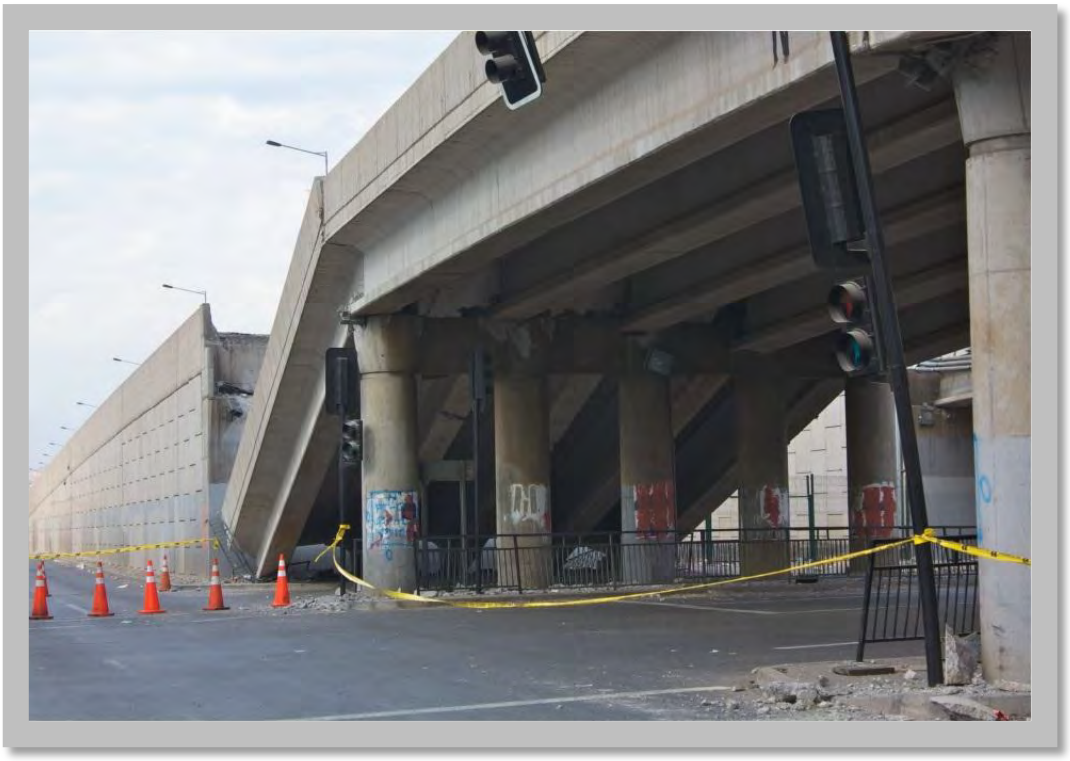


Figure 5.1: Oregon Bridge Seismic Design History (Source: Peter Dusicka, PSU)

The vulnerabilities of Oregon's bridges are complex and differ from bridge to bridge and from site to site. Some bridges are prone to more than one type of seismic deficiency, and a few may need to be replaced. ODOT has already conducted research and investigation to develop the best approach for mitigating the problem. Worldwide experience has shown that, while we are not knowledgeable enough to predict the exact time that an earthquake will strike, we can be proactive to save lives and speed up the recovery process.

The following photos and diagrams describe some of the most common vulnerabilities of highway bridges and one of the possible retrofits to mitigate that type of failure.

LOSS OF MOBILITY AFTER A MAJOR SEISMIC EVENT: BRIDGES

The combination of very strong and prolonged ground shaking, followed closely by a powerful and damaging tsunami—and by multiple strong aftershocks in the succeeding days and months—makes the Cascadia subduction zone earthquake the most dangerous natural hazard for Oregon, especially for Oregon's coastal communities. The ground shaking will cause destruction of buildings and roads, downed power lines, blocked streets, ruptured gas lines (resulting in explosions and fires), and broken water and sewer lines, creating a largely uninhabitable environment in many areas.

Oregon, or even the entire nation, has never witnessed a disaster of this magnitude in modern history; therefore, we can only speculate about how this event will impact Oregonians. Unlike other crises, such as a highway crash or a house fire, in which fire trucks and ambulances will arrive within a few minutes to rescue people in need, the situation after a Cascadia subduction zone earthquake will involve disruptions of emergency services along with everything else. There will not be enough firefighters to assist every household or business, nor enough medical staff to help every injured person, nor enough police officers to go door to door reminding people to be calm and quickly move to higher ground to avoid the oncoming tsunami. In order to gain some insight into what would happen after a major

Cascadia subduction zone earthquake, we can look at a very similar situation elsewhere: the earthquake and tsunami in Japan on March 11, 2011 (see Figure 5. 6).

Figure 5.6: Before and after the March 11, 2011 earthquake and tsunami in Japan (Source: cbsnews.com)

Coastal Area Impacts

Assuming most of our citizens have a basic understanding about the effects of a subduction earthquake, a massive movement of people away from the coast is expected. Acknowledging that no immediate help will be available, many people will try to drive away from shore and out of reach of the tsunami—but, our transportation network will not be able to handle this huge, confused and panicked traffic. Coastal residents have been advised to get away from the shore on foot, but tourists and commercial travelers are not likely to know that.

For most of Oregon's coastal cities, U.S. 101 serves as the main route to other destinations. Unfortunately, after a Cascadia subduction zone earthquake, most of this route will be impassable. Most bridges carrying U.S. 101 were not designed for seismic loading and will suffer major damage under the expected ground shaking. Many other bridges, if they survive the shaking itself, will be washed away by

the tsunami. In addition to the bridge damage, many highway segments are expected to become heavily damaged and impassible due to landslides. The latest assessment of state-owned bridges in Oregon shows that of 135 total bridges carrying U.S. 101, 56 bridges are expected to collapse, and 42 bridges will be heavily damaged. Some of these bridges are signature bridges and registered as historic.

East-West Corridor Impacts

East-west corridors between the coast and the Willamette Valley are the next tier of alternatives for people escaping from the disaster zone and for emergency crews responding to impacted areas. Unfortunately, the bridges on these corridors are also vulnerable to ground shaking, landslides, and liquefaction of supporting soils, so it is likely that these segments will not all be passable. The overall condition of bridges on these routes is moderately better than those carrying U.S. 101; however, there are many weak links along these routes that will make them impassable as well.

Route	Total No. of	Bridges	Heavily
U.S. 30 (Hwy 92)	27	6	3
U.S. 26 (Hwy 47)	52	3	10
OR 99W & OR 18 (Hwy 91 & Hwy 39)	35	5	4
OR 34 & U.S. 20 (Hwy 210 & Hwy 33)	42	7	3
OR 569 & OR 126 (Hwy 62 & Hwy 69)	50	9	9
OR 38 (Hwy 45)	19	1	3
OR 42 (Hwy 35)	47	23	5

Figure 5. 7: Vulnerability of Bridges on East-West Corridors (Source: ODOT – Bridge Section)

Because of the terrain these highways were built on, many of them lack options for detouring traffic around a bridge that collapses. The situation can become even more critical if the earthquake strikes during winter, when many of the state's secondary routes experience seasonal closure. Figure 5.7 shows the results of an inventory and damage assessment of state bridges located along the major routes connecting U.S. 101 to Interstate 5, when subjected to a Cascadia subduction zone event.

Interstate 5 and Mid-Willamette Valley Impacts

Interstate 5 (I-5) will also have some major problems after a Cascadia subduction zone earthquake. With the majority of bridges on I-5 built just before the modern seismic design specifications were developed, the most important segment of Oregon's transportation network may be fragmented, with some areas not operational after such an earthquake, depending upon the intensity and epicenter of the quake and its aftershocks. During the recent Oregon Transportation Investment Act (OTIA) program, ODOT was

able to replace many deficient structures along this route; however, the main criterion for the selection of these bridges was the need to support current truck load requirements, and not necessarily to meet current seismic standards. Thus, several bridges that already have been identified as vulnerable to earthquake shaking are still in active service. From a total of 348 bridges carrying both northbound and southbound traffic, five bridges are expected to collapse and 19 bridges to be heavily damaged during the Cascadia subduction zone event.

Interstate 5 is expected to be the main corridor of traffic flow after the Cascadia subduction zone event. Because of its location and capacity, and because U.S. 101 is expected to be impassable, I-5 will become the critical backbone route for emergency response after the earthquake. To the extent I-5 is operable, emergency support can be staged along the corridor, and responders will be able to reach the coastal cities either through the east-west corridors (once these corridors become accessible) or by other means.

Interstate 5 becomes an even more important route during the statewide recovery effort. Many scientists believe that the Cascadia subduction zone event will be a mirror image of the 2011 Tohoku earthquake that hit Japan. This means that most of our coastal cities will be heavily damaged, and restoring their previous living environment will not be an easy task. Along with extensive building damage, many ports and airports in these cities will also be heavily damaged and most likely will not be operational immediately after the event. This puts more emphasis on the need for a resilient transportation network. Because we expect that the initial help for impacted coastal areas will come first from cities along I-5 and later from the rest of the state and entire Northwest region, we have identified I-5 as the most vital route for post-earthquake recovery.

Central Oregon U.S. 97 and Highways through the Cascades

In the event that Interstate 5 is not operational, particularly in areas without viable detours, U.S. 97 will be a critical facility for ongoing interstate commerce and for staging response and recovery efforts. Redmond Municipal Airport is a staging site for federal emergency response in Oregon. East-west corridors through the Cascades provide access to the more vulnerable parts of the state and are therefore a necessary part of the response and recovery system. Because there is far less likelihood of damage to facilities in these areas, they will be relied upon extensively after a Cascadia subduction zone event.

LOSS OF MOBILITY AFTER A MAJOR SEISMIC EVENT: LANDSLIDES & ROCKFALLS

Slope failures are as common to earthquakes as structural collapse, liquefaction, and ground deformation. Strong ground shaking from a Cascadia subduction zone event will trigger countless new slope failures and activate existing landslides. Reactivation of the known landslides alone will be catastrophic during the ensuing seismic emergency. Additional failure of weak slopes and embankments or reactivation of previously unknown landslides will further compound the catastrophe. Not only will the landslides occur during and soon after the main earthquake, strong aftershocks will also affect other landslides and slopes that will become more prone to failure in the ensuing months. Landslides will

continue to impede rescue and relief efforts long after the shaking has stopped. Figure 5.8 shows one of the common vulnerabilities of unstable slopes.

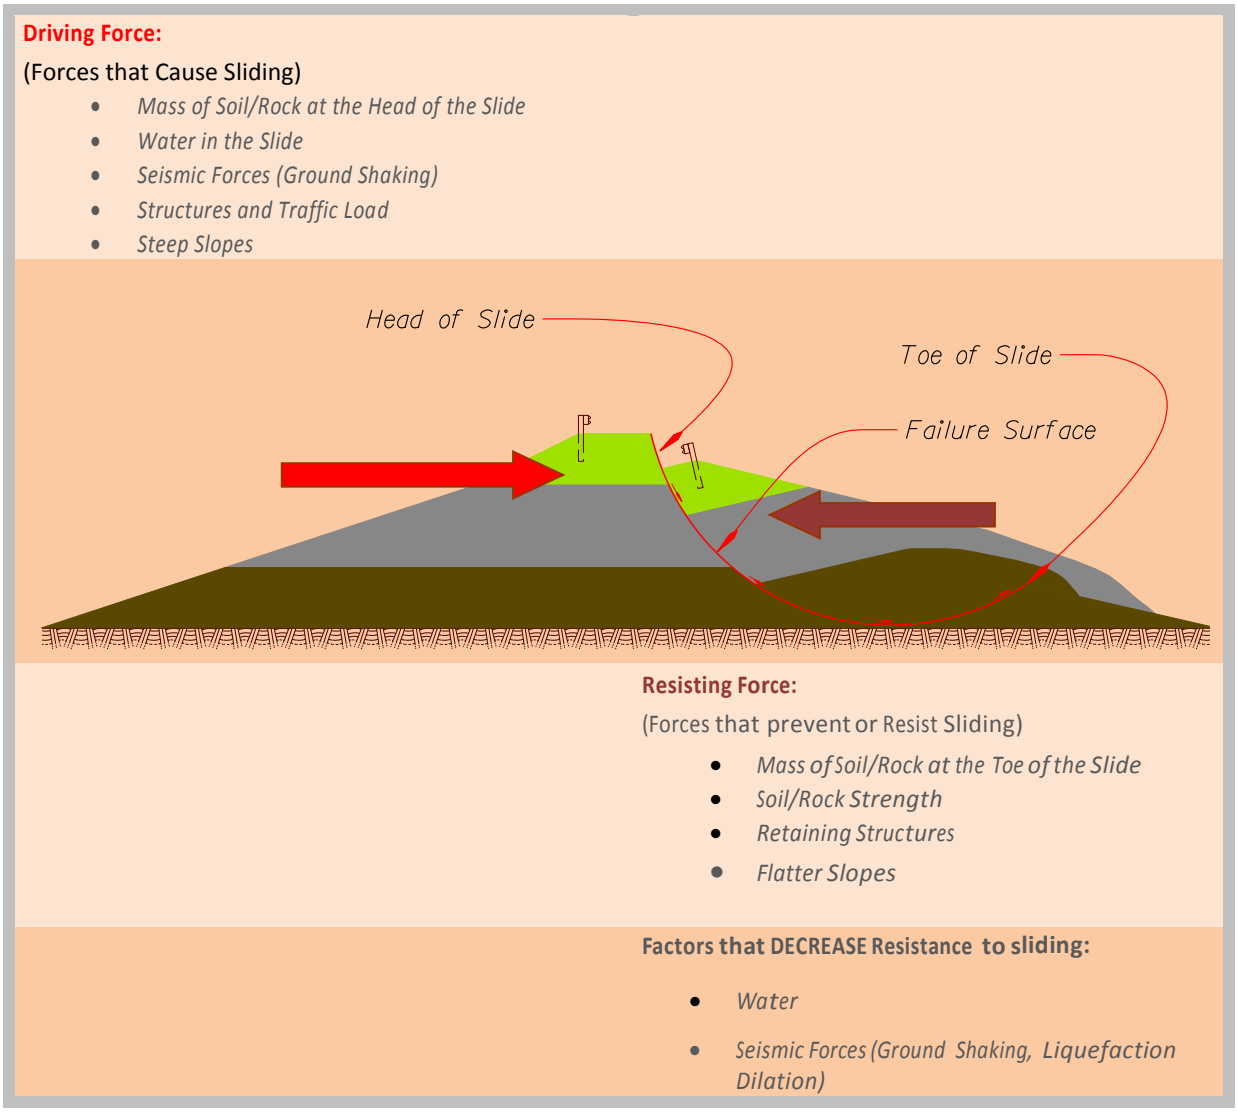

Figure 5. 8: Design Approach for Slide Mitigation (Source: ODOT – Geo-Environmental Section)

Landslides are one of the most significant secondary effects of earthquakes and, apart from the primary earthquake itself, one of the leading immediate causes of earthquake-related deaths worldwide. Currently, there are about 1,700 known landslides that directly affect the highway system between the Willamette Valley and the Oregon coast. Undoubtedly, western Oregon will be overwhelmed by the landslides that will accompany a Cascadia subduction zone earthquake. Landslides will affect all phases of the disaster, triggering a variety of consequences, including:

- Immediate injury or loss of life during the seismic event, as in the case of:
    - Motorists struck by rockfall or landslides/slide debris originating from slopes above the road.
    - Motorists striking materials in the roadway.
    - Motorists driving into collapsed roadways.
    - Motorists pushed off the roadway by landslides.
    - Vehicles or persons buried under slide debris.
- Immediate damage to the transportation infrastructure (resulting from numerous small to average-sized landslides and very large landslides), which becomes:
    - An impediment to tsunami evacuation.
    - An obstruction to rescue and evacuation efforts.
    - A hindrance both to recovery in the immediate aftermath and to long-term economic recovery.
- Long-term highway closures due to landslides.
- Ongoing landslides from weakened slopes.
- Disruption of utilities that share highway right-of-way.
- Long-term mitigation of very large landslides that will impede repairs to bridges and other facilities.
- Massive consumption and shortages of fuel and other material resources used in landslide repair work.

Steep slopes, weak soil and rock, heavy rainfall, and high groundwater are all conditions that can lead to slope failure and are widespread throughout the state, particularly in the western half. Almost every highway in western Oregon is affected in some way by landslides. Where the listed conditions exist, slopes are at a much higher risk of failure during an earthquake. The greatest hazards, however, are the existing known landslides and the existing slides that are yet to be discovered. Recent research by the U.S. Geological Survey (USGS) has shown that seismogenic landslides (that is, new slides initiated by earthquakes) tend to move a few inches to a few feet, while existing slides reactivated by earthquakes are more likely to move several yards. Highways traversing mountainous terrain will be the most disrupted; however, routes in low-lying areas, such as the Willamette Valley, will also be affected by liquefaction and lateral spreading, which can result in the failure of otherwise stable embankments and fills.

The following photos and diagrams describe some of the most common slope failure modes and one of the possible mitigation strategies for that type of failure.

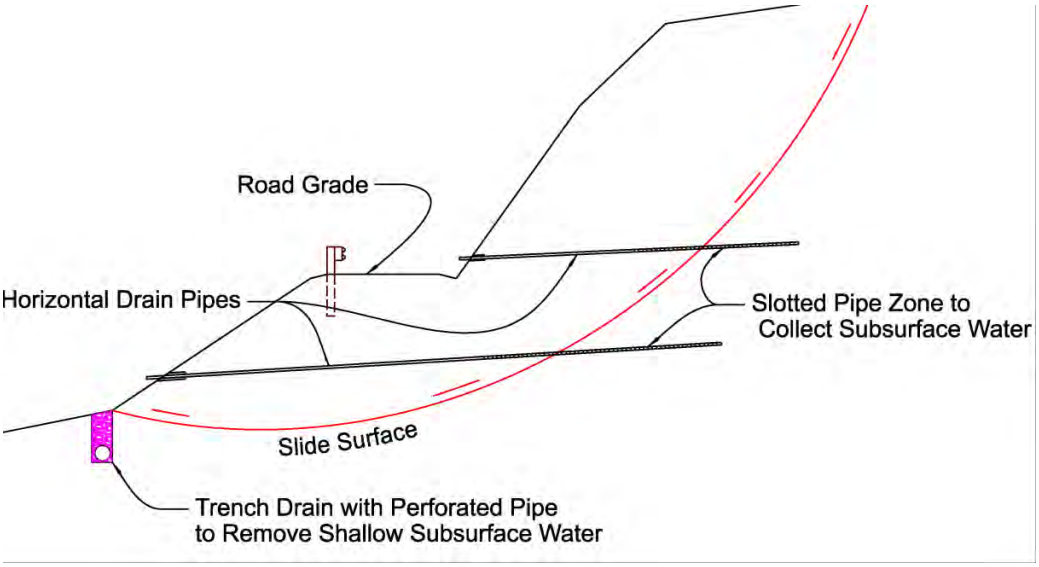

Figure 5.13: Drainage is one of the most cost-effective methods for landslide mitigation (Source: ODOT – Geo-Environmental Section)

Coastal Area: Impacts from Landslides and Rockfalls

As most residents of coastal Oregon know, there are numerous service disruptions on U.S. 101 every year from active landslides and rockfalls. It is a challenge for the agency just to keep this route functioning during normal winter weather. The results that strong ground shaking and the accompanying tsunami from a Cascadia subduction zone earthquake will have on this route are almost unimaginable, considering the large number of unstable slopes that will be affected by these forces.

Currently, 526 known unstable slopes directly affect U.S. 101. Many of these slides will fail catastrophically during the primary earthquake, while many others will fail during or soon after the tsunami. Slopes that do not immediately fail during the primary seismic event will be destabilized to varying degrees and may fail soon after, either during strong aftershocks or else at some time during the rescue and recovery efforts. Not only will coastal residents have to contend with the primary effects of the Cascadia subduction zone earthquake, but their evacuation, rescue, and recovery will be further hindered by landslides and rockfalls. Their escape from the tsunami may be blocked by failed slopes, and many could also become landslide victims.

East-West Corridor Impacts from Landslides and Rockfalls

If we take the hazard posed by landslides and rockfalls into account, the east-west routes connecting U.S. 101 to Interstate 5 are only marginally better than U.S. 101 itself. These routes traverse very steep terrain that is underlain by generally weak materials. In addition, the Oregon Coast Range experiences very high rainfall each year, which further serves to weaken slopes and embankments. A high number of landslides occur in this area on an annual basis, and a very high number should be expected during a Cascadia subduction zone event, solely on the basis of the geologic conditions.

What makes these routes particularly vulnerable is the existence of very large landslides along them. These existing slides are expected to have the highest amounts of displacement during an earthquake. Whole mountainsides can move tens of yards vertically and horizontally, taking the entire roadway with them. These landslides have the capacity to close roads for several weeks while efforts are made to reconstruct roadways or build detours around the slides. Recent LiDAR technology, where available, has led to the discovery of many of these large, sometimes ancient, landslides. In some cases, the slides were previously known, as they have had some effect on the highway in the past. In other cases, highways traverse enormous landslide features that were not known to exist and have been inactive since their initial failure. It has been theorized that many of the known large, ancient landslides in the Oregon Coast Range and the Columbia River Gorge are the result of past Cascadia subduction zone events.

Interstate 5 and Mid-Willamette Valley: Impacts from Landslides and Rockfalls

Interstate 5 and other highways in the Willamette Valley are not without their own landslide and rockfall vulnerabilities. Many fills and embankments were either constructed of or on liquefiable soils in areas with high groundwater, making them particularly susceptible to earthquakes. Interstate 5 also traverses

mountainous terrain in the southern part of the state, and unfavorable geology contributes to ongoing slope instability along I-5 in the Portland area.

In all, there are 49 known landslide and rockfall areas along I-5. Other unstable areas are suspected. In the event of a Cascadia subduction zone earthquake, therefore, the most important route in the state will not be without problems. Many of the slides through the Willamette Valley are minor and can be readily mitigated. Most of the slides in the Portland area have been treated, but some could result in lengthy repairs and service disruption. For the Portland area, adequate detours exist in areas that are not as vulnerable to landslides, but delays will occur. The greatest concern for this route is the mountainous areas of southern Oregon. Unfavorable geology—in terms of geologic structure, materials, and groundwater—has formed some very large, complex landslides in this area. These slides have the capacity to cut this route off on the southern end for many weeks while repairs take place or detours are constructed.

Rail Transportation

Rail lines are generally privately owned businesses, not public entities. Detailed vulnerability assessments of this part of Oregon's infrastructure have not been conducted, although generalizations can be drawn about its possible performance based on experience in other regions where major earthquakes and tsunamis have occurred. Funding for such detailed studies may be problematic due to the private ownership status of railroads.

Figure 5.14: Landslide damage on the UPRR between Chemult and Eugene
(Source: ODOT – Rail Division)

Trunk Lines

- California State Line to Klamath Falls
    - UPRR: Several miles of dredged fill, one highway overpass, two tunnels in California
    - BNSF: Two major bridges, one highway overpass
- Klamath Falls to Chemult
    - UPRR/BNSF: One major bridge, five highway overpasses
- Chemult to Redmond
    - BNSF: Two major bridges, five highway overpasses
- Redmond to OT Junction (BNSF); OT Junction to Troutdale (UPRR)
    - Seven major bridges, three tunnels, twenty-three highway overpasses
- Chemult to Eugene
    - UPRR: Fourteen major bridges, twenty-one tunnels, seven highway overpasses, six snow and rock sheds
    - Major historical landslide
- Eugene to Portland
    - UPRR: Fifteen major bridges, thirty-two highway overpasses
- Portland Terminal Area (Troutdale to Portland (UPRR); Vancouver, WA, to Portland (BNSF))
    - Four major bridges, forty-two highway overpasses

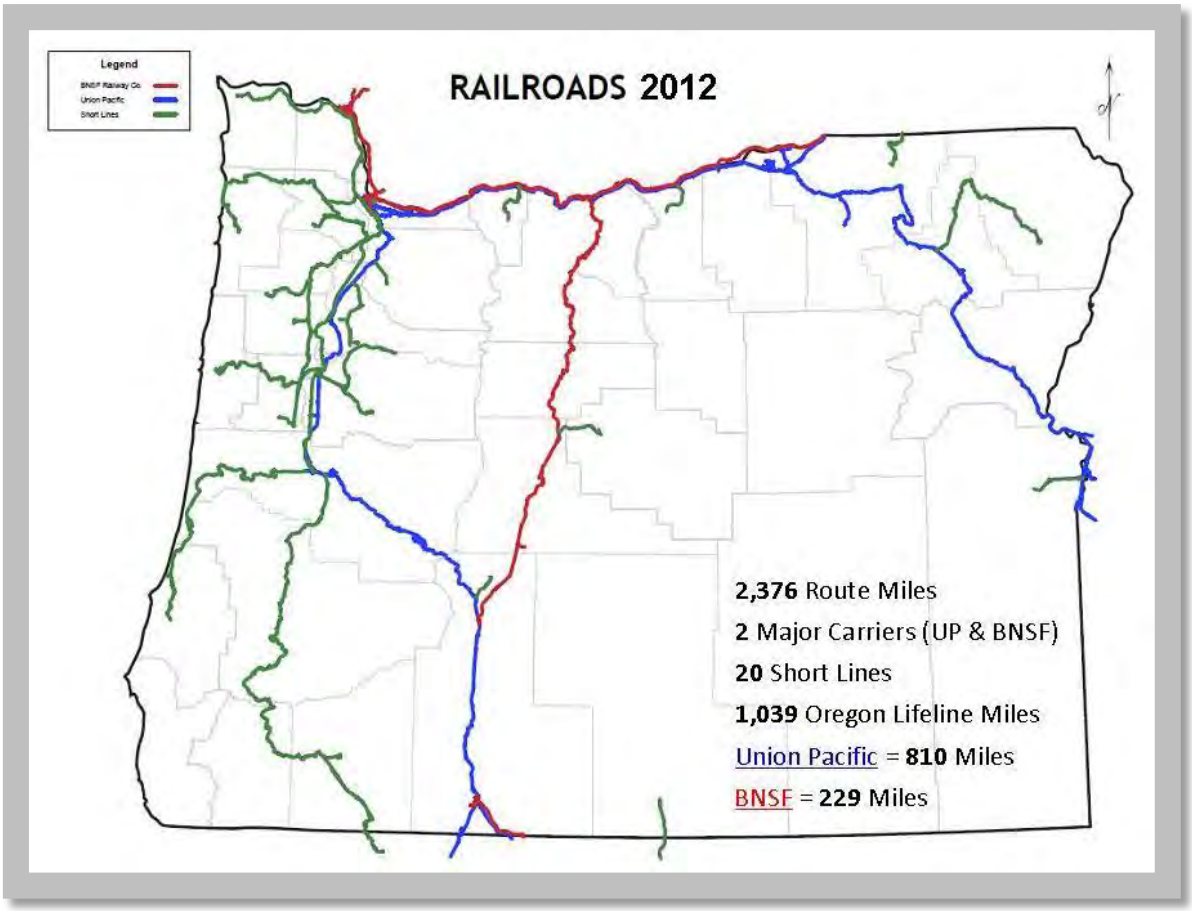

Figure 5.15: Railroad Corridors (Source: ODOT – Rail Division)

Detours for Trunk Lines

- Siskiyou Line (California to Eugene): Steep grades, twenty-four major bridges, eleven tunnels, twenty highway overpasses
- Oregon Electric Line (Eugene to Tigard): Fifteen major bridges, seven highway overpasses
- West Side District (Albany to Tigard): Fifteen major bridges, two highway overpasses
- Tigard to Willsburg Junction and connection with UPRR Trunkline: Three major bridges, three highway overpasses

Coastal Branch Lines

- Coos Bay Rail Link: Forty-nine major bridges, eight highway overpasses, nine tunnels
- Astoria District: One tunnel, six highway overpasses
- Albany to Toledo: Forty major bridges, one tunnel, three highway overpasses

Air Transportation

The state of Oregon has an extensive aviation system that provides valuable transportation options for the public, ranging from small airports in remote regions of the state to large commercial service airports. Ninety-seven public-use airports provide support to the economic health and vitality of Oregon and contribute to the quality of life for its citizens and visitors.

- Fifty-seven public-use airports are partially supported by FAA and included in the National Plan of Integrated Airport System (NPIAS).
- Sixteen public-use airports are either owned by other municipalities or are privately owned.
- Over 400 private airports and landing strips are located within Oregon.

The 2007 Oregon Aviation Plan established five categories of airports, based on the definitions outlined within the National Plan of Integrated Airports System (NPIAS), the design criteria outlined by the Airport Reference Code (ARC), and the facilities inventory.

CATEGORY I: COMMERCIAL SERVICE AIRPORTS
These airports support some level of scheduled commercial airline service in addition to a full range of general aviation aircraft. This includes both domestic and international destinations.

CATEGORY II: URBAN GENERAL AVIATION AIRPORTS
These airports support all general aviation aircraft and accommodate corporate aviation activity including business jets, helicopters, and other general aviation activity. The primary users are business related and service a large geographic region, or they experience high levels of general aviation activity.

CATEGORY III: REGIONAL GENERAL AVIATION AIRPORTS
These airports support most twin and single engine aircraft, may accommodate occasional business jets, and support regional transportation needs.

CATEGORY IV: LOCAL GENERAL AVIATION AIRPORTS
These airports primarily support single engine, general aviation aircraft, but are capable of accommodating smaller twin-engine general aviation aircraft. They also support local air transportation needs and special use aviation activities.

CATEGORY V: REMOTE ACCESS AND EMERGENCY SERVICE AIRPORTS
These airports primarily support single-engine, general aviation aircraft, special use aviation activities, and access to remote areas; or they provide emergency service access.

The following list identifies airports within each category that have the potential to maintain or quickly restore operational functions after a major earthquake. The Transportation Task Group arranged these 29 airports into a tier system to indicate the priorities for making future investments. Tier 1 (T1) is comprised of the essential airports that will allow access to major population centers and areas

considered vital for both rescue operations and economic restoration. Tier 2 (T2) is a larger network of airports that provide access to most rural areas and will be needed to restore major commercial operations. Tier 3 (T3) airports will provide economic and commercial restoration to the entire region after a Cascadia subduction zone event.

Figure 5.16: Oregon Airports (Source: Oregon Department of Aviation)

The Portland International Airport (PDX) is one of Oregon's vital transportation network links. As the state's major airport, PDX will play a key role in re-establishing our economy by facilitating the movement of people, goods, and services after a major statewide emergency event. Other airports in Oregon will also play a vital role during the post-disaster emergency response and initial recovery phase. During the emergency response, for example, displaced residents, injured people, and the elderly may need to be evacuated by means of airports; and airports will also provide a staging area for needed supplies (such as water, food, medical supplies, and materials for temporary housing). Until highway and rail transportation can be fully restored, air transportation, along with ships off the coast, will be the lifelines for Oregon's citizens.

Figure 5.17: An aerial view of Port of Portland (Source: Port of Portland)

As described previously in this chapter, after a Cascadia subduction zone event, 29 airports have the potential for minimal damage, and operational service could be restored within a short timeframe. However, without a complete vulnerability assessment of these 29 airports, we cannot be certain which airports would be operational after an earthquake of magnitude 9.0. Based on Oregon Department of Geology and Mineral Industries (DOGAMI) tsunami inundation maps, we can predict with reasonable accuracy which airports would survive a tsunami. After studying these maps, we concluded that 8 out of 15 coastal airports will not survive due to the inundation of ocean water and debris. In the absence of a complete vulnerability assessment, our assumption is that seven of the coastal airports may survive a tsunami, but we do not know if they will survive an earthquake. Those seven airports are Tillamook, Siletz Bay State, Newport, Florence, Bandon State, Cape Blanco State, and Brookings.

Note: We did not consider the eastern airports in this particular scenario, as those airports are expected to sustain little to no damage during a subduction zone earthquake.

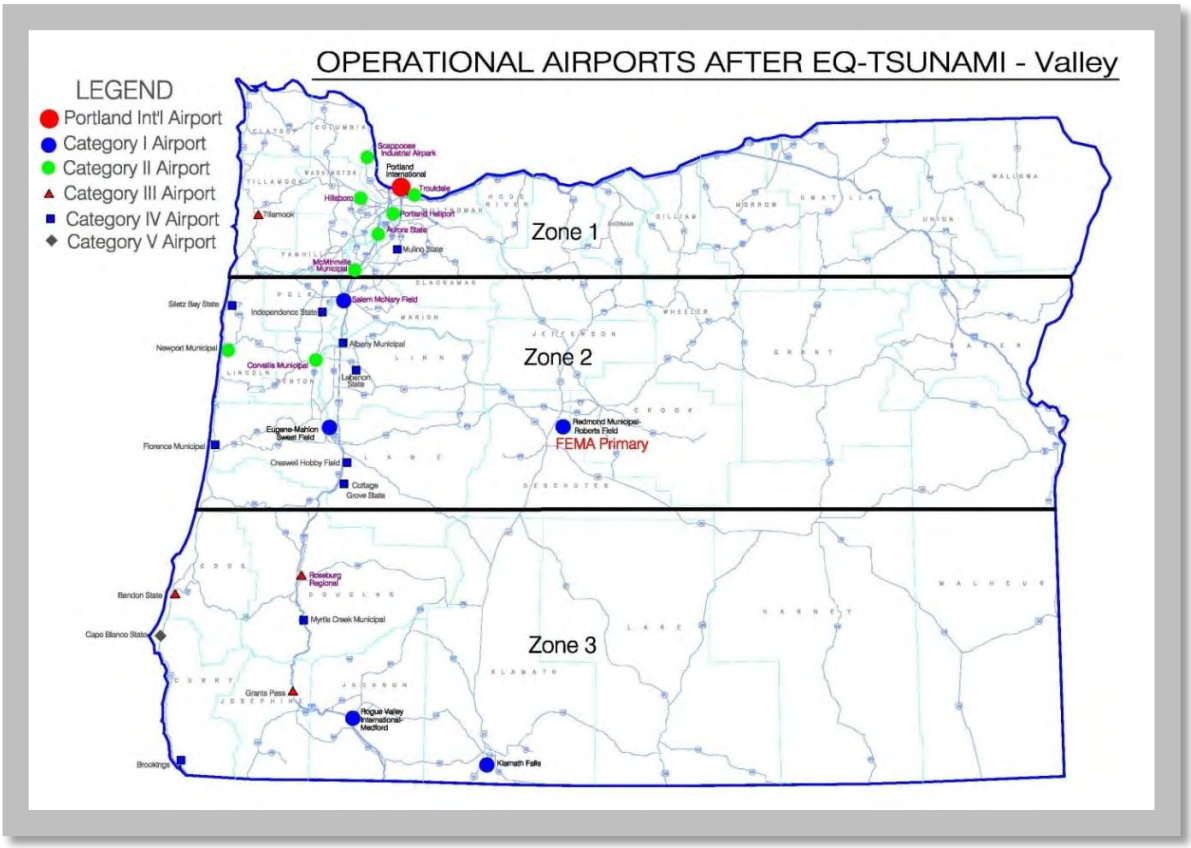

Figure 5.18: Emergency service zones served by air transportation (Source: Oregon Department of Aviation)

Columbia and Willamette Navigation Channels

The Columbia and Willamette Rivers are important transportation corridors for the states of Oregon and Washington. The lower Columbia (Pacific Ocean to Portland) and lower Willamette Rivers are deep draft channels and are critical for connecting transpacific trade to the region and the state. The mid-Columbia and Snake Rivers (Portland to Lewiston, Idaho) are shallow draft, inland waterways along which significant cargo can be moved from the east to the Portland region. Multiple dams and locks are necessary for the operation of this river route. Redundancy does not exist for these dams and locks—a cause for concern because the river channels may be obstructed when bridges collapse during a significant earthquake. A Cascadian event could significantly impact the river system and shipping channels. The jetty at the month of the Columbia is susceptible to severe damage from significant seismic event and tsunami. Failure of the jetties would significantly impact the channel. The channel depth at the mouth would likely be severely constrained due to sands migrating in from the beaches adjacent to the jetties. Additionally, the navigability of the Columbia River Bar would be difficult and unsafe for many vessels.

Critical factors affecting marine terminal viability include the condition of navigation channels immediately following a seismic event and how quickly and successfully resources can be deployed to

assess and clear navigation channels of silt and structural obstructions. Shipping channels would be constrained as a result of lateral spreading of the channel banks, which will shift sediment into the channel. In addition, the pile dike systems along the river, which are intended to prevent sediments from migrating into the channel, are susceptible to failure during a major seismic event. Significant failures could dramatically impact the hydrology of the Columbia River. Depending on the seismic impact, deep-draft ships that are in transit in the waterway could become stuck due to a sudden shifting of material. This shift would cause the navigation channel to become shallower, cutting off navigation by other vessels and endangering the ships themselves. Additionally, structures that collapse into the navigation channel would need to be removed to allow ships to pass safely. Initially, shallow-draft barges may be the only viable option to move material and goods to and from marine terminals; or ship calls will be diverted to other, unaffected ports and regions. Marine terminals near the coast will also be exposed to the effects of tsunami waves, which could severely impact dock structures and support facilities. Timely restoration of the channel to resume current shipping operations is dependent upon the availability of dredges and federal funding authorizations.

In preparation for a Cascadia subduction zone event, dredging capabilities and resources should be identified and plans developed to assess and acquire services to ensure that the Columbia River navigation channel is cleared of sediment and returned to a minimal, and ultimately full, level of service. Pre-event analysis should be considered to identify which areas are likely to be most vulnerable to large-volume sediment movement during a Cascadia subduction zone event. Such analysis will help facilitate planning and ensure that resources will be dispatched to the areas of highest vulnerability. Following a Cascadia subduction zone event, hydrographic resources will need to be deployed to assess the condition of the navigation channel along its entire length and identify segments that need urgent dredging to re-establish river navigation of deep-draft ships. Disposal sites should be identified at strategic locations to align with dredging capabilities.

An assessment of contracting resources capable of accomplishing dredging in the region should be developed and agreements should be considered to establish who will have first rights to those construction resources. Such an assessment should also include the creation of an inventory of dredging resources and capabilities. It is expected that USACE will manage dredging activities and direct resources to areas of highest priority and need. Advance coordination with environmental permitting and regulatory agencies should be considered to ensure that dredging and placement do not violate statutory requirements.

RIVER PORTS

The vulnerability of marine terminals and navigable waterways to the effects of a major seismic event is highly variable and depends on many factors. There are several major elements associated with a marine terminal that have different—but interdependent—risks.

Some of the major elements of marine terminals that are critical to maintaining functional operation include dock structures; berths; dock-side equipment associated with material loading and unloading;

intermodal systems serving the marine terminals, including rail, roads, and bridges; the land on which the terminals were developed and its associated geotechnical characteristics; levee structures that protect marine commercial districts and, in some cases, aviation facilities; and river channels that provide passage for deep-draft vessels. These elements should be analyzed both individually and as parts of an overall system that serves marine cargo operations.

Dock structures are comprised of a wide array of systems of differing ages and with varying abilities to withstand seismic impacts. Their capacity to survive a great earthquake is dependent not only on the materials and methods used to construct them, but on their age, their condition, and the stability of the land beneath and surrounding them. For example, many marine facilities were constructed on fill material placed over historic wetlands. Such material is generally fine and granular in nature and susceptible to liquefaction if provisions are not made to resist such forces or relieve the pore pressure resulting from a high water table and seismic shaking. A structurally sound dock structure must also be supported by stable adjoining land. As has been noted in seismic events worldwide, lateral spreading (caused by seismically induced liquefaction) of the land adjacent to dock structures has contributed significantly to their damage profile. Stabilizing the adjoining land to resist lateral spreading minimizes the damage to the dock, reduces the sloughing of soil into the berth prism, and allows for a faster return to service of the dock and loading equipment.

The integrity of intermodal connections to other transportation systems, including rail, roads, and bridges, is critical to the functionality and viability of marine ports. The integrity and operability of the regional power grid and on-site generation capabilities are also critical to marine terminal operations. These elements are addressed in other sections of this report, but are noted here to emphasize the overall integration of the system that serves marine terminals.

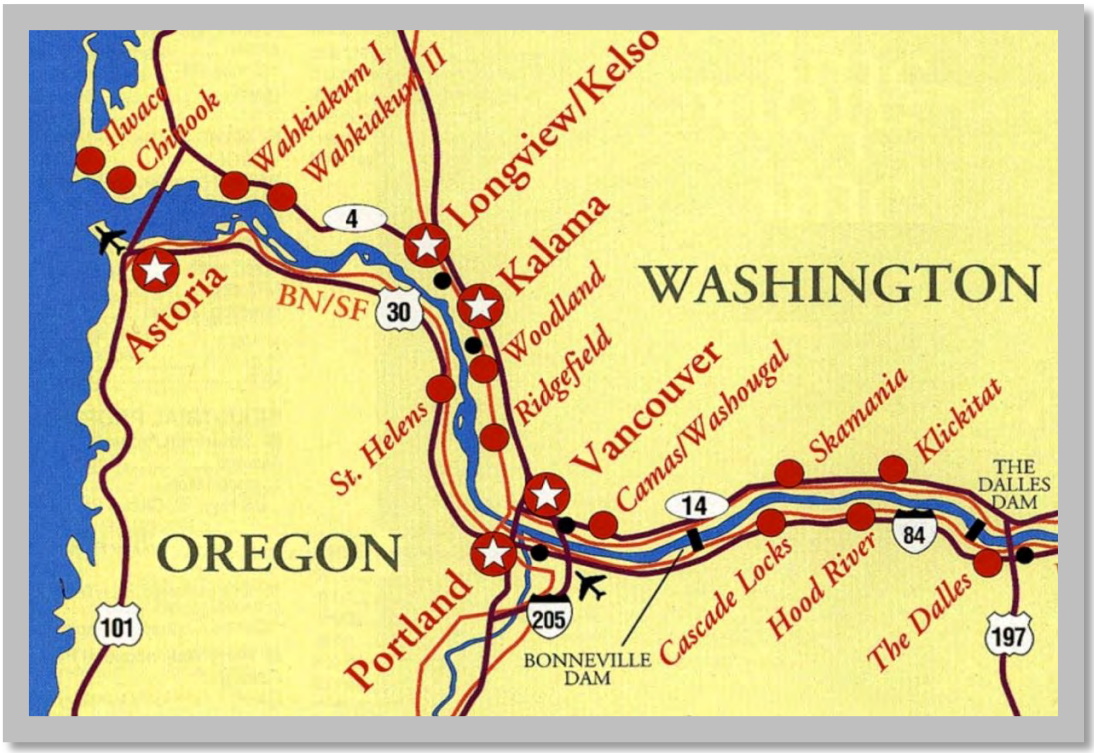

Figure 5.19: Columbia River Channel and port (Source: Port of Portland)

COASTAL INLET JETTIES

The tsunami generated by a Cascadia earthquake measuring magnitude 8–9 could range in height from 5 to 30 feet along the present shore face. In addition, co-seismic subsidence (caused by the release of built-up strain in the tectonic plates) may induce immediate lowering of the coastal margin by 2 to 8 feet (Atwater and Hemphill-Haley, 1997). In other words, the elevation of the shoreline is expected to drop during the earthquake and just before the first tsunami waves arrive.

The effect of a tsunami of this size on the coastal inlet jetties of the Pacific Northwest would be significant and transient: the overland flow of the tsunami is likely to destabilize the roots of all the jetties by eroding the morphology along the jetty roots, which may be flanked by the overland flow. Immediate repairs would be needed to re-secure the jetty roots. The seaward ends of the jetties could be affected by significant, severe scour due to the volume of water transported into and out of the inlet in response to the tsunami's passage and residual circulation. A significant volume of sediment may be mobilized and deposited within the inlet.

Violent shaking during the earthquake is also likely to destabilize many jetty areas having a side slope steeper than 1V:2H. Liquefaction of the jetty foundation may occur and initiate jetty settlement and toe failure. If vertical co-subsidence occurs with the Cascadia subduction zone earthquake, the long-term effects on the jetties of the lowering of the existing land margin by two to eight feet may be more profound than the earthquake and tsunami. Jetty freeboard could be significantly reduced and depth-

limited wave height would be significantly increased. This effect would significantly increase the rate of jetty degradation and expose the landward areas of each jetty to increased wave loading and overtopping. Jetties that were in a good state of repair (or recently rehabbed) would be more resistant to earthquake related damages as opposed to jetties that were in a condition of deferred repair.

Following such an event, a triage approach would be implemented at USACE coastal navigation projects to assess the condition of jetties, inlets, and navigation channels. High tonnage, deep-draft projects would be given higher priority than shallow-draft, low tonnage projects. Estimates for channel shoaling (required dredging) and jetty damage (required repairs) would be developed, and, if available, resources would be mobilized to re-establish a minimum level of functionality for the navigation infrastructure.

Immediate response for high priority coastal navigation projects (within our ability to respond) would be to secure the jetty roots, if these areas were breached. A breached jetty root can lead to reformation of the inlet's channel and loss of navigation. Rapid placement of stone/rip-rap along the breached jetty (at the root) would be executed, sufficient to stop tidal flow through the breached area. If required, the navigation channel may be dredged in affected areas to make it navigable again. In the long term, the affected jetties may require expedited maintenance to address damage.

COASTAL PORTS

Coastal ports in Oregon are essential for the economies of the coastal communities and will be critical for disaster response and subsequent economic recovery. Unfortunately, they are also at risk for catastrophic damage in the event of a Cascadia subduction zone earthquake and subsequent tsunami. Elements of port infrastructure that should be considered priorities include jetty/breakwater structures protecting entrances, navigation channels, docks and piers, slips, pier-side equipment, structures, and transportation linkage with rail, air, and highway.

The vulnerability of jetties and breakwaters to the potential actions of an earthquake and tsunami should be analyzed further, along with the potential effects that vertical shifting, silting, debris, and obstruction could have on channel depths. Necessary reinforcement of jetties and breakwaters is essential to maintain port entrances, as is continuing maintenance-dredging of channels.

Dock and pier structures will be exposed to severe damage due to surging currents, debris impacts, possible tsunami inundation, and liquefaction (where piers are built on fill material). Reinforcement of pier and shore-side bulkheads, which could limit damage and allow for faster recovery of port operations, should be considered a priority.

Due to their locations, the intermodal connections of most coastal ports are critical for port functions. It is necessary that Oregon prepare for and mitigate against damage to rail links, bridges, highways, adjacent airports, power supplies, and communications. Critical equipment and structures will also need to be identified and reinforced for use as maritime disaster response command centers and subsequent recovery and rebuilding efforts.

Waterborne rescue and recovery operations may have to be provided through coastal ports; this may be the only viable option for many of Oregon's coastal communities if highway corridors fail. So even though the infrastructure of many coastal ports may be devastated, their very locations will have to serve as landing sites for waterborne support (from barge, amphibious, and shipping operations). Temporary facilities provided by barges and cranes may be used to restore makeshift docks quickly for rescue and recovery operations, as was experienced in Haiti. Functionality for commerce would take longer.

Transportation resilience planning and preparation for coastal ports is critical to minimize post-event casualties, speed rescue, and allow for the economic recovery of the Oregon coast. In addition to supporting rescue and recovery operations after the earthquake and tsunami, coastal ports should serve as recovery hubs from which transportation reconstruction can reach out along the coast while transportation corridors between coastal and inland areas are being restored.

Public Transit Services

Five public transit regions correspond to ODOT highway regions. Within these regions are approximately 113 significant public transit agencies and several dozen more subcontractors who provide various forms of publicly-funded transportation service, including demand response, intercity service, and alternative transportation options. The role played by public transit service has proven to be critical during the initial response to and recovery from other major natural disasters, earthquakes included. It should therefore be considered a major component of our disaster preparedness plan.

Oregon has a full spectrum of transit providers, ranging in size from very large to very small, and extending geographically from large urban centers, such as Portland, to small coastal communities and remote rural eastern Oregon towns. Transit services in some form are provided in all 35 Oregon counties and to nine federally-recognized Indian tribal communities. About 128.5 million one-way rides are provided for Oregon residents and visitors each year. Public transit buses and smaller vehicles log 52.1 million miles of travel each year, providing over three million total annual hours of public transit operating service statewide.

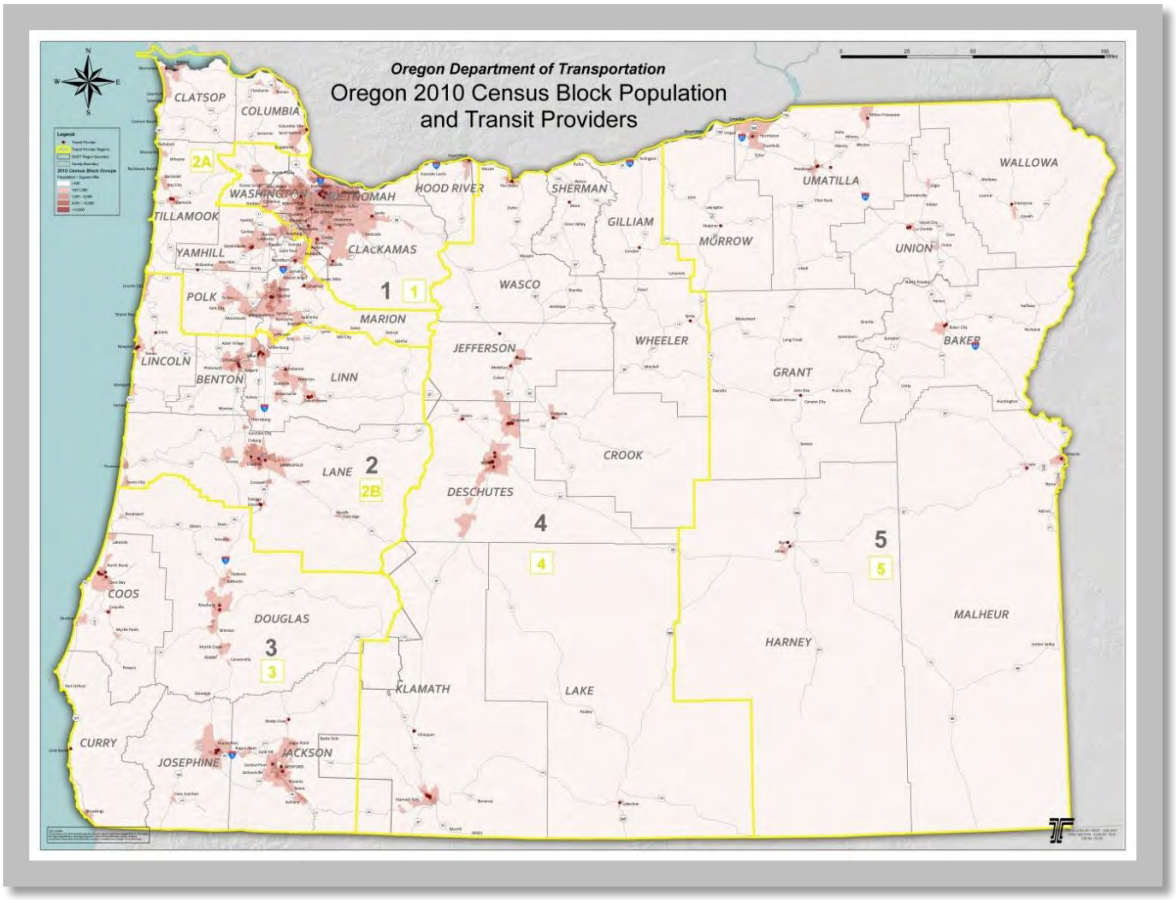

Figure 5.20: Oregon 2010 Census Block Population and Transit Providers (Source: ODOT Public Transit & GIS Technical Services)

Tri-Met, Lane Transit District (LTD), and Salem-Keizer Transit are the three largest transit agencies in the state. These are large, sophisticated agencies with their own extensive emergency management planning, incident command and response systems, and business recovery/resilience plans and procedures in place, all of which have been developed cooperatively with other public agencies and first responders in their respective areas. Additional systems, designated as small urban systems by the Federal Transit Administration and including the Rogue Valley area, Bend-Redmond, Corvallis, Albany, Grants Pass, and the Tri-Cities area, also have varying levels of detailed local emergency planning and recovery plans in place.

The remaining public transit agencies are rural or small town systems with often minimal resources in place to conduct significant planning and very few financial resources to invest in resilience following a catastrophic natural disaster. Excluding Tri-Met, LTD, and Salem-Keizer, the remaining 110 transit agencies share over $107 million in federal and state grants awarded through ODOT, with approximately two-thirds of available funding going towards simply maintaining daily or weekly operations and one-third toward capital expenditures (primarily replacement buses).

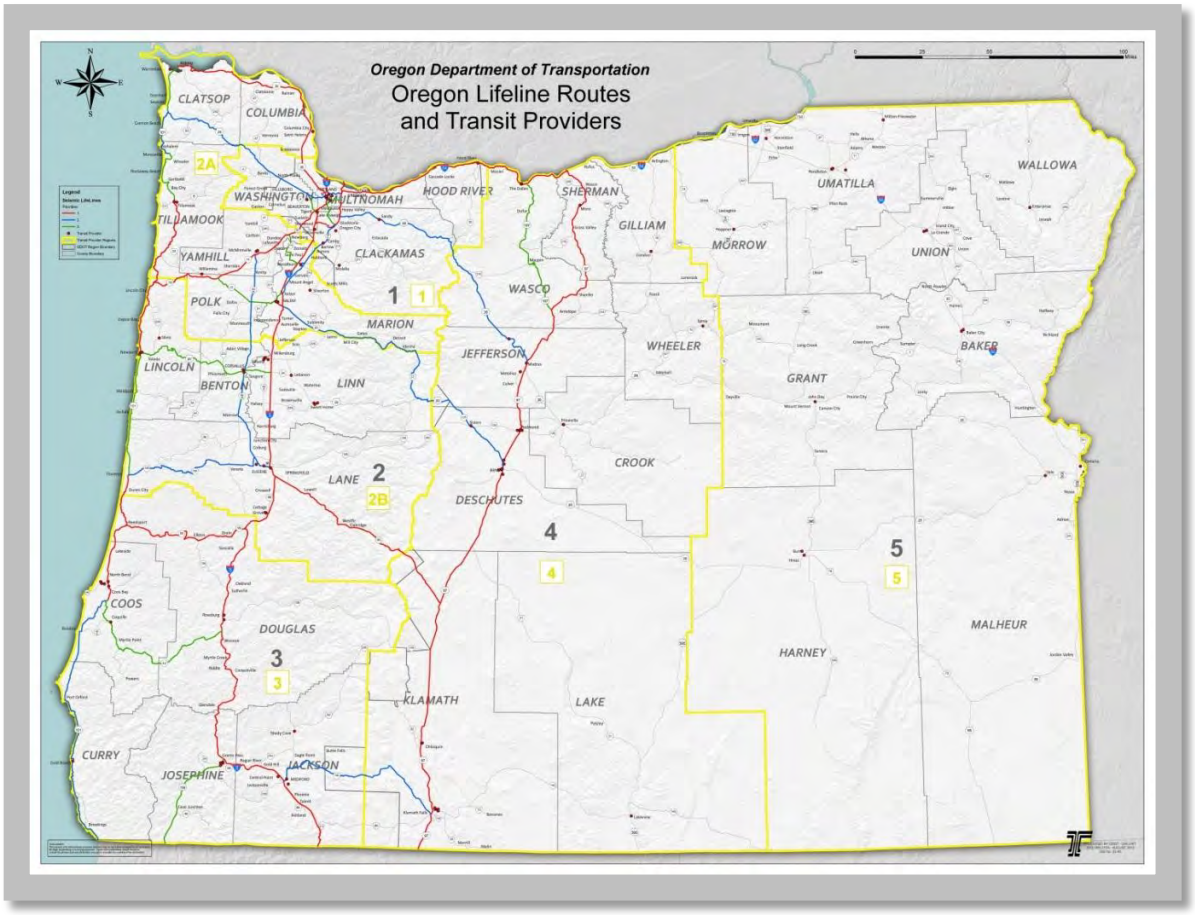

Figure 5.21: Oregon Transit Providers (Source: ODOT Public Transit & GIS Technical Services)

Transit agencies could play an important role in helping Oregon recover from a major natural disaster. Oregon transit agencies are positioned to serve the major state population centers. Public transit buses, in conjunction with school district buses, may be able to assist with emergency evacuation—either before the event, in the case of predictable natural disasters, or after the event, in situations such as a great earthquake, in which people must be transported out of an impacted area. Public transit buses could also be used to transport emergency workers or supplies to and from affected areas; to transport workers to recovery-related jobs when private automobile traffic is constrained due to road conditions and fuel supplies; and to transport seniors, persons with disabilities, and injured citizens to and from medical treatment appointments or to places where they can shop for food and other necessities.

Combining buses purchased through ODOT with those buses purchased directly by the larger urban agencies, over 1,500 buses and transit vehicles are currently deployed across the state; adding district school bus fleets would increase that number by several thousand. Most transit buses are equipped with wheelchair lifts, which, during emergency relief efforts, could also be useful in transporting and deploying both emergency personnel and their accompanying supplies and gear.

Transit providers are generally located on Oregon's lifeline routes. While this means that transit agencies are well placed to be able to assist with response and recovery activities, it also means that the transit system is dependent on local roads and highways and cannot respond if roads are impassable. Once roadways are cleared for minimum critical vehicle travel, public transit vehicles may be deployed by emergency command for the purposes of evacuating residents and transporting relief personnel.

Depending on the scale and location of the Cascadia subduction zone event and the resulting direction of tsunami wave generation, some coastal transit facilities, such as Columbia County CC-Rider, Sunset Empire Transit District, Tillamook County Transportation District, Lincoln County Transportation District, and Coos Bay Area Transit, may be inundated by the tsunami and consequently unable to respond. The ability of non-coastal transit agencies to assist coastal transit agencies is dependent on whether highways connecting the Willamette Valley to the coast remain passable. In particular, landslide risks may impair transit's ability to respond. Region 2 has the highest landslide risk (that is, this region has more historical landslide sites).

The importance of the human factor in recovery activities following a major emergency is often under-rated. Public transit is dependent on drivers, mechanics, dispatchers, and supervisors all working together to maintain and support daily operations. Some transit drivers are volunteers. Personnel must first be able to get to central agency locations, where both vehicle and communication assets must be operable, in order to provide public services. This also means there must be a way for these men and women to know that their families and loved ones are safe while they return to work. Although some emergency response personnel, such as firefighters and National Guard troops, do have commercial driver's licenses, they are generally not accustomed to driving buses, nor are they necessarily familiar with local streets and routes. Most importantly, drivers for demand-response transit services know where the vulnerable populations in their communities reside, which can be critical to saving lives in the hours and days immediately following a catastrophic event.

In summary, for public transit service restoration, short-term resilience is largely dependent on at least three primary factors:

- The condition and accessibility of the repaired roadway and (in coastal and valley areas) the bridge system.
- The ability of transit agency drivers, mechanics, dispatchers, and other key staff to respond following a catastrophic event.
- The status and availability of fuel supplies.

Longer-term resilience will also depend largely on the availability and prioritization of expenditure of public relief funds in the impacted areas. Certainly, without federal and state financial assistance, few of our local transit agencies would have the internal financial resources to finance major infrastructure rebuilds. These factors are difficult to forecast accurately given both the predicated severity of the

natural event upon which the resilience assessment is based and the competing demands for public funds which would follow.

Local Roads and Streets

For many communities, the local road and street system provides the only access to many critical facilities following a disaster event. These facilities include hospitals, fire stations, and locations where temporary food and housing are to be provided. Local roads and streets can also provide detours around failed state highway system facilities. One of the observations made after the recent subduction zone earthquake in Chile was that the local road and bridge system tended to survive better than the state system. This was because the local roads tended to be straighter and wider, which resulted in larger roadway cuts and fills. As a result, many of the local roads and streets were used as detours for damaged state highway roadways and bridges. On the other hand, because many local roads and streets are narrow, with very sharp curves, they cannot safely accommodate a high volume of traffic.

In addition to local roads and streets, Oregon has thousands of miles of forest roads, and it may be possible to use these for low-volume, temporary local detours in the event of a major disaster. Many of these forest roads are privately owned and will also be subject to significant damage in a Cascadia subduction zone earthquake. Nonetheless, such local-road detours will likely serve emergency responders, repair crews, and vehicles transporting food and other critical supplies, and will therefore play an important role as recovery efforts progress and a minimum level of service is restored.

Resilience Gap Analysis Summary

Where possible, the gap analysis is based on an engineering evaluation of vulnerability and seismic resistance. Where engineering or other technical studies have not been completed, the analysis is subjective, based on generalizations of leading indicators, such as year of construction, seismic code at the time of design and construction, assessment of current conditions, and comparison with performance of similar facilities in subduction zone earthquakes in other areas of the world. Where detailed studies have not been completed, recommendations are included for further studies to fill the gap.

The current state of Oregon's transportation systems and the anticipated time to restore service after a Cascadia subduction zone event is represented in the figure shown below. The table also provides targets for the relative time needed to restore service if the system were strengthened or retrofitted.

Oregon Transportation Resiliency Status

***Key to the Table**

TARGETS TO ACHIEVE DIFFERENT LEVELS OF RECOVERY:	
Minimal: (A minimum level of service is restored, primarily for the use of emergency responders, repair crews, and vehicles transporting food and other critical supplies.)	R
Functional: (Although service is not yet restored to full capacity, it is sufficient to get the economy moving again—e.g. some truck/freight traffic can be accommodated. There may be fewer lanes in use, some weight restrictions, and lower speed limits.)	Y
Operational: (Restoration is up to 90% of capacity: A full level of service has been restored and is sufficient to allow people to commute to school and to work.)	G
ESTIMATED TIME FOR RECOVERY TO **60%** OPERATIONAL GIVEN CURRENT CONDITIONS:	S
ESTIMATED TIME FOR RECOVERY TO **90%** OPERATIONAL GIVEN CURRENT CONDITIONS:	X

TABLE NOTES:

1) SLR = Seismic Lifeline Routes (See Maps on Figure 5. 23 and 5. 24)

2) While temporary facilities can be used as an interim measure, it is anticipated that the prioritization of public relief funds would tend to push reconstruction of permanent transit facilities out into longer timeframes.

3) Critical needs evacuation and emergency usage of transit rolling stock would be at the direction of emergency operations center personnel.

4) Restoration of regular on-demand, fixed route, and intercity bus service is contingent on the extent of earthquake and tsunami damage, and on our ability to repair roads and bridges in all tiers of the state highway system and local roads.
5) Minimal level of service may indicate a heliport option only.
6) On these line segments, normal traffic is one train each way daily; consequently, restoration of minimal service means the same as functional.
7) Minimal level of service indicates the heliport option only. Due to the airport's proximity to the Pacific Ocean and elevation, the airport may be subject to relocation after the tsunami event.

Figure 5.22 – The current state of Oregon's transportation systems and the anticipated time to restore service after a Cascadia subduction zone event

HIGHWAY TRANSPORTATION

Sizable investments are needed to allow the highway system to be usable shortly after a major event. The total estimated cost to repair all seismically deficient bridges and unstable slopes is in the hundreds of millions of dollars; however, options exist for phased retrofitting that will provide the maximum degree of mobility with reasonable investments. The manner and timing of funding will influence how and where Oregon is prepared for rescue and recovery.

Analysis suggests that the longer the state delays increasing its investment in bridge and slope strengthening, the greater the cost and potential adverse effects an earthquake will have on the state's economy. If risks related to bridges and slopes are left unaddressed, the odds grow every day that we will be unprepared for an increasingly likely major earthquake. Oregon should therefore develop an investment package to begin a strategic retrofitting and replacement program for the state's bridges and unstable slopes. Securing both the interstate system in vulnerable areas and other key lifeline routes is the first priority, followed by critical city and county connector routes.

The strategic investment plan should be implemented in three tiers that build on each other. The Tier 1 routes listed in Figure 5. 23 (Phase 1 and then Phase 2) are considered top priorities for ensuring the greatest return on investment to support rescue and recovery operations. Strengthening Tiers 2 and 3 (Figure 5. 24) would follow as funding becomes available. This strategy anticipates that ODOT will continue bridge retrofits and slope strengthening in combination with other projects, even as it shifts to a more strategic, corridor-based approach to maximize potential future investments in seismic retrofitting.

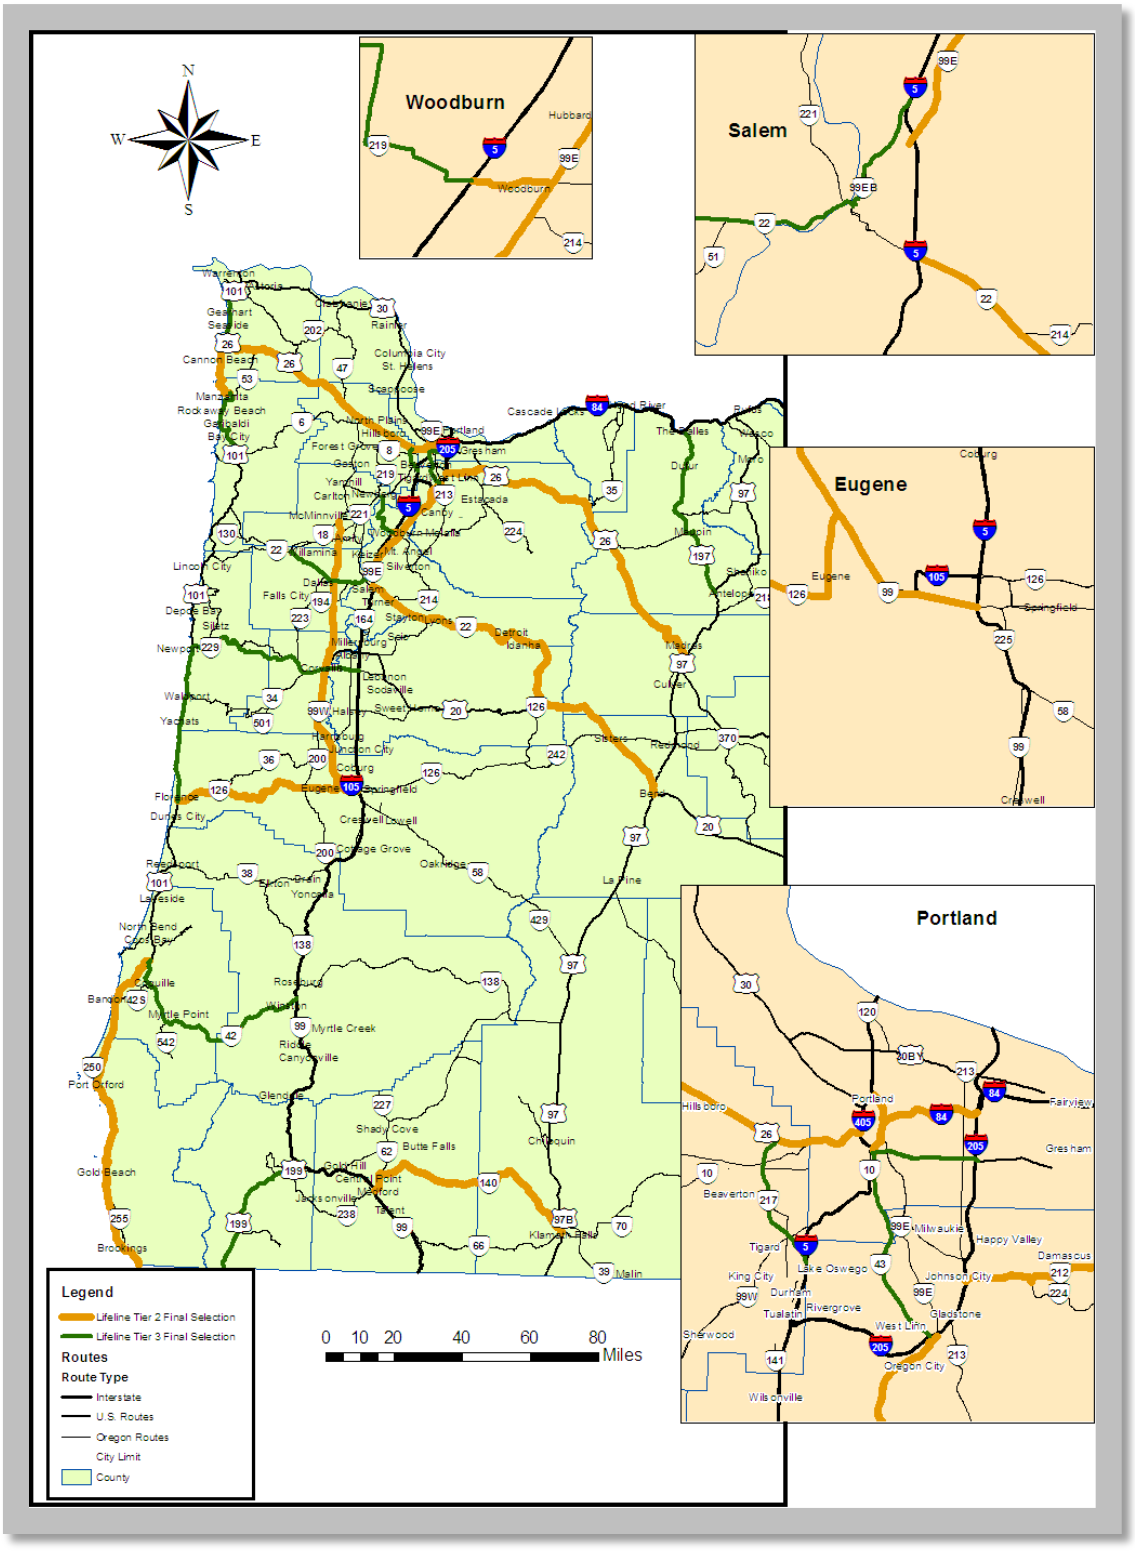

Figure 5.24 –Map of Seismic Options Program: Tier 2 & 3 Routes (Source: ODOT – Bridge Section)

RAIL TRANSPORTATION

A detailed vulnerability study and gap analysis should be done to identify strengthening and retrofit needs.

AIR TRANSPORTATION

A detailed vulnerability study and gap analysis should be done to identify strengthening and retrofit needs.

RIVER PORTS

A detailed vulnerability study and gap analysis should be done to identify strengthening and retrofit needs.

COASTAL PORTS

A detailed vulnerability study and gap analysis should be done to identify strengthening and retrofit needs.

PUBLIC TRANSIT SERVICES

A strategic investment strategy for public transit needs to start with the allocation of funds for gathering information, planning, and building collaboration with local and regional emergency planners. Specific projects for tactical hardening or relocation of certain transit structures and facilities may prove to be a valuable off-shoot of this effort, but in order to prioritize those and other potential expenditures, we first need to inventory and gather basic information about all transit resources in the four impact zones:

- An updated inventory of transit assets (buses, vans, fuel supplies, communications equipment, and repair facilities)—both those inside and those outside of the areas expected to be affected by the disaster—will be helpful. This should also include private carriers and school districts that may be of use in emergency response and recovery.
- An inventory of the assets of each facility, including general description, footprint, construction type, year built, and generator facilities, can provide a first-cut at seismic vulnerability estimation for those facilities that have not yet completed seismic assessments for a Cascadia-level event.
- Public transit needs to be included in emergency response preparations. As was recently revealed by Japan's Tohoku earthquake and the resulting tsunami impacts in Curry County and Del Norte County, transit agencies had not been at the table in emergency preparedness planning. A county-by-county assessment of transit's inclusion, role, and assigned activities for emergency preparedness should be conducted, and, where lack of involvement is indicated, inclusion and involvement should be formally encouraged.
- Assessment of the locations and needs of vulnerable and at-risk clients in all impact areas should be a priority. The lack of such information was a major factor in a number of deaths associated with Hurricane Katrina, many of which were potentially preventable. This is something each

local provider can do, with perhaps some general guidance and consistency of format provided at a statewide level.

- Transit agencies need to assess and prepare an inventory of routes, making note of the risk and vulnerability of both current transit routes and alternate routes; the inventory should identify alternate routes ahead of the actual event.
- Local transit providers should develop an emergency human resources plan that identifies:
    - Who their critical personnel are.
    - Where they live.
    - Full contact information.
    - Who is and who is not likely to be able to respond following an emergency.
    - Contingency plans for resuming at least minimal service using available and alternate personnel.
- Two aspects of preparedness should be considered for public transit: resilience planning and emergency response functions. These may include different roles for transit agencies, and they may entail different performance expectations. These differing roles and responsibilities need to be defined. The existence of mutual aid agreements with other local agencies and with nearby transit agencies should be identified; and, if do not exist, they should be encouraged as a means of building and sustaining collaboration and resilience.

LOCAL ROADS AND STREETS

As the strategic investment plan is implemented on the state highway system, certain elements of the local road and street system must also be retrofitted:

- In a few locations, critical emergency service facilities are separated from the state lifeline system by a substandard bridge. These bridges need to be retrofitted at the same time as the nearby state highway.
- Local road and street detours should be retrofitted wherever either of the following conditions exist:
    - The local road detour can be retrofitted for much less money than a retrofit on the section of state highway or bridge.
    - The local road detour can provide a substantially reduced time to restore the lifeline corridor to the minimal level of service for the use of emergency responders, repair crews, and vehicles transporting food and other critical supplies.

URBAN AREAS TRANSPORTATION

This chapter focuses mainly on statewide mobility between major hubs, cities, and towns. It is recognized, however, that travel within urban areas is also very important for rescue and recovery.

Large urban areas have critical needs for transportation resilience due to the relatively high volume of needs of a large population and the relatively high impact urban areas have on the state's economy.

Urban areas, such as Portland Metro, Eugene, Salem, Bend, Grants Pass, and Medford, face a large geographic barrier in the Columbia, Willamette, Deschutes, and Rogue Rivers and Bear Creek. These weak links in the urban transportation network create a potential for longer-term impacts because of the amount of time it is likely to take to restore traffic over large river bridges and to address problems caused by liquefiable soils along the river banks.

Most cities have established emergency response plans that identify critical facilities such as hospitals, fire stations, law enforcement facilities, schools, and emergency supply depots. Critical utility facilities, energy sources, and fuel depots are also needed for economic recovery. Access to these areas will be necessary to facilitate recovery, but specific modes and routes to provide this have not been identified in this study. This work is needed before a comprehensive plan for resilience can be finalized.

Transportation Interdependency Assessment

The Transportation Task Group determined that significant vulnerabilities exist for all transportation modes in western and central Oregon. While the desired approach is to raise the level of resilience of each mode by means of improvements programmed over a fifty-year timeframe, this may not be feasible due to the extremely high cost. The purpose of the interdependency effort was to select a multimodal transportation system that would provide the highest level of mobility to the largest area or to the highest population centers for the least cost.

The Transportation Task Group considered recommendations that would lead to a plan of measured improvements in ten-year increments that would include the most effective system of interconnected modes. The focus of this effort is to establish the resilience of portions of a transportation system—comprised of various modes—that would provide the greatest benefit for short-term rescue and longer-term economic recovery. To this end, the task group selected a minimum network of highway routes, termed a *backbone system*, and then supplemented it with other modes to provide statewide connectivity at what was perceived to be the lowest retrofit cost. The backbone system was identified as:

- I-5, from I-84 (Portland) to OR 58
- I-84, from I-5 (Portland) to U.S. 97
- U.S. 97, from I-84 to the California border
- OR 58, from I-5 to U.S. 97

Two alternate, interim transportation systems were assumed. The overall philosophy driving the selection process of the first system was that the movement of goods and people is likeliest, or most easily assured, along U.S. 97 (from both the north and the south and along the BNSF railroad line from

Klamath Falls), which also provides access to the Redmond airport in central Oregon. This assumption is supported by the low vulnerability of the highway, railroad line, and airport in comparison to routes and sites in western Oregon. The Redmond Municipal Airport was considered a key to short term mobility, because it would likely be available immediately following a Cascadia subduction zone earthquake. The Redmond airport should not need much investment to remain fully operational, although no specific study has been conducted to confirm this assumption. From the Redmond airport, goods and people would be easily distributed, by means of fixed-wing aircrafts, to Class 1 and commercial airports along the I-5 corridor. The task group considered this approach to be a high priority due to the high efficiency of fixed-wing aircrafts for moving people and freight. Goods and people would then access coastal areas by helicopter (a flight lasting approximately one half-hour each way). Airports in remote and coastal areas that can handle helicopters were identified as the second highest or moderate priority, with the resilience of the local roads and streets that provide access to those airports rated as equally important.

An alternate or redundant interim transportation system would serve Oregon from the west from ships, some anchored off shore for as long as needed. Goods and people would have access to the ships either through selected coastal ports hardened for use shortly after an event or by helicopter. Mobility from the ports to major population centers along the coast and inland would be achieved via hardened portions of U.S. 101 and selected local roads and streets.

The backbone highway system and seven airports are considered high priorities and should be made resilient within 10 years. The high-priority airports include:

- Redmond
- Portland International
- Salem
- Eugene
- Roseburg
- Medford
- Klamath Falls

Tier-1, Phase-2 Highway Lifeline Routes include segments of the coast highway (U.S. 101) and three highway segments connecting U.S. 101 to I-5. These segments should be considered moderate priorities as part of the multimodal transportation system. Airports designated as moderate priorities (to be hardened within 20 years) include:

- Scappoose/Hillsboro (one of these)
- Tillamook
- Siletz Bay (Lincoln City)

- Newport
- Florence
- Cape Blanco
- Brookings

North Bend and Astoria airports are very vulnerable, because they are both likely to be under water following a Cascadia subduction zone earthquake and tsunami. Both airports, however, may be potential recovery hubs due to the presence of the Coast Guard there. Unless the North Bend and Astoria/Warrenton facilities are completely destroyed, the Coast Guard intends to establish field facilities (tents/trailers) and begin operating those facilities as soon as possible after the event. (Airfields, which are unusable by fixed wing airplanes, may still be completely functional for helicopters as soon as the water recedes).

RAIL LINES

The task group considered the utility of rail lines in order to provide some redundancy to the basic backbone system, although nearly all the rail infrastructure predates modern seismic engineering standards. Rail lines into Redmond are considered a high priority, because Redmond is the hub for air transportation. The high priority mainline from Klamath Falls to Chemult is shared by BNSF Railway (formerly the Burlington Northern and Santa Fe Railroad) and UP (Union Pacific Railroad). The high priority BNSF mainline continues from Chemult to the Columbia River just west of Biggs. The UP mainline along the south side of the Columbia River from Portland to Idaho is also considered to be a high priority. The UP mainline from Chemult to Eugene and paralleling I-5 all the way to Portland is considered a moderate priority, because it is assumed that the cost of making the section through the Cascade Range resilient is very high.

All rail routes from the Willamette Valley to the coast are moderate to low priorities due to their vulnerabilities. The Coos Bay line could be functional to Reedsport after a Cascadia subduction zone event; but it is unlikely to be functional all the way to Coos Bay. The Tillamook line has been out of service since December 2007, with no plan for repairs. In general, short-line routes do not look very resilient, as they have not been built to current standards. There is very little rail redundancy outside of the Willamette Valley.

COASTAL AND RIVER PORTS

River and coastal ports are considered to be both part of a redundant system (in relation to the basic backbone system) and, in some cases, the primary access for specific areas. The task group considered it important to take into account the capabilities of the maritime industries, the Navy/Marine Corps, and the Coast Guard to bring in supplies by sea and distribute them to the state via air. The task group noted that this was done very effectively in Haiti.

River Ports

The Port of Portland has a very large capacity for handling supplies and is considered to be a major focus for restoring the economy after a seismic event. This port will be doing selective strengthening in the near future. The following upriver ports could provide significant supply links, although their levels of vulnerability and the vulnerability of the intervening locks still need to be confirmed:

- Arlington
- Morrow
- The Dalles
- Cascade Locks
- Umatilla

In addition, it was noted that the Port of St. Helens has a significant commodities capacity.

Locks are not designed to current seismic standards. In addition, seismic standards for locks are lower than for other structures. Seismic resistance is not an element of current evaluations conducted on river locks.

The overall plan needs to include a resilience evaluation of the Columbia River channel:

- An event could modify the channel's shape such that some larger vessels may not be able to navigate the river following an event.
- Dredging will likely be needed to restore the shipping channel following an event.
- Bridge failures could block the river for a period of time.
- The failure of dams or locks could block river navigation for an extended period of time.
- Elevation changes, subsidence, and other morphological changes could result in permanent changes to channels.

Coastal Ports

Coastal ports may be a significant lifeline for selected communities along U.S. 101. Immediately after a Cascadia subduction zone event, the coastal ports are not expected to be usable without some level of reconstruction. A detailed study is needed to determine whether there are practical ways to harden coastal ports so that they can be quickly restored and rendered operational. There is a study underway concerning identification of potential beach landing sites for naval vessels that would not require port facilities. The most practical solution may be to stockpile key resources at coastal locations. Such resources would include:

- Bailey bridges.
- Floating docks.

- Dredging equipment.

The task group recognized that storage of resources can be expensive, and consideration of deterioration and maintenance may lower the desirability of this option. Maintaining contingency contracts with local contractors who have the ability to repair structures or install temporary structures is considered a best practice.

Key roads are also needed to support port activity. Most of these connections are local agency routes that are considered to be the same level of priority as the coastal ports.

OTHER CONSIDERATIONS

- One of the issues that arose as the task group considered interdependencies is the lack of direct correlation between the modes. For example, air and water transport generally have definite take-off and landing points, although helicopters and beach landing craft can significantly extend the range of those modes to nonconventional landing areas. The highway system, on the other hand, has innumerable connections and no prescribed end points.
- Focusing simply on hardening the Phase 1 routes of OSLR Tier 1 will not ensure highway access to many coastal communities. If coastal communities are served primarily by air after an event, we would still need to consider local route resilience to make the most of the air corridors.
- The overall plan needs to take into consideration the potential for partial or complete failure of dams. Potential impacts and consequences of a failure could be extremely serious for rescue and recovery.

Alternate Routes

Selected local agencies were asked to assess the condition of their roads and streets in order to propose local bypasses (alternate routes) for the designated lifeline routes of the state highway system. The objective was to identify the places where the use of the local highway may be a more cost effective or practical means of making the transportation network resilient. Some examples are listed below.

- Klamath County proposed an 11-mile bypass of U.S. 97. This segment avoids the rockfall area north of Klamath Falls. Although this rockfall risk would be critical during an earthquake, the fallen rocks could be moved quickly out of the way shortly after the event. Moreover, the proposed bypass has liquefaction risk. The main north-south railroad is also next to the slide area. Because this railroad segment will be a Tier 1 facility, protection measures need to be planned. Such a protection scheme will likely protect both the highway and the railroad.
- Astoria suggested a route that runs parallel to U.S. 101 and bypasses Young's Bay Bridge. This parallel route has a few smaller bridges, would cost less to retrofit, and is at a higher elevation (no tsunami threat).

- Tillamook County noted an alternate route that parallels U.S. 101. This county route has small bridges and one major bridge, which is scheduled to be replaced in 2015. Connections to the airport and hospital would also need to be added.
- Albany suggested alternate north-south and east-west routes. The east-west route also connects to the hospital.
- Portland proposed priority local routes to hospitals, their lifeline routes on arterials connecting to the state highway lifeline routes, and connections to fuel depots.

Several other proposed local alternative routes are included in the ***Local Agency Alternatives to State Highway Lifeline Routes (http://www.oregon.gov/ODOT/HWY/BRIDGE/docs/laashlr.pdf)***, a supplement to this Report. These routes will be studied at a later time as possible alternatives to state highway lifeline routes.

Public Transit

As noted earlier in this chapter, public transit agencies could play an important role in helping Oregon recover from a major natural disaster. The overall plan should therefore include funds to inventory public transit facilities and rolling stock (both inside and outside the projected impact areas) and to coordinate the integration of public transit into local and regional emergency relief and business recovery planning, including the development of mutual aid agreements where appropriate.

TRANSPORTATION INTERDEPENDENCY SUMMARY

The task group determined that no single transportation mode can be feasibly retrofitted to provide adequate mobility after a major Cascadia event for all areas of the state. A plan for strengthening particular components of each mode—to provide a combination of highway, air, rail, water ports, and local access roads—was developed that offers a cost effective strategy to increase mobility in incremental steps.

Recommendations

Recommendations for improving the resilience of transportation are based on the assumption that incremental improvements will be made over a 50-year timeframe. Phased investments to improve mobility are envisioned in order of priority and were chosen to best leverage cross modal improvements that will facilitate movement of goods and people on a multimodal transportation system. The recommended approach is to establish redundancy by routing people, supplies, and services from the east by air from Redmond Municipal Airport to hardened airports in the Willamette Valley, and by highway along I-84 and OR 58 to I-5 in the Willamette Valley to areas accessible by highways, and then by helicopter to isolated areas. Concurrently, people, supplies, and services would be able to travel from the sea through selected ports and then along portions of U.S. 101 or by helicopter to isolated areas.

Recommendations are presented for short-term goals and long-term goals.

SHORT-TERM RECOMMENDATIONS

- **Complete an updated inventory of local agency transit, port, and rail assets (such as service buildings, buses, vans, fuel supplies, communications equipment, repair facilities, and human resources, including identifying the needs of vulnerable and at-risk clients), assuring access to school buildings and hospitals, which could be used during emergencies.**
- **Complete a statewide evaluation, assessment, and gap analysis of:**
  - Local agency roads and streets, including public transit. (Define the roles of local agencies, transit, port, and railroads in resilience planning and assessment of alternate routes.)
  - Coastal and river port facilities, including jetties and breakwaters, the Columbia River channel (103.5 miles long, 43 feet deep, 600 feet wide), the levee system, dams and locks, port entrance channels, pile dikes, and specifically, Port of Portland facilities (including access to and the vulnerability of the four terminals that are interdependent with two rail lines, the river barge system, and two interstate highways) and the liquefaction vulnerability at Portland International Airport (PDX).
  - Railroads—specifically, the UPRR (Willamette Valley) and BNSF (Central Oregon) trunk north-south rail lines and three railroad short lines (Astoria District, Albany-Toledo, and CBRL) with access to coastal communities.
  - Ninety-seven public-use airports.
- **Encourage Federal agencies, such as USCG and the Corps of Engineers, to complete an assessment and gap analysis of Federal facilities that support transportation resilient planning.**
- **Develop a mitigation policy and retrofit plan for the assets and service facilities of vulnerable bridges, including all co-located utilities (such as power, communication, gas, water, and wastewater lines); rockfalls and unstable slopes; the 29 airports listed in the airport section of Chapter 5; river and coastal ports; the Columbia River channel, including emergency re-dredging options; local roads, streets, and transit; rail (on a corridor basis along the critical trunk and regional segments); and intermodal connections. Identify Redmond Municipal Airport (Roberts Field) as a key distribution point for other airports, and harden it as necessary so it will be operational after a major event; identify coastal and river ports or heliports as redundant access from ships stationed off shore for medical facilities and delivery of supplies from out of state, and the Columbia River as a priority with continued dredging. Encourage the development of formal cooperative assistance agreements with local agencies, nearby transit providers, rail providers, ports, and highway agencies.**
- **Continue to refine and gain consensus for the strategy contained in the interdependency section of Chapter 5 to optimize the recommendations for an incremental program for achieving resilience in western Oregon and to provide service to coastal areas and other potentially isolated areas with a combination of air, ports, regional rail, and highway segments, including**

consideration of the following airports and water transportation as the redundant first line of operational sites supporting lifeline highways:

- Redmond Municipal Airport
- Portland International Airport
- Salem Airport
- Eugene Airport
- Roseburg Airport
- Medford Airport
- Klamath Falls Airport
- Scappoose/Hillsboro Airport (one of these)
- Tillamook Airport
- Siletz Bay Airport (Lincoln City)
- Newport Airport
- Florence Airport
- Cape Blanco Airport
- Brookings Airport
- Selected Coastal and River Ports
- Columbia River Channel

► **Enhance the proposed Highway Lifeline Maps by considering the use of highway segments owned by cities and counties to provide access to critical facilities. Prioritize local routes to provide access to population centers and critical facilities from the identified Tier-1 routes. When developing projects for seismic retrofit of highway facilities, consider whether a local agency roadway may offer a more cost effective alternative for all or part of a lifeline route.**

LONG-TERM RECOMMENDATIONS

► **Enhance design and maintenance standards and requirements for bridges and unstable slopes, transit, rail, ports, and airfields based on the priority of a lifeline route.**

► **Develop a temporary bridge installation policy and standards, including an assessment of the number of temporary bridges or amount of temporary bridge materials to stockpile for emergency use. Coordinate with the DOTs of neighboring states to create an inventory of (portable, temporary) Bailey bridges that includes notes on their locations and transportation methods. Consider procurement of additional temporary bridge materials.**

► **Support research on retrofit methods and strategies for Cascadia subduction zone earthquake loads. Support research on tsunami effects, and develop a design policy for tsunami loads.**

6. Energy

Introduction

The Pacific Northwest has a high likelihood of a magnitude 9.0 earthquake on the Cascadia subduction zone, which would produce minutes of strong ground shaking, coastal subsidence, landslides, liquefaction, lateral spreads, and a coastal tsunami. Seismic provisions in Oregon's building codes were first explicitly adopted in 1993. In contrast, Oregon's critical energy infrastructure (CEI) is not governed by a uniform set of design and construction codes. Much of the existing CEI has been constructed with seismic design deficiencies. To minimize extensive direct earthquake damage, indirect losses, and possible ripple effects, substantial improvements to the critical energy infrastructure are necessary.

GOAL

The goal of the Energy Task Group is to provide policy recommendations to the state legislature to make Oregon's critical energy infrastructure more resilient against a Cascadia subduction zone earthquake and tsunami within 50 years.

WHAT DOES BEING RESILIENT MEAN

The Oregon Seismic Safety Policy Advisory Commission (OSSPAC) has defined resilience as follows: "*Oregon citizens will not only be protected from life-threatening physical harm, but...because of risk reduction measures and pre-disaster planning, communities will recover more quickly and with less continuing vulnerability following a Cascadia subduction earthquake and tsunam*i."

SCENARIO

Because the impacts of the scenario M9.0 subduction zone earthquake and tsunami will vary depending on location, the steering committee recommended that, for the purposes of this study, the state be divided into separate regions. In addition to the tsunami, significant levels of shaking are expected, which will lessen in intensity the further one is from the coast.

The Energy Task Group adopted the following impact regions within Oregon, as recommended by the steering committee for all sectors:

- Coast/Tsunami Region: This is the part of the Oregon coast that is in or adjacent to the projected tsunami inundation zone.
- Coast/Seismic Region (earthquake-only): This is the part of the Oregon coast that is outside the tsunami inundation zone, but likely to experience peak ground acceleration (g) from .3 to .45.
- Willamette Valley Region: This region is likely to experience peak ground acceleration (g) from .15 to .3.

- Eastern Oregon Region: This region is likely to experience peak ground acceleration (g) from .01 to .15.

HISTORY

Over the course of the past five years, the Oregon Department of Geology and Mineral Industries (DOGAMI), the Oregon Public Utility Commission (OPUC), and the Oregon Department of Energy (ODOE) have been promoting awareness of the seismic vulnerabilities of Oregon's critical energy infrastructure by communicating with local, state, and federal government officials, energy operators, Oregon citizens, and the media through high profile activities, such as the following:

- April 2, 2007—Conducted a full-day leadership forum and workshop on the seismic readiness of critical energy infrastructure. This event was held at the OPUC's Main Hearing Room. The goal was to promote the importance of seismic vulnerability studies of critical energy infrastructures to utilities' executives and senior engineers, bringing together speakers from across the United States with expert knowledge on seismic readiness. The workshop addressed four critical areas:
    - Cascadia earthquake hazards and risk
    - Critical energy infrastructure vulnerability to earthquake damage
    - State-of-practice lifeline seismic vulnerability studies and application
    - Case studies of vulnerability studies by BPA and Pacific Gas and Electric (PG&E)
- August 21, 2007—The OSSPAC chairman sent a letter (based on input from DOGAMI and the OPUC) to Governor Kulongoski and members of the legislative assembly. The letter, which emphasized the urgent need to ensure the reliability of energy in earthquakes, addressed several key points:
    - Restoration of electricity and gas after a localized earthquake event are likely to be addressed relatively quickly, depending on the level of damage, with support for response coming from the region and potentially from across state borders.
    - Because of the potentially catastrophic impacts to critical energy infrastructures, the restoration of the energy sector after a Cascadia subduction zone earthquake is expected to take much longer should it occur today. The initial and immediate response, such as obtaining emergency generators for critical facilities, will likely require assistance from the Oregon National Guard and from other states.
    - The critical element of educating Oregonians on their level of responsibility should ideally be done in cooperation with the other West Coast states and the Canadian province of British Columbia so that everyone affected will be receiving the same information on how to be self-sustaining. Without exception, everyone on the West Coast will be assuming more responsibility (public, private, personal), so the better informed and educated people are, the more responsive everyone will be when the need to help each other arises.

- The letter also recommended that the governor take three immediate actions:
  - Oregon needs to mobilize on vulnerability assessments of pre-disaster inventories and systems.
  - Oregon needs to form cooperative agreements (by a specified timeframe) with other states before the earthquake disaster. These states should include Idaho, Utah, and others east of Oregon. Agreements should include the Oregon PUC. Note that making arrangements after the disaster would be inefficient. It is appropriate to acknowledge that the natural gas and electric IOUs and many COUs already have mutual aid agreements in place with other operators, some well outside the potentially affected areas.
  - Proactive education is needed for families and individuals; this should include instructions to be self-sustaining for weeks or months (not days). Without personal preparedness, local and state agencies and private companies alike will not have the personnel/staff they need to meet the multitude of demands involved in emergency response.
- August 26, 2009—ODOE, DOGAMI, and OPUC, via a hazard mitigation grant, conducted a Seismic Event Tabletop Exercise with most energy and fuel operators in the northwest industrial area of Portland (on the Willamette River). About five miles of the riverfront in this area near the St. Johns Bridge includes a concentration of critically important infrastructure on very poor soils that are highly susceptible to earthquake-induced permanent ground deformation. The purpose of the exercise was to promote awareness and resilience of critical energy infrastructures in Oregon. The outcomes were used to better understand the risk associated with earthquake hazards, and findings were shared with city and state leaders. One result of the exercise was to increase the urgency of taking immediate pre-disaster mitigation steps, preparing to take additional steps in the future, and improving planning for future disasters. Another result was a proposal to advance the seismic portion of the OPUC safety and reliability audits by specifying requirements for seismic vulnerability assessments. This work provided the basis for the Energy Assurance Plan Grant with NASEO.

- January 04, 2010—ODOE in partnership with OPUC and DOGAMI (Team) applied for the Energy Assurance Program (EAP) Initiative sponsored by the National Association of State Energy Offices (NASEO). The grant program required completion of the EAP within three years. The Oregon EAP was completed this past June (Wang et al., 2012). The main goal of establishing an Energy Assurance Plan for Oregon was to help all stakeholders make the state of Oregon resilient against any major incident, catastrophic or otherwise, so that Oregon will not go for long periods of time without the proper energy supply to meet its needs. In the application process, the Team identified the Cascadia subduction zone earthquake as the most severe catastrophic event Oregon will experience. With this perspective, the Team focused its attention

on the most vulnerable energy area in our state, which was identified in the Hazard Mitigation Grant Tabletop Exercise, addressed above.

The Energy Assurance Plan and Oregon's Critical Energy Infrastructure Hub

The Energy Assurance Plan (EAP) (Wang et al., 2012) has become the main plan for our state, and even though it is focused primarily in the NW Industrial area of Portland along the Willamette river (CEI Hub), its findings and recommendations are applicable throughout the state's western region. It is also appropriate to acknowledge that the EAP work has been the driving force behind the Energy Task Group in its pursuit of policy recommendations to make our critical energy infrastructures resilient against a Cascadia subduction zone earthquake. Six magnitude 5.0 or greater earthquakes have occurred within the Portland metropolitan area in the past 150 years. The Cascadia subduction zone has produced more than 40 large magnitude earthquakes in the past 10,000 years. The most recent, which occurred on January 26, 1700, was an estimated magnitude 9.0. These occurrences and extensive scientific understanding of seismic processes indicate that it is highly likely that a Cascadia subduction zone earthquake will strike the region again.

Figure 6.1: Fuel tank farms and marine terminals along the Willamette River's edge near US Highway 30. For geographic reference to Figures 29 and 31, note the three parallel water inlets (Basemap: Google Earth)

Oregon's critical energy infrastructure hub (CEI Hub) covers a six-mile stretch on the lower Willamette River between the southern tip of Sauvie Island and the Fremont Bridge on U.S. Highway 30. This relatively small area in Portland is the site of liquid fuel, natural gas, and electrical infrastructure and facilities; it is also an area with significant seismic hazard. The energy sector facilities in the CEI Hub include:

- All of Oregon's major liquid fuel port terminals.
- Liquid fuel transmission pipelines and transfer stations.
- Natural gas transmission pipelines.
- A liquefied natural gas storage facility.
- High voltage electric substations and transmission lines.
- Electrical substations for local distribution.

More than 90 percent of Oregon's refined petroleum products come from the Puget Sound area of Washington State. Oregon imports the liquid fuel by pipeline and marine vessels; it passes through the CEI Hub before it is distributed throughout Oregon to the end users. (One large consumer is the Portland International Airport.) In addition, a portion of the state's natural gas fuel supply passes through the CEI Hub; and a high voltage electrical transmission corridor both crosses the area and supplies power to it.

Figure 6.2: Site Map of the Critical Energy Infrastructure (CEI) Hub on the western bank of the Lower Willamette River area in NW Portland, Oregon. The CEI Hub, outlined in red, stretches for six miles. (Google Earth)

EARTHQUAKE RISK STUDY FOR THE CRITICAL ENERGY INFRASTRUCTURE HUB

The Oregon Department of Geology and Mineral Industries (DOGAMI) conducted an earthquake risk study on Oregon's CEI Hub as part of the Oregon Energy Assurance Project (EAP) with the Oregon Department of Energy (ODOE) and Public Utility Commission of Oregon (OPUC). The study focuses on a large-magnitude Cascadia earthquake, which, because of widespread shaking and vulnerable infrastructure, poses a high risk to the health and safety of Oregonians and the region's economy. The study identifies and defines the CEI Hub area, assesses the seismic hazards, and identifies the vulnerabilities of the petroleum (liquid fuel), natural gas, and electrical energy facilities in the CEI Hub.

Oregon's Natural Hazards

Oregon has numerous natural hazards. These range from high probability (fires) to low probability (volcanic eruptions). Earthquakes are considered to have a moderate probability because earthquakes in Oregon are rare. The earthquake vulnerability score for Oregon, however, is very high because a portion of Oregon's existing infrastructure has been designed and constructed without seismic resistance considerations. The earthquake consequence score is also very high because damage will likely be widespread and, in many places, severe. Finally, the earthquake overall risk score is very high because when a major earthquake occurs, it may result in loss of life, economic damages, and long-term impacts.

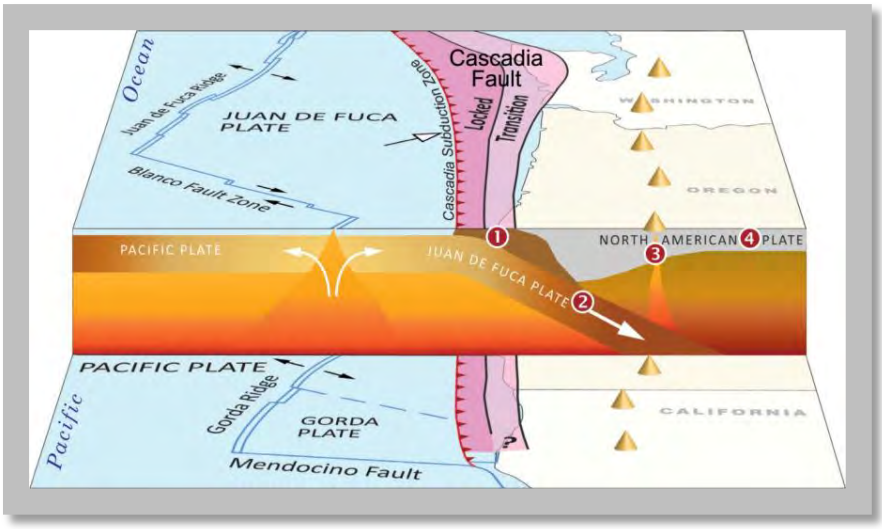

Figure 6.4: Cascadia seismic source is Oregon's most threatening fault and can produce a magnitude 9 earthquake and accompanying coastal tsunami waves. (Source: DOGAMI)

Potential Effects of an Earthquake

A portion of Oregon's electricity and natural gas infrastructure, as well as a majority of its fuel oil infrastructure, is concentrated in the CEI Hub. A magnitude 8 or 9 Cascadia subduction zone earthquake would impact the CEI Hub with:

- Ground shaking
- Liquefaction (a phenomenon in which a water-saturated soil, such as sand, softens and loses strength during strong earthquake ground shaking)
- Lateral spreading (where layers of soil at the surface of the land permanently move laterally due to earthquake shaking)
- Landslides
- Co-seismic settlement (where the ground surface is permanently lowered due to seismic shaking)
- Bearing capacity failures (when the foundation soil cannot support the structure it is intended to support)

In addition, secondary seismic hazards could be initiated. These include:

- Seiches (waves that oscillate in water bodies; such waves are often initiated by ground shaking)
- Fire
- Hazardous material releases (including by sloshing of liquid agitated by ground shaking)

- Tsunamis (Tsunami waves are expected to damage coastal areas, including ports along the coast and Columbia River mouth, but are not expected to cause significant damage in Portland's waterways.)

Liquefaction and lateral spreading hazards are of primary concern to the oil terminals that handle Oregon's liquid fuel supply. The CEI Hub is adjacent to the Willamette River and has extensive deposits of highly liquefiable soils. These soils (made of sands, silts, gravels, and clays) have been deposited both by natural river activity and by human activities, such as the hydraulic placement of material dredged from the river or debris deposited as landfill. For this reason, DOGAMI performed ground deformation analyses to better understand the nature of the hazard and the possible mitigation that will be needed to address it. A section on the deformation analyses is included in this study.

Energy Facilities in the CEI Hub

DOGAMI staff and others visited all relevant energy companies with facilities in the CEI Hub. DOGAMI and ODOE staff conducted site visits at these petroleum facilities: BP, Chevron, ConocoPhillips, KinderMorgan (KM) fuel terminals and pipeline, McCall Oil, Nustar, and Shell. The liquid fuel facilities often include transmission and distribution pipelines, piers or wharves, tank farms, loading racks, control buildings, electrical distribution equipment, and many other components. The liquid fuel transmission system includes gate stations and transmission and distribution pipes at the Columbia and Willamette river crossings. DOGAMI and OPUC staff also conducted site visits of natural gas and electrical facilities owned by NW Natural, Portland General Electric, and the Bonneville Power Administration (BPA).

General Findings

The CEI Hub facilities have infrastructure that ranges from about 100-years–old and built to no or very antiquated standards to new infrastructure built to the current state-of-practice standards. Because of the wide range of ages and associated construction practices, the seismic vulnerability of the facilities also spans a wide range. Based on visual observations, engineering judgment, and information from facility operators, major seismic vulnerabilities exist in the CEI Hub. The vast majority of the facilities are constructed on soils susceptible to liquefaction. Some critically important structures appear to be susceptible to significant damage in a major earthquake, while structures that were installed more recently are expected to have better seismic performance. In addition, DOGAMI discovered that older building codes and practices did not adequately address many non-building structures that exist in the CEI Hub, such as tanks, pipes, and piers. Current building codes do not adequately address the seismic deficiencies in existing CEI Hub facilities.

Sector Specific Findings

- Liquid Fuel
    - *Liquid fuel pipeline:* The CEI Hub's petroleum facilities receive liquid fuel via two methods: 1) the liquid fuel transmission pipeline and 2) marine vessels. The

transportation method and amounts vary due to product demand, transportation costs, weather, and other conditions. The liquid fuel pipeline was largely constructed in the 1960s when the regional seismic hazards were unknown and state-of-practice construction techniques did not include any reference to seismic standards. The regional seismic hazards are now known to be significant, and the soils at the river crossings are known to be susceptible to liquefaction and lateral spreading. The 1960s vintage pipeline design did not consider ground movements from lateral spreading at river crossings or other earthquake-induced stresses on the pipelines that may cause damage and multiple breaks. A break in the pipe would have a significant impact on all of the petrochemical facilities in the CEI Hub and could result in a statewide fuel shortage.

- *Liquid fuel supply:* Liquefaction vulnerabilities are known to have been addressed in the case of only three existing tanks. The tank farms in the fuel terminals of the CEI Hub have on average a three- to five-day supply of regular unleaded gasoline and diesel fuel. Premium gasoline is subject to daily delivery and is heavily dependent on whether the intercompany pipeline on Front Avenue is operational. If the supply chain is disrupted by pipe breaks north of the CEI Hub and by closure of the shipping channel to the west, fuel would quickly become scarce. Options to transport fuel from the east and south and by air are very limited.

- *Shipping channel:* The navigational channel from the mouth of the Columbia River to the lower Willamette River is used by marine vessels to transport fuel. The mouth of the Columbia River is expected to have tsunami damage, and the channel is expected to experience slope failure, which would close the channel to traffic. It is possible that bridges and other overhead river crossings would also be damaged and could temporarily block the waterway. Closure of the shipping channel would prevent marine vessels from delivering either liquid fuel or emergency response and recovery equipment.

- *Marine terminals:* All of the port facilities in the CEI Hub have significant seismic risks due to liquefaction, lateral spreading, and seiches. Some older piers were constructed without any seismic protection, have deteriorated, and are likely to fail even in a moderate earthquake. If oil products are released and contaminate the navigable waterway, the waterway may be closed to river traffic, thus impeding emergency response activities as well as the supply chain. The local capacity to fight fires and clean up hazardous material spills is limited.

- *Portland International Airport (PDX):* PDX airport receives 100 percent of its liquid fuels from a terminal in the CEI Hub. The airport has a limited on-site fuel supply. If the pipeline between the CEI Hub and the airport fails, then the airport would likely experience a shortfall, and operations would be impacted.

Figure 6.5 Lateral timber bracing for steel plumb piles in the CEI Hub is considered inadequate by California's MOTEMS standards. (DOGAMI photo)

Figure 6.6: An example of a damaged pier in the 2010 Chile earthquake (ASCE Technical Council on Lifeline Earthquake Engineering – TCLEE, 2010)

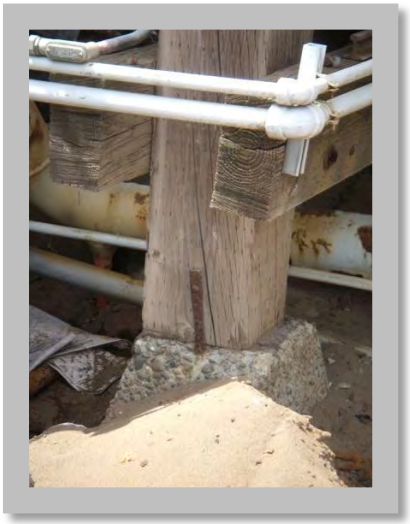

Figure 6.7 and 6.8: This under-designed oil terminal pier foundation (left) in area with high susceptibility for liquefaction and lateral spreading in the CEI Hub and the poor timber-to-concrete oil terminal pier connection and exposed rebar foundation (right) in the CEI Hub are considered inadequate (Source: DOGAMI photo)

Figure 6.9: The connection on this pier in the CEI Hub appears to have deteriorated due to a split in the timber beam. This type of damage suggests that the condition of the structure may not be routinely monitored and maintained and that the overall pier is seismically vulnerable (Source: DOGAMI photo)

Figure 6.10: The approach (foreground) to the 1966 Astoria-Megler Bridge that spans the Columbia River has major structural deficiencies that could lead to a collapse following an earthquake. Damaged bridge sections could block waterway access to the CEI Hub. (DOGAMI photo)

- Natural Gas. Oregon's largest natural gas service provider receives the majority of its natural gas from pipelines that cross under the Columbia River near St. Helens, Sauvie Island, and also between Washougal, Washington, and Troutdale, Oregon. One of the natural gas pipelines crosses under the Multnomah Channel near the gate station at the southern end of Sauvie Island. The soils at these river crossings are subject to liquefaction and lateral spreading, and the pipes are of 1960s vintage. However, natural gas pipelines constructed after the mid-1950s have been found to perform very well during significant seismic events. Oregon's largest natural gas

supplier has the strategic advantage of on-system storage (within the company's service territory), which would allow the company to provide natural gas service to unaffected customers while any damaged natural gas pipelines supplying the area are being restored.

- Electricity
    - Electrical facilities and systems have significant seismic risk due to ground shaking and ground failure, including liquefaction and lateral spreading. Seismically vulnerable facilities include substations and transmission lines in the CEI Hub as well as facilities outside of the CEI Hub, including power plants, substations, and transmission lines, all of which are important for distribution. Major vulnerabilities in the CEI Hub include the control buildings, transformers, and other electrical equipment in yards at the substations, and transmission towers near the Willamette River. Damage is likely to occur to both the transmission system and the distribution system in the CEI Hub. Damage to the electrical grid will likely result in a blackout in the CEI Hub and elsewhere.

Findings of the Bonneville Power Administration

Bonneville Power Administration (BPA) has conducted a comprehensive seismic vulnerability study of their system and has had a long-term seismic mitigation program in place since 1993. This program includes:

- Investment protection (e.g. anchoring transformers).
- Power system recovery of critical paths (e.g. hardening of equipment at one of multiple bays within a major substation).

The first phase of BPA's mitigation program includes bracing and restraining critical equipment and seismically upgrading critical building facilities west of the Cascade Range. Seismic strengthening in the substation yard would typically include: anchoring high-voltage power transformers, bracing transformer conservators and radiators, replacing seismically vulnerable live tank circuit breakers with more robust dead tank circuit breakers, adding damping systems to existing live tank circuit breakers, hardening transformer bushing storage facilities, and replacing rigid bus connections with flexible bus. These mitigation techniques will improve the reliability of seismic performance. Additional phases of the seismic mitigation program will include facilities east of the Cascade Range.

BPA has a critical 115 kV and 230 kV high voltage transmission river-crossing in the CEI Hub as well as a substation. At the substation in the CEI Hub, some of the high-voltage equipment had been anchored and braced to withstand earthquake motions. BPA is in the process of conducting seismic strengthening of the control building and equipment inside the control building (for example, bracing computer floors, control cabinets, battery racks, ceilings, and pipes) and additional mitigation in the yard. BPA has conducted subsurface, liquefaction and lateral spreading analyses at one of the transmission tower sites at the Willamette River crossing and has concluded that severe ground movement (up to 25 feet)

towards the river channel is possible. Until mitigated, it is likely that at least two transmission towers would experience extensive damage, be inoperable, and require repair or replacement; and power lines could temporarily block river traffic, including the pathway to the oil terminals. The BPA transmission towers at the Willamette River crossing are scheduled to be seismically analyzed, to have a seismic mitigation design completed in 2013, and to be mitigated by 2014.

Recent unpublished BPA Cascadia earthquake scenario studies of the existing transmission line system indicate that BPA's main grid would require between 7 and 51 days for completion of emergency damage repairs to the transmission line system (Oregon and Washington) after a magnitude 9.0 Cascadia earthquake. This scenario assumes many ideal conditions (for example, that BPA employees and contractor resources are immediately available, all roads and bridges are passable, and sufficient fuel is available), which is optimistic.

Figure 6.11 and 6.12: Left: These high voltage electrical transmission towers are built on a river bank in the CEI Hub susceptible to lateral spreading. (DOGAMI photo) Right: Structural damage to a high voltage transmission tower located at a river crossing in 2010 Chile earthquake. (ASCE Technical Council on Lifeline Earthquake Engineering – TCLEE)

Impacts to Oregon

Based on visual observations, engineering judgment, limited analyses, information from the facility operators, city records, and available literature, significant seismic risk exists in the CEI Hub. Some critically important structures appear to be susceptible to substantial damage in a major earthquake—with catastrophic consequences. Breaks in liquid fuel and natural gas transmission pipes are possible. Damage to liquid fuel, natural gas, and electrical facilities in the CEI Hub is also possible. The waterway may be closed as a result of the damage and may need to be cleaned up before it can be reopened.

Due to the existing seismic hazards, the vulnerability of the exposed infrastructure, and the potential consequences of an earthquake given both these factors, Cascadia earthquakes pose substantial risk to the CEI Hub and to Oregon. Not only are the energy sector facilities in the CEI Hub dependent on other sectors and systems in Oregon, including transportation and communication, they are interdependent

upon each other. A major Cascadia earthquake and tsunami would likely produce impacts larger than any event the state has previously faced. Western Oregon may face a temporary electrical blackout, isolated natural gas service outages, and liquid fuel shortages. Mitigating the risk that a future major Cascadia earthquake poses to the energy sector can lessen energy infrastructure damage and enable faster recovery of services to support other critical lifeline services.

OPERATOR EFFORTS TO PREPARE FOR A CASCADIA SUBDUCTION ZONE EVENT

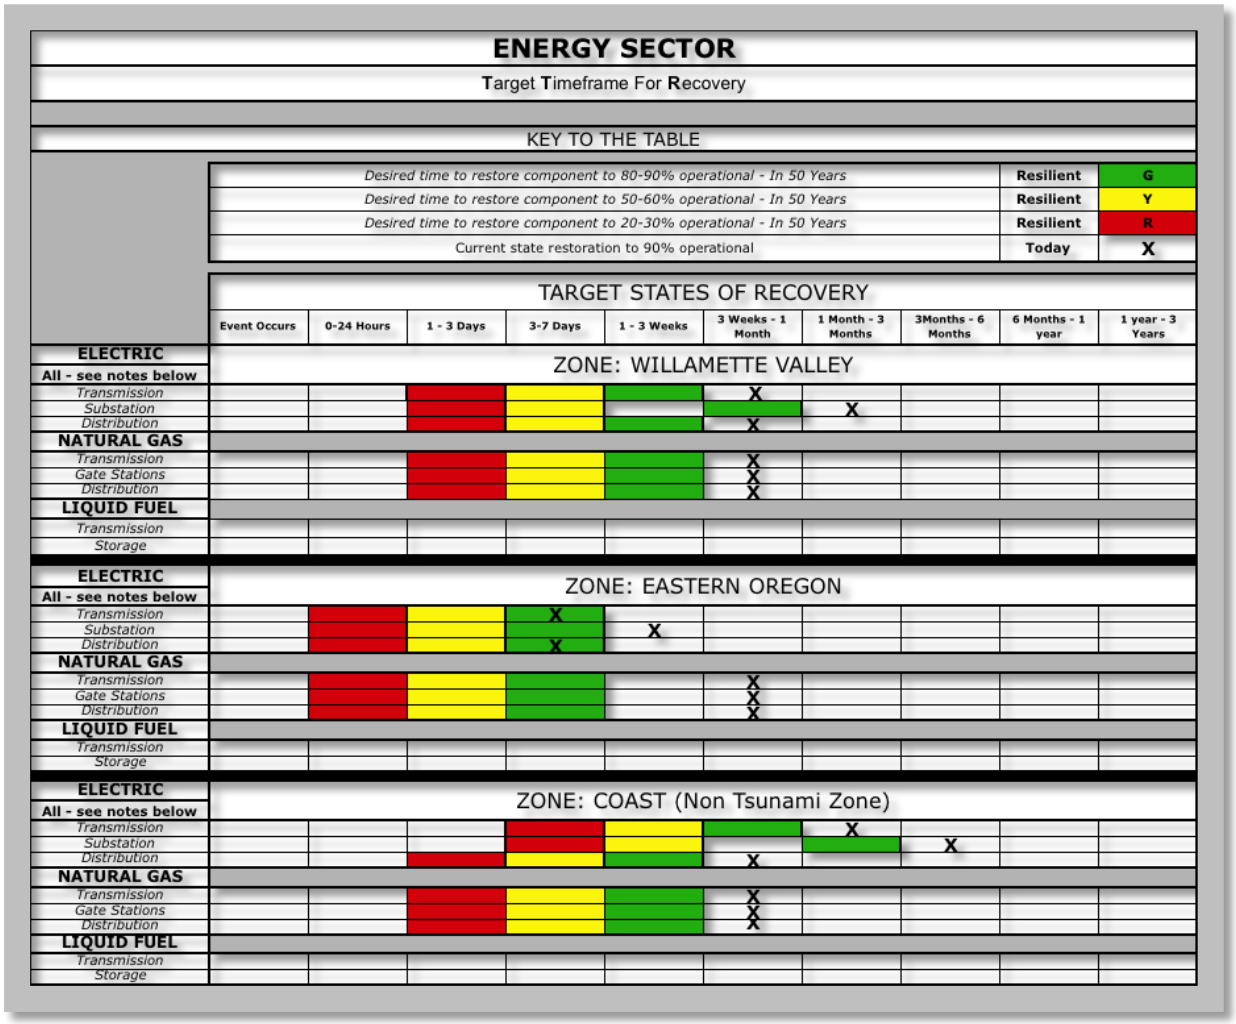
For decades, the energy sector has recognized the need to prepare its systems for seismic events and other disasters that could have an impact on customers, and energy operators have made progress toward improving their resilience to a major seismic event. Operators are constantly updating and replacing their energy infrastructure, and in the process of replacement, they upgrade the new facilities to current design standards.

Energy providers comply with federal standards and regulations related to the siting, design, construction, and safe operation of infrastructure to make sure that risks, such as earthquakes, are evaluated and addressed as necessary to ensure the safe and reliable operation of the electrical grid and interstate and intrastate natural gas pipelines. At the state level, the providers of those utilities regulated by the Public Utility Commission of Oregon meet on a regular basis to provide updates to regulators regarding their preparations for disasters and response and to continually evaluate how they can improve and strengthen energy systems.

Within the energy sector, the operators improve their approach to building resilient systems by participating in professional organizations that set the industry's standards and address risk evaluation. Further benefits are gained from interaction with companies that have experienced low frequency, high impact events, such as earthquakes, because these companies are able to share tactics that proved to be beneficial in preparing and recovering from such events. Moreover, the operators have entered into mutual aid agreements with other energy providers outside the region. Such agreements will make it possible to mobilize significant quantities of skilled personnel and materials to support the response to a major natural forces disaster. Finally, on an ongoing basis, the operators have built internal planning processes to ensure an orderly and effective response to any event that significantly disrupts business operations. These actions are significant and have made the energy sector better prepared to respond to major events today than it was previously.

Over the past 25 years, NW Natural has implemented an aggressive, enhanced pipeline safety program to replace older infrastructure that may not be as resilient to a Cascadia subduction zone event. The company completed the replacement of all cast iron pipe in 2000 and will complete the replacement of its bare steel piping infrastructure in the near future. The current underground piping systems have a high level of ductility (flexibility) which allows the pipe to perform well in a seismic event. Since 2002, the company has implemented new Integrity Management Programs for its transmission and distribution systems to address threats (including seismic events) to the safe and reliable operation of the pipelines.

Expected Service Restoration Time Frames



The expected service restoration time frames (see Figure 6.13) are based on the assumption that roads and telecommunications are functioning so as to support restoration of the energy infrastructure. In areas where service restoration is impractical, the service provider is not expected to meet the restoration timeframes. Establishing target timeframes for the tsunami inundation zone, beyond a minimal level of capability to support response, is not practical. For that reason the tsunami inundation region is not depicted in the matrix presented below. A large amount of planning and prioritizing will need to be undertaken to identify which areas will be rebuilt first.

Recommendations

- **The Oregon Public Utility Commission (OPUC) should provide oversight for the seismic preparedness of those energy providers that are currently jurisdictional.**
- **Develop regulatory oversight for energy sector companies that are not regulated by the OPUC and create engagement in seismic mitigation efforts for those companies, including appropriate cost recovery for such oversight function.**
- **The state should provide immunity of liability, in statute, for those seismic vulnerabilities that are identified by the operators during their seismic vulnerability assessments.**
- **To identify vulnerabilities of operator-defined Critical Energy Infrastructure (CEI) facilities, energy sector companies should conduct seismic vulnerability assessments. Operators should then develop plans to mitigate the seismic risks associated with the identified CEI vulnerabilities.**
- **Energy sector companies should institutionalize long-term seismic mitigation programs and should work with the appropriate oversight authority to further improve the resilience and operational reliability of their Critical Energy Infrastructure (CEI) facilities.**
- **Form a public-private partnership with the objective of reducing the state's vulnerability to seismic events by evaluating the diversification of locations for the storage of liquid fuels and identification of new liquid fuel energy corridors (new locations to be defined).**
- **The state of Oregon should require that, in emergency situations, liquid fuel wholesale and retail operators provide both access to and alternate means of delivering fuels to the end users.**
- **Evaluate the options for improving power supply to coastal areas located outside of the tsunami inundation zone.**
- **Utilize the Oregon Office of Emergency Management's public-private sector position to help ensure coordinated planning, information sharing, and interoperability among critical organizations and agencies. The position will also ensure that work being performed by this entity and its partners helps provide public education and outreach to local, county, and state agencies and organizations.**

► **The state of Oregon should provide statutory authority for a prescriptive waiver of routine permitting requirements and processes for the design, construction, and restoration of energy infrastructure and subsequent actions, if it is determined that the waiver is in the public interest and is necessary to address an actual or impending emergency caused by a natural or manmade disaster.**

Restoration Status Assumptions - Cascadia Subduction Zone Earthquake

1- Transportation routes including roads, airports, bridges, etc. will be available for energy provider use to perform assessments, deliver materials and rebuild infrastructure as required.

2- All fuel needs will be available to support energy provider restoration operations.

3- For areas dependent upon third party electric transmission providers, restoration times assume their system will be available to support restoration efforts.

4- Interstate gas transmission pipelines will be able to provide service in advance of the restoration times for local distribution.

5- Roseburg / Medford areas are included with Willamette Valley for evaluation purposes.

6- The % of restoration references it to customers who are able to take natural gas or electric service delivery.

7- Communication systems will be available for energy provider's use.

8- For Pacific Power the coastal service territory includes a combination of tsunami and non-tsunami prone areas. Where facilities provider service to non-tsunami prone areas pass through or reside in tsunami impact areas, the estimated impact of tsunami on these facilities is included in restoration times.

9- The State of Oregon has provided statutory relief and/ or waiver from typical permitting requirements and processes associated with the design, construction and/ or restoration of the energy infrastructure.

10- The bulk of generation is outside of the Willamitte Valley , so the focus is on the Transmission.

7. Information and Communications

Introduction

Oregon's information and communication systems are especially vulnerable to damage resulting from a Cascadia subduction zone earthquake. Some of the inherent seismic vulnerabilities of the systems include the following:

- The systems are highly dependent on other resources—such as power and transportation as well as skilled staff—to remain operational and to complete needed repairs.
- The systems are financially dependent on consistent revenue streams to fund ongoing operations, maintenance, and debt service obligations.
- Essential facilities, including central offices and towers, are often located in areas that make them vulnerable to damage from liquefaction of alluvial soils and landslides.
- Many facilities were designed and constructed before the seismic design standards that reflect the current state of knowledge of regional seismicity were established.

THE EXISTING STATE

If it were to occur today, a Cascadia subduction zone earthquake would result in catastrophic impacts to the information and communications systems throughout western Oregon:

The Oregon coast would most likely experience strong ground shaking for over three minutes. Facilities within the tsunami inundation zones would be extensively damaged; in many cases, they would not be repairable. Facilities outside of the tsunami zone would be heavily damaged, disrupting current levels of service for periods measured in months. Cabling that runs through conduits supported on or in transportation bridges is likely to be damaged or severed completely when the bridges fail.

The Coast Range would experience strong to moderate ground shaking. Well-engineered structures may perform well, but older structures are likely to fail. Major impacts to the systems in the Coast Range include the high potential for landslides and the failure of bridges that support cables across geological features.

The Willamette Valley would experience moderate ground shaking. Well-engineered structures may perform well, but many older structures would likely fail, including central offices and buildings supporting antennas. One of the major impacts in the central valley, especially in the Portland Metro area, would be from liquefaction: extensive alluvial and fill deposits along rivers would lose strength, lose bearing capacity, and move towards riverbanks. Liquefaction could adversely impact buried utilities as well as antenna towers and buildings.

THE SYSTEM'S COMPONENTS

The Information and Communication Technology Task Group focused on wireless and wired communications and information systems that provide services to businesses, municipalities, and individuals. For the purpose of this resilience plan, system components include:

- **Central Offices.** A switching unit, installed in a telephone system serving the general public, having the necessary equipment and operating arrangements for terminating and interconnecting lines and trunks (McGraw-Hill, 2003). Central offices include the following types:
    - *Tandem office:* A telephone office that makes connections between local offices in an area where there is such a high density of local offices that it would be uneconomical to make direct connections between them (McGraw-Hill, 2003).
    - *Local office:* A telephone central office, which terminates subscriber lines and makes connections with other central offices, usually equipped to serve 10,000 main telephones of its immediate community (McGraw-Hill, 2003).
    - *End office:* A telephone central office that connects directly to the customer (Answers.com).
- **Remote Terminals.** A remote terminal is generally any type of switching or routing equipment that is located outside of the traditional telephone central office. Most are linked by fiber optic cable either directly to the central office or to a SONET (Synchronous Optical NETwork). Some older remote terminals are linked by T1s back to the central office over copper pairs.

Figure 7.2: The overhead lighting fixtures in a Central Office failed during an earthquake. Note the equipment in the background was supported by "jiffy poles" after the earthquake. Mexico City earthquake, 1985. (Source: Alex Tang)

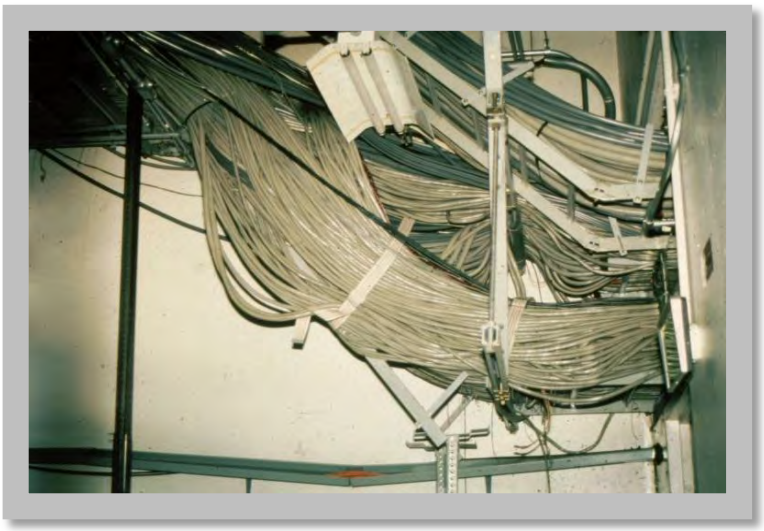

Figure 7.3: Overloaded cable rack failed in relatively minor (M=5.8), Whittier Narrow earthquake, California, 1987. (Source: Alex Tang)

Figure 7.4: Telecom equipment and HVAC ducting failure. It is hard to tell which was the main cause of failure; it has several combinations, inadequate anchoring, un-braced duct supports, etc. Mexico City earthquake, 1985. (Source: Alex Tang)

- **Internet Exchange Points (IX or IXP).** A physical infrastructure through which Internet service providers (ISPs) exchange Internet traffic between their networks (autonomous systems). At these exchange points, major carriers accept traffic from each other and agree to carry one another's packets to their downstream destination points without charge. (Answers.com)
- **Submarine Cable Landings** (Answers.com)
    - *Submarine cable landing station:* This may or may not be required, depending on whether, for example, the submarine cable requires power to power submarine repeaters or amplifiers.
    - *Submarine cable termination station:* This is the point at which the submarine cable connects into the land-based infrastructure or network. A cable termination station may be the same facility as the cable landing station, or it may be many miles away.
- **Antennas.** These may be:
    - Mounted on buildings owned by the communications provider or on leased space on another building.
    - Tower mounted.
    - Satellite antennas (for system up/down links and not the satellite service of an end user).
    - Transmitter antennas for broadcast radio and TV.

- **Cables.** These may be:
    - Underground.
    - Inducted, conduit, buried plant (underground cable vaults).
    - Buried.
    - Aerial cable (overhead/above ground).
- **Outside Plants.** Examples include:
    - Splice cases.
    - Repeaters (that may require power).

Resilience Goal, Objectives, and Scope

Goal

The goal of this plan is to provide recommendations that, if implemented, would ensure that within 50 years the information and communication systems in the state of Oregon are made resilient against a magnitude 9.0 Cascadia subduction earthquake and tsunami.

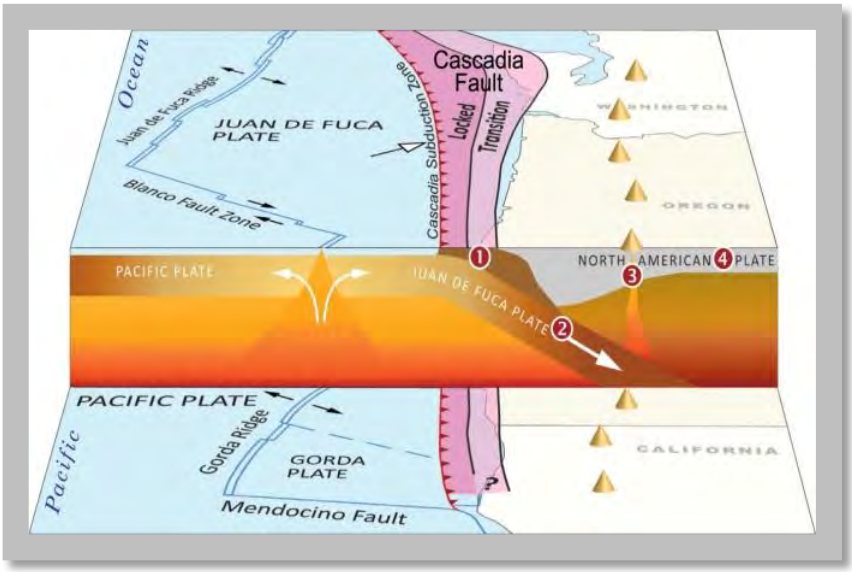

Figure 7.5: Cascadia seismic source is Oregon's most threatening fault and can produce a magnitude 9 earthquake and accompanying coastal tsunami waves. (Source: DOGAMI)

The resilience goal for the information and communication systems is to provide for immediate emergency communications followed by phased restoration, within specified time periods, for various areas of the state. In order to establish resilience goals, the information and communication systems were assessed in four geographical areas:

- The tsunami inundation zone along the coast. This area was defined using Oregon Department of Geology and Mineral Resources (DOGAMI) maps.
- The part of the coast that is not susceptible to tsunami (from the Oregon coastline to the Coast Range summit).
- The valley (from the summit of the Coast Range to the summit of the Cascades).
- Eastern/Central Oregon.

Objectives and Targets

The task group viewed performance capability (for the purposes of recovery) across all information and telecommunications systems that support voice and data communications. The restoration objectives are based on the assumption that all other lifelines, such as roads and electricity, are functioning at a level that will support restoration of the information and communications infrastructure. In areas where the *customer* is not ready to accept service, then the service provider is not expected to meet these restoration timeframes. In the early phases of recovery, achieving these capabilities may require the use of temporary contingencies (such as mobile cellular towers) while more permanent repairs and installations are being done.

Establishing target timeframes for the tsunami inundation zone, beyond a minimal level of capability to support response, is not practical. A large amount of planning and prioritizing will need to be undertaken to identify which areas will be rebuilt first. These will then be the areas in which the information and communications systems will be re-established first.

Resilience targets for information and communications systems were established for three levels to assist in establishing priorities for resilience and restoration activities and projects:

- **Minimal.** A minimum level of service is restored, primarily for the use of emergency responders and repair crews and in support of critical health and human services (mass care). The estimated capability at this level is 20–30 percent. In the early phases of recovery, achieving these capabilities may require the use of temporary contingencies (such as mobile cellular towers) while more permanent repairs and installations are being done.
- **Functional.** Although service is not yet restored to full pre-event capacity, it is sufficient to get the economy moving again (such as for business uses, including credit card transactions and banking). Limits may be placed on uses that take up a lot of capacity, such as streaming video. The estimated capability at this level is 50–60 percent.
- **Operational.** Restoration is up to at least 90 percent of capacity. A full level of service has been restored and is sufficient to allow people to use the system for non-essential activities, such as entertainment. The estimated capability at this level is 80–90 percent.

The attached table (see Figure 7.16) reflects the target capabilities for each zone across all information and communications systems. This approach permits greater flexibility in how the systems are

recovered, which may change with the continuous changes in technology (that is, the systems may become less dependent on large towers).

WHAT DOES BEING RESILIENT MEAN

To understand what resilience means in the context of information and communication technology, the task group referred first to the definition of resilience that was adopted for the resilience report as a whole: "Oregon citizens will not only be protected from life-threatening physical harm, but...because of risk reduction measures and pre-disaster planning, communities will recover more quickly and with less continuing vulnerability following a Cascadia subduction earthquake and tsunami." The task group then looked at Oregon's position on the *resilience triangle* and at the characteristics of resilient systems.

The Resilience Triangle

The basic principle of the resilience triangle is that the smaller the triangle, the higher the resilience. Higher resilience requires minimal reductions in critical lifeline services after a disaster, speedy recovery of those services, and an overall improved service level as a result of rebuilding damaged systems and implementing better systems. The resilience triangle diagram indicates that Chile and Japan have high levels of earthquake resilience—this reflects Chile's performance after a magnitude 8.8 earthquake in 2010 (ASCE TCLEE, 2010) and Japan's performance after a magnitude 9.0 earthquake in 2011 (Nojima, 2012) (notwithstanding Japan's nuclear energy issues). At the current stage, Oregon's infrastructure has low resilience and is expected to have significant loss of sector services and a slow recovery time.

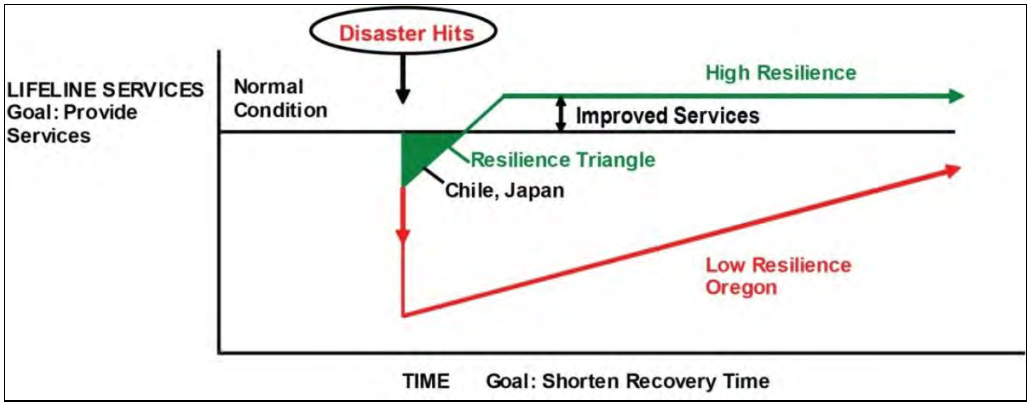

Figure 7.6: Resilience Triangle (Wang, Bartlett, and Miles, 2012)

Characteristics of Resilient Systems

Based on research conducted after disasters around the world, some basic system characteristics have been identified that enable communications and information technology systems to be resilient. Resilient systems tend to be:

- Decentralized.
- Meshed or integrated.

- Built to withstand the potential hazard, but without an expectation of 100-percent survivability.
- Capable of recovering (within two to four weeks of the event) whichever components of the system did not survive.
- Able to handle a surge in demand through system performance levels or implementation of controls.
- Upgraded by means of continuous hardening of vulnerable components within the system.

Plan Development

PLANNING CONSIDERATIONS

The task group took into consideration the following items during the development of the plan:

- Resilience planning needs to address the capacity of the system. In major events, landline and wireless telecommunications can be quickly overwhelmed by demand, even if they are 100-percent operational.
- Wireless communications technology is evolving rapidly and the technology that influences planning decisions and recommendations today may not be in existence 25 to 50 years from now.
- Hardline and wireless communication systems typically install their new technology into existing infrastructure (i.e., buildings, power poles, towers, vaults, and conduits). This means that 21st century technology may be housed in, or mounted on, a structure built in the early to mid-1900s.
- The resilience plan should consider business continuity recommendations for the companies that provide communication, information, or telecommunications services and systems, especially to customers who perform critical services and other functions related to life safety.
- Wireless communication systems include antennas installed on leased space on buildings that the communications providers do not own or control. The locations of the buildings, relative to the coverage and demand requirements, are the key factors in the placement decisions, not the resilience of the structures or their location outside of the known hazard areas.
- Restoration of aerial (overhead) telecommunication wires is secondary to the restoration of aerial (overhead) power lines.
- Lifeline interdependence is a key factor that governs the final resilience plan.

INTERDEPENDENCIES

Information and communications systems have several connections with other resilience planning task groups that directly impact their resilience and ability to recover:

- **Buildings**
    - Structural integrity of buildings housing system components as well as business services and call centers.
    - Structural integrity of buildings with wireless system antennas mounted on them.
- **Transportation**
    - Transportation routes typically include utility easements for overhead and underground information and communication systems.
    - Access to system facilities after an earthquake is essential for restoration as well as for maintaining emergency power systems.
    - Bridges convey utilities, as well as vehicles, over geological barriers.

- **Utilities**
    - Because information and communications systems share common easements with other utilities, coordination is required to achieve restoration.
    - Overhead utilities share common infrastructure (such as poles); coordination will therefore be required to achieve restoration.
    - Information and communications systems are dependent on other utilities to provide and restore their services (such as electricity).
- **Energy**
    - Electrical power is needed to run the equipment.
    - Fuel is needed for emergency generators and to supply the vehicles used for emergency response and repair work.
- **Business Resilience**. Information and communication service providers need to be resilient so that they are able to restore service quickly to their customers.

Figure 7.8: Circuit Boards pulled out and fan to get some air cooling due to failure of the air conditioning unit. Fortunately, the site had power and they could open windows to allow cool air to come in. Izmit (Kocaeli) earthquake, Turkey, 1999. (Source: Alex Tang)

Assessment of Performance

GENERAL ASSESSMENT

A complete, detailed assessment of all the telecommunications and information systems in Oregon is not possible without detailed systems data from all the service providers. From a system-wide

perspective, however, a general assessment can be made based on information that is generally available. This information includes:

- Design standards and age of structures relative to the expected performances of buildings, towers, and other structures in the tsunami inundation zone.
- Design standards and age of structures relative to the expected performances of buildings, towers, and other structures and taking into account the relative levels of shaking expected at varying distances from the subduction zone.
- Expected performances of bridges that are an integral part of the hardwire infrastructure.
- Potential impacts that landslides and liquefaction will have on the towers, poles, buried utilities, buildings, and bridges that convey cable across rivers and ravines.
- The capabilities analyses of other sectors, particularly the electrical utilities, which have similarities with portions of the information and communications systems and are an integral part of maintaining and re-establishing information and communications capabilities.
- Capabilities and capacity—including resources (material and technical resources), mutual aid programs, spares, tools, and equipment—after a major disaster.

Figure 7.9: Inadequate anchorage and poor overhead bracing details resulted in equipment toppling. Mexico City earthquake, 1985. (Source: Alex Tang)

It should also be noted that even if a structure (building or tower) were to survive an event, damage to improperly secured equipment can result in the loss of operational capability.

Depending on the general availability of the equipment (off-the-shelf versus specifically designed and manufactured), it could take longer to replace or repair the equipment than it does to repair or replace the building.

ASSESSMENT BY ZONE

Using the general assessment criteria, the task group did an assessment of performance capabilities for each of the four geographic areas (see also the attached figure in Figure 7.16):

Zone 1: Coast—Tsunami Zone

All communications and information technology infrastructure within the tsunami inundation zone will sustain major damage or be destroyed. The ability to operate any equipment that survives both the earthquake and the tsunami will depend on the availability of electrical power and whether crews are able to access the equipment in order to perform maintenance and repairs.

- **Buildings.** All buildings in the inundation area will be destroyed or heavily damaged.
    - Few buildings are built to current seismic code and even fewer are built to the critical facility level (which is designed to increase the chances that the structure will be usable after the earthquake).
    - Those structures not destroyed by the earthquake will be inundated by the tsunami waves.
- **Equipment**. Equipment in buildings.
    - Existing standards for communications and information technology do not appear to address the protection of equipment from damage during large seismic events.
    - Improperly secured equipment can be damaged or destroyed even if the structure that houses it survives both the seismic shaking and the tsunami waves.
- **Towers.** Antenna towers in the inundation zone have the same probabilities of being damaged and destroyed as the buildings.
    - A number of the towers and antennas are located on existing buildings and will be only as reliable as the buildings they are on.
    - Even if towers are free standing and reinforced to withstand the shaking and the tsunami waves, the equipment on the towers must be positioned above the inundation height of the tsunami wave and properly secured to avoid damage from the shaking.
    - Free standing towers without properly constructed foundations could fail due to liquefaction.
- **Aerial Cables.** Overhead lines that survive the scenario earthquake will be destroyed by the tsunami wave (with the possible exception of those on the outer most edges of the inundation area).
    - Cross arms, connectors, and insulators that are designed to break away in high winds to reduce the potential damage to the utility poles could also give way during the seismic event.
    - Liquefaction can cause utility poles to lean or topple.

- Debris in the tsunami inundation waves will have significant impacts on utility poles and lines.

- **Underground Lines**. Depending on the amount of liquefaction and shearing forces, the earthquake could be just as devastating to the underground utilities as to the overhead lines. While the tsunami wave may have little direct impact on buried lines, the failure of utility vaults, salt water inundation of underground conduits, and loss of terminal posts will be just as disruptive as the physical loss of the lines.
    - Breaks in the underground lines are hard to locate unless there is some obviously related disturbance of the ground or activity in the vicinity of the break.

Zone 2: Coast—Earthquake-Only Zone

Only structures built to withstand the expected level of shaking are likely to be usable after the earthquake. Even these structures, however, will have limited functional capability if they are without utilities and there is no way to access them.

Figure 7.10: Cell site collapsed with the commercial building collapse. Chi Chi earthquake, Taiwan, 1999. (Source: Alex Tang)

- **Buildings**.
    - Few buildings are built to current seismic code and even fewer are built to the critical facility level (which is designed to increase the chances that the structure will be usable after the earthquake).
    - The tsunami, failure of bridges, and landslides can isolate facilities that survive the shaking, further limiting their use.

- **Equipment.** Equipment that is not properly secured for the expected level of shaking or protected from cascading events (such as the sprinkler system going off) could be damaged and require an extended period of time for repair or replacement.
    - Existing standards for communications and information technology do not appear to address the protection of equipment from damage during large seismic events.
    - Improperly secured equipment can be damaged or destroyed even if the structure that houses it survives.
- **Towers.** Antenna towers are likely to be damaged both by shaking during the scenario earthquake and by liquefaction. Towers located in the Coast Range are also prone to possible impacts from landslides.
    - Even if towers are free standing and reinforced to withstand the shaking, the equipment on the towers must be properly secured to avoid damage from the shaking.
    - Surviving towers will not be usable unless power and other utilities are available.
    - Connectivity between towers or between towers and landline networks may be disrupted as microwave dishes move, underground cables are severed by landslides, and utility lines break when the bridges they span fail.
- **Aerial Cables**. Overhead lines will be prone to failure during the expected shaking of the scenario event due to the lateral forces on the lines and poles as well as liquefaction and landslides.
    - Cross arms, connectors, and insulators that are designed to break away in high winds to reduce the potential damage to the utility poles could also give way during the seismic event.
    - Liquefaction can cause utility poles to lean or topple.
    - Landslides can damage or destroy utility poles located on steep slopes.
- **Underground Lines.** Depending on the amount of liquefaction and shearing forces, the earthquake can be just as devastating to the underground utilities as to the overhead lines.
    - Breaks in the underground lines are hard to locate unless there is some obviously related disturbance of the ground or activity in the vicinity of the break.
    - Underground lines can be severed by landslides and by the failure of the bridges that support them across geological features such as rivers and ravines.

Zone 3: Valley

Only structures built to withstand the expected levels of shaking are likely to be usable after the earthquake. Even these structures, however, will have limited functional capability if they are without utilities and there is no way to access them.

- **Buildings.** While the expected shaking in the valley during this scenario earthquake will not be as great as on the coast, a significant number of buildings in the valley were built prior to current seismic code.
    - Very few buildings associated with information and communications technology have been built to the critical facility level (which is designed to increase the chances that the structure will be usable after the earthquake).
    - While the structural components of a building may survive the earthquake, failure of nonstructural components, including windows, HVAC systems, lighting, and plumbing, can render the facility unusable for an extended period of time.
- **Equipment.** Equipment that is not properly secured for the expected level of shaking or protected from cascading events (such as the sprinkler system going off) could be damaged and require an extended period of time for repair or replacement.
    - Existing standards for communications and information technology do not appear to address the protection of equipment from damage during large seismic events.
    - Improperly secured equipment can be damaged or destroyed even if the structure that houses it survives.

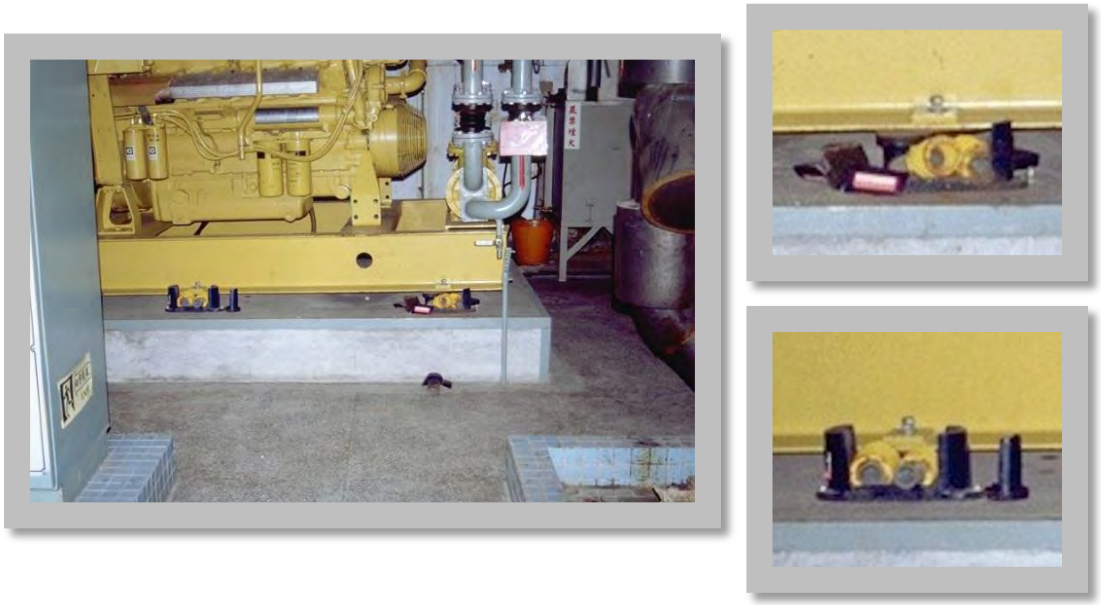

Figure 7.11a and 7.11b: Close-up of the two vibration isolation units. The cause of the failure was due to lack of details to limit the generator displacement during the strong shaking.

Figure 7.11: Backup generator failure - the vibration isolators of this unit all failed after the earthquake. Chi Chi earthquake, Taiwan, 1999. (Source: Alex Tang)

- **Towers**. Antenna towers may be damaged by the shaking during the scenario earthquake as well as by liquefaction. Towers located in the Coast Range and West Hills could also be damaged by landslides.

  - A number of the towers and antennas are located on existing buildings and will be only as reliable as the buildings they are on.
  - Even if towers are free standing and reinforced to withstand the shaking, the equipment on the towers will need to be properly secured to avoid damage from the shaking.
  - Surviving towers will not be usable unless power and other utilities are available.
  - Connectivity between towers or between towers and landline networks may be disrupted as microwave antennas move, underground cables are severed by landslides, and utility lines break when the bridges they span fail.

- **Aerial Cables**. While the damage is expected to be less severe in this zone than on the coast, overhead lines could fail during the expected shaking of the scenario event due both to the prolonged lateral forces on the lines and poles and to liquefaction and landslides.
  - Cross arms, connectors, and insulators that are designed to break away in high winds to reduce the potential damage to the utility poles could also give way during the seismic event.
  - Liquefaction can cause utility poles to lean or topple.
  - Landslides can damage or destroy utility poles located on steep slopes.
- **Underground Lines**. Depending on the amount of liquefaction and shearing forces, the earthquake can be just as devastating to the underground utilities as to the overhead lines.
  - Breaks in the underground lines are hard to locate unless there is some obviously related disturbance of the ground or activity in the vicinity of the break.
  - Underground lines can be severed by landslides and by the failure of the bridges that support them across geological features such as rivers and ravines.

Zone 4: Eastern Oregon

In this zone, capabilities will be more dependent on the availability of power than damage or physical loss of structures and equipment.

- **Buildings.** Older and poorly built structures (for example, unreinforced brick buildings) that are located in areas identified in the scenario earthquake as likely to sustain moderate and moderate-to-heavy damage will sustain damage and could partially collapse.
  - Very few buildings associated with information and communications technology have been built to the critical facility level (which is designed to increase the chances that the structure will be usable after the earthquake).
  - While the structural components of a building may survive the earthquake, failure of nonstructural components, including windows, HVAC systems, lighting, and plumbing, can render the facility unusable for an extended period of time.

- **Equipment.** Equipment that is not properly secured for the expected level of shaking or protected from cascading events (such as the sprinkler system going off) could be damaged and require an extended period of time to repair or replace.

Figure 7.12: The battery rack is designed to resist lateral force with very light cross bracing. The batteries, however, were not secured on the rack and fell, resulting in reserve power failure San Fernando earthquake, California, 1971. (Source: Alex Tang)

  - Existing standards for communications and information technology do not appear to address protection of equipment from damage during large seismic events.
  - Improperly secured equipment can be damaged or destroyed even if the structure that houses it survives.

- **Towers.** Antenna towers may be damaged by the shaking during the scenario earthquake as well as by landslides if the towers are located on steep slopes.
  - A number of the towers and antennas are located on existing buildings and will be only as reliable as the building they are on.
  - Even if towers are free standing and reinforced to withstand the shaking, the equipment on the towers must be properly secured to avoid damage from the shaking.
  - Surviving towers will not be usable unless power and other utilities are available.

- **Aerial Cables.** Overhead lines could fail in areas that experience higher levels of shaking due both to the prolonged lateral forces on the lines and poles and to landslides that are triggered by the earthquake.
  - Cross arms, connectors, and insulators that are designed to break away in high winds to reduce the potential damage to the utility poles could also give way during the seismic event.

- Landslides can damage or destroy utility poles located on steep slopes.

- **Underground Lines**. Underground lines are likely to be the least impacted in this zone.
  - Breaks in the underground lines are hard to locate unless there is some obviously related disturbance of the ground or activity in the vicinity of the break.
  - Underground lines can be severed by landslides and by the failure of the bridges that support them across geological features such as rivers and ravines.

Target Timeframes for Recovery

Performance capability for recovery purposes is viewed across all information and telecommunications systems that support voice and data communications. The restoration objectives are based on the assumption that all other lifelines, such as roads and electricity, are functioning at a level that will support restoration of the information and communications infrastructure. In areas where the *customer* is not ready to accept service, the service provider is not expected to meet these restoration timeframes.

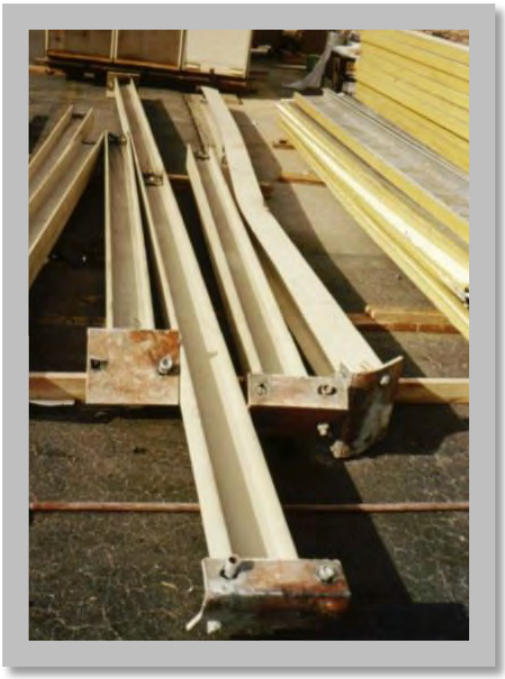

Figure 7.15 – Collection of damaged bracing beams removed from Central Office. Northridge earthquake, California, 1994. (Source: Alex Tang)

Establishing target timeframes for the tsunami inundation zone, beyond a minimal level of capability to support response, is not practical. A large amount of planning and prioritizing will need to be undertaken to identify which areas will be rebuilt first. These will then be the areas in which the information and communications systems will be re-established first.

KEY TO THE TABLE

Target Timeframe for recovery:

Operational: Restoration is up to 90% of capacity: A full level of service has been restored and is sufficient to allow people to use the system for non-essential activities (such as entertainment). 80%–90%

Functional: Although service is not yet restored to full pre-event capacity, it is sufficient to get the economy moving again (e.g. business uses for credit cards and banking). Limits may be placed on uses that take up a lot of capacity (such as streaming video). 50%–60%

Minimal[1]**:** A minimum level of service is restored, primarily for the use of emergency responders, repair crews, and in support of critical health and human services (mass care). 20%–30%

Estimated time, under current conditions, for system-wide recovery to be at (or 90% of) pre-event capacity

Figure 7.16– Target States of Recovery: Information and Communications Technology Sector

Resilience Gap Analysis Summary

The table in Figure 7.16 shows significant difference between the current capabilities of the system and the target capabilities, especially at the coast and in the valley. As the threat of a magnitude 9.0 subduction zone earthquake is recognized and new design and building standards are adopted and implemented in response to it, new construction of information and communications infrastructure will be more likely to achieve the resilience targets. Without changes in policy and other incentives,

however, we do not foresee any significant changes in the performance capabilities of existing system components.

- Companies in this sector should institutionalize long-term seismic mitigation programs and should work with the appropriate agencies and stakeholders to achieve timely and effective mitigation to ensure that their facilities are resilient and their operations reliable.
    - Require that central offices, Internet exchanges, remote terminals, and submarine cable landings be built or retrofitted to meet the *critical facility* standard.
    - Include within site development and zoning codes the requirement that information and communications technology structures be built to withstand the potential impacts of a scenario earthquake and tsunami. This should include:
        - Limitations on building in tsunami inundation areas.
        - Limitations on construction of antenna towers on buildings that do not meet the critical facility standard.
        - Accounting for potential liquefaction and slope instability when constructing towers, buildings, underground utilities, and overhead lines.
    - Adopt clear, statewide uniform standards, like the NEBS (Network Equipment-Building System), for the adequate performance and bracing of information and telecommunications equipment that must withstand the scenario event, and establish a mechanism for reliable enforcement.
    - Establish a hardened backbone for information and telecommunications systems in conjunction with the ODOT's hardening of primary transportation routes.
- Companies in this sector should work with the state of Oregon to build Oregon's seismic resilience to a Cascadia earthquake.
    - Adopt pro-active practices and a risk management approach to help achieve seismic resilience.
    - Encourage a culture of awareness and preparedness in relation to the seismic vulnerability of the energy sector, and stress the need to conduct long-range energy planning.
- Create an ongoing marketing and education program for Oregon to craft the resilience message for the public. This is to bring about a cultural shift toward preparing for the catastrophic Cascadia subduction zone earthquake and to learn the cost of becoming prepared.
    - Create a public information officer position (for the state) and assign to it responsibility for this marketing and education program.
    - Involve all types of media in promoting this new culture of preparedness.
- Recommend the state and municipalities should include system resilience criteria in their requests for proposals when contracting for telecommunications and information services.

Recommendations

As demonstrated in Chile (ASCE TCLEE, 2010), resilience can be achieved within a 50-year period without unrealistic amounts of new investment. Companies in this sector should be encouraged to institutionalize long-term seismic mitigation programs and to work with the appropriate agencies and stakeholders to achieve timely and effective mitigation to ensure that their facilities are resilient and their operations reliable. Towards that end, the task group proposed the following recommendations for consideration:

- **Information and communications companies should conduct seismic vulnerability assessments (SVA) on all of their infrastructure facilities, and they should work with the appropriate agencies and stakeholders to achieve timely completion of the assessments to understand existing vulnerabilities.**
  - The Public Utility Commission of Oregon (OPUC) is the proper oversight authority for all telecommunications utilities that are subject to the OPUC's Oregon Administrative Rules.
  - The OPUC may need to define the criteria for seismic vulnerability assessments.
  - The OPUC should review the results of the seismic vulnerability assessments and the systems' resilience to other natural disasters (within the scope of their mission).
  - The implementation of this recommendation could also involve the participation of the Oregon Department of Geology and Mineral Industries (DOGAMI), the Building Codes Division, and the Oregon Seismic Safety Policy Advisory Commission (OSSPAC).
- **Provide liability waiver language in statute for vulnerabilities identified in the seismic vulnerability assessments that are above operators' current normal operations.**
- **Companies in this sector should institutionalize long-term seismic mitigation programs.**
- **Utilize the Oregon Office of Emergency Management's public-private sector position to help ensure coordinated planning, information sharing, and interoperability among critical organizations and agencies. The position will also ensure that work being performed by this entity and its partners helps provide public education and outreach to local, county, and state agencies and organizations.**
- **The state of Oregon should provide statutory authority for a prescriptive waiver of routine permitting requirements and processes for the design, construction, and restoration of communication and information infrastructure, if it is determined that the waiver is in the public interest and is necessary to address an actual or impending emergency (and subsequent actions) caused by a natural or manmade disaster.**

8. Water and Wastewater Systems

Introduction

Oregon's water and wastewater systems are especially vulnerable to damage resulting from a Cascadia subduction zone earthquake. Some of the inherent seismic vulnerabilities of water and wastewater systems include:

- The systems tend to be large and complex, consisting of a combination of pipeline networks serving large areas and concentrated facilities (such as treatment plants and pump stations), with numerous potential points of failure.
- The systems are highly dependent on other resources—such as power, transportation, chemicals, and skilled staff—to remain operational and to complete needed repairs.
- The systems are financially dependent on consistent revenue streams to fund ongoing operations, maintenance, and debt service obligations.
- Essential facilities, such as intakes, treatment plants, pump stations, and outfalls, are often located near rivers and lakes and are vulnerable to damage from liquefaction of alluvial soils.
- Many critical facilities, such as reservoirs, pump stations, and treatment plants, were designed and constructed before the adoption of seismic design standards that reflect the current state of knowledge of regional seismicity.
- Pipeline networks include extensive use of non-ductile (inflexible) materials, such as concrete and cast-iron pipe, which tend to fail during strong ground motion.
- Pipelines are especially vulnerable to failure from permanent ground deformation (resulting from liquefaction and landslides), because the deformation causes *push-on* pipe joints to separate.
- Water and sewer pipelines tend to be prone to failure at connections to aboveground structures, such as reservoirs, treatment plants, pump stations, and service connections to homes.
- Water from leaks and breaks in water pipelines and private plumbing systems will cause collateral damage, drain available water storage, and contribute to loss of water supply and pressure, which will in turn result in a loss of fire protection capability.
- The performance of gravity sanitation and storm sewers depends on accurate grades and slopes, which are disrupted by ground displacement resulting from liquefaction.
- Failures of storm sewers can contribute to localized flooding during even minor rain events, resulting in collateral damage.

THE EXISTING STATE

If it were to occur today, a Cascadia subduction zone earthquake would result in catastrophic impacts to existing water and wastewater systems throughout western Oregon. The Oregon coast would most likely experience strong ground shaking for over three minutes. Facilities within the tsunami inundation zone would be extensively damaged; in many cases, these facilities would not be repairable. Facilities outside of the tsunami zone would be heavily damaged, with total loss of water and wastewater services for periods measured in months and, in some cases, years.

The Willamette Valley would experience moderate ground shaking. Well-engineered structures may perform well, but many older structures would likely fail, including treatment facilities, reservoirs, and pump stations. One of the major impacts to large population centers would be from liquefaction: extensive alluvial and fill deposits along rivers would lose strength, lose bearing capacity, and move towards riverbanks. Old cast iron water pipelines buried in the liquefied soil would snap, and modern pipelines constructed of ductile iron and PVC would likely pull apart at joints, resulting in a total loss of water pressure throughout communities. Large drainage structures along riverbanks in liquefiable areas would likely move, severing connecting piping and rendering the structures useless. Examples of the type of damage likely to occur are illustrated in Figures 8.1–8.7.

Water for Fire Suppression

In the current state of readiness, existing water systems would experience extensive leaks and breaks in water supply pipelines. These leaks, coupled with loss of water supply facilities, such as treatment plants and pump stations, would drain the water systems. This loss of volume and pressure would critically limit the availability of water supply for conventional urban firefighting: fire hydrants would be rendered useless, and many fire sprinkler systems would be inoperable (even those sprinkler systems that remain intact).

Urban and suburban firefighting strategies would resemble those commonly used in rural areas: water for fire suppression would only be available from lakes, rivers, streams, swimming pools, and any surviving local water storage reservoirs. Fire engines would draft from these sites and rely on tankers to move water to fires. The combination of transportation infrastructure damage, compromised emergency communications systems, and high emergency incident volumes, would limit the ability of fire departments to respond to individual incidents. Fire departments would have to identify, assess, and prioritize responses and would focus on life safety and containment rather than trying to extinguish every fire. Photos of previous earthquake-relate fire events are shown in Figures 8.8–8.10.

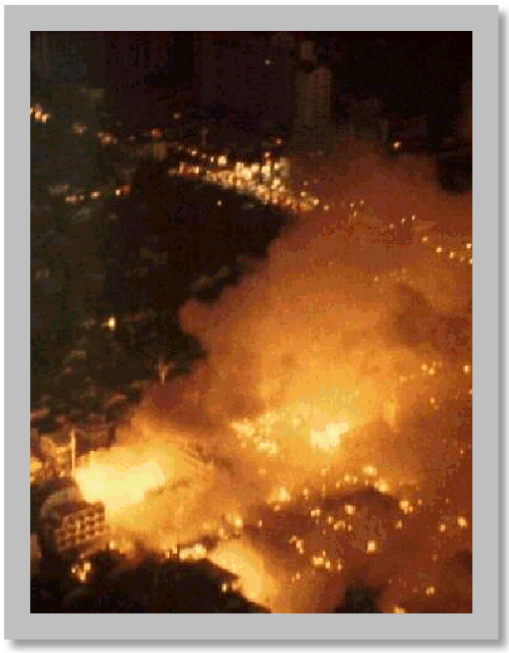

Figure 8.10: Conflagration resulting from water system failures, Great Hanshin earthquake, Kobe, Japan, 1995 (Source: Photo Source Unknown)

Potable Water Supplies

In the current state of readiness, water utilities would be unable to provide water from the existing distribution system. Communities would rely on emergency supplies for the first one to two weeks, depending on location and on the condition of transportation infrastructure. Some areas would have *no* water supplies during that time. Water for healthcare facilities such as hospitals would be severely restricted. Emergency water supplies would meet only subsistence needs (for example, direct consumption and very limited bathing). For the first one to two months, water would be delivered via tankers to smaller tanks and bladders distributed throughout the community. People would wait in line to fill their containers and then carry the water home. Some water would come from portable water

treatment units provided by the military, equipment suppliers, and foreign countries; however, the quantity of water supplied from those resources would be small compared to demands. Photos of water distribution following other earthquakes are presented in Figures 8.11–8.13.

Figure 8.13: People waiting for water, Haiti earthquake, Port Au Prince, 2010 (Source: Photo by Don Ballantyne)

Manufacturing facilities, hotels, restaurants, and even office buildings that depend on water would be closed. Within several weeks of the event, a few restaurants might reopen using paper plates, but in many locations, water for use in bathrooms, dish washing, and laundry could be delayed for months.

A month following the earthquake, water supplies, treatment facilities, and transmission systems would begin to come online and replace the portable treatment units. People would still need to carry water from distribution points to their homes and businesses. In the hardest hit areas—the Oregon coast and areas with liquefiable soils—it may take six months to a year or more for water services to be restored to individual homes and businesses.

Wastewater Facilities

Sewers and pump stations in liquefiable areas would be heavily damaged. Large pump stations along rivers would likely settle or tilt, shearing off connecting piping. Sewage would overflow into nearby bodies of water. In areas distant from water bodies, raw sewage would likely flow into gutters and ditches, making its way through the surface water drainage system. In many cases, sewage would likely back up into homes and businesses. Because there would be little water available to flush toilets, sewage flows would be small, except in areas served with combined sewers. In many cases, people would attempt to use toilets in their houses and flush with a bucket of water. Because there would not be enough water to move the solids effectively downstream, sewers would plug within the first few weeks.

Figure 8.16: Sewer line that floated to the surface as a result of liquefaction, Dagupan, Philippines, 1990. (Source: Photo by Don Ballantyne)

In areas where the potable water system is still functioning, wastewater would be generated and discharged into rivers, streams, and lakes. Rivers would quickly become polluted with wastewater solids, as they were prior to the advent of treatment plants in the first half of the twentieth century. Water treatment plants that draw raw water from contaminated rivers would likely become compromised or would require extraordinary measures, such as operating at very low treatment rates and high dosing rates for treatment chemicals.

In many locations it would take a year before the sewage collections system is functioning and three years before major trunk lines and treatment plants are fully restored to their pre-earthquake functionality. In these situations, people would likely turn to using chemical toilets, available in limited numbers, and latrines.

Water and Wastewater Resilience Planning

Re-establishing water and wastewater service will be a crucial element in the overall recovery of communities after a Cascadia subduction zone earthquake. Water for fire suppression, first aid, emergency response, and community use, as well as water for normal health and hygiene, will be required soon after the event. Functioning wastewater systems that help protect the community from sewage contamination, health hazards, and disease outbreaks will be essential.

The time required to re-establish water and wastewater services will depend largely on the pre-event condition of the systems, the actual intensity and duration of the event, the size and complexity of the systems, and the availability of staff and the financial and material resources needed to complete

repairs. In addition, damage to other infrastructure, such as the transportation, communications, fuel, and power systems, may control the time required to restore water and wastewater infrastructure.

The Oregon Resilience Plan's Water and Wastewater Task Group included participation by various industry professionals, including representatives from academia, municipalities, special districts, and consultants. Communities participating in the planning effort are summarized in Figure 8.17. These utilities represent about five percent of the population of coastal communities and about 40 percent of the population of western Oregon.

System / Community	Sector
City of Portland	Water & Wastewater
Tualatin Valley Water District	Water
City of Bend	Water
City of Gresham	Water
City of Pendleton	Water
City of Salem	Water & Wastewater
Clean Water Services	Wastewater
Coos Bay - North Bend Water Board	Water
Eugene Water & Electric Board	Water
Rivergrove Water District	Water

Figure 8.17: Water and Wastewater Systems Participating in the Water and Wastewater Task Group

The Water and Wastewater Task Group also included experts from three universities, consulting engineers who specialize in water and wastewater facilities, and the representatives of a fire and emergency response agency. The task group met monthly from February 2012 through August 2012, building on existing information and on group members' working knowledge of existing systems to assess the performance of existing systems and estimate the time required to restore water and wastewater service to the populations affected by the scenario earthquake.

RESILIENCE GOALS, OBJECTIVES, AND SCOPE

First, the Water and Wastewater Task Group identified performance goals for the time required to restore water and wastewater service to affected communities. This effort consisted of developing a phased approach to water system upgrades before a Cascadia subduction zone earthquake and recovery after, defining categories or groups of functional characteristics of systems, and identifying resilience goals for each category.

A Phased Approach

Given the size and inherent vulnerability of most water and wastewater systems, it was assumed that costs of seismic mitigation would exceed the resources of most providers' 50-year capital improvement

programs. Therefore, to provide water to critical areas and establish wastewater service to protect public health and safety as soon as possible following the seismic event, a phased approach to system recovery was developed. The phased approach is built upon having hardened backbone elements of the water and wastewater systems. The backbone system would consist of key supply, treatment, transmission, distribution, and collection elements that, over the 50-year timeframe, have been upgraded, retrofitted, or rebuilt to withstand a Cascadia subduction zone earthquake.

The backbone water system would be capable of supplying key community needs, including fire suppression, health and emergency response, and community drinking water distribution points, while damage to the larger (non-backbone) system is being addressed. The backbone wastewater system would protect the community from health hazards and minimize environmental impacts associated with raw sewage as larger repair and response efforts are underway. Identification of a community's backbone water and wastewater systems would become essential to maximizing the effectiveness of investments in resilience and ultimately to expediting recovery efforts following a Cascadia subduction zone earthquake.

The proposed approach—each community establishes a backbone water system—does not alleviate critical water and wastewater concerns following a Cascadia subduction zone earthquake. Large portions of the water distribution system will remain vulnerable and presumably inoperable. In addition, vulnerabilities of the wastewater collection and treatment system will likely result in raw sewage discharges to receiving waters and public health risks in affected communities.

Functional Categories of Water and Wastewater Systems

Using the professional judgment of group members, the Water and Wastewater Task Group established categories of water and wastewater infrastructure based on functional characteristics of the systems. These categories also reflected the proposed backbone structure to accommodate phased recovery of the systems. The categories of system functions are described below.

Domestic Water Supply

- **Potable water available at supply source (water treatment plants, wells, impoundments).** This category represents the initial point of the finished water supply system. Given the age, geotechnical vulnerability, and complexity of many treatment plants, a phased recovery was assumed and would be dedicated to seismically hardening the treatment processes. Communities with more resilient storage may consider longer recovery timeframes for the supply source, as they could rely on stored water in lieu of producing more treated water.
- **Main transmission facilities, pipes, pump stations, and reservoirs operational.** This category refers to the backbone system discussed above. The intent is to be able to convey water from resilient storage and treatment plants to key distribution points as soon as possible following the event. Manual operation of valves—to isolate the backbone system from damaged areas of the system and minimize water loss—accounts for some of the delay in implementation.

- **Water supply to critical facilities available.** This category assumes critical facilities will be nearly fully operational due to on-site water storage or the capacity of the local supply. Critical facilities, such as hospitals and first-aid facilities, command and control centers, and industries essential to recovery and restoration efforts, should be identified for individual communities.
- **Water for fire suppression at key supply points**. Thorough planning efforts, involving fire officials and emergency responders, should identify key supply points for reliable access to water for fire suppression. These areas should be included in the backbone system.
- **Water for fire suppression at fire hydrants.** Water will be available at fire hydrants when leaks and breaks in the distribution system have been repaired. Communities in heavily damaged areas will likely not be able to rely on fire hydrants until the majority of the distribution system is operational. Until that benchmark can be reached, communities would have to rely on the key fire-suppression supply points and fire-suppression strategies described above.
- **Water available at community distribution centers/points.** As in the case of fire hydrants, the distribution of water to individual homes and neighborhoods may not be possible given damage to the distribution system. If community distribution centers/points are provided at strategic locations along the hardened backbone, people can have access to potable water soon after the event. Such issues as the logistics of staffing and setting up a distribution center and of identifying containers were also considered during the development of the target recovery timeframes for this category.
- **Distribution system operational.** In order to provide water throughout the community (including fire hydrants), the distribution system would need to be operational. Through vulnerability assessment, material stockpiles, supply identification, and workforce planning, communities would be able to target anticipated repairs as part of their comprehensive response and recovery efforts.

Wastewater Systems

- **Threats to public health and safety controlled.** Minimizing the threat to public health and safety must be a top priority. Through vulnerability assessment and system planning, communities can identify key lift stations, river crossings, and components that could pose serious threats to public health and safety and can plan response efforts accordingly.
- **Raw sewage contained and routed away from population**. Closely tied to threats to public health and safety, the intent of this category is to make sure raw sewage can be routed away from the population. A key factor in establishing the target timeframes for this category is the anticipated availability of the workforce, equipment, and back-up power.
- **Treatment plants operational to meet regulatory requirements**. When establishing the target timeframes for these components, the task group considered the typical proximity of wastewater treatment plants to rivers and liquefiable soils. Based on historical events, it was

assumed that treatment plants would at first be operating at lower regulatory requirements given the emergency situation. As repairs are made, the treatment plants would resume meeting applicable discharge requirements.

- **Major trunk lines and pump stations operational.** Through assessment of vulnerability and back-up power capability, communities can identify the key pump stations that will be needed to maintain the functionality of the major trunk lines. As treatment plants return to normal operation, the available storage in the trunk lines can be utilized to store raw sewage as needed to minimize threats to public health and safety and route raw sewage away from the population.
- **Collection system operational.** As repairs to key pump stations, trunk lines, and treatment plants are completed, the available work force, equipment, and resources can be focused on repairing the collection systems that serve individual neighborhoods. Damage to and limited functionality of collection systems should be addressed as part of the comprehensive response and recovery efforts. Community sanitary collection centers and community education efforts should be considered.

WATER AND WASTEWATER RECOVERY GOALS

Recovery goals were established for each functional category for water and wastewater systems. Due to the unique characteristics of various regions of the state, recovery goals were developed for each of three geographic regions: the Oregon coast, the Willamette Valley, and eastern Oregon.

The proposed target recovery times were developed based on the considerations described above, using input from a range of water and wastewater professionals participating in the Oregon Resilience Plan effort, and based on input from the Business Task Group. In general, the recovery goals established by the professionals who participated in the Water and Wastewater Task Group were longer than the two-week goal identified by the Business Task Group. These longer goals were based on the professional judgment of the Water and Wastewater Task Group and took into account the consideration that a goal of two weeks would require replacement of essentially all existing water and wastewater system infrastructure. Finally, the intended objectives of the Business Task Group's goal for a two-week recovery were generally met by the proposed phased approach of a seismically hardened backbone for water and wastewater systems.

The proposed target recovery times are based on typical water and wastewater systems in the specified geographic zone. Estimates of recovery times assume the typical system has implemented comprehensive resilience improvements, including upgrades to its backbone system, over the 50-year planning horizon. It is further assumed that the resilient backbone is capable of withstanding the anticipated impact of a Cascadia subduction zone earthquake with minimal damage. It is recommended that those responsible for individual systems establish their own target recovery goals as part of a system-specific assessment to reflect the particular configuration of the individual system and the needs of the community it serves.

Recovery tables were developed for each of three geographic zones of the state, with performance goals established for each functional category within each zone. These tables include the following:

- Table in Figure 8.18: *Coastal.* This includes the parts of the Coast that are not in tsunami inundation zones and extends as far as the Coast Range.
- Table in Figure 8.19: *Valley.* This includes the Willamette Valley and the western-flank of the Cascades, including major population centers in the state.
- Table in Figure 8.20: *Eastern.* This includes all areas east of the summit of the Cascades.

As shown in the tables, the performance goals for recovery times vary widely within the state. In particular, the target recovery times for the Coastal zone are significantly longer than those of the Valley and Eastern zones. This difference is due in part to the following considerations:

- Coastal communities are physically closer to the fault than the communities in the Valley and Eastern zones and will therefore experience greater physical damage, more disruption, and longer recovery times. Achieving target recovery times similar to those of the other zones will require greater effort and expenditure by coastal communities.
- The population density of the Coastal zone is far lower than that of the Valley zone; therefore, the per capita cost of repairs will likely be far higher for coastal communities. Similarly, the per capita cost for the Eastern zone is expected to be lower given the lower anticipated damage for that zone.
- Coastal communities have fewer resources (in terms of number of residents, available equipment, consultants, and contractors) to aid with the recovery process and help restore systems. The competing priorities of the population and economic centers of the state will also affect the speed at which coastal communities are able to recover. Mobilization of assistance from other jurisdictions will take additional time and be affected by interdependencies with other essential services, including transportation, energy, and communications.

Figure 8.20: Water & Wastewater Sector: Central / Eastern Zone

Assessment of System Performance

The Water and Wastewater Task Group used available data, experience from other similar events, and professional judgment to estimate the performance of existing water and wastewater systems in response to a Cascadia subduction zone earthquake. The task group developed estimates of pipeline failure rates and facility failures and identified other likely failure mechanisms. From these assessments, the task group estimated the recovery times for the existing systems of the water and wastewater

facilities in the coastal and valley zones. This approach and resulting recovery times for existing systems are presented below.

ESTIMATES OF PIPELINE FAILURES

Water Distribution Systems

The process used to predict the performance of water distribution systems included a preliminary inventory of types of pipeline material for six water systems (Portland Water Bureau, Eugene Water and Electric Board, City of Gresham, Tualatin Valley Water District, Coos Bay - North Bend, and Salem). After assembling the available information on pipe lengths and materials, the task group superimposed these distribution systems onto maps of the scenario magnitude 9.0 Cascadia subduction zone earthquake showing peak ground acceleration, liquefaction potential (displacement), and landslide potential. The task group then used empirical data from the American Lifeline Alliance to predict the number of breaks and leaks for typical distribution systems. Figure 8.21 provides a summary of results for the participating utilities. The damage to those systems was assumed generally to represent the degree of damage to all the systems on the coast and in the Willamette Valley.

Characteristic	Estimate
Total Length of Pipe (miles)	4,592
Total Number of Breaks (number)	2,656
Total Number of Leaks (number)	941
Total Number of Services (number)	385,600
Service Line Breaks—Utility Side (2%)	7,712
Service Line Breaks—Customer Side (5%)	19,280

Figure 8.21: Estimate of Water Pipeline Breaks & Leaks for Participating Utilities

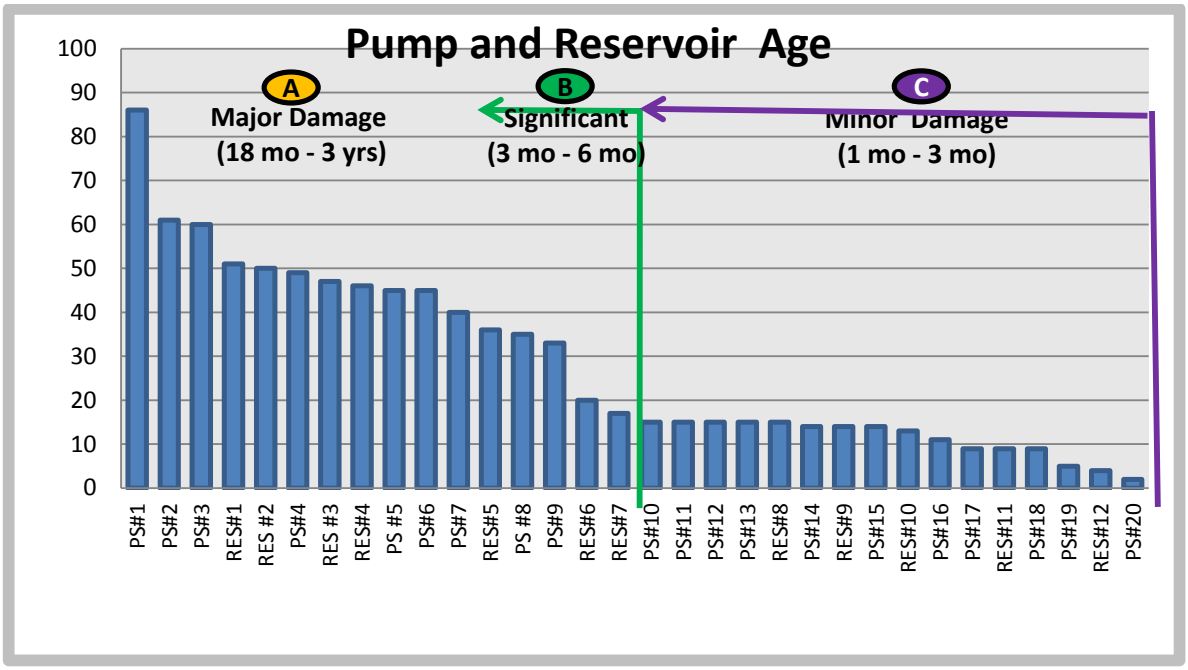
Wastewater Collection Systems

There is no comprehensive guideline for wastewater collection system collapses in response to a seismic event. Experience indicates the following general relationships:

- The ratio for sewer pipe collapses to water pipeline breaks and leaks is about 1:10 (in other words, one sewer pipe collapse for every 10 water pipeline breaks and leaks).
- Each collapse requires replacement of about 100 feet of pipe, and one manhole is required for every 400 feet of collapsed pipe (in other words, one manhole replacement is needed for every four sewer collapses).

Based on these assumptions, it was projected that the participating utilities would experience a total of about 360 sewer collapses and about 90 manholes replacements as a result of a Cascadia subduction zone earthquake.

Assessment of Water and Wastewater Structures



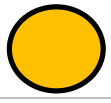
Participating utilities also compiled available data on the construction and age of critical water and wastewater facilities, such as treatment plants, pump stations, and reservoirs. To identify the degree and severity of likely failures of existing facilities, the task group compared the age distribution of existing facilities to the building code seismic requirements that were in effect at the time the facilities were constructed. Figure 8.22 is an example of the typical output that the task group used to estimate (for each utility) the damage that facilities may experience.

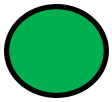
Based on this preliminary assessment, the following general observations were made regarding existing key structures:

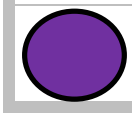
- Reservoirs and Tanks
    - Nearly all reservoirs and tanks are likely to experience some damage at the connection between the buried pipe system and the reservoir structure.
    - 33 percent of total tankage was built before 1960 and had no lateral force requirements—these tanks will most likely fail and release contents.
    - 30 percent of total tankage was built between 1960 and 1970 and had only a .06 gravity lateral force requirement—tanks that are near the epicenter will most likely fail and release contents.
    - 12 percent of total tankage was built between 1970 and 1990 and had only a .12 gravity lateral force requirement—tanks that are close to the epicenter will most likely fail and release contents.
    - 12 percent of total tankage was built between 1990 and 2000 and had somewhat more stringent lateral force requirement—these tanks will most likely suffer some damage, but may not release contents.
    - 13 percent of total tankage was built after 2000 and had stringent lateral force requirements—these tanks will most likely remain intact.
- Pump Stations
    - Nearly all pump stations are likely to experience some damage at the connection between the buried pipe system and pump station structure.
    - 13 percent of pump stations were built before 1960 and had no lateral force requirements—these stations will likely fail structurally and mechanically.

  - 22 percent of pump stations were built between 1960 and 1970 and had only a .06 gravity lateral force requirement—these stations will likely fail structurally and mechanically if located near the epicenter.
  - 12 percent of pump stations were built between 1970 and 1990 and had only a .12 gravity lateral force requirement—these stations will likely fail structurally and mechanically if located close to the epicenter.
  - 31 percent of pump stations were built between 1990 and 2000 and had somewhat more stringent lateral force requirement—these stations will most likely suffer some damage, but may be usable after repairs.
  - 19 percent of pump stations were built between 2000 and 2009 and incorporated stringent lateral force requirements—these stations are likely to remain intact and functional.
  - 3 percent of pump stations were built after 2009. They meet current code and are most likely to remain intact and be functional.

- Treatment Plants
  - Water and wastewater treatments will generally respond in similar ways.
  - Treatment plants built on liquefiable soils without special design for liquefiable soils are likely to suffer catastrophic damage due to foundation failures.
  - The identification of and mitigation for liquefaction generally did not become standard practice until the late 1990's.







Performance Group	Seismic Retrofit Date	Expected Performance Level	Description of Expected Performance	Approximate Restoration Time
	Pre-1975	Collapse Prevention	*Major Structural Damage *Structure on verge of collapse *Replacement necessary	18 months to 3 years
	1975–1993	Life Safety	*Significant structural and nonstructural damage *Repair possible but replacement may be more economical	3 to 6 months
	1994–Present	Immediate Occupancy, Life Safety	*Minor to moderate structural and nonstructural damage *Repairs needed	1 to 3 months

Figure 8.22: Example of Facility Age Distribution and Building Code Requirements

ADDITIONAL FACTORS

In addition to pipeline failures and the age of facilities, the task group considered other factors when preparing estimates of damage and resulting times to restore water and wastewater services; these factors included seismic hazards, interdependencies, and historical performance.

Anticipated Seismic Hazards

A number of seismic hazards other than shaking and ground motion are associated with a Cascadia subduction zone earthquake.

- *Liquefaction:* Liquefaction occurs when shaking during the seismic event causes a temporary increase in ground water pressure—the result is a loss of soil bearing capacity. Liquefaction can cause structures to settle and pipe connections to shear. The probability of liquefaction occurring is medium to high in the Valley as well as in portions of the Coast. In the Valley, areas such as those near Forest Grove, McMinnville, Albany, Woodburn, and along the Columbia River, have the highest risk of liquefaction. Along the coast, areas such as Astoria, Tillamook, Waldport, Florence, and Coos Bay have the highest risk of liquefaction.
- *Landslides:* The likelihood of permanent ground deformation due to landslides is high to very high for the Coastal and generally low for the Valley and Eastern zones.
- *Lateral spreading:* Displacement of soil structure can cause shearing of pipes and settlement of structures.
- *Shaking:* Sudden ground motion can cause liquids in a tank or reservoir to slosh and impose forces on a tank wall beyond its design capacity. An unanchored tank may rock, breaking connecting piping. As sloshing continues, rocking may cause the tank to buckle or burst. (Barnett, E.A., Weaver, C.S., et al. 2005)
- *Tsunami inundation:* Target recovery times and current recovery times were not established for those portions of the coastal zone that are in the inundation zone.

Interdependencies

A utility provider's ability to respond after the earthquake and restore water and wastewater service to the community will be impacted by the anticipated performance of other areas of the community.

- *Transportation Corridors.* The availability of transportation corridors, including bridges, highways, and rail lines, will impact the ability of repair and response crews to access damaged portions of the system and transport the materials they need to make repairs.
- *Energy and Fuels.* The region is expected to experience widespread electrical power outages and shortages of fuels as a result of a Cascadia subduction zone earthquake. This lack of critical resources will severely limit operation of pump systems and back-up generators; it will also limit the ability of utility providers to transport goods and employees.
- *Supply Chain.* Linked closely with transportation corridors, the ability to locate, purchase, and transport repair materials will impact recovery timeframes.
- *Work Force Availability.* Anticipated damage to community infrastructure, including homes and neighborhoods, will impact the ability of repair and response crews to mobilize. Personal injury and care of family members and dependents will be a high priority for many.

Historical Performance

When estimating recovery times, the task group considered the impacts of recent seismic events in other locations as well as the recovery efforts that followed.

- *Christchurch, New Zealand* (The Stronger Christchurch Infrastructure Rebuild Team, 2012). Water supply was re-established to 70 percent of households within one week. The wastewater treatment plant was badly damaged, although it continued to operate at reduced capacity. As a temporary measure, the effluent pumped into the ocean was not treated to the usual level.
- *Tohoku, Japan* (Floyd, 2012). In the 2011 Tohoku earthquake, 90 percent of people evacuated effectively; although around 20,000 people died or are missing. 200,000 people were in the inundation zone at the time of the earthquake.
- *Haiti.* (Ballantyne, 2012). Before the earthquake, over 50 percent of Port-au-Prince residents had no water service and only 10–12 percent had piped connections with intermittent service. After the earthquake, distribution networks were non-functional for most of the city. The primary water issue is distribution. Sewage collection networks were non-existent in the city before the earthquake and became a major problem in the contamination of fresh water and resulting disease outbreaks.

Estimated Recovery Timeframes for Existing Systems

Estimates of recovery times were developed for each of the three geographic zones of the state, with performance estimates made for each functional category within each zone. The resulting estimates of recovery times for existing systems, without resilience upgrades, are summarized in Figures 8.18, 8.19 and 8.20.

RESILIENCE GAP ANALYSIS SUMMARY

As indicated in Figures 8.18 and 8.19, existing water and wastewater systems are generally not able to meet the target recovery goals. This section presents notable gaps between performance goals and estimated recovery times for existing systems and summarizes typical seismic improvements needed to achieve the performance goals. Due to the distance between the epicenter of the earthquake and the facilities, damage within the Eastern zone (Figure 8.20) was not considered of sufficient consequence to warrant further analysis at this time.

PERFORMANCE GAPS

The water and wastewater sector tables for the Coastal and Valley zones (Figures 8.18 and 8.19) reveal significant gaps between the desired performance goals and anticipated performance of existing facilities. In general, performance of water systems in the Valley will be gauged based on availability of water at critical facilities (such as hospitals), which will establish the degree of mitigation necessary. In the Coastal zone, the need for fire flows at key supply points tends to establish the critical degree of

mitigation necessary. For both Coastal and Valley wastewater systems, the need to contain raw sewage overflows and control threats to public health tends to establish the degree of mitigation necessary.

It is important to recognize that the identified gaps reflect anticipated goals and performance for a typical system. In fact, each community or system must conduct its own seismic assessment of the existing facilities, determine what expectations the governing board and the community have for post-earthquake performance of the system, and develop a plan to achieve those expectations.

General observations regarding performance gaps and potential mitigation strategies that may be required to bridge these gaps are summarized below. Assumptions behind these observations are summarized in Figure 8.23.

In reviewing the proposed mitigation scenarios, seismically induced liquefaction stands out as a common vulnerability of critical facilities, because nearly all water and wastewater treatment plants are built near rivers. These facilities were built at times when seismically induced liquefaction was not well understood. Mitigation of seismically induced liquefaction at many of these plants may not be possible in a practical sense, because it would require reconstruction of existing foundations of large treatment structures while the existing facilities remain in operation. Effective mitigation of this critical and widespread vulnerability may require rebuilding these plants on more stable soils.

Water Systems

Notable performance gaps include:

- Water supply at critical facilities (90 percent level) will require one to three years on the Coast and one to three months in the Valley.
- Water supply for fire suppression at key supply points (90 percent level) will require one to three years on the Coast and three to seven days in the Valley.

For typical systems, potential improvements needed to achieve performance goals in the Coastal zone include:

- Hardening transmission facilities (river crossings, bridges, landslide areas, etc.) where possible.
- Replacing existing transmission facilities where hardening is impractical or impossible.
- Installing additional line valves to isolate damaged sections.
- Stockpiling critical replacement parts.
- Hardening valve and other control facilities.
- Providing for vacuum relief valves where needed to prevent pipeline collapse.
- Installing earthquake shutoff valves at appropriate locations.

- Replacing vulnerable pump stations built before 1970; hardening (as needed) pump stations that were built after 1970 so that they meet current standards.
- Replacing flow control equipment when it reaches the end of its current economic life.
- Rebuilding and redesigning transitions between soft piping, such as mains and hard piping at tanks and pump stations.
- Replacing 20 to 30 percent of the transmission systems using more earthquake resistant design standards and more earthquake resistant materials.
- Replacing 20 to 30 percent of the distribution systems using more earthquake resistant design standards and more earthquake resistant materials.
- Replacing tankage built before 1960 with earthquake resistant designs.
- Hardening tankage built after 1960 so that it meets current codes.
- Incorporating seismic resilience objectives into future capital improvement projects.

For typical systems, potential improvements needed to achieve performance goals in the Valley zone include (dates provide only general guidance):

- Hardening existing transmission facilities (river crossings, bridges, liquefaction, landslide areas, etc.) where possible.
- Replacing existing vulnerable transmission facilities where hardening is impractical or impossible.
- Installing additional line valves to isolate damaged sections.
- Stockpiling critical replacement pieces.
- Hardening valve and other control facilities.
- Providing for vacuum relief valves where needed to prevent pipeline collapse.
- Installing earthquake shutoff valves at appropriate locations, such as selected storage facilities and areas of the distribution system that are highly vulnerable.
- Replacing pump stations built before 1970; hardening pump stations built after 1970 so that they meet current standards.
- Replacing flow control equipment when it reaches the end of its current economic life.
- Rebuilding and redesigning transitions between soft piping, such as mains and hard piping at tanks and pump stations.
- Replacing 80 to 90 percent of the transmission facilities using more earthquake resistant materials.

- Replacing 20 to 30 percent of the distribution systems using more earthquake resistant design standards and more earthquake resistant materials.
- Replacing tankage built before 1960 with tankage of earthquake resistant design.
- Hardening tankage built after 1960 so that it meets current code.
- Incorporating seismic resilience objectives into future capital improvement projects.

Wastewater Systems

Notable performance gaps include the following:

- Threats to public health and safety are expected to exist for one to three years on the Coast and six months to a year in the Valley.
- Less than 90 percent of the raw sewage is expected to be contained or routed away from the population centers for one to three years on the Coast and for six months to a year in the Valley.

Research is required to develop sewer designs that will be resistant to permanent ground deformation resulting from a Cascadia subduction zone earthquake.

For typical systems, potential improvements needed to achieve performance goals in the Coastal zone include:

- In liquefiable soils, replacing 50 to 60 percent of the collection system with more earthquake resistant materials.
- In liquefiable soils, replacing 50 to 60 percent of the trunk lines with more earthquake resistant materials.
- Relocating or seismically upgrading wastewater treatment plants built before 2000 and all treatment plants built in areas subject to liquefaction.
- Rebuilding or seismically hardening pump stations built before 2000.
- Providing for emergency power and emergency treatment chemicals.
- Incorporating seismic resilience objectives into future capital improvement projects.

For typical systems, potential improvements needed to achieve performance goals in the Valley zone include:

- In liquefiable soils, replacing 50 to 60 percent of the collection system with more earthquake resistant materials.
- In liquefiable soils, replacing 80 to 90 percent of the trunk lines with more earthquake resistant materials.

- Relocating or seismically upgrading wastewater treatment plants built before 2000 and all treatment plants built in areas subject to liquefaction.
- Upgrading or seismically hardening pump stations built before 2000.
- Providing for emergency power and emergency treatment chemicals.
- Incorporating seismic resilience objectives into future capital improvement projects.

Number	Assumption
1	Recovery tables for the Coast and Valley represent an accurate assessment of what the impact of a magnitude 9.0 Cascadia earthquake on the resource would be should the earthquake occur now; sector tables also represents a consensus regarding the timeframes desired to make Oregon more resilient in 2063 should the same scenario occur then.
2	In the absence of other vulnerability studies, analysis of the facilities of Eugene Water & Electric Board (EWEB) is indicative of performance of similar facilities in the Willamette Valley.
3	Segregation of Coastal, Valley and Eastern responses is appropriate for this level of discussion.
4	Availability of other components of the infrastructure, such as electric power and chemicals, will not be a factor in achieving the desired 2063 restoration timeframes. That is, the water and wastewater industry needs to plan to be resilient without other infrastructure, such as power, telecommunications, and banking. Another assumption is there will be limited availability of construction materials, contractors, chemical deliveries, financial resources, and so forth.
5	Time-block brackets in the columns on the two tables represent the timeframe for the desired availability. Infrastructure will be available sometime in the time block, but this will most likely be toward the end of the bracketed time rather than beginning. For example, the first column is labeled *0–24 hours*. It is unlikely that resources will be available one minute or one hour or even 12 hours after the primary shaking stops; it is more likely that resources will be available near the end of the first 24 hours after the event. The expectation of timeframes needs to be clearly communicated to emergency services, hospitals, and other first responders.
6	In many instances, the three time targets (20–30%, 50–60%, and 80–90% operational) make little difference in the development of resilience scenarios; many of the facilities likely to be damaged cannot be repaired in the time difference given between blocks, because there will not be enough skilled human resources in the region to repair mains or fix treatment plants.
7	Mitigation of external vulnerabilities, such as liquefaction, landslides, and fires at buildings on adjacent properties, is a part of the gap analysis.
8	The gap will be closed (more or less) using the economic resources linearly (1/50 per year), with the most effective mitigation—focused on the system's backbone—taking place first.
9	The information presented in this report outlines the additional resources needed and not the replacement of infrastructure that would naturally take place as infrastructure wears out or exceeds its practical or economic life.
10	With the exception of the pipes, the damage estimates, recovery timeframes, and required expenses are the same for both wastewater treatment systems and water systems; for example, if it takes a month to fix a water pump station, it will take a month to fix a similarly damaged wastewater lift station.
11	Discharge of raw sewage is permissible during the initial period of a declared emergency, but compliance with most applicable discharge regulations will be required after the emergency period ends.
12	80 percent availability means that 80 percent of a given system will be available, not that 80 percent of the system capacity will be available.
13	The members of the task group expect that the material in this report will be communicated with stakeholders, such as elected officials and the public at large. It is hoped that agreement can be reached concerning stakeholders' expectations and the resources needed to fulfill those expectations. Negotiation to balance expectations and resources must take place.

Figure 8.23: Assumptions Related to Performance Gaps and Proposed Seismic Mitigation Improvements

Recommendations

- **Begin aggressive public information efforts to re-set public expectations for a realistic response time. Local governments should consider using local and state planning processes and tools to integrate seismic resilience into their community development and hazard preparation policies.**
  - The old guideline of having a 72-hour emergency survival kit falls far short of the anticipated needs given the extensive impacts of a Cascadia subduction zone earthquake. Even if basic supplies could be readily and broadly dispersed, it would likely take more than three days to achieve that dispersal, and emergency supplies would still fall short of what many people need to avoid deteriorating health (for example, medications, medical equipment, and ongoing healthcare support). There is clear value in members of the public having robust emergency supplies. In many areas, subsistence levels of food and water may be available within a week, but the public should be advised that response will take much more than 72 hours, and recovery times will likely be measured in months. This is especially important in coastal communities where response times could be measured in weeks, and recovery times could be measured in years.
  - The majority of jurisdictions in Oregon maintain local hazard mitigation plans, which can incorporate hazard identification, vulnerability and risk assessments, and mitigation strategies of public facilities and services. *Oregon's Statewide Planning Goals and Guidelines*, especially Goal 7 (Areas Subject to Natural Hazards) and Goal 11 (Public Facilities and Services), provides an opportunity through the Comprehensive Plan process to address the vulnerabilities of water and wastewater systems and devise policies and implementing measures to reduce risk.

- **Public agencies should be advised that the Oregon Water/Wastewater Agency Response Network (ORWARN) is a vital resource and membership is recommended.**

  ORWARN consists of member utilities and cities that provide mutual-aid response following an emergency. It is recommended that all water and wastewater service providers in the state join. This applies to agencies from both sides of the Cascades, because agencies from eastern Oregon will potentially become vital service providers to their counterparts on the coast and in the valley.

- **Service providers from all sectors should be required to have a seismic response plan that includes resources normally provided by a functioning infrastructure.**

  Communities are highly dependent on multiple service providers. These providers need comprehensive emergency response and recovery plans in order for their staff and related resources (contractors, consultants) to address seismic events. Non-infrastructure resources, such as emergency supplies of food and water, communications (including satellite phones), and sister-agency relationships, are vital resources for meeting emergency response and recovery

requirements. Event planning and training at the community level are important tools for building these response networks.

- **Service providers from all sectors are advised to plan for and support employee preparedness.**

  Previous events have demonstrated that the availability of employees can become a limiting factor in timely response and recovery of vital services following an event. To minimize delays in response and recovery, critical service agencies should provide their employees with the information and training they require to ensure that their families are safe and cared for. Employees have primary responsibility for their own and their families' preparedness; employers should clearly communicate preparedness expectations, but should also provide as much support as practical.

- **Water-related industry associations and manufacturers should be strongly encouraged to evaluate the need for seismic design standards for pipelines.**

  Industry associations, such as the American Water Works Association and the Water Environment Federation, currently do not have seismic standards for the design of pipelines. These associations should be encouraged to develop such standards and to educate their members on the availability and application of the standards.

- **Service providers for all essential sectors should be encouraged to develop business continuity plans.**

  In light of the highly interdependent nature of essential service sectors, all essential service providers should be encouraged to coordinate with other service providers to assure availability of essential services following an event. For example, water providers will need access to mapping of other buried utilities to complete repairs of water pipelines. Each essential service provider also needs to be prepared to sustain and maintain its workforce to avoid creating impediments to other service providers. This may include resources such as on-call contracts/agreements with contractors, consultants, and suppliers of other essential resources (for example, fuel suppliers, material suppliers, and equipment suppliers) to establish priorities and commitments following events.

- **Seismic vulnerability criteria should be incorporated into overall capital improvement project planning and asset management priorities.**

  Investing in infrastructure solely for improved seismic resilience may be too costly in many cases; however, a phased implementation of improvements can provide multiple benefits (improved capacity, better reliability, and reduced operation and maintenance costs). Service providers are encouraged to take advantage of planned renewal and replacement projects as opportunities to improve seismic resilience at relatively limited incremental cost.

Water-Specific Recommendations

- **Require water systems to complete a seismic risk assessment and mitigation plan as part of the existing requirement for five-year updates to water system master plans.**

  It is assumed that the Oregon Health Authority (OHA) would add this requirement to existing requirements for water system master plans. The required seismic risk assessment would identify and assess the likelihood and consequences of seismic failures. The resulting seismic assessment and mitigation plan would be subject to review and verification of documentation as part of the routine water system survey performed by OHA. The risk assessment should include a process for establishing target recovery goals for the area served. Seismic criteria may be based on hazard vulnerability analyses, building codes, and the findings of the Oregon Department of Geology and Mineral Industries (DOGAMI), because not all systems in Oregon (for example, those in eastern and central Oregon) may need to plan for a Cascadia subduction zone earthquake.

- **Encourage firefighting agencies and water providers to establish joint standards for use in planning the firefighting response to a large seismic event.**

  Water providers, fire departments, and emergency managers should lead their communities in establishing realistic standards and clear, mutually adopted expectations for water supply and firefighting priorities in the aftermath of a Cascadia subduction zone earthquake. This would result in joint fire and water decisions on strategies such as seismic valves and auxiliary water supply points. Rather than mandating a one-size-fits-all standard, the resulting solutions should be community-specific.

- **Water providers should be required to identify and coordinate key water supply points as part of periodic updates to water system master plans.**

  Water providers, in coordination with emergency response agencies and transportation agencies, should plan for key water supply and distribution points for firefighting as well as supply points for public distribution of emergency supplies. In many cases, minor investments in system infrastructure may be required to maximize the effectiveness, safety, and security of these supply points.

- **The Oregon Health Authority (OHA) should be encouraged to include a seismic design requirement as part of routine design review of water system improvements.**

  OHA currently provides review and approval of proposed designs of water system improvements. OHA review should include verification that seismic considerations have been incorporated into the design of proposed projects. It is not intended that OHA would verify the adequacy of the design; rather, OHA would simply confirm that seismic criteria were incorporated in the design. The goal of this recommendation is to ensure that seismic considerations are incorporated into designs for critical facilities. A review might include checking for items such as flexible connections to tanks, use of restrained joints, and consideration of geologic hazards. This additional verification is especially

important for pipelines, because there are currently no seismic standards for pipeline design (in contrast, the building code establishes seismic design requirements for structures).

► **Encourage the Oregon Department of Environmental Quality (DEQ) and the Oregon Health Authority (OHA) to establish goals and expectations for post-earthquake regulatory compliance and applicable standards.**

DEQ and OHA should work with utilities to establish acceptable practices and operational standards for use during emergency conditions. For example, will it be acceptable to discharge into waters of the state the chlorinated water from main breaks and main repairs? The agencies should also work together to:

- Identify and address potential analytical laboratory capacity limitations.
- Identify potential regulatory and laboratory strategies.
- Provide training to utilities on resulting recommendations.

Wastewater-Specific Recommendations

► **Require wastewater agencies to complete a seismic risk assessment and mitigation plan as part of periodic updates to facility plans.**

It is assumed that the Oregon Department of Environmental Quality (DEQ) would add this requirement to existing requirements for facility plans. The required seismic risk assessment would identify and assess the likelihood and consequences of seismic failures. The resulting seismic assessment and mitigation plan would be subject to review and verification of documentation as part of the routine assessments conducted by DEQ. The risk assessment should include a process for establishing target recovery goals for the area served. Seismic criteria may be based on hazard vulnerability analyses, building codes, and the findings of the Oregon Department of Geology and Mineral Industries (DOGAMI), because not all systems in Oregon (for example, eastern and central Oregon) may need to plan for a Cascadia subduction zone.

► **Wastewater agencies should be encouraged to conduct more complete characterizations of the impacts of estimated recovery times for seismic events.**

In preparing this report, the Water and Wastewater Task Group found that data on the anticipated performance of Oregon's wastewater systems in response to a seismic event is limited. Once additional information becomes available as a result of implementing the preceding recommendation, it is further recommended that this resilience plan be updated accordingly.

► **Encourage the Oregon Department of Environmental Quality (DEQ) to identify and coordinate with wastewater agencies on expectations for the levels of service, regulatory compliance, and applicable standards to be used following a major seismic event.**

DEQ should work with utilities to establish acceptable practices and operational standards for use during emergency conditions. For example, will it be acceptable to discharge raw sewage to receiving water following a disaster declaration? DEQ should also attempt to:

- Identify and address potential analytical laboratory capacity limitations.
- Identify potential regulatory and laboratory strategies.
- Provide training to utilities on resulting recommendations.

► **Encourage public health and wastewater agencies to coordinate and establish agreements for the use of temporary sanitary services (portable toilets) immediately after a seismic event.**

There are currently no clear lines of authority or defined responsibilities for temporary, emergency sanitation services such as portable toilets. To the extent possible, this should be pre-established by public health and wastewater service providers.

► **Encourage public health, water, and wastewater agencies to plan for significant water quality impacts to the Willamette and Columbia rivers downstream from Portland.**

It is likely that there will be extensive impacts due to potential failure of pipes at river crossings, leaking from fuel storage tanks, and other contamination and untreated discharges. This could result in significant adverse impacts on water supply for downstream communities that draw water from the Columbia River.

9. Looking Ahead

This *Oregon Resilience Plan* focuses on Oregon's physical infrastructure, with a special emphasis on business and community continuity following a Cascadia earthquake and tsunami. Because the state's physical infrastructure supplies the foundation for community resilience, we believe that the recommendations proposed here, if implemented over the next 50 years, will enhance our infrastructure, strengthen our communities, and support the growth of the state's economy.

This is a timeframe much longer than typical of government planning efforts, but the *Oregon Resilience Plan* is intended to inform and underpin statewide policies. To affirm Oregon's commitment to sustained action, OSSPAC needs to work with the Joint Ways & Means Committee of Oregon's Legislative Assembly to track and report on progress toward seismic resilience at the beginning of each legislative session, to keep the 50-year goal in view.

Because the level of economic development and the condition of infrastructure varies among Oregon communities, we suggest that local communities use the framework and the gap-analysis methodology presented in this report to conduct more refined assessments of local seismic and tsunami hazards, and develop community-specific recommendations to meet their unique response and recovery needs.

A Cascadia earthquake and tsunami will affect both Oregon and Washington. Both states share common challenges, among them the interstate bridges and the Columbia River navigation channel as well as the regional power grid and liquid fuel supply. In particular, Oregon gets almost one hundred percent of its liquid fuel from suppliers in Washington, delivered via pipeline and river. We believe that it would be beneficial for both states to work together at a regional level to address the common challenge of resilience to a region-wide seismic event. The "Resilient Washington State" initiative, completed this year by the Seismic Safety Committee of Washington State's Emergency Management Division, supplies an opportunity to begin.

The challenges of resilience are not limited to disaster preparedness; they are being recognized in many areas that require foresight and the coordination of public and private sector efforts. We encourage a broader public conversation that will bring other state agencies, businesses, and interest groups to the table for an exploration of resilience with respect to natural hazards, land use, climate change, and other topics characterized by systems interdependencies and long-time horizons. We have much to learn from one another about this new way of thinking.

This planning effort, with its emphasis on seismic resilience, is OSSPAC's first attempt to consider seismic risk from a perspective other than emergency preparedness and response. The report, compiled entirely by volunteers who contributed their skills and expertise, is less comprehensive than we might have wished, due to the limited time and resources available for the task. OSSPAC intends to monitor events around the world, and to update and augment the report as we are able to do so. We already recognize

the need to expand the planning effort in the future to include the following areas: (1) local community planning, (2) human resilience, (3) civic infrastructure, and (4) joint regional planning with Washington State.

The *Oregon Resilience Plan* is fundamentally about people—about preserving our communities and workforce to help businesses bounce back quickly from a natural disaster, so that the energies of commerce can propel recovery. Infrastructure investment will certainly lay a solid foundation to make timely recovery possible. However, human resilience supported by Oregon's civic infrastructure (community- based, non-governmental, and faith-based organizations) is needed to achieve full community resilience.

From natural disasters around the world, we have learned that civic infrastructure is especially critical during the first weeks after a disaster, before organized government assistance can be delivered. We believe that civic organizations, too, need to conduct seismic vulnerability assessment and to develop mitigation plans to ensure that expected services will be delivered.

On the topic of human resilience, we recognize the paramount importance of public health. We urge a commitment to the education and outreach necessary to keep the state's population as healthy as possible, so that the citizens themselves are ready physically and mentally to withstand disasters of any form.

Personal preparedness is a cornerstone of human resilience. Private and nonprofit sector leaders including the American Red Cross, drawing on experience with disaster response and recovery in many settings, emphasize a need to design and deliver training that reaches all students and educators in Oregon's K-12 schools, all local government employees, and all employees and guests of Oregon's tourism industry. The state, along with business leaders, must do more to support and facilitate these efforts. Everyone will play a role in disaster response and recovery; training must reach beyond those public and private sector employees who have essential response duties.

A resilient physical infrastructure, a healthy population, and a robust government and civic infrastructure to provide services to those in need will equip Oregon to withstand a Cascadia earthquake and tsunami, and to expedite response and recovery efforts. With determination, we can achieve that goal.

Appendix I HR-3 and Supporting Documentation

Enrolled

House Resolution 3

Sponsored by Representative BOONE; Representatives COWAN, KRIEGER, ROBLAN, WITT, Senators COURTNEY, JOHNSON, KRUSE, VERGER, WHITSETT

Whereas Oregon is known to be seismically active, with geological faults creating earthquake hazards in most of the state, including its most highly populated counties; and

Whereas the most serious risks linked to earthquakes in Oregon are associated with the Cascadia fault, recognized as one of the world's most dangerous faults and capable of generating megathrust earthquakes at least 1,000 times more powerful than the magnitude 6.8 Nisqually, Washington, earthquake of February 2001 and producing associated tsunamis capable of affecting extensive areas of the Oregon coast; and

Whereas geological evidence documents about 41 earthquakes of magnitude 8 and larger on sections of the Cascadia fault during the last 10,000 years, yielding an average interval between events of about 240 years; and

Whereas the most recent megathrust earthquake on the Cascadia fault, estimated to be about magnitude 9, occurred on January 26, 1700; and

Whereas many of the earthquakes on the Cascadia fault have been separated by intervals shorter than the time elapsed since the most recent Cascadia earthquake; and

Whereas an earthquake of magnitude 8 or larger and its associated tsunami would have devastating impacts to coastal communities and throughout western Oregon, causing thousands of casualties and premature deaths and inflicting tens of billions of dollars in physical damage that would have crippling impacts on the state's economy; and

Whereas policies now in place are insufficient to protect citizens and businesses in Oregon from the ground shaking and waves associated with a Cascadia megathrust earthquake and to ensure a smooth economic recovery after that event; now, therefore,

Be It Resolved by the House of Representatives of the State of Oregon:

That concern for the protection of life and the resumption of commerce should guide the State of Oregon in the development and implementation of resilience policies that address the risks posed by a Cascadia megathrust earthquake and tsunami; and be it further

Resolved, That Oregon's most forward-thinking policies and programs to advance resilience to earthquakes include the Seismic Rehabilitation Grant Program, fully enacted with general obligation bond funding by the 75th Legislative Assembly in 2009; and be it further

Resolved, That the strengthening of collapse-prone public structures, including, but not limited to, K-12 schools, community colleges and public safety facilities, should be recognized by the Governor and Legislative Assembly as top investment priorities in this state's capital budget; and be it further

Resolved, That seismic improvements to K-12 schools, community colleges and public safety facilities funded by Seismic Rehabilitation Grants should be recognized with placards affixed to the reinforced structures; and be it further

Resolved, That this state's investment in Seismic Rehabilitation Grants and in other programs and resources to accomplish seismic upgrades of public buildings should be expanded to the extent fiscal prudence allows; and be it further

Resolved, That this state should make investments in additional evacuation options for Oregon coastal communities that cannot ensure adequate protection of their residents and visitors from tsunamis because of distance from safe ground; and be it further

Resolved, That this state should make investments necessary to establish a Critical Transportation Infrastructure providing reliable lifelines for emergency response and economic recovery in the aftermath of a Cascadia earthquake and tsunami; and be it further

Resolved, That this state should make investments necessary to establish a Critical Energy Infrastructure comprising transmission networks for electricity, liquid fuels and natural gas hardened to withstand a Cascadia earthquake and tsunami; and be it further

Resolved, That seismic resilience should be viewed as a necessary complement to environmental sustainability and endorsed as a priority by the Governor and the Legislative Assembly; and be it further

Resolved, That the Seismic Safety Policy Advisory Commission should lead and coordinate preparation of an Oregon Resilience Plan that reviews policy options, summarizes relevant reports and studies by state agencies and makes recommendations on policy direction to protect lives and keep commerce flowing during and after a Cascadia earthquake and tsunami; and be it further

Resolved, That the commission should enlist the participation of the Governor's public safety advisor, state agencies, commissions and other advisory bodies, as needed, to assemble an integrated view of current state capabilities and gaps in resilience planning; and be it further

Resolved, That the Oregon Resilience Plan and recommendations should be delivered to the Legislative Assembly no later than February 28, 2013, so that the inevitable natural disaster of a Cascadia megathrust earthquake and tsunami does not cause an unprecedented catastrophe for the State of Oregon.

Adopted by House April 18, 2011

Kent Yu, PhD
Chairman, Oregon Seismic Safety Policy Advisory Commission
P.O.Box 14370
Salem, OR
97309 5062

Dr. Yu:

On Tuesday, November 8, 2011 I had the pleasure of spending time with the working session of the National Earthquake Hazard Reduction Program (NHERP) Advisory Committee. There, I was honored to meet Deborah Boone, Oregon State Representative and sponsor of Oregon House Resolution 3, which directs the creation of an Oregon Resilience Plan to prepare for the statewide impacts of a Cascadia earthquake and tsunami. I would like to wholeheartedly applaud Representative Boone, yourself, and the rest of the Oregon Seismic Safety Policy Advisory Commission on this initiative..

President Obama's top priority is the safety and security of the American people. I thank you for your leadership and your ongoing contribution to our Nation's resilience.

Sincerely,

Richard Reed
Special Assistant to the President for
National Security Affairs and
Senior Director for Resilience

Deborah Boone
State Representative

October 17, 2011

Richard A. Reed
Senior Director for Resilience Policy
National Security Council
The White House
1600 Pennsylvania Avenue NW
Washington, DC 20500

Dear Mr. Reed,

I am writing in regard to your responsibility for implementation of Presidential Policy Directive 8 on National Preparedness. According to that Directive, "*Each national planning framework shall include guidance to support corresponding planning for State, local, tribal, and territorial governments.*"

During the November 2011 meeting of the NEHRP Advisory Committee on Earthquake Hazard Reduction, I have asked Advisory Committee member Yumei Wang to share with you a copy of Oregon House Resolution 3, which I sponsored and my colleagues adopted unanimously in Oregon's House of Representatives on April 18, 2011.

H.R. 3 directs our state Seismic Safety Policy Advisory Commission (OSSPAC), on which I serve, to prepare an Oregon Resilience Plan to make recommendations on policy direction to protect lives and keep commerce flowing during and after the next Cascadia earthquake and tsunami expected to strike our state.

This is the first step Oregon will take to prepare comprehensively for the statewide impacts of a Cascadia earthquake and tsunami, and the only example of state legislation to initiate seismic resilience planning of which I am aware. Our intent is to address, to the extent feasible, the five mission areas identified in PPD-8: prevention, protection, mitigation, response, and recovery.

I would like to request your endorsement in writing of Oregon's resilience planning efforts, as a State initiative consistent with the intent of PPD-8 and worthy of support in its development and implementation by all branches and agencies of Oregon's state government and by appropriate

federal agencies.

Your letter to OSSPAC Chairman Dr. Kent Yu (address below) endorsing Oregon's resilience planning commitment will provide timely encouragement as we begin to engage the state's leadership in preparing the Oregon Resilience Plan during the next several months.

Thank you for your dedication to national preparedness and resilience.

Sincerely,

Rep. Deborah Boone

JOHN A. KITZHABER, MD
Governor

January 4, 2012

Kent Yu, Ph.D, Chair
Oregon Seismic Safety Policy Advisory Commission
P.O. Box 14370
Salem, OR 97309

Dear Dr. Yu,

The Oregon Seismic Safety Policy Advisory Commission (OSSPAC) has a challenging mission to educate the public about our seismic risks and inform diverse policy decisions. Through OSSPAC's dedicated efforts, though, the State of Oregon and its citizens have become increasingly aware that we live in an earthquake-prone region.

This month will mark the 312th anniversary of the last major earthquake and resulting tsunami from the Cascadia Subduction Zone that sits off Oregon's coast. Throughout this year, OSSPAC will be drafting an Oregon Resilience Plan to help us better prepare for the next major earthquake and tsunami.

A focused resiliency effort can better prepare us for catastrophic disasters as well as help us weather our more common emergencies like storms, floods and fires. OSSPAC has had wide participation from state agencies, local governments, businesses and non-profits and I encourage their continued engagement on this critical effort.

Thank you for all of OSSPAC's efforts to date and for continuing to be a powerful voice for a more prepared and resilient Oregon.

Sincerely,

John A. Kitzhaber, M.D.
Governor

CREW
AHEAD OF THE WAVE

A RESOLUTION requesting that the Cascadia Region Earthquake Workgroup endorse Oregon State and Oregon Seismic Safety Policy Advisory Council in creating a more resilient state through their resiliency planning efforts in support of 2011 Oregon House Resolution 3 (Oregon Resiliency Planning).

WHEREAS, a Cascadia Subduction Zone generated earthquake and tsunami poses significant risk to life, property, the environment, and the regional economy, and

WHEREAS, the Cascadia Region Earthquake Workgroup, has a vision of a disaster resilient region, and

WHEREAS, the Cascadia Subduction Zone represents a common hazard in the Pacific Northwest and the shared risk that affect the Cascadia Region; and

WHEREAS, the Cascadia Region Earthquake Workgroup supports efforts to reduce vulnerability,

NOW THEREFORE,

BE IT RESOLVED BY THE BOARD OF DIRECTORS THAT:

The Cascadia Region Earthquake Workgroup is supportive of the goals and objectives identified in 2011 Oregon House Resolution #3; and

Resolved, that the Cascadia Region Earthquake Workgroup will provide support similar to that provided to Washington State Seismic Safety Committee's Resilient Washington State Initiative; and

Resolved, that the Cascadia Region Earthquake Workgroup will help promote the findings of resilience planning efforts from the Pacific Northwest to further reduce identified risks and improve seismic resilience.

Adopted by the Cascadia Region Earthquake Workgroup Board of Directors this 25th day of January, 2012, and signed by me in authentication of its adoption this 25th day of January, 2012.

President of the Cascadia Region Earthquake Workgroup

Appendix II January 26, 2012 workshop

Oregon
John A. Kitzhaber, MD, Governor

Seismic Safety Policy Advisory Commission
Oregon Emergency Management

Fax: (503) 373-7833

Oregon Resilience Planning Overview

Background

A Cascadia earthquake and tsunami has the potential to cause an unparalleled economic and human catastrophe for the State of Oregon because its impacts are region-wide. Over 40 great earthquakes of magnitude 8 and larger have struck Western Oregon during the last 10,000 years. The current calculation of a 37% conditional probability that a Cascadia earthquake will strike Oregon within the next 50 years means that it is now prudent to understand and take steps to mitigate this risk to our economy and to our businesses, homes, and communities.

In April 2011, the Oregon House of Representatives unanimously passed House Resolution 3 (sponsored by Rep. Deborah Boone, D-Cannon Beach), which directs Oregon Seismic Safety Policy Advisory Commission (OSSPAC) to "lead and coordinate preparation of an Oregon Resilience Plan that . . . makes recommendations on policy direction to protect lives and keep commerce flowing during and after a Cascadia (megathrust) earthquake and tsunami." The Plan and recommendations are due to be delivered to the Oregon Legislative Assembly by February 28, 2013.

Richard A. Reed, President Obama's Senior Director for Resilience Policy, and Oregon Governor John Kitzhaber have acknowledged our resilience planning efforts and have provided their endorsement.

Resilience

Resilience as defined in House Resolution 3 means that Oregon citizens will not only be protected from life-threatening physical harm, but that because of risk reduction measures and pre-disaster planning, communities will recover more quickly and with less continuing vulnerability following a Cascadia Subduction earthquake and tsunami. OSSPAC defines the Cascadia earthquake to be a Magnitude 9.0 Cascadia Subduction earthquake with an average recurrence of once every 500 years.

To achieve the goal of rapid recovery, we need arrangements in place for government continuity, resilient physical infrastructure, and business/economic continuity. Resilient physical infrastructure is the foundation.

Resilience Planning Objective and Methodology

Oregon Seismic Safety Policy Advisory Commission (OSSPAC) will lead and coordinate with government agencies, academia, business and professional communities to develop a comprehensive 50-year resiliency plan so that the state will become a resilient state by 2062. It will work with various government agencies and advisory bodies to collect available studies and reports and develop data as appropriate to:

- assess **conditions** of existing critical facilities and lifeline systems,
- evaluate **effectiveness** of current design and construction practices relative to earthquake resilience,
- develop **desired performance targets** (in terms of usability and timeframe required for the restoration of services) to meet resilience goals, and
- prepare **recommendations** for statewide policies and actions to achieve the desired performance targets.

We will utilize concepts and ideas developed for San Francisco by the San Francisco Planning + Urban Research Association (SPUR) and by the Resilient Washington State initiative in our neighbor to the north, and apply them to a statewide level. The final SPUR documents for the Resilient City project in San Francisco can be found at http://www.spur.org/resilient_city.

To promote communication with the general public and policy makers, we will strive to use language appropriate for a general audience and minimize use of highly specialized technical vocabulary when developing the resilience plan.

Resilience Planning Organizational Structure

Oregon Seismic Safety Policy Advisory Commission (OSSPAC) will be leading and coordinating the preparation of the plan through its Resilient Oregon Steering Committee. OSSPAC Steering Committee consists of five commissioners as follows:

Kent Yu (Chair, Public member/Structural)
Jay Wilson (vice Chair, Public member/local government)
Althea Rizzo (OEM, State Earthquake/Tsunami Manager)
Ian Madin (DOGAMI)
Stan Watters (Public member/Utilities)

As a state commission with limited staff and resources at its command, OSSPAC must depend on voluntary assistance from Oregon's government agencies, academic, business, and professional communities to complete this task. OSSPAC has assembled one Advisory Panel and eight task work groups that represent a broad cross section of contributors, including policy advisors, government officials, emergency/business continuity managers, professors, engineers, scientists, business representatives, sustainability practitioners and others.

Advisory Panel

OSSPAC will seek strategic advice from the Advisory Panel throughout the development of the resilience plan. Its makeup is also intended to augment OSSPAC's overall capabilities and broaden OSSPAC representation from government, legislature, geographic region, and business.

The Advisory Panel currently consists of

Cameron Smith (Public Safety Advisor to the Governor)
The Hon. Peter Courtney/Ryan Mann (Oregon Legislature)
JR Gonzalez (Oregon PUC)
Bruce Johnson (ODOT)
Ed Dennis (Oregon Dept. of Education)
Yumei Wang (NEHRP)
Onno Husing (Oregon Coastal Zone Management Assn.)
Nate Wood, Ph.D. (USGS)
Scott Ashford, Ph.D. (OSU)
Chris Goldfinger, Ph.D. (OSU)
Andre LeDuc (U of O)
Jeff Soulages (Intel)
Edward Wolf (Oregon citizen)
Leon Kempner (Regional/Bonneville Power Administration)
Don Lewis (DOGAMI)
Jean O'Connor (Oregon Health Authority)

Eight Task Groups

OSSPAC Steering Committee has established eight task groups to address the state's critical facilities and its energy, water/wastewater, transportation, and telecommunications systems, mitigate tsunami risk, and enhance business continuity. The state's Department of Geology and Mineral Industries (DOGAMI) will support our work with mapped depictions of Cascadia earthquake scenarios based on the best available science.

Eight task groups are listed below:

1. Magnitude 9.0 Earthquake/Tsunami Scenario led by Ian Madin (OSSPAC/DOGAMI)
2. Critical/Essential Buildings led by Ed Quesenberry and Trent Nagele (SEAO)
3. Energy led by Stan Watters (OSSPAC/Port of Portland) and JR Gonzalez (PUC)
4. Telecommunications led by Althea Rizzo (OSSPAC/OEM) and Mike Mumaw (OSSPAC/Beaverton)
5. Transportation (Highways + Bridges/Ports/Railroads) led by Bruce Johnson (ODOT)
6. Tsunami Risk Mitigation led by Jay Wilson and Jay Raskin
7. Water and Waste Water System led by Mike Stuhr (PWB) and Mark Knudson (TVWD)
8. Business Continuity led by Susan Steward (OSSPAC/BOMA) and Gerry Williams (OSSPAC)

Magnitude 9.0 Earthquake/Tsunami Scenario Group will develop:

- Ground shaking intensity maps
- Tsunami Inundation maps
- Landslide and liquefaction maps

All other task groups will utilize the various maps developed to generate their resiliency plans. The task group makeup is expected to vary from one group to another due to the difference of the sectors. However, we expect each group to have at least one emergency manager, one engineer, and one business representative.

The Critical Building Task Group will address:

- Emergency Operations Centers
- Education facilities (K-12, College and University);
- Healthcare facilities (Hospitals and MOBs)
- Police and Fire Stations
- Critical government administration/services facilities
- Emergency sheltering facilities
- Community retail centers
- Financial/banking buildings
- Residential housing
- Vulnerable buildings (Un-reinforced masonry buildings and non-ductile concrete buildings)

The Energy Task Group will address the systems listed below:

- Electricity
- Natural Gas
- Liquid Fuel
- Alternative Energy – Solar, Wind and others
- Dams

The Telecommunications Task Group will address the systems listed below:

- Communication Network and Database
- Telecommunication Infrastructure

The Transportation Task Group will address the systems listed below:

- Bridges (owned by ODOT, Counties, or Cities)
- Airports and river and sea ports
- Railroads
- Mass Transit (Trimet)
- Columbia River

Tsunami Risk Mitigation Group will address the following:

- Tsunami evacuation
- Zoning and land use policy
- Critical facilities
- Re-building community
- Debris management

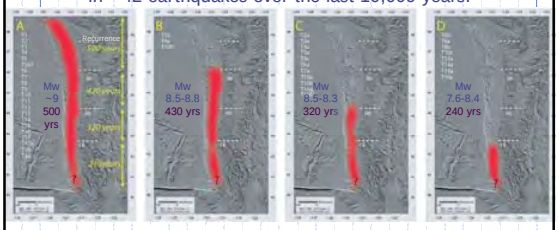
The Water and Wastewater Task Group will address the systems listed below:

- Drinking water storage, transmission, and distribution systems
- Wastewater collection systems and treatment plants

Interdependency issues among different lifeline sectors will be addressed through coordination of the steering committee and collaboration of Group leaders at a regular monthly meeting.

January 26, 2012 Kickoff Workshop

We will kick off the Oregon resiliency planning effort on January 26, 2012 (the 312th anniversary of the most recent Cascadia earthquake) at the Port of Portland.



We anticipate that the participants will get an overview of House Resolution 3 and the roadmap of the Oregon resilience plan, and learn about what Washington has accomplished with its Resilient Washington State initiative. During the breakout sessions, the leaders of each task group will facilitate and lead the discussion of the scope of their group, and work with their participants to develop action plans and schedules. Each task group will assign a designated participant to take notes, and the OSSPAC steering committee will assemble a final document based on information submitted by all workgroups. A second workshop will be scheduled in the fall of 2012 for each group to report their progress.

Oregon Resilience Planning Workshop

January 26,2012
Port of Portland

Cascadia Subduction Zone Earthquakes

Turbidites show how much of the subduction zone ruptured in ~42 earthquakes over the last 10,000 years.

(Modified from Goldfinger et al. (in press) by adding magnitude estimates and some labels)

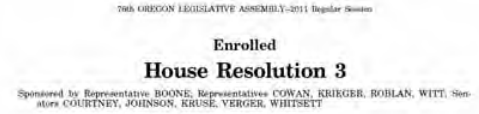
- 20 earthquakes ruptured all of the subduction zone.
- 2 to 3 earthquakes ruptured three quarters of subduction zone
- 19 earthquakes ruptured the southern half or quarter of the subduction zone

Acknowledgment

- Port of Portland for providing meeting venue
- CREW for sponsoring lunch
- Degenkolb for sponsoring morning coffee

Cascadia Earthquake Hazards and Risk

PACIFIC NORTHWEST



- Cascadia Subduction Zone
- 1994 – Oregon Building Code w/Seismic Design Provisions
- Interval 500 yrs for M9.0
- M9 on 1/26/1709

Seismic Concerns

- Progressive Government and community
- Unclear building performance
- Different standards for performance among different lifeline sectors
- Lack of inter-sector coordination
- Limited understanding by political leadership and the public of the potential performance of buildings and lifelines

January 26 Resilent Oregon kickoff by Kent Yu

House Resolution 3

76th OREGON LEGISLATIVE ASSEMBLY--2011 Regular Session

Enrolled

House Resolution 3

Sponsored by Representative BOONE, Representatives COWAN, KRIEGER, ROBLAN, WITT, Senators COURTNEY, JOHNSON, KRUSE, VERGER, WHITSETT

- Protect citizens and businesses from shaking and tsunami
- Ensure rapid economic recovery

OSSPAC Mission

Broad Political Support

- Richard A. Reed, President Obama's Senior Director for Resilience Policy
- Oregon Governor John Kitzhaber
- State Agencies
- CREW, SEAO, ASCE, AIA
- Oregon businesses and local government
- Academia
- Neighbors, Friends and Colleagues

OSSPAC

- 18 members appointed by Governor
- Six representatives of government (Bldg Codes, DOGAMI, DLCD, OEM, ODOT, DOE)
- Six representatives of public interest (Legislature, Red Cross etc.)
- Six representatives of industry and stakeholders (Struct., Banking, local govern., multi-family, Bldg Owner, Utilities)
- The mission of OSSPAC is to increase or improve:
  1) earthquake awareness, education and preparedness;
  2) earthquake risk information;
  3) the earthquake safety of buildings and lifelines;
  4) geoscience and technical information; and
  5) emergency pre-disaster planning, response and recovery efforts
- http://www.oregon.gov/OMD/OEM/osspac/osspac.shtml

Agenda

Time	Event	Presenter
9:00 a.m.	Greeting and Introduction	Kent Yu, OSSPAC Chair Cale Ash, CREW President
9:20 a.m.	Introduction into Resiliency Planning in Oregon	General Caldwell/OR OEM, Rep. Deb Boone
9:40 a.m.	OSSPAC Mission Summary of House Resolution 3	Kent Yu
10:00 a.m.	Framework for Oregon Disaster Resiliency Plan	Kent Yu Jay Wilson, OSSPAC Vice-Chair
10:45 a.m.	BREAK	
11:00 a.m.	Washington State Disaster Resiliency Plan	John Schalling, WA EMD
11:30 a.m.	Orientation of Task Force Break out groups	Althea Rizzo, OR OEM Jay Wilson
12:00 a.m.	LUNCH	Pick up lunches
12:20 p.m.	Task Group Work Sessions	Facilitated by Task Group leads
2:45 p.m.	BREAK	
3:00 p.m.	Task Group Briefings (5 minutes per group)	Presented by Task Group leads
3:45 p.m.	Next steps	Kent Yu
4:00 p.m.	End Workshop	

Oregon's Seismic Safety Legislation

- 2001 law "life safety" in schools by 2032
- 2002 Ballot Measure 15 amended Constitution: allows bonds to fix schools
- 2005 4 Bills (2007 schools report on web)
- 2007 Funds & staff establish grant program
- 2009 Seismic Retrofit Grant program
  - $30 M ($15M schools, $15M emergency response facilities)
- 2011 Cascadia Resilience Planning

Y.Wang

January 26 Resilent Oregon kickoff by Kent Yu

House Resolution 3

- Directs (OSSPAC) to "lead and coordinate preparation of an Oregon Resilience Plan that . . . makes recommendations on policy direction to protect lives and keep commerce flowing during and after a Cascadia (megathrust) earthquake and tsunami."
- The Plan and recommendations to be delivered to the Oregon Legislative Assembly by February 28, 2013.

Resilience Planning Objective and Methodology

HR3 Resilience Definition

- Protect Citizens from physical life-threatening harm (from Earthquake and Tsunami)
- Community recover rapidly with less vulnerability through mitigation and pre-disaster planning
- Cascadia Earthquake is M9.0 with average 500 years return.

Resilience Planning Objective

- Look at 50-year time window
- Develop a comprehensive plan so that state is resilient by 2062
- Utilize concepts and ideas by SF Planning +Urban Research Association and from Resilient Washington Initative

HR 3 Resilience Definition

- To Achieve Rapid Recovery, Require Government Continuity, Resilient Physical Infrastructure, Business Continuity
- Resilient Physical Infrastructure is the foundation

How Much Damage Can a City Endure?

Chile - 2010

New Zealand - 2011

The Resilient City

- A Resilient City can take "the Punch" of an event and through preparedness and the impromptu response of those affected, and recover quickly.
- Goal: Save the people, their neighborhoods, their cultural heritage and their local economy
- Resilience is sustainable

Transparent Hazard Definitions for the Region

Category	Hazard Level
Routine	Likely to occur routinely in the region (**50/50**)
Expected	Reasonably expected to occur once during the useful life of a structure or system **(10/50, 500)**
Extreme	Reasonably be expected to occur on a nearby fault **(2/50, 2500)**

SPUR Approach:

- Define concept of ***resilience*** in the context of disaster planning and recovery
- Establish ***performance goals*** for the "expected" earthquake that supports the definition of resilience
- Define transparent ***performance measures*** that help reach the performance goals
- Make ***Recommendations*** for new buildings, existing buildings and lifelines

Transparent Performance Measures for Buildings

Category	Performance Standard
Category A	***Safe and operational***: Essential facilities such as hospitals and emergency operations centers
Category B	***Safe and usable during repair***: "shelter-in-place" residential buildings and buildings needed for emergency operations
Category C	***Safe and usable after repair***: current minimum design standard for new, non-essential buildings
Category D	***Safe but not repairable***: below standard for new, non-essential buildings. Often used as a performance goal for existing buildings undergoing voluntary rehabilitation
Category E	***Unsafe – partial or complete collapse***: damage that will lead to casualties in the event of the "expected" earthquake - the killer buildings

Performance Goals for the "Expected" Earthquake

Phase	Time Frame	Condition of the built environment
I	1 to 7 days	Initial response and staging for reconstruction
II	7 to 60 days	Workforce housing restored – ongoing social needs met
III	2 to 36 months	Long term reconstruction

Lifelines and workforce are the key elements

Seismic Performance
Life Safe and Operational

Seismic Performance
Life Safe and Usable During Repair

Seismic Performance
Unsafe (Collapse)

Seismic Performance
Life Safe and Useable after Repair

Transparent Performance Measures for Lifelines

Category	Performance Standard
Category I	Resume 100% service within 4 hours
Category II	Resume 90% service within 72 hours
	95% within 30 days
	100% within 4 months
Category III	Resume 90% service within 72 hours
	95% within 30 days
	100% within 3 years

Seismic Performance
Life Safe but not repairable

Target States of Recovery for Building & Infrastructure

Phase	Time Frame	Focus of Attention
I	1 to 7 days	Initial response and staging for reconstruction

EOC's,
City Buildings,
Hospitals,
Police and Fire Stations,
Shelters

Building Category A: "Safe and Operational"
Life Line Category I: "Resume essential service in 4 hours"

Target States of Recovery for Building & Infrastructure

Phase	Time Frame	Focus of Attention
II	7 to 30 days	Workforce housing restored – ongoing social needs met

Residential structures,

Schools,

Community retail centers,

Doctors offices

Building Category B: "Safe and usable while being repaired"

Life Line Category II: "Resume 100% workforce service within 4 months"

Oregon Resilience Planning Organizational Structure

Target States of Recovery for Building & Infrastructure

Phase	Time Frame	Focus of Attention
III	2 to 36 months	Long term reconstruction

Industrial Buildings

Commercial buildings

Historic buildings

Building Category C: "Safe and usable after repair"

Life Line Category III: "Resume 100% commercial service within 36 months"

Overall Structure

- OSSPAC
- OSSPAC Steering Committee
- Advisory Panel
- Eight Workgroups

Oregon Resilience Planning Steps

- assess **conditions** of existing critical facilities and lifeline systems,
- evaluate **effectiveness** of current design and construction practices relative to earthquake resilience,
- develop **desired performance targets** (in terms of usability and timeframe required for the restoration of services) to meet resilience goals, and
- prepare **recommendations** for statewide policies and actions to achieve the desired performance targets.
- Recommendations will be prepared in plain, layman language.

OSSPAC Steering Committee

- Kent Yu (Chair, Public member/Structural)
- Jay Wilson (vice Chair, Public member/local government)
- Althea Rizzo (OEM, State Earthquake/Tsunami Manager)
- Ian Madin (DOGAMI)
- Stan Watters (Public member/Utilities)

Advisory Panel

- Cameron Smith (Public Safety Advisor to the Governor)
- The Hon. Peter Courtney/Ryan Mann (Oregon Legislature)
- JR Gonzalez (Oregon PUC)
- Bruce Johnson (ODOT)
- Ed Dennis (Oregon Dept. of Education)
- Yumei Wang (NEHRP)
- Onno Husing (Oregon Coastal Zone Management Assn.)
- Nate Wood, Ph.D. (USGS)
- Scott Ashford, Ph.D. (OSU)

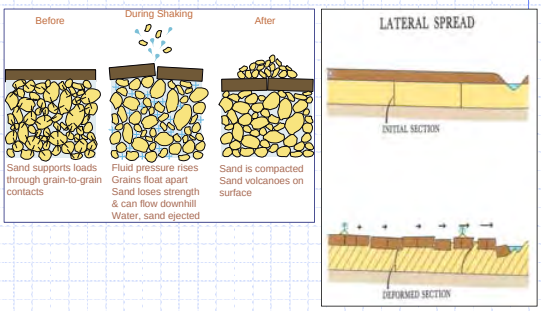
Earthquake/Tsunami Group

- Led by Ian Madin (DOGAMI)
- Magnitude 9.0 Earthquake/Tsunami Scenario Group will develop:
  1) Ground shaking intensity maps
  2) Tsunami Inundation maps
  3) Landslide and liquefaction maps

Advisory Panel (continued)

- Chris Goldfinger, Ph.D. (OSU)
- Andre LeDuc (U of O)
- Jeff Soulages (Intel)
- Edward Wolf (Oregon citizen)
- Leon Kempner (Regional/Bonneville Power Administration)
- Don Lewis (DOGAMI)
- Jean O'Connor (Oregon Health Authority)

Strong Shaking and Tsunami

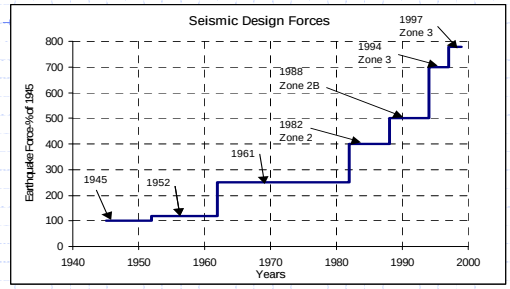


- Strong Ground Shaking (M9 w/ 3 min shaking)
- Tsunami within 25 minutes

Eight Workgroups

- Magnitude 9.0 Earthquake/Tsunami Scenario
- Critical/Essential Buildings
- Energy
- Telecommunications
- Transportation
- Tsunami Risk Mitigation
- Water and Waste Water Systems
- Business Continuity

Liquefaction & Lateral Spreading



Liquefaction

Oregon Education and Emergency Facilities

Critical Building Group

- Led by by Ed Quesenberry and Trent Nagele (SEAO)
- The Critical Building Task Group will address the buildings listed below:
  - Emergency Operations Centers
  - Education facilities (K-12, College and University);
  - Healthcare facilities (Hospitals and MOBs)
  - Police and Fire Stations
  - Critical government administration/services facilities
  - Emergency sheltering facilities
  - Community retail centers
  - Financial/banking Buildings
  - Residential Housing
  - Killer buildings (URM and non-ductile RC buildings)

URMs and Non-ductile Concrete

Energy Group

- Led by Stan Watters (OSSPAC/Port of Portland) and JR Gonzalez (PUC)
- The Energy Task Group will address the systems listed below:
  - Electricity
  - Natural Gas
  - Liquid Fuel
  - Alternate Energy – Solar, Wind and others
  - Dams

Transportation Group

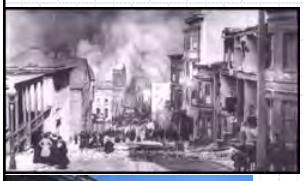
- Led by Bruce Johnson (ODOT)
- The Transportation Task Group will address the systems listed below:
  - Bridges (owned by ODOT, Counties or Cities)
  - Airports and Seaports
  - Railroads
  - Mass Transit (Trimet)
  - Columbia River

Energy: Liquid Fuel, Electrical Systems

(Credit: Yumei Wang)

Tsunami Risk Mitigation Group

- Led by Jay Wilson/Jay Raskin
- Tsunami Risk Mitigation Group will address the following:
  - Tsunami evacuation
  - Zoning and Land use policy
  - Critical facilities
  - Re-building community
  - Debris management



Telecommunications Group

- Led by Mike Mumaw (OSSPAC/Beaverton) and Althea Rizzo (OSSPAC/OEM)
- The Telecommunication Task Group will address the systems listed below:
  - Communication Network and Database
  - Telecommunication Infrastructure

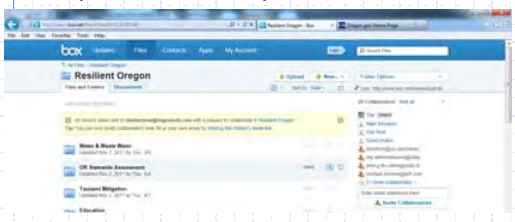
Water and Waste Water Group

- Led by Mike Stuhr (PWB) and Mark Knudson (TVWD)
- The Water and Wastewater Task Group will address the systems listed below:
  - Water storage, transmission, and distribution systems
  - Wastewater collection systems and treatment plants

Water and Wastewater

Project Schedule

Business Continuity Group



- Led by Susan Stewart (BOMA) and Gerry Williams (OSSPAC)
- Goals:
  - Raise Earthquake/Tsunami Awareness
  - Gauge Earthquake/Tsunami Preparedness
  - Gather input/ideas from Business for other workgroups to improve resilience plan

Project Schedule

- 100% Completion on February 2013
- 90% completion in December
- 75% completion in September 2012 (2nd Workshop)
- 45% completion in June 2012
- 15% completion in March 2012
- Kickoff workshop in January 2012 (Today)
- Initial Planning (11/2011 thru 1/12)

Oregon Resilience Planning Platform

- Virtual team with modern communication
- Online collaboration platforms (Box, Dropbox, Evernote…)

Next Steps

January 26 Resilent Oregon kickoff by Kent Yu

Next Steps

- Apply for funding in February 2012
- Special OSSPAC on February 21, 2012
- Invite Group Leaders to OSSPAC Meeting to discuss inter-dependency issues.

Reach Out

Thank You

Resiliency Planning Task Groups Work Session Orientation

January 26, 2012

Jay Wilson
OSSPAC, Vice Chair

QuickTime™ and a decompressor are needed to see this picture.

Oregon Seismic Safety Policy Advisory Commission

Resiliency Planning Task Groups Work Session Orientation

- How will the "final" document be synthesized and condensed from the work products produced from each group?
- A professional writer will work with each committee to develop the final report that will synthesize all of the different parts to form a unified document.

OSSPAC

Resiliency Planning Task Groups Work Session Orientation

- Work sessions will be facilitated by team leads.
- Each group will have topics to initiate discussion at this breakout session.
-
- Session will be about 2 hours long.

OSSPAC

Resiliency Planning Task Groups Work Session Orientation

- Will there be a uniform work product format that each group will be working from?
- OSSPAC Steering Committee will develop a template of specific issues that each committee must address as part of their work.
- The template will be used to maintain consistency of mission and format between committees.
- Mid year will be a 50% deadline.

OSSPAC

Task Groups and Leads

MAGNITUDE 9.0 EARTHQUAKE/TSUNAMI SCENARIO
led by Ian Madin (OSSPAC/DOGAMI)

CRITICAL/ESSENTIAL BUILDINGS
led by Ed Quesenberry and Trent Nagele (SEAO)

ENERGY
led by Stan Watters (Port of Portland) and JR Gonzalez (PUC)

Oregon Public Meeting Law

Task Group leads should work closely with OSSPAC staff to meet State Requirements for proper notification of public meetings.

http://www.oregon.gov/OMD/OEM/osspac/osspac.shtml

ORS regarding public notice states "a reasonable time" of notice must be given, and special meetings just have to give at least 24 hours' notice.

A Bill was recently passed regarding posting all public meeting notices on The State's new "Transparency" state website.
It lists all boards and commissions and all meetings. See link below.

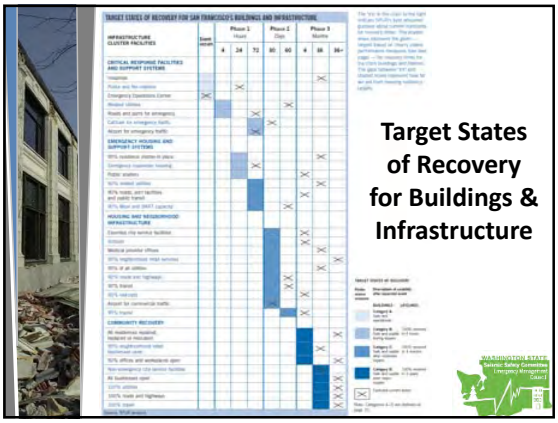
The Resilient Washington State Initiative

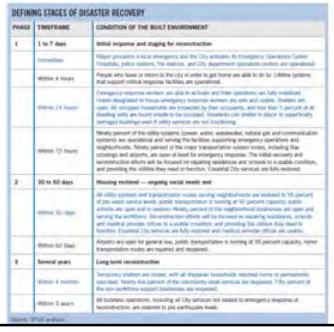


OSSPAC Meeting
January 26, 2012

Background

- The Resilient Washington State Initiative project is based upon the San Francisco Urban Planning and Research Association (SPUR) Report, entitled "*The Resilient City*", which examines the current state of resilience to a scenario quake in San Francisco.
- Initial report includes 4 major policy sections - Defining Resilience, The Dilemma of Existing Buildings, Building it Right the First Time, and Lifelines.
- Three subsequent reports released during the course of the RWS project.

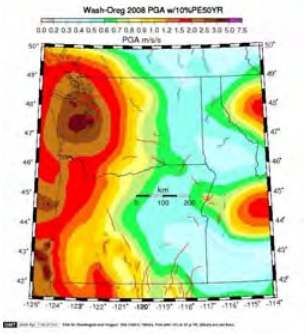
Presentation Overview



- Project Background
- "The Resilient Washington State Initiative"
- Project Approach & Preliminary Results
- A few early lessons learned… some considerations for Oregon

Target States of Recovery for Buildings & Infrastructure

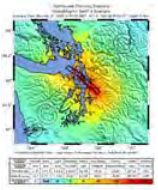
So, what is the "Resilient Washington State Initiative"?



Incorporate Transparent Performance Measures

Resilient Washington State

- *Purpose* - Provide a framework for improving Washington's resilience when earthquakes occur.
  - Framework includes more effective seismic mitigation policies and recommendations for legislation and policy changes to improve and enhance statewide seismic safety.
- *Timeframe* – Goal of making the state resilient in 50 years.
  - Implementation plan by short-, mid-, long-term



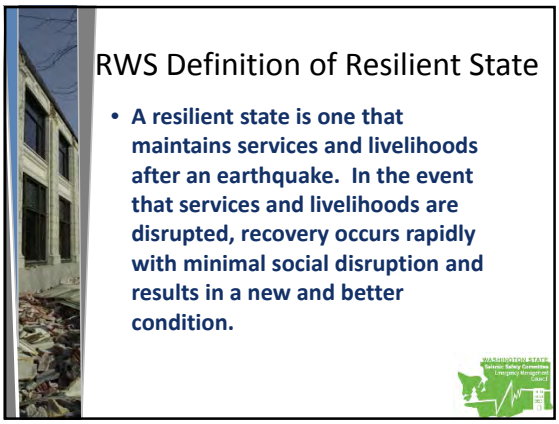
Resilient Washington State

Resilient Washington State

Earthquake Hazard:

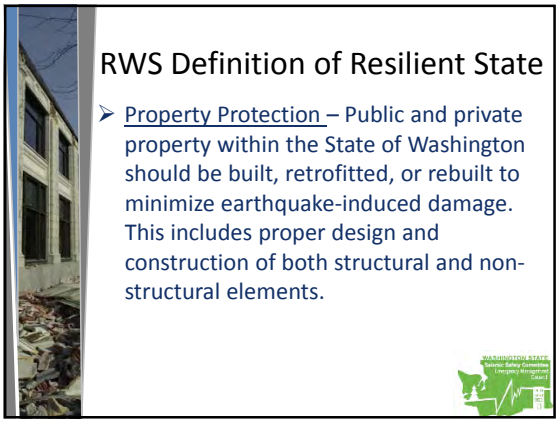
- Not possible to define single EQ scenario at a State level.
- Identified a suite of scenarios from the 20 scenario earthquakes developed in 2009 by personnel from the WA EMD, WA DNR, USGS, and FEMA for use in planning efforts.

So, what *IS* resilience?

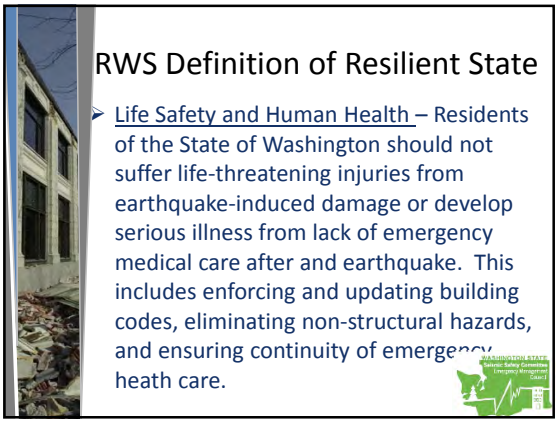


Resilient Washington State

Earthquake Hazard:

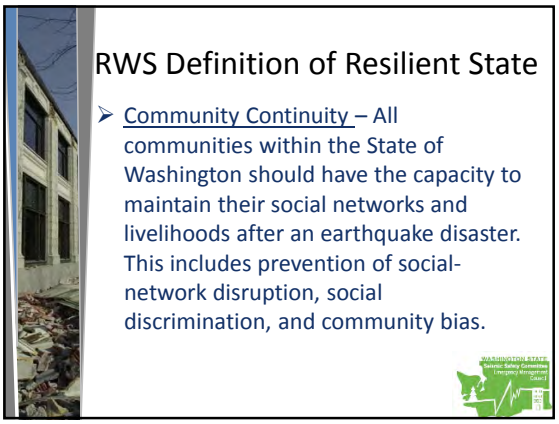


- M7.2 Seattle Fault, M7.4 Southern Whidbey Island Fault, M7.1 Tacoma Fault, M7.3 Saddle Mountain Fault, M6.8 Cle Elum Fault, and M9.0 Cascadia.
- Scenarios define geographic area of impact.
- Consider Ground Motions consistent with USGS 10/50 PGA maps.



Defining Resilience

- SPUR uses engineering standards –how many building demolitions (or infrastructure failures), and how long a recovery time for various levels of EQ.
- Resilience as a disaster, but not a catastrophe.
- Ability to recover – govern, lifelines to resume in short time frame, people stay in homes, resume normal living routine in weeks and return to new "normal" in few years.



RWS Definition of Resilient State
• A resilient state is one that maintains services and livelihoods after an earthquake. In the event that services and livelihoods are disrupted, recovery occurs rapidly with minimal social disruption and results in a new and better condition.

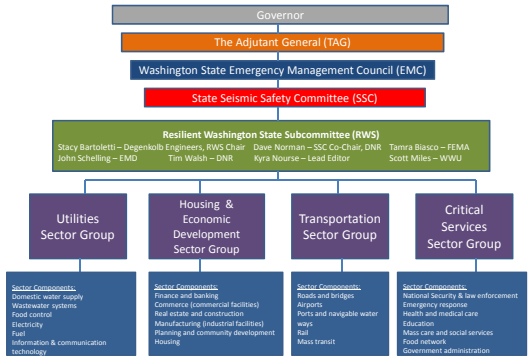
RWS Definition of Resilient State
➢ Environmental Protection – The natural resources and ecosystems of Washington State should be managed in such a way as to minimize earthquake-induced damage. This includes the use of proper growth management, accident response capacity, and industrial safety measures.

RWS Definition of Resilient State
➢ Property Protection – Public and private property within the State of Washington should be built, retrofitted, or rebuilt to minimize earthquake-induced damage. This includes proper design and construction of both structural and non-structural elements.

RWS Definition of Resilient State
➢ Life Safety and Human Health – Residents of the State of Washington should not suffer life-threatening injuries from earthquake-induced damage or develop serious illness from lack of emergency medical care after and earthquake. This includes enforcing and updating building codes, eliminating non-structural hazards, and ensuring continuity of emergency
heath care.

RWS Definition of Resilient State
➢ Economic Security – Residents and businesses within the State of Washington should have access to income opportunities to meet basic needs before and soon after an earthquake. This includes sufficient employment opportunities, market access, distribution capacity, and supplier access.

RWS Definition of Resilient State
➢ Community Continuity – All communities within the State of Washington should have the capacity to maintain their social networks and livelihoods after an earthquake disaster. This includes prevention of social-network disruption, social discrimination, and community bias.



Overall Project Approach

- Established RWS Subcommittee under WA SSC

- Reviewed existing information and incorporated new data from the USGS/ DNR/EMD Scenario Catalog Project as a starting point.
- Hosted a workshop engaging key stakeholders and local jurisdictions in the process.
  - A truly Resilient State is made up of Resilient cities, counties, & tribes - local jurisdictions can adopt this approach (i.e. San Francisco model) at a smaller scale.

Resilient Washington State – Organizational Structure

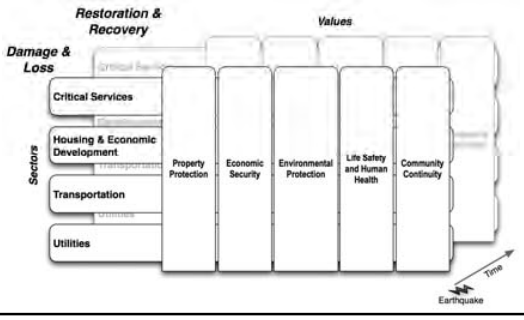
Overall Project Approach (cont.)

- Conducted an online survey of subject matter experts to help identify current capabilities
- Established formal Sector Groups with subject matter expert co-leads to facilitate information gathering from key partners and obtain buy in.
  - Sector Groups work independently using common guidance
- Hosted a follow-up workshop to deconflict results and review interdependencies
- RWS Subcommittee provides report

Resilient Washington State

Objectives of Sector Groups:

- Evaluate the current condition Sector and assess how quickly they can be restored.
- Develop targets for the desired restoration time frame.
- Define the vulnerabilities and key interdependencies.
- Prepare recommendations for statewide action to achieve desired targets.



Resilient Washington State Sectors

- Critical services
- Housing and economic development
- Transportation
- Utilities

*Each **sector** is comprise of multiple* possible ***components***

*Each **sector** has different **restoration** capacity & targets with respect to each RWS **value***

Sectors, Values, and Restoration

Resilient Washington State

Process and Timing:

- 2009 – RWS Committee Formed
- 2010 – RWS Committee Developed Framework
- 9/17/2010 – Stakeholder Workshop to form Sector Groups
- 12/2/2011 – Concluding Workshop
- Q1 2012 – Draft Report
- Q2 2012 – Final Report

- Questions?

A few early lessons learned:

- Planning for multiple scenarios at a state level is TOUGH!
  - Consider examining one at a time
  - Leverage FEMA-State Cascadia planning process & data
- Tables as tools, not products
  - Consider having a starting draft and have the experts 'tell you where you're wrong' to keep out of the weeds
- Mitigation vs. Response
  - Interconnected, but what is your goal? Which one is the priority for your planning?

So, what does 'being resilient' mean to Oregon?

Registration for Jan 26, 2012 Workshop

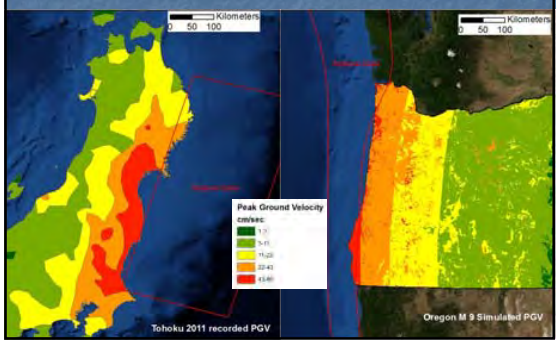
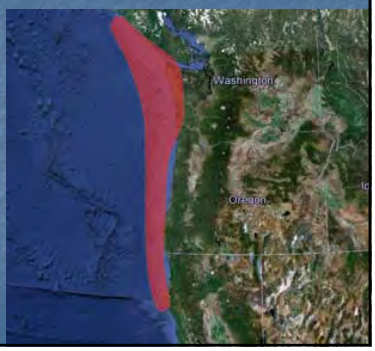
Appendix III October 5, 2012 Workshop



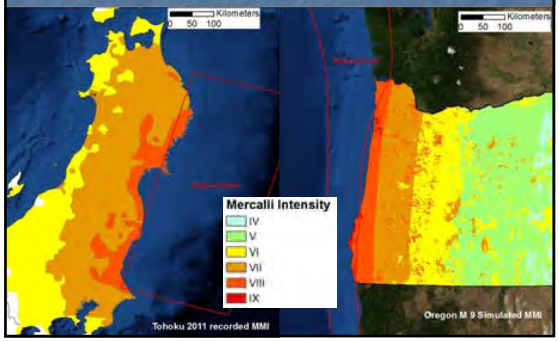
Past Cascadia earthquakes vary widely in location and size.

19 events | 4 events | 9 events | 10 events

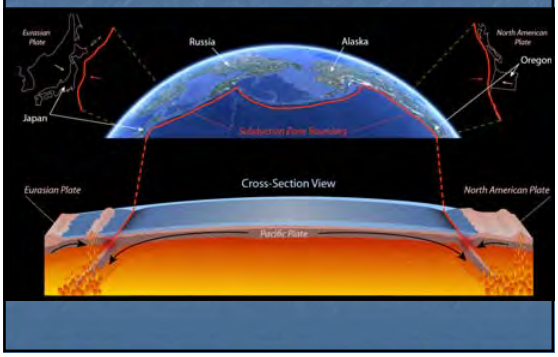


Data from USGS Professional Paper 1661-f

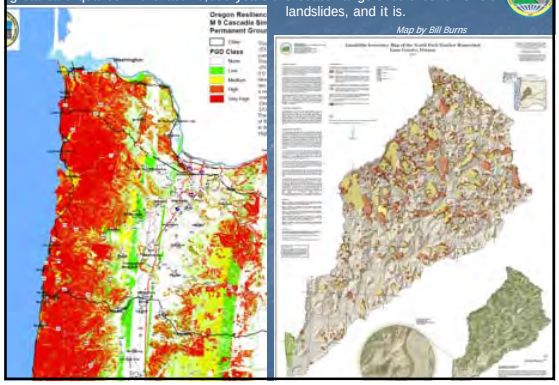
The simulated M 9 PGV values used for the resilience plan assessments are broadly comparable to values recorded in the 2011 Tohoku earthquake.



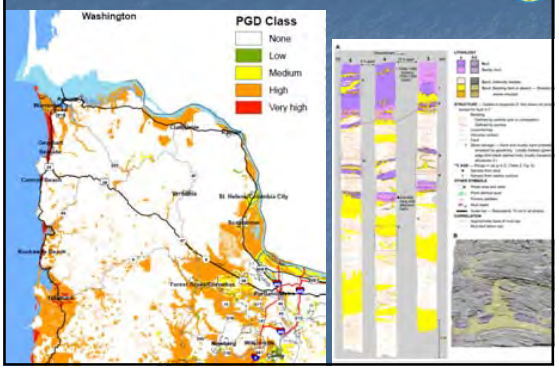
The Plan scenario was based on a full-margin rupture of magnitude 9. Maps were prepared for:



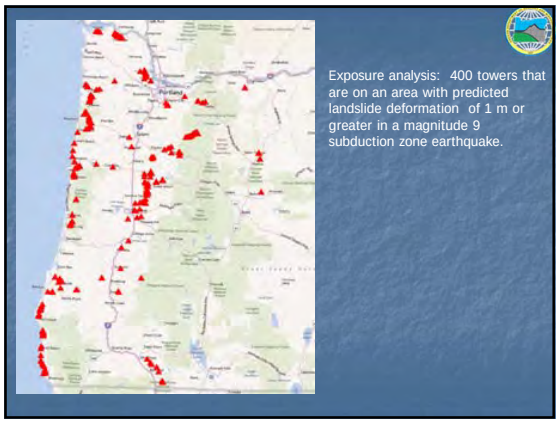
- Peak Ground Acceleration
- Peak Ground Velocity
- Landslide Probability
- Landslide Deformation
- Liquefaction Probability
- Liquefaction Displacement
- Tsunami inundation
- Co-Seismic subsidence
- Mercalli Intensity



The simulated M 9 MMI values used for the resilience plan assessments are also broadly comparable to values recorded in the 2011 Tohoku earthquake.

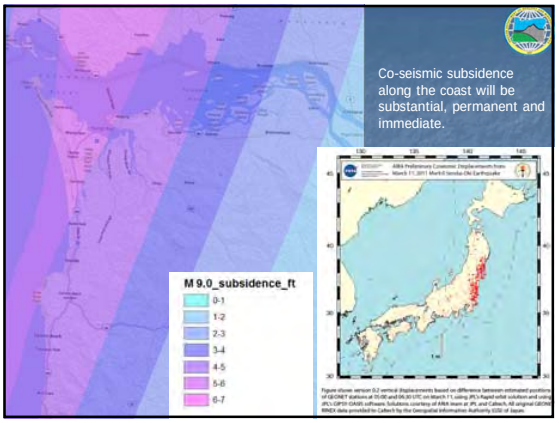


Oregon is a geologic mirror-image of Northern Japan. In both places, the Pacific Ocean floor is sliding beneath the adjacent continents along giant faults called subduction zones. *(Graphic by Dan Coe, DOGAMI)*



The M 9 landslide model shows high landslide susceptibility, so with over 40 great earthquakes in the last 10,000 years the Coast Range should be full of old landslides, and it is.

The model also predicts high levels of liquefaction and liquefaction ground deformation, and again the geologic record agrees.



Exposure analysis: 400 towers that are on an area with predicted landslide deformation of 1 m or greater in a magnitude 9 subduction zone earthquake.

Modeled Tsunami inundation at Rockaway Beach. Inundation depends strongly on the size of the earthquake.

SB 379 Model | "M" model | "XXL " Model

Co-seismic subsidence along the coast will be substantial, permanent and immediate.

October 5 business community presentation by Susan Steward and Gerry Williams

Business/Community Continuity

The State does not have policies that assure a level of resiliency, emergency response and recovery are in place and actively maintained for the state, county, city and businesses.

Recommendations:

- Require all county and city Emergency Operations Centers (EOC) to establish a Business BEOC function, web site and staff position that are coordinated at the State level by the State's BEOC function to provide local support to businesses for resiliency, response and recovery activities.
- Require all state, county, and city departments have annual reviews/exercises of Continuity of Operations Plans (COOP) in place.
- Offer eBRP toolkit at no cost to businesses larger than 10,000 square feet or 25 number of employees. This information must be available to the private sector, upon request at no charge.
- Offer training for all communities, prioritizing communities in a high-risk area *(Oregon Coast, etc.)*.
- Require all business licensed in Oregon to certify during the licensing process that they have emergency response and business continuity plans.
- Establish a state program to provide for ATC 20 Certified inspectors. State assumes cost/risk/liability for state sponsored/trained inspectors. State also provides liability protection for business owners from contractor's erroneous good faith estimates.
- Require business certifications for out of state business coming to provide recovery support.

Business/Community Continuity

The Business /Community Continuity Sub-Committee (BCC) approached the 50 year preparedness goal for businesses and workforce by dividing the effort into three main areas:

- Resiliency – what can be done now to help businesses prepare for, recover from and remain in Oregon at the state, county, city and business levels after an event?
- Emergency Response – what can the state, county, city and the businesses do to respond to an event to minimize the impact to businesses' physical assets, supporting infrastructure and workforce; allowing business to resume activity in the shortest possible time?
- Recovery - what can the state, county, city and the businesses do to facilitate their economic recovery?

Business/Community Continuity

Uncertainty about how businesses will respond during an earthquake.

Recommendations:

- Identify all buildings greater than 10,000 square feet that they expect will survive a major event. State will create and maintain a public database of all critical buildings, locations of emergency shelters, etc. Included in the database will be the status of risk areas including stable electrical power, reliable communications; logistics: rail, airport, roadways, water ways; water & sanitation; and waste disposal.
- Provide resources to help building owners seismically upgrade their asset(s). State to act as a "clearing house" for seismic funding options including: tax reduction incentives; federal and state grants, or low interest loans; state to ensure a timely business recovery loan process. (Consider resources such as the Small Business Administration disaster loans for businesses following an event).
- Work with the Building Codes Division (BCD) to require all buildings greater than 50,000 square feet to have gas piping to be equipped with a gas shutoff valve.

Business/Community Continuity

Sub-Committee Findings

- The State does not have policies that assure a level of resiliency, emergency response and recovery are in place and actively maintained for the state, county, city and businesses
- Uncertainty about how businesses will respond during an earthquake
- The State needs to align its resiliency, emergency response and recovery plans with the Department of Homeland Security's Critical Infrastructure Sectors to assure coordination planning/response for natural disasters and terrorist attacks

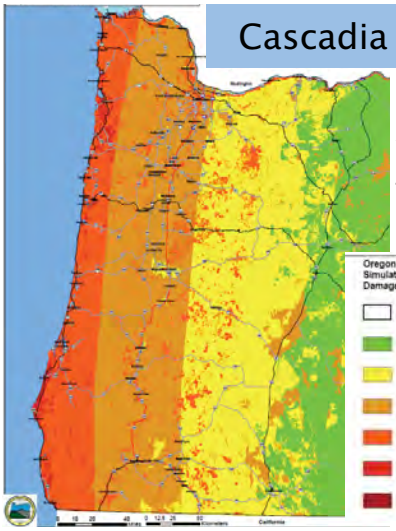
Business/Community Continuity

The State needs to align its resiliency, emergency response and recovery plans with the Department of Homeland Security's Critical Infrastructure Sectors to assure coordination planning/response for natural disasters and terrorist attacks.

Recommendations:

- Use the 18 Critical Infrastructure Sectors: Food & Agriculture; Banking & Finance; Chemical, Commercial Facilities; Communications; Critical Manufacturing; Dams; Defense Industrial Base; Emergency Services; Energy; Government Facilities; Healthcare & Public Health; Information Technology; National Monuments & Icons; Nuclear Reactors; Materials & Waste; Postal & Shipping; Transportation Systems; and Water, to list all related companies in Oregon and require them to certify they have emergency response and business continuity plans in place and are exercises or used annually.
- State to use the Business EOC (BEOC) function to coordinate the command, control and communications (C3) of the listed companies for providing evidence of certification, exercising and event response. Require all critical infrastructure companies to register with their local BEOC's and provide business and emergency contact information of their senior operations personnel.
- Legislature to mandate that cities throughout Oregon provide a risk assessment of their major lifelines, develop clear instructions for citizens how to evacuate the city, and develop a plan to transport workers and emergency supplies necessary for recovery.

Oregon Resilience Plan
Coastal Resilience Workgroup

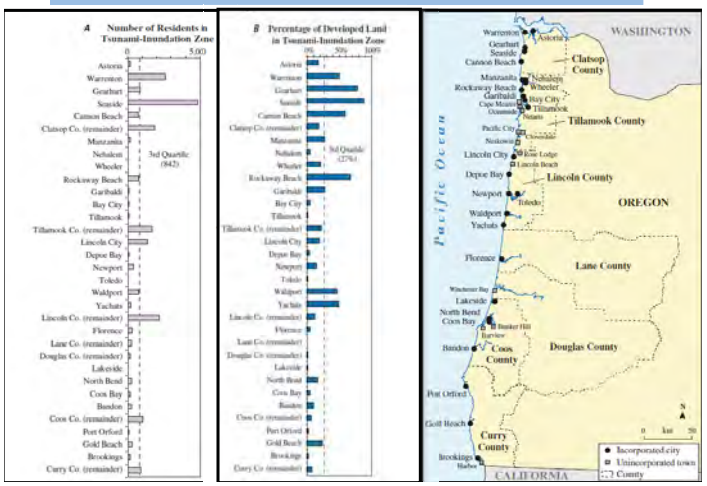


Advisory Panel Meeting
October 5, 2012

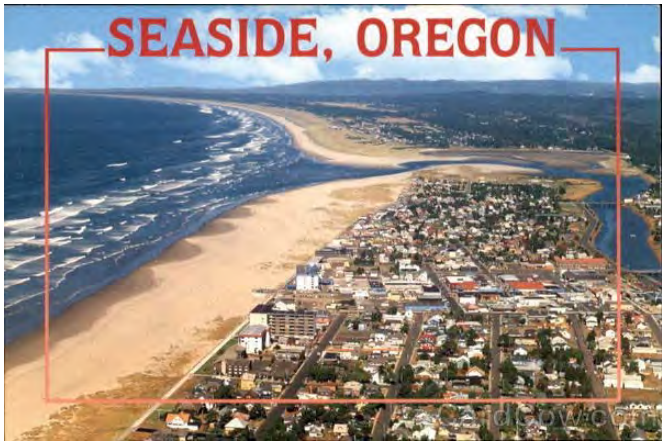
Jay Wilson
OSSPAC, Vice Chair

Oregon Seismic Safety Policy Advisory Commission

Cascadia Planning Map



Planning Zones
1. Central Oregon
2. I-5/Willamette Valley
3. Coast EQ Affected Zone
4. Coast Tsunami-Affected Zone



Coast –Most Significant Issues

- **Comprehensive Approach for Life Safety**
  - Evacuation and shelter for people displaced
  - Short-term and long-term housing
- **Target for 90% Restoration of Services in Two Weeks – Reasonable? Possible?**
  - Greatest immediate and long-term needs for assistance in the State (per capita).
  - Interdependency between Tsunami and EQ Zones
  - Weather-dependent capabilities?
- **Mitigation, Recovery and Reconstruction**
  - Land use guidance for community relocations
  - Return of Community Economic Base
- **Debris Management**

Tsunami Life Safety

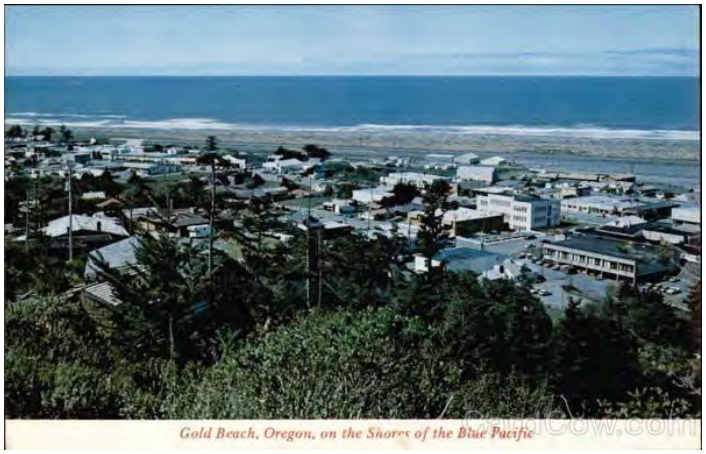
Tsunami Destination

Tsunami Destination - Depot Bay

Tsunami Destination - Newport

Tsunami Destination - Florence

Tsunami Destination - Winchester Bay

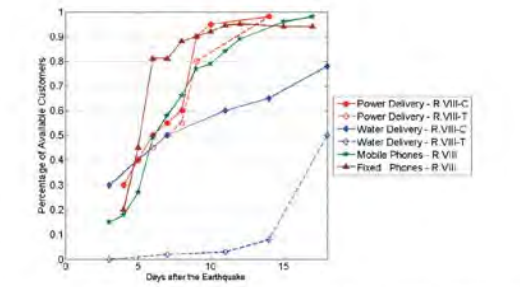


Tsunami Destination - North Bend

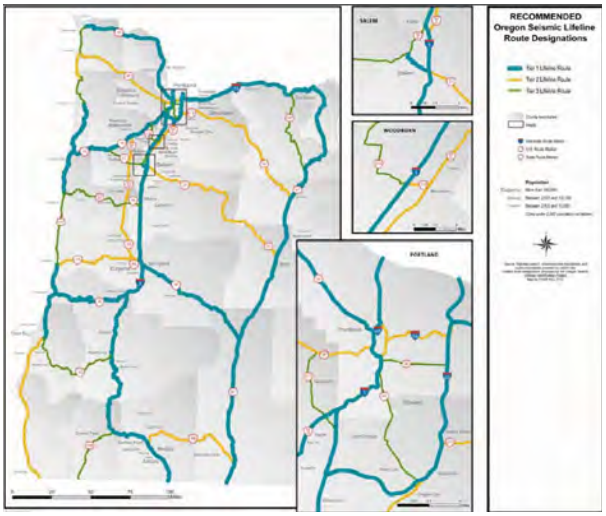
Tsunami Destination

Tsunami Destination - Gold Beach

Earthquake vs. Tsunami Zone

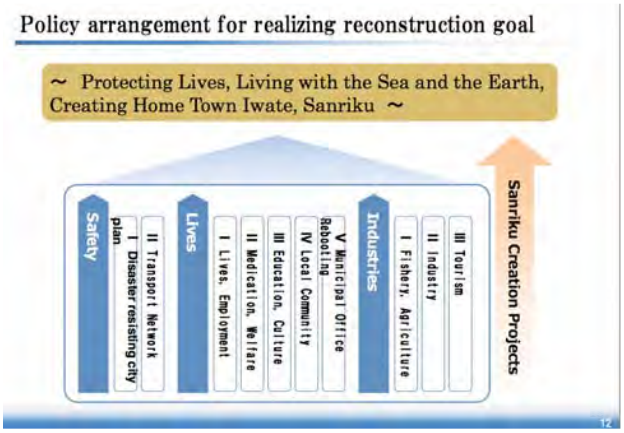


Minamisanriku Tsunami Zone - Zero Capacity



Most Significant Issues

- Expected Recovery Timeline of 90% Services?



Empirical restoration times for power delivery, water distribution, and telecommunications. The letters C and T indicated the cities of Concepción and Talcahuano, respectively. Both cities are in Region VIII, whose capital is Concepción.

Debris Management

Reconstruction and Recovery

Relationship Between Sustainability and Disaster Resilience

Source: Public Entity Research workgroup OSSPAC

ENERGY TASK GROUP

Electric
Natural Gas
Liquid Fuel

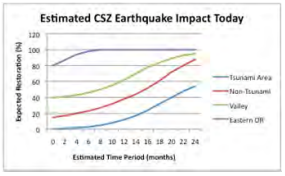
The Risks by Sector

- Liquid Fuels Delivery Systems
  - the liquid fuel transmission pipeline
    - Liquid fuel pipeline was largely constructed in the 1960s when the regional seismic hazards were unknown and state-of-practice construction techniques at that time did not include any reference to seismic standards
  - marine vessels
- Storage – The bulk in tank Farms

Earthquake/Tsunami Scenario

- 4 Distinct Regions
  - Coastal Tsunami
  - Coastal Non-Tsunami
  - Valley
  - Eastern Oregon
- Oregon's critical energy infrastructure (CEI) are not governed by a uniform set of design and construction codes
  - Much of the existing CEI has been constructed with severe seismic design deficiencies
  - New critical infrastructure is often constructed without adequate seismic provisions
  - To minimize extensive direct earthquake damage, substantial improvements to the CEI are necessary

The Risks by Sector



- Shipping channel
  - The navigational channel from the Columbia River mouth to the lower Willamette River is used to transport fuel by marine vessels
  - The Columbia River mouth is expected to have tsunami damage and the channel is expected to experience slope failure, which would close the channel to traffic
  - It is possible that bridges and other river crossings, such as buried gas pipelines and electrical crossings, would be damaged and temporarily block the waterway
    - The regional seismic hazards are now known to be significant and the soils at the river crossings are susceptible to liquefaction and lateral spreading
  - Closure of the shipping channel would prevent marine vessels from delivering liquid fuel as well as emergency response and recovery equipment from being delivered

CSZ Resiliency - Today

The Four Regions

- Tsunami Impacted Coastal areas
- Tsunami Not-Impacted Coastal areas
- Valley
- Eastern Oregon

Recovery Timeframe Graphical Representation

Impact of a CSZ earthquake today for each of the 4 regions, with the exception of Eastern Oregon, would be catastrophic!

The Risks by Sector

- Marine terminals
  - All of the port facilities in the CEI Hub have significant seismic risks due to liquefaction, lateral spreading, and seiches
  - Some older piers were constructed without any seismic protection, have deteriorated, and are likely to fail in even a moderate earthquake
  - If oil products are released and contaminant the navigable waterway, the waterway may be closed to river traffic thus impeding emergency response activities as well as the supply chain
  - The local capacity to fight fires and clean hazardous material spills is limited.

The Risks by Sector

- Fuel supply
  - Only three existing tanks are known to have addressed liquefaction vulnerabilities
  - The fuel terminals in the CEI Hub on average have a three to five day supply in the tank farms for regular unleaded gasoline and diesel fuel
  - Premium gasoline is subject to the daily delivery and heavily dependent on whether the intercompany pipeline on Front Avenue is operational
  - If the supply chain is disrupted by pipe breaks north of the CEI Hub and closure of the shipping channel to the west, fuel would quickly become scarce
  - Options to transport fuel from the east and south and by air are very limited.

The Risks by Sector

- Electricity
  - The bulk of the electrical networks were not built to withstand moderate to significant earthquakes
  - Electrical facilities and systems have significant seismic risk due to ground shaking and ground failure, including liquefaction and lateral spreading
  - Seismically vulnerable facilities include substations, Switch Stations, transmission lines, power plants, and key distribution substations
- CSZ damage to the western electrical grid will likely result in grid blackout
- BPA is the only transmission operator that has taken seismic vulnerability seriously

The Risks by Sector

- Portland International Airport (PDX)
  - PDX airport receives 100 percent of their liquid fuels from a terminal in the CEI Hub
  - PDX has a limited on-site fuel supply
  - If the pipeline between the CEI Hub and PDX fails, then PDX would likely experience a shortfall and operations would be impacted.

Impacts to Oregon

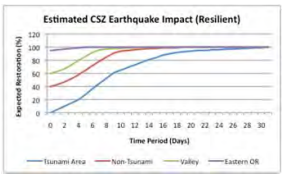
- Based on visual observations, engineering judgment, limited analyses, and limited information from the facility operators, and available literature, significant seismic risk exists in the CEI
- Some critically important structures appear to be susceptible to significant damage in a major earthquake with catastrophic consequences
- Multiple liquid fuel transmission pipe breaks and natural gas transmission pipe breaks are possible
- Damage to liquid fuel, natural gas, and electrical facilities will occur.
- The waterway would likely be closed and require clean up.

The Risks by Sector

- Natural Gas
  - Oregon's largest natural gas service provider receives the majority of their natural gas from pipelines that cross under the Columbia River both near Sauvie Island and also between Washougal, Washington and Troutdale, Oregon
  - One of the natural gas pipelines crosses under the Willamette River at Multnomah Channel near their gate station at the southern end of Sauvie Island
  - The soils at these river crossings are subject to liquefaction and lateral spreading
  - The natural gas company's storage capacity is limited and pipe breaks could lead to a natural gas shortfall in the state as well as explosions or fires.

Impacts to Oregon

- Due to a combination of the existing seismic hazards, vulnerability of the exposed infrastructure and potential consequences, Cascadia earthquakes pose substantial risk to the CEI in Oregon
- Not only are the energy sector facilities dependent on other sectors and systems, including transportation and communication, they are interdependent upon each other
- A major Cascadia earthquake and tsunami would likely produce an unprecedented catastrophe much larger than any disaster the state has faced.
- Western Oregon will likely face an electrical blackout, extended natural gas service outages, liquid fuel shortage, as well as damage and losses in the tens of billions of dollars in a future major Cascadia earthquake
- Preparing for a catastrophic disaster to become more resilient is needed to improve personal safety and security, and safeguard communities and businesses.



Recommendations

- Energy sector companies should conduct ***Seismic Vulnerability Assessments*** on all of their systems or facilities, and should work with the appropriate local, state, tribal and federal government agencies and stakeholders to achieve timely completion of the assessments to understand existing vulnerabilities.
- Energy sector companies should institutionalize long-term ***seismic mitigation programs;*** and should work with the appropriate local, state, tribal and federal government agencies and stakeholders to achieve timely and effective mitigation to ensure facility resilience and operational reliability.

CSZ Resiliency in 50 years

The Four Regions

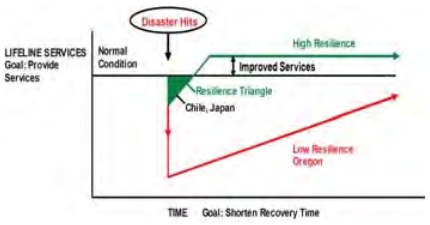
- Tsunami Impacted Coastal areas
- Tsunami Not-Impacted Coastal areas
- Valley
- Eastern Oregon

Recommendations

- The State of Oregon's ***Homeland Security Council or OPUC*** should be given the authority to review the vulnerability and resilience of the energy sector to earthquakes and other natural disasters within the scope of their mission.
- Energy sector companies and the State of Oregon should ***build Oregon's seismic resilience*** to a Cascadia earthquake.
  - Adopting pro-active practices and a risk management approach will help achieve seismic resilience. Encouraging a culture of awareness and preparedness concerning the seismic vulnerability of the energy sector including long range energy planning should be conducted.

Policy Recommendations

- Legislature establish a new regulatory authority with oversight authority on seismic resiliency of Critical Energy Infrastructures
  - Oregon Homeland Security Council (Oregon Revised Statute ORS 401.109)
  - Oregon Public Utility Commission
- Mandate all energy service providers complete Seismic Vulnerability Assessments (VA) and long-term Mitigation Plans by February 28, 2015, and report back to the Overseeing Authority.
- Mandate all energy service providers implement the top 10% findings from the VA by February 28, 2025, and provide annual performance reports to Overseeing Authority
  - The remaining 90% be incorporated in the normal operations & maintenance, and capital projects plan, with the goal of achieving resiliency by February 28, 2065.
- Mandate all energy service providers provide annual performance reports to Overseeing Authority.



Electric Specific Recommendation

- Perform an Oregon regional electrical systems study within 1 year (feb 28, 2014)
  - It can be done independent of IOUs and COUs
  - Independent of infrastructure ownership
  - Provide broad reliability picture of the electrical systems
  - It can be shared in 1 year

(This has been done for the New Madrid earthquake area by US DOE's Argonne National Lab.)

Resilience Triangle (modified from MCEER)

Multidisciplinary Center for Earthquake Engineering Research

RESILIENT OREGON Workshop

October 5, 2012

TRANSPORTATION Assessment

Resilient OREGON Workshop

October 5, 2012

Highway Transportation

- Majority of Highway bridges built well before Seismic Specifications were available
- Landslides and Rockfalls make our highways even more vulnerable
- ODOT has performed a initial assessment of state owned bridges and landslide inventory West of Cascades
- A Draft of Highway Lifelines has been proposed, along with a mitigation plan

Resilient OREGON Workshop

October 5, 2012

Transportation Workgroup

- Highway Transportation
- Rail Transportation
- Air Transportation
- Water Transportation (River and Ocean Ports)
- Public Transit Services
- Local Agency Representatives
- Consultants
- Academia

Resilient OREGON Workshop

October 5, 2012

Highway Transportation

- The Highway Lifeline Maps and Seismic Options Report presented to OTC (06/21/2012)
- Highway assessment shows 3+ years needed to restore 90% capacity on Western OR
- 1-3 years restoring 60% capacity of Tier 1 Routes
- Accessing the damaged structures becomes an issue

Resilient OREGON Workshop

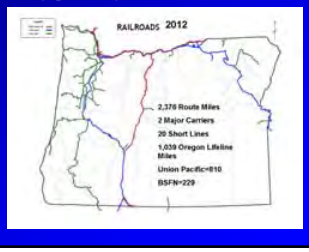
October 5, 2012

Transportation Workgroup

- Monthly meetings (in person, phone, or i-Link)
- Multimode Transportation Workshop (Sep. 17)
- Draft Report sent out on October 1st
  - *Resiliency Target: Minimal, Functional, and Operational
- Appendix "A"
  - * Highways, Rail, Airports, Ports, Public Transit
- Appendix "B"
  - * Local Transportation System

Resilient OREGON Workshop

October 5, 2012



October 5 Transportation presentation by
Bruce Johnson and Albert Nako

Resilient OREGON Workshop
October 5, 2012

Rail Transportation

- Rail lines are generally privately owned
- Older bridges
- Landslides
- Liquefaction
- Tunnels
- No redundancy (long detours)

Resilient OREGON Workshop
October 5, 2012

Public Transit

- 5 – public transit regions in Oregon
- Public transit buses & school district buses can assist on emergency evacuation
- Coastal Transit facilities may have their own problems
- Factors controlling the resiliency
  - * Road Conditions
  - * The ability of drivers to respond
  - * Availability of fuel supplies

Resilient OREGON Workshop
October 5, 2012

Air Transportation

- 97 public-use airports in Oregon
- Redmond – FEMA Primary
- 57 – partially supported by FAA
- 28 – state owned (ODA)
- 16 – other municipalities
- >400 – private owned
- Runways – an issue

Resilient OREGON Workshop
October 5, 2012

Local Roads and Streets

- On the same condition as State Highways
- Cities & Counties identified alternative Routes
  - * Can be retrofitted for less $$
  - * Can be restored much quicker for Emergency Resp.
- A few cities (Portland, Albany) have identified local lifelines connecting to hospitals and emergency centers

Resilient OREGON Workshop
October 5, 2012

Water Transportation

- **River Ports**
- Docks – at risk
- Liquefaction
- Navigation Channel
- Major river crossings
- Dams & Locks

Resilient OREGON Workshop
October 5, 2012

Interdependency Assessment

- Supplement a highway "backbone" system with other modes to provide a statewide connectivity at the perceived lowest retrofit cost
- The highway backbone system:
  - * I-5, from I-84 (Portland) to OR58
  - * I-84, from I-5 (Portland) to US97
  - * US97, from I-84 to the CA Border, and
  - * OR58, from I-5 to US97

Resilient OREGON Workshop

October 5, 2012

Interdependency Assessment

- High priority Airports:
  - * Redmond – FEMA
  - * Portland International
  - * Salem
  - * Eugene
  - * Roseburg
  - * Medford
  - * Klamath Falls

These airports should be made resilient within 10 years

Resilient OREGON Workshop

October 5, 2012

Interdependency Assessment

- Ports considered part of Multimode Transportation System:
  - * Port of Portland
  - * The Dalles
  - * Hood River
  - * Cascade Locks
  - * Boardman

The overall plan needs to include a resiliency evaluation of the Columbia River channel

Resilient OREGON Workshop

October 5, 2012

Recommendations

- Perform selective vulnerability assessments in priority order for each transportation mode
- Identify local lifeline routes and detour routes for higher redundancy
- Develop mitigation strategies for other transportation modes, similar to highway's
- Further refine the Interdependency Strategy to ensure a statewide connectivity

CRITICAL/ESSENTIAL BUILDINGS

- **Hospitals (60 facilities)**
- **Police/Fire Stations (109 police, 595 fire)**
- **Emergency Operations Centers (82)**
- **K-12 Schools (2,377 facilities)**
- **Emergency Sheltering Facilities**
- **Community Retail Centers and Banks**
- **Single Family Residential (960,000 est.)**
- **URM and Non Ductile Conc. Bldgs (40,000+ est.)**
- **Critical Government Facilities**

TABLE 1 ASSESSMENT APPROACH

2007 DOGAMI Statewide Structural Needs Assessment (SSNA)

- **Rapid Visual Screening (FEMA 154)**
- **Each building evaluated individually**
- **Screening factors include type of structure, age, occupancy, soil type, vertical irregularity, plan irregularity**

TABLE 1 ASSESSMENT APPROACH

2007 SSNA Data Set

- **Engineering Review, and conversion to Recovery Score**
  - Emergency Operations
  - Police and Fire Stations
  - Healthcare Facilities
  - K-12 Schools
  - Emergency Sheltering*

TABLE 2 ASSESSMENT APPROACH

FEMA HAZUS Model

- **Statistical analysis based on census data**
- **Estimates quantity, size, type and age of structures**
- **Statistically determines expected damage for estimated building set**

TABLE 2 ASSESSMENT APPROACH

FEMA HAZUS Model

- **Converted damage estimates to Recovery Score**
  - Residential Housing
  - Community Retail Centers and Banks
  - Vulnerable Buildings*
  - Critical Government Facilities

FINDINGS

RECOMMENDATIONS

4.4.1 Existing Buildings

- **Exempt Buildings (4.4.1.1)**
  - One and two-family dwellings
  - Buildings in low seismic hazard area
  - Exempt buildings
- **Building Inventory (4.4.1.2)**

RECOMMENDATIONS

4.4.1 Existing Buildings

- **Upgrade Nonstructural Elements of Essential and Hazardous Facilities (4.4.1.5)**
- **Passive Trigger Seismic Strengthening Program (4.4.1.6)**
- **Require Disclosure of URM and Non-ductile Concrete Building's Seismic Resistance (4.4.1.8)**
- **Limitation of Liability (4.4.1.9)**

RECOMMENDATIONS

4.4.1 Existing Buildings

- **Mandatory Seismic Strengthening (4.4.1.3)**
  - URM and Non-ductile Concrete Buildings
    - Essential Facilities within 20 years
    - All others within 30 years
  - Hospitals within 15 years
  - EOC, Police, Fire within 30 years (non URM)
  - Buildings damaged by Earthquakes

RECOMMENDATIONS

4.4.2 New Buildings

- **Siting (4.4.2.1)**
- **Incentives for Performance Based Design (4.4.2.2)**
- **Permit Review of Significant Structures by Licensed Structural Engineers (4.4.2.3)**
- **Expand certain Special Inspections and Structural Observations (4.4.2.4)**

RECOMMENDATIONS

4.4.1 Existing Buildings

- **K-12 Schools (4.4.1.4)**
  - Expand seismic rehab grant program
  - Prioritize replacement of URM's
  - Require ASCE-31 seismic assessments
  - Database of school seismic assessments
  - Statewide plan to resume education

RECOMMENDATIONS

4.4.3 State Office of the Structural Engineer

- **Establish a lead agency for implementing and coordinating statewide seismic/structural resilience policy.**
- **Advocacy and education**
- **Assist other state agencies**
- **Research**
- **Develop administrative rules and standards**

RECOMMENDATIONS

.

- **4.4.3 Earthquake Performance Rating System**
  - Voluntary
  - Applicable to all building types, new and old
- **4.4.5 Education**
  - Public awareness
  - Education in schools
  - Contractor education

RECOMMENDATIONS

.

- **4.4.6 Timeline**
  - Now is the time to get started!
- **4.4.7 Emergency Response**
  - Database of post-earthquake inspectors
  - Establish protocols for volunteers
  - Strengthen Good Samaritan laws

THANK YOU!

INFORMATION AND COMMUNICATIONS TECHNOLOGY

Oregon Resilience Plan Workshop

October 5, 2012

Information and Communications Technology

- In the early phases of recovery achieving these capabilities may require the use of temporary/interim contingencies (i.e., mobile cellular towers) while more permanent repairs and installations are being done.
- Establishing target timeframes for the tsunami inundation zone, beyond a minimal level of capability to support response, is not practical. A large amount of planning and prioritizing will need to be undertaken to identify which areas will be rebuilt first. These will then be the areas in which the information and communications systems will be re-established first.

Information and Communications Technology

KEY TO THE TABLE

Target Timeframe for recovery:

Operational: *Restoration is up to 90% of capacity: A full level of service has been restored and is sufficient to allow people to use for non-essential needs like entertainment. 80%-90%*

Functional: *Although service is not yet restored to full pre-event capacity, it is sufficient to get the economy moving again (e.g. business uses for credit cards and banking). Limits may be placed on uses that take up a lot of capacity like streaming video. 50% - 60%*

Minimal: *A minimum level of service is restored, primarily for the use of emergency responders, repair crews, and in support of critical health and human services (mass care) 20% – 30%*

Estimated time, under current conditions, for system wide recovery to be at or 90% of pre-event capacity

G

Y

R

×

Information and Communications Technology

TARGET STATES OF RECOVERY: INFORMATION AND COMMUNICATIONS TECHNOLOGY SECTOR

	Event occurs	0–24 hours	1–3 days	3–7 days	1 week–2 weeks	1 month – 3 month	3 month – 6 month	6 month -1 year	1 year–3 years	3 + years
ZONE 1 – COAST/TSUNAMI ZONE				R						
Buildings (includes Central Offices, Internet Exchange Points, and Cable Landings)									×	
Equipment in Buildings and on towers									×	
Towers									×	
Underground Lines									×	
Overhead Lines									×	

Information and Communications Technology

Planning Notes:

- Performance Capability for the purpose of recovery is viewed across all information and telecommunications systems supporting voice and data communications.
- The restoration objectives are based on an assumption that all other lifelines, such as roads and electricity, are functioning at a level that will support restoration of the information and communications infrastructure.
- In areas where the "customer" is not ready to accept service, then the service provider is not expected to meet established restoration timeframes.

Information and Communications Technology

TARGET STATES OF RECOVERY: INFORMATION AND COMMUNICATIONS TECHNOLOGY SECTOR

	Event occurs	0–24 hours	1–3 days	3–7 days	1 week–2 weeks	1 month – 3 month	3 month – 6 month	6 month - 1 year	1 year–3 years	3 + years
ZONE 2 – COAST/ NON-TSUNAMI ZONE			R	Y	G					
Buildings								×		
Equipment in Buildings								×		
Towers								×		
Underground Lines							×			
Overhead Lines							×			

Information and Communications Technology

TARGET STATES OF RECOVERY:
INFORMATION AND COMMUNICATIONS TECHNOLOGY SECTOR

	Event occurs	0–24 hours	1–3 days	3–7 days	1 week– 2 weeks	1 month – 3 month	3 month – 6 month	6 month - 1 year	1 year– 3 years	3 + years
ZONE 3 – VALLEY		R	Y	G						
Buildings						×				
Equipment in Buildings						×				
Towers						×				
Underground Lines						×				
Overhead Lines					×					

Recommendations

- Include in site development and zoning codes the requirement for Information and Communications technology structures to be built to withstand the potential impacts of a scenario earthquake and tsunami.
  - This should include limitations on building in tsunami inundation areas, construction of antenna towers on buildings that do not meet the critical facility standard and accounting for potential of liquefaction and slope instability when construction towers, buildings, underground utilities and overhead lines.

Information and Communications Technology

TARGET STATES OF RECOVERY:
INFORMATION AND COMMUNICATIONS TECHNOLOGY SECTOR

	Event occurs	0–24 hours	1–3 days	3–7 days	1 week– 2 weeks	1 month – 3 month	3 month – 6 month	6 month - 1 year	1 year– 3 years	3 + years
ZONE 4 – EASTERN OREGON	R	Y	G							
Buildings					×					
Equipment in Buildings					×					
Towers				×						
Underground Lines				×						
Overhead Lines				×						

Recommendations

- Adopt clear statewide uniform standards, like the NEBS (Network Equipment-Building System), for the adequate performance and bracing of information and telecommunications equipment need to withstand the scenario event and establish a mechanism for reliable enforcement.
- In conjunction with the ODOT's hardening of primary transportation routes, establish a hardened backbone for information and telecommunications systems

Recommendations

Recommended changes in practice that would make the sector compliant in 50 years.

- Establish oversight authority to a State entity that would be responsible for overseeing the resilience of the information and telecommunications industry operating and/or providing services in Oregon.
- Require Central Offices, Internet Exchanges, remote terminals and submarine cable landings to be built to or retrofitted to the "critical facility" standard.

Suggested Policy Changes

~~Three~~ Four suggested policy changes to enable those changes in practice?

1. Legislature establish a new regulatory authority to the Oregon Homeland Security Council (Oregon Revised Statute ORS 401.109) on seismic information and communication resiliency and security issues in cooperation with other relevant authorities.

Suggested Policy Changes

2. Mandate that information and communication service providers complete Seismic Vulnerability Assessments and long-term Mitigation Plans by February 28, 2014, and report to Oregon Homeland Security Council (Oregon Revised Statute ORS 401.109) and other relevant authorities.

Suggested Policy Changes

3. Mandate the information and communication service providers harden all Priority Paths (to achieve a resilient backbone) by February 28, 2018, and provide annual performance reports to Oregon Homeland Security Council (ORS 401.109) and other relevant authorities.
4. Mandate the information and communication service providers harden systems to the performance target restoration objectives by February 28, 2023, and provide annual performance reports to Oregon Homeland Security Council (ORS 401.109) and other relevant authorities.

QUESTIONS

Water/ Wastewater Committee

Resilience Workshop
5 October, 2012

Water & Wastewater Sector Table – Valley Zone

KEY TO THE TABLE

TARGET TIMEFRAME FOR RECOVERY:

Desired time to restore component to 80-90% operational — G
Desired time to restore component to 50-60% operational — Y
Desired time to restore component to 20-30% operational — R

TARGET STATES OF RECOVERY: WATER & WASTE WATER SECTOR

	Event occurs	0–24 hours	1–3 days	3–7 days	1 week– 2 weeks	2 weeks– 1 month	1 month – 3 month	3 month – 6 month	6 month -1 year	1 year– 3 years	3 + years
Domestic water supply											
Potable water available at supply source. (WTP, wells, impoundment)		R	Y		G			X			
Main transmission facilities, pipes, pump stations, and reservoirs ("backbone") operational		G					X				
Water supply to critical facilities available.		Y	G				X				
Water for fire suppression – at key supply points.		G		X							
Water for fire suppression – at fire hydrants.				R	Y	G			X		
Water available at community distribution centers/points			Y	G	X						
Distribution system operational			R	Y	G				X		
Wastewater systems											
Threats to public health & safety controlled.			R	Y		G			X		
Raw sewage contained & routed away from population		R		Y			G		X		

Water and Wastewater Systems Participating in the W&WW Work Group

System / Community	Sector
City of Portland	Water & Wastewater
Tualatin Valley Water District	Water
City of Bend	Water
City of Gresham	Water
City of Pendleton	Water
City of Salem	Water & Wastewater
Clean Water Services	Wastewater
Coos Bay – North Bend Water Board	Water

Water & Wastewater Sector Table – Central / Eastern Zone

KEY TO THE TABLE

TARGET TIMEFRAME FOR RECOVERY:

Desired time to restore component to 80-90% operational — G
Desired time to restore component to 50-60% operational — Y
Desired time to restore component to 20-30% operational — R

TARGET STATES OF RECOVERY: WATER & WASTE WATER SECTOR

Estimate of Water Pipeline Breaks & Leaks for Participating Utilities

Characteristic	Estimate
Total Length of Pipe (miles)	4,592
Total Number of Breaks (number)	2,656
Total Number of Leaks (number)	941
Total Number of Services (number)	385,600
Service Line Breaks – Utility Side (2%)	7,712
Service Line Breaks – Customer Side (5%)	19,280

Why so vulnerable?

- Large, complex systems, above and below ground
- Highly dependent on other, vulnerable resources
  - Energy, transportation, chemicals
- Essential facilities in low lying areas along lakes, rivers, coastlines
  - Vulnerable to liquefaction
- Old facilities designed before reasonable seismic criteria in place
- Use of non-ductile materials vulnerable to ground motion
- Collection/distribution systems connections to above ground facilities

Major Recommendations

- General Recommendations
  - Public information campaign to "reset" expectations.
  - ORWARN is a vital resource. W/WW utilities should belong
  - Seismic response plans
  - Employee preparedness plans
  - Seismic design standards for pipelines
  - Business continuity plans
  - Seismic vulnerability criteria should be incorporated in all capital improvement planning

Closing the Gap – Water Systems

- Harden transmission facilities (bridges, river crossings, landslide areas)
- Install additional isolation valves
- Replace vulnerable pump stations built before 1970. Harden those built after
- Rebuild/redesign transitions between in-ground piping and above ground structures
- Replace 20-30% of transmission system piping (Coastal)
  - 80-90% (Valley)
- Replace 20-30% of distribution system piping (Coastal)(Valley)
- Replace tankage built before 1960.
- Harden tankage built after 1960.
- Incorporate seismic resiliency objectives in all future capital projects

Major Recommendations

- Water Specific
  - OHA to require seismic risk assessment as part of master plans
  - Encourage firefighters and water utilities to develop joint earthquake response plans
  - Identify and coordinate key water supply points
  - OHA to require seismic design considerations as part of routine design review
  - DEQ and OHA to establish goals and expectation for compliance following an event

Closing the Gap – Wastewater Systems

- Liquefiable soils, replace 50-60% of collection systems (Coastal and Valley
  - 50-60% for trunk lines (Coastal)
  - 80-90% for trunk lines (Valley)
- Relocate or seismically upgrade treatment plants built before 2000
  - And all plants in liquefaction zones
- Rebuild or seismically harden pump stations built before 2000
- Provide for emergency power and chem supply
- Incorporate seismic resiliency into future capital improvement projects

Major Recommendations

- Wastewater Specific
  - DEQ to require a seismic risk assessment as part of periodic update of facililty plans
  - Wastewater agencies encourage to conduct more complete characterization of the impacts of estimated recovery times for seismic events
  - DEQ to coordinate with wastewater agencies on expectations for levels of service, compliance and standards following a major seismic event
  - Establish agreements for temporary sanitary services after an event
  - Encourage all agencies to plan for significant water quality impacts to Willamette and Columbia Rivers

Appendix IV List of Oregon Resilience Plan Contributors

Advisory Panel

Name	Affiliation
Cameron Smith	Governor's Office
Peter Courtney/Dana Richardson	State Legislature
Lee Beyer	State Legislature
JR Gonzalez	Formerly Oregon Public Utility Commission
Bruce Johnson	Oregon Department of Transportation
Ed Dennis	Formerly Oregon Dept. of Education
Yumei Wang	DOGAMI/NEHRP
Onno Husing	Formerly Oregon Coastal Zone Mgmt Association
Nate Wood	U.S. Geological Survey
Scott Ashford	Oregon State University
Chris Goldfinger	Oregon State University
Andre LeDuc	University of Oregon
Jeff Soulages	Intel
Edward Wolf	Oregon Citizen
Leon Kempner	Bonneville Power Administration
Vicki McConnell	DOGAMI/WSSPC
Jean O'Connor	Oregon Health Authority
Dave Harlan	Ports Manager

OSSPAC Steering Committee

Kent Yu (Chair, Public member/Structural)
Jay Wilson (Vice Chair, Public member/local government)
Althea Rizzo (OEM, State Earthquake/Tsunami Manager)
Ian Madin (DOGAMI)
Stan Watters (Public member/Utilities)

Earthquake and Tsunami Scenario Task Group

Name	Role	Affiliation	Category
Ian Madin	Chair	DOGAMI/OSSPAC	State Agency
Bill Burns		DOGAMI	State Agency
Art Frankel		US Geological Survey	Federal
Chris Goldfinger		Oregon State University	University
Matthew Mabey		Oregon Dept. of Transportation	State Agency
George Priest		DOGAMI	State Agency
Yumei Wang		DOGAMI	State Agency
Ivan Wong		URS/EERI	Engineer

Business & Work force Continuity Task Group

Name	Role	Affiliation	Category
Susan Steward	Co-Chair	BOMA/OSSPAC	Assoc. for Building Owners
Gerry Willliams	Co-Chair	Construction Research/OSSPAC	Private consulting
Lori Chamberlain		Oregon Business Association	Business Association
Patrick Estenes		The Standard	Insurance
Kelley Okolita		Regence	Healthcare
Patrick Slabe		New Seasons Market	Food Retail
Bert Sorio		Regence	Healthcare
Jeffrey Soulages		Intel	High tech
Rick Van Dyke		Cambia	Healthcare
Bryce Ward		EcoNorthwest/OSSPAC	Economist

Coastal Communities Task Group

Name	Role	Affiliation	Category
Jay Wilson	Co-Chair	Clackmas County/OSSPAC	Local Government
Jay Raskin	Co-Chair	Ecola Creek/OSSPAC	Tsunami Advocate
Jacque Betz		Florence City Manager - Central Coast	Local Government
D-Rep Deborah Boone		Legislature - North Coast	State Legislature
Josh Bruce		Oregon Partnership for Disaster Resilience - State Level	University
Charlie Davis		Bandon City Planner and Emergency Manager - South Coast	Local Government
Sue Graves		Lincoln County School District - Central Coast	Local School District
Dave Harlan		Ports Manager State of Oregon	State Agency
Jeffrey Hepler		US Army Corps - Debris Management Program Manager	Federal
Maggie Kirby		Craft3 Development Manager	Non-profit Financial
R-Sen Jeff Kruse		Legislature - South Coast	State Legislature
Margo Lalich		Clatsop County Public Health Director	Local Government
Jack Lenox		Coquille Tribe Community Planner/Em Mgr - South Coast	Tribal Government
Gary Milliman		Brookings City Manager - South Coast	Local Government
Sam Steidel		City Councilor, Cannon Beach	Local Government
Wayne Stinson		Douglas County Emergency Manager - Central Coast	Local Government
Laren Woolley		Oregon Department of Land Conservation and Development	State Agency

Critical Buildings Task Group

Name	Role	Affiliation	Category
Ed Quesenberry	Co-Chair	Equilibrium Engineers LLC	Engineer
Trent Nagele	Co-Chair	VLMK	Engineer
Andre Barbosa	Resource Manager	Oregon State University	University
David Bugni	Secretary	David Bugni & Associates	Engineer
Ed Dennis		Dept. of Education	State Agency
Kimberly Dills		OHA/Center for Disease Control and Prevention	State Agency
Shane Downing		ORARNG	State Agency
Shelly Duquette	Public Relations	City of Portland	Local Government
Jennifer Eggers	Meeting Coordinator	Degenkolb Engineers	Engineer
Joe Gehlen	Resource Manager	Kramer Gehlen	Engineer
Tonya Halog		J.G. Pierson	Engineer

Name	Role	Affiliation	Category
Robert Johnson		Johnson & Broderick Engineering	Engineer
Kevin Kaplan		VLMK	Engineer
Amit Kumar	Treasurer	City of Portland BDS	Local Government
Dominic Matteri		Kramer Gehlen	Engineer
Anne Monnier	Data Manager	KPFF	Engineer
Willy Paul		Kaiser Permanente	Healthcare Provider
Josh Richards	Resource Manager	KPFF	Engineer
Tim Rippey		TM Rippey Consulting Engineers	Engineer
Richard Rogers		Oregon Building Codes	State Agency
Terry Shugrue	Data Manager	Turner Construction	Contractor
Jason Thompson		KPFF	Engineer
Mark Tobin		KPFF	Engineer
Jim Weston		Sacred Heart Medical Center/PeaceHealth	Healthcare Provider
Michael Wieber		NW Seismic Retrofit	Contractor
Edward Wolf	Public Relations	Freelance Writer and Analyst	Oregon Citizen

Transportation Task Group

Name	Role	Affiliation	Category
Bruce Johnson	Chair	ODOT Bridges	State Agency
Martin Callery		Port of Coos Bay	Port
Lieutenant Meredith Condon		USCG	Federal Agency
Chris Corich		Oregon State Aviation Board	State Agency

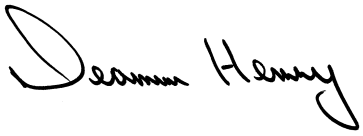
Oregon State Energy Assurance Plan

Oregon Department of Energy
Oregon Public Utility Commission

August 2012

Acknowledgements



A number of Oregon State agencies work together with industry to help ensure Oregon has an adequate supply of reliable and affordable energy. This Oregon State Energy Assurance Plan reflects our collective efforts towards meeting that goal.

The Oregon Department of Energy (ODOE) maintains this plan as well as the Oregon Petroleum Contingency Plan. The Oregon Public Utility Commission (OPUC) maintains the Electricity and Natural Gas Emergency Response Plans. These responsibilities are explained more fully in Chapter 6 of this plan.

There are three key additions from previous versions of this plan. First, ODOE staff is evaluating the integration of renewable resources into emergency response planning. Second, OPUC staff guided the work of contractors to begin assessing whether smart grid technologies can be integrated into the state's response strategies to energy emergencies. And third, staff from the Oregon Department of Geology and Mineral Industries conducted a seismic vulnerability assessment of the state's critical energy hub located in an eight mile area along the water front in Northwest Portland. This included conducting onsite inspections of fuel terminals, substations, and natural gas facilities and systems. These findings, once complete, will assist ODOE and OPUC to better understand the risk associated with earthquake hazards, modify emergency response plans and procedures for energy emergencies, and determine mitigation measures as appropriate for the energy sectors.

Executive Summary

OREGON STATE ENERGY ASSURANCE PLAN

In the aftermath of the 1970s fuel crisis, the U.S. Department of Energy (USDOE) began working with state energy offices under the State Energy Program to coordinate and facilitate energy emergency planning activities. As the designated State Energy Office, the Oregon Department of Energy (ODOE) was responsible for developing and maintaining the State Energy Emergency Plan under the State Energy Program. ODOE was required to review and update the State Energy Emergency Plan annually for submission to USDOE as the state energy Plan of Record.

The September 2009 Oregon Energy Emergency Response Plan was revised and renamed the Oregon State Energy Assurance Plan as a result of a grant awarded to ODOE by the USDOE's Office of Electricity Delivery and Energy Reliability (DOE/OE) to enhance state government energy assurance resiliency. As a result, new information was added to the state's 2009 plan. This includes information on seismic vulnerabilities and earthquake impacts on the critical energy infrastructure in Oregon from a magnitude 9 Cascadia Subduction Zone earthquake.

Furthermore, the state is considering the integration of new energy portfolios like alternative fuels as well as smart grid technologies into Oregon's response strategies to energy emergencies to improve energy assurance resiliency.

"Resiliency" is defined as the ability of a critical infrastructure to absorb, adapt to, and/or rapidly recover from a potentially severe and disruptive event. "Critical infrastructure" involves energy lifelines that, if disrupted, could significantly impact public health and safety, the economy, and/or national security. Any prolonged interruption of the supply of basic energy - whether it is petroleum products, electricity, or natural gas - could do considerable harm. As a result, improving energy assurance and resiliency in Oregon's energy infrastructure is intended to help mitigate the impacts of an energy supply interruption and help the state return to normal conditions as quickly as possible, regardless of the cause of the interruption.

Oregon's energy assurance and resiliency planning takes into account four key components. This includes: 1) understanding the energy infrastructure, Oregon's Energy Profile, and system interdependencies, 2) assessing potential risks and hazards threatening the state's critical energy infrastructure and considering short and long-term mitigation measures to reduce risk and vulnerability, 3) developing effective plans and procedures to help minimize the impacts of an energy supply interruption and rapidly restore the energy infrastructure should an emergency occur, and 4) increase public awareness.

The Oregon State Energy Assurance Plan is designed to provide an overview of the first three components to help achieve the fourth component, which is to increase general awareness of the energy infrastructure, risks to the state energy lifelines, and the state's approach to restore fuel, power, and natural gas should an emergency occur.

As mentioned on the “Acknowledgements” page, work on Smart Grid technologies, integrating renewables into emergency response planning, and earthquake vulnerability assessments are not yet completed. In addition, workshops and exercises will be conducted to provide additional insight. It will be through these studies and activities that recommendations for mitigation measures to reduce risk and vulnerability will eventually be developed and then vetted.

The Oregon State Energy Assurance Plan is not an emergency response plan. It is instead an introduction to how Oregon prepares for, responds to, and recovers from energy emergencies. This will eventually include actions and considerations to reduce risk before an emergency occurs. Energy emergency response plans are much more detailed and provide procedures and checklists prescribing how decision-makers and emergency responders are to:

- accomplish pre-identified tasks and objectives to make emergency notifications
- monitor and assess the severity of an energy emergency
- issue protective actions and decisions
- provide situation awareness reports
- provide emergency information to the news media and the public
- activate, staff, and operate an Emergency Operations Center
- other critical tasks to effectively recover from energy emergencies and restore the energy infrastructure.

Energy sector-specific emergency response plans for fuel, natural gas, and electricity are developed and maintained by ODOE and the Oregon Public Utility Commission (OPUC). ODOE developed and maintains the Oregon Petroleum Contingency Plan, which includes the state’s Fuel Allocation Program. OPUC developed and maintains the Natural Gas Emergency Response Plan and the Electricity Emergency Response Plan.

The Oregon State Energy Assurance Plan complies with the National Association of State Energy Officials (NASEO) guidelines, the NASEO Energy Assurance Planning Framework, the National Response Framework, the National Infrastructure Protection Plan, and the National Incident Management System. The Oregon Energy Assurance Plan is also consistent with the Oregon Emergency Management Plan and Oregon Revised Statute (ORS) 401 to "coordinate the activities of all public and private organizations providing emergency services within this state."

ODOE will review and update the Oregon State Energy Assurance Plan annually or as needed to reflect changing response trends and strategies and to incorporate lessons learned from exercises or response to actual energy emergencies.

CHAPTER 1

Introduction

OREGON STATE ENERGY ASSURANCE PLAN

INTRODUCTION

In 2009, Oregon and other states throughout the nation received American Recovery and Reinvestment Act (ARRA) funding from DOE/OE. The purpose of this funding was to enable the states to create or update their energy assurance plans to facilitate recovery from disruptions to the energy supply and enhance reliability.

Energy assurance for state and local governments is a major element of improving the nation's energy sector resiliency. It involves a large array of activities that fall into three main phases: planning and preparedness, mitigation and response, and education and outreach.

Planning and Preparedness involves understanding the energy infrastructure and identifying key assets; designing and updating energy emergency response plans; training personnel; and conducting exercises that test the effectiveness of response plans.

Mitigation and Response includes monitoring events that may affect energy supplies; assessing the severity of disruptions; providing situational awareness; coordinating restoration efforts; and tracking recoveries.

Education and Outreach includes communicating and coordinating with key stakeholders; increasing public awareness; and forming partnerships across sectors and jurisdictions.

OREGON STATE ENERGY ASSURANCE PLAN APPROACH AND FORMAT

Chapter 1: Introduction - This Chapter provides an overview of the format of the plan.

Chapter 2: Energy Infrastructure Overview – This chapter provides a brief overview of the energy infrastructure in the United States. In order to effectively plan, prepare for, respond to, and recover from energy emergencies, it is imperative to first understand how the petroleum, natural gas, and electricity supply and distribution systems work and how they are interdependent.

Chapter 3: Oregon Energy Profile – This chapter describes the conventional energy sources generated, imported, and consumed in Oregon. Understanding Oregon's energy profile can assist emergency planners and decision-makers in identifying vulnerabilities to the state's energy supply and distribution systems.

Chapter 4: Potential Role of Energy Efficiency and Renewable Energy Resources in Energy Assurance Planning in Oregon – This chapter profiles the renewable energy resources within the state. This chapter also examines the possibility of incorporating these resources when more traditional sources of energy are in short supply. This includes bringing new applications such as Smart Grid technology into the state's energy assurance planning to lower risk and improve energy assurance and resiliency in Oregon.

Chapter 5: Types of Energy Emergencies – This chapter explains the types of hazards in the Pacific Northwest that can impact Oregon's critical energy infrastructure. Having a clear understanding of the hazards that could impact the state's energy resources helps emergency planners and decision-makers better identify mitigation measures to reduce the risk and vulnerabilities.

Chapter 6: Overview of Energy Sector-Specific Emergency Response Plans – This chapter provides an overview of how the state prepares for and responds to fuel, electricity, natural gas, and liquefied natural gas emergencies in Oregon. Despite energy assurance efforts, emergencies impacting our energy resources will occur. Understanding roles and responsibilities, what resources are available, what actions are to be taken and how emergency information will be provided is essential to a rapid recovery.

Chapter 7: Ensuring Program Readiness – This chapter provides an overview of the activities ODOE and OPUC conduct to ensure decision-makers and emergency responders are prepared to implement the energy sector-specific emergency response plans.

Appendices – This section provides reference materials and supporting documents to the Oregon State Energy Assurance Plan.

The ARRA initiative cited the State Energy Assurance Guidelines as a model to guide Oregon's update of the Oregon State Energy Assurance Plan. These Guidelines were developed by NASEO in collaboration with the National Association of Regulatory Utility Commissioners (NARUC) and funded by DOE/OE.

Chapter 2

Energy Infrastructure Overview

OREGON STATE ENERGY ASSURANCE PLAN

INTRODUCTION

Energy is the essential force powering business, manufacturing, and the transportation of goods and services to serve the American and world economies. Energy supply and demand plays an increasingly vital role in our national security and the economic output of our nation. It is not surprising that the United States spends over 500 billion dollars annually on energy. Given the importance of their reliable and secure operations, understanding the behavior of energy infrastructures - particularly when stressed - is crucial.

The nation's energy infrastructure consists of thousands of miles of electricity lines and oil and natural gas pipelines and other resources that are geographically dispersed and connected in all 50 states and territories.

- About 204,000 miles of long-distance transmission lines move power from region to region.
- Two million miles of oil pipelines in the United States are the principal mode for transporting oil and petroleum products such as gasoline. They account for about 66 percent of domestic product movement and are an efficient way to move petroleum and petroleum products.
- Virtually all natural gas in the United States is moved via pipeline.

ENERGY SECTOR PROFILE AND ASSETS

The energy sector includes widely dispersed assets related to three key energy resources: petroleum, electric power, and natural gas.

Petroleum	Electricity	Natural Gas
Crude Oil • Onshore/Offshore Fields • Terminals • Transport (tanker vessels & pipelines) • Storage Petroleum Processing Facilities • Refineries • Terminals • Transport (tanker vessels & pipelines) • Storage Distribution • Pipelines • Barges and Tanker Vessels • Trucks Control Systems Petroleum Markets	Generation • Fossil Fuel Power Plants (coal – gas – oil) • Nuclear Power Plants • Hydroelectric Dams • Renewable Energy Transmission • Substations • Lines • Control Centers Distribution • Substations • Lines • Control Centers Control Systems Electricity Markets	Production • Onshore fields • Offshore fields Processing Transport (pipelines) Distribution (pipelines) Storage Liquefied Natural Gas Facilities Control Systems Gas Markets

Petroleum and natural gas share similarities in methods of extraction, fuel cycles, and transport, but the facilities and commodities are separately regulated and have multiple stakeholders and trade associations. Energy assets and critical infrastructure components are owned by private, federal, state and local entities, and by some energy consumers, such as large industries and financial institutions (often for backup power purposes).

PETROLEUM SUPPLY AND DISTRIBUTION SYSTEM

The petroleum portion of the energy sector includes the production, transportation, and storage of crude oil; the processing of crude oil into petroleum products; the distribution and storage of petroleum products; and sophisticated control systems to coordinate storage and transportation.

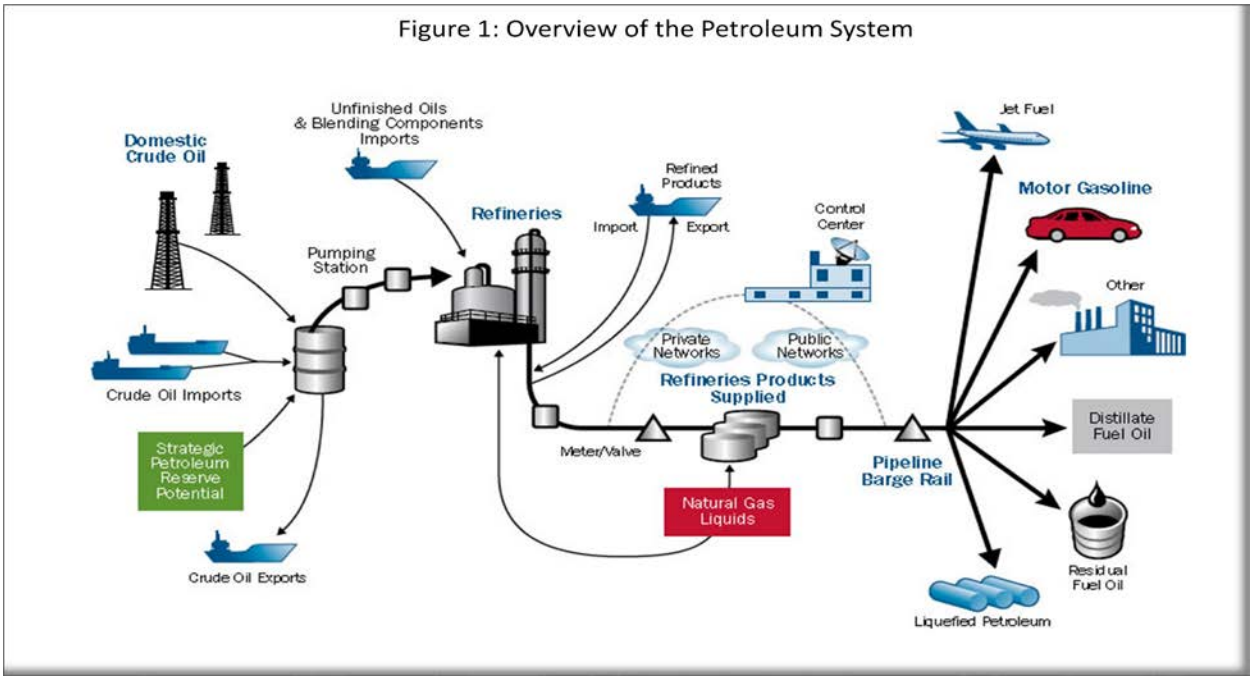
Pipelines are critical for the gathering, transmission, and distribution of petroleum. The oversight of pipeline security is the responsibility of Department of Homeland Security's Transportation Security Administration (TSA). The petroleum supply and distribution system include:

Onshore and offshore fields - U.S. crude oil production is concentrated onshore and offshore along the Texas-Louisiana Gulf Coast, extending inland through west Texas, Oklahoma, and eastern Kansas. There are also significant oil fields in Alaska along the central North Slope and the California coastline.

The U.S. also imports nearly 60 percent of the petroleum used in the nation from Canada, Mexico, the Middle East, South America, and Africa.

Crude Oil Drilling, Gathering, and Processing – This sector of the petroleum industry includes a large number of facilities, such as wellheads, gas and oil separation plants, compressor stations, water treatment units, etc., for both onshore and offshore areas.

Import Marine Terminals – Crude oil is received into the United States at import terminals, which usually consist of a berth or port facility for the tankers, unloading facilities, storage facilities, and a system of pipelines to move the crude.



Crude Oil Transport – Privately owned pipelines transport most of the crude oil in the United States. Waterborne transportation modes, including ocean tankers and barges, are also used.

Crude Oil Storage – Import terminals always incorporate storage facilities. In addition, the Strategic Petroleum Reserve has huge underground salt caverns along the coastline of the Gulf of Mexico. The reserve has the capacity to hold 727 million barrels and is the world's largest supply of emergency crude oil.

Refineries – Refineries process crude oil into petroleum products such as gasoline, diesel fuel, jet fuel, and home heating oil. The Gulf Coast has more than twice the crude oil refining capacity of any other U.S. region.

Petroleum Product Transport – Petroleum products are mainly transported by pipeline, tanker, barge, railroad tank cars and trucks. The products are shipped to terminals for temporary storage before transport to smaller petroleum delivery stations in market areas.

Figure 1: Overview of the Petroleum System

Petroleum Product Storage – Petroleum products are stored both above and below ground in tank farms and storage fields to minimize unwanted fluctuations in pipeline throughput and product delivery. As an example, DOE's Northeast Home Heating Oil Reserve stores two million barrels of home heating oil at commercial terminals in the Northeast. This oil is intended for distribution during severe heating-oil supply disruptions in that part of the country.

Petroleum Control Systems - Control systems like the Supervisory Control and Data Acquisition (SCADA), continuously monitor, transmit, and process pipeline data. This includes flow rate, pressure, and speed. The SCADA systems monitor and control pumping stations and track terminal inventories. SCADA gathers information, such as where a leak on a pipeline has occurred, and transfers the information back to a central site. This alerts the home station that the leak has occurred, analyzes its importance, and displays the information in a logical and organized fashion.

In an energy emergency, Strategic Petroleum Reserve oil could be distributed by competitive sale. Decisions to withdraw crude oil from the reserve are made by the President under the authorities of the Energy Policy and Conservation Act.

ELECTRICITY SUPPLY, GENERATION, TRANSMISSION, AND DISTRIBUTION SYSTEM

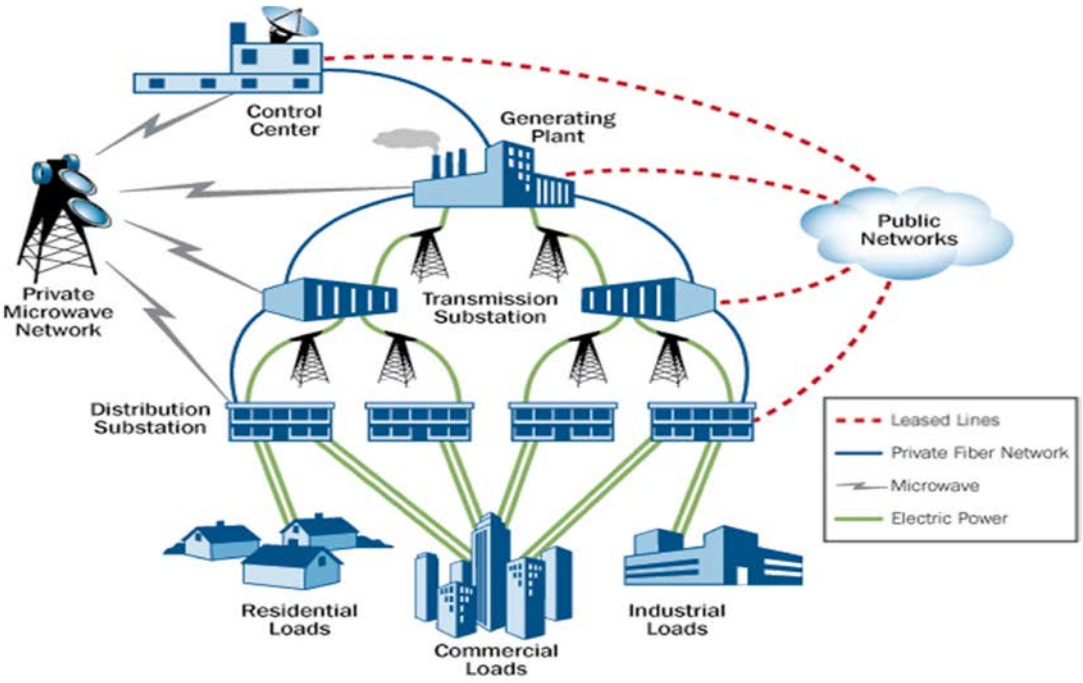
The electricity portion of the energy sector includes the generation, transmission, and distribution of electricity. The use of electricity is universal, spanning all sectors of the U.S. economy. Electricity system facilities are dispersed throughout the North American continent. Although most assets are privately owned, no single organization represents the interests of the entire sector.

The North American Electric Reliability Corporation (NERC), through its eight Regional Reliability Councils, provides a platform for ensuring reliable, adequate, and secure supplies of electricity through coordination with many asset owners. NERC develops and enforces mandatory reliability standards for the bulk electric power system in the United States, Canada, and a portion of Baja Mexico.

Electricity generation from the burning of fossil fuels - - coal, natural gas, and oil - - provides more than 70 percent of the electricity generated in the United States. Virtually all coal is mined domestically and then transported to power plants by rail and barge. Natural gas and oil are transported to power plants by pipeline.

Additional sources of electricity generation include nuclear and hydropower. Renewable energy sources including solar, wind, and geothermal account for a small but growing percentage of national electricity generation.

Electricity transmission, distribution, and control systems include:



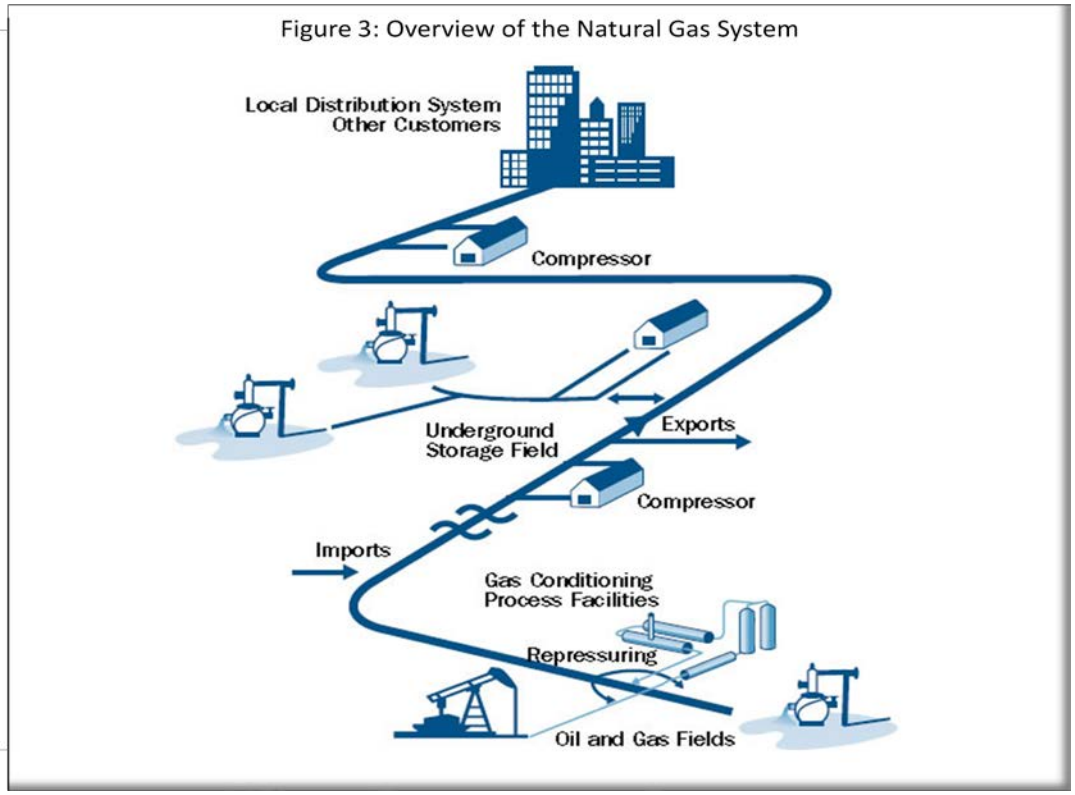
Transmission Lines - Transmission lines serve two primary purposes: They move electricity from generation sites to customers and they interconnect systems. Voltages in the transmission system are high, which makes it possible to carry electric power efficiently over long distances and deliver it to substations near customers.

Transmission and Distribution Substations - Substations are located at the ends of transmission lines. A transmission substation located near a power plant uses large transformers to increase the voltage to higher levels. At the other end of the transmission line, a substation uses transformers to step transmission voltages back down so the electricity can be distributed to customers.

Control Centers - Control centers have sophisticated monitoring and control systems and are staffed by operators 24 hours per day, 365 days per year. These operators are responsible for several key functions, including balancing power generation and demand; monitoring flows over transmission lines to avoid overloading; planning and configuring the system to operate reliably; maintaining system stability; preparing for emergencies; and placing equipment out of and back into service for maintenance and emergencies.

Distribution Lines - Distribution lines carry electricity from substations to end users.
Control Systems like SCADA monitor the flow of electricity from generators through transmission and distribution lines. These electronic systems enable efficient operation and management of electric systems through the use of automated data collection and equipment control.

Figure 2: Overview of the Electricity System



NATURAL GAS PRODUCTION, PROCESSING, TRANSPORT, AND DISTRIBUTION SYSTEM

The natural gas portion of the Energy Sector includes the production, processing, transportation, distribution, and storage of natural gas; liquefied natural gas (LNG) facilities; and gas control systems

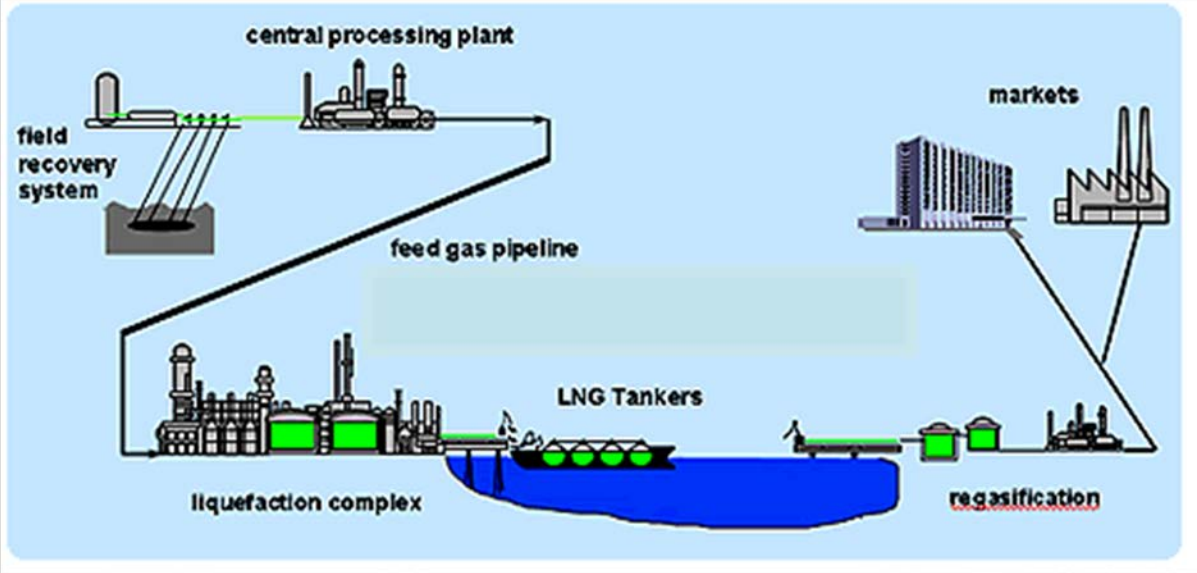
Natural Gas Production – The Gulf of Mexico and Texas are the largest gas-producing regions in the United States. The two regions account for almost half of all U.S. natural gas production. Other key sources of natural gas are the Rocky Mountains and New Mexico. The U.S. also imports significant quantities from Canada.

Natural Gas Processing – Natural gas processing consists of separating all of the various hydrocarbons and fluids from the pure natural gas to produce pipeline-quality dry natural gas. Most U.S. natural gas processing plants are located near production facilities in the Southwest and Rocky Mountain States. The natural gas extracted from a well is transported to a processing plant through a network of gathering pipelines.

Figure 3: Overview of the Natural Gas System

Natural Gas Transportation – The interstate natural gas pipeline network transports natural gas from processing plants in producing regions to areas with high natural gas demands, particularly large urban areas. Compression stations along the pipeline transmission route keep the gas moving at the desired pressure.

Natural Gas Distribution – Local distribution companies typically transport natural gas from interstate pipeline delivery points to end users through thousands of miles of distribution pipe. Delivery points for local distribution companies are often termed city gates, especially for large municipal areas, and are important market centers for the pricing of natural gas.



Natural Gas Storage – Gas is typically stored underground and under pressure as an efficient way to balance discrepancies between supply input and market demand. Three types of facilities are used for underground gas storage: depleted reservoirs in oil and/or gas fields, aquifers, and salt caverns. Facilities serving the interstate market are subject to Federal Energy Regulatory Commission (FERC) regulations; otherwise they are State-regulated. Most working gas held in storage facilities is held under lease with shippers, local distribution companies, or end users who own the gas.

Gas Market Centers - Currently, 37 natural gas market centers operate in the United States and Canada. These centers provide gas shippers with many of the physical capabilities and administrative support services formerly handled by interstate pipeline companies as bundled sales services. These centers have developed new and unique Internet-based access to gas trading platforms and capacity release programs; provide title transfer services between parties that buy, sell, or move their gas through the centers; and offer connections with other pipelines and access to storage services. These markets and their information systems are critical components of the natural gas infrastructure.

LIQUEFIED NATURAL GAS SUPPLY AND DISTRIBUTION SYSTEM

LNG is natural gas cooled to approximately -260° Fahrenheit at normal air pressure. It is odorless, non-toxic, non-corrosive and less dense than water. Essentially, it is the same natural gas more than 63 million Americans use to heat and cool their homes, only in a liquid state.

Figure 4: LNG Supply and Distribution Chain

The conversion of natural gas into liquid is called liquefaction and is achieved through refrigeration. Liquefaction reduces the volume of natural gas by approximately 600 times, making it more economical to transport and store. Upon reaching its destination, LNG is stored as a liquid before being warmed back into a gas and sent out via pipelines as natural gas.

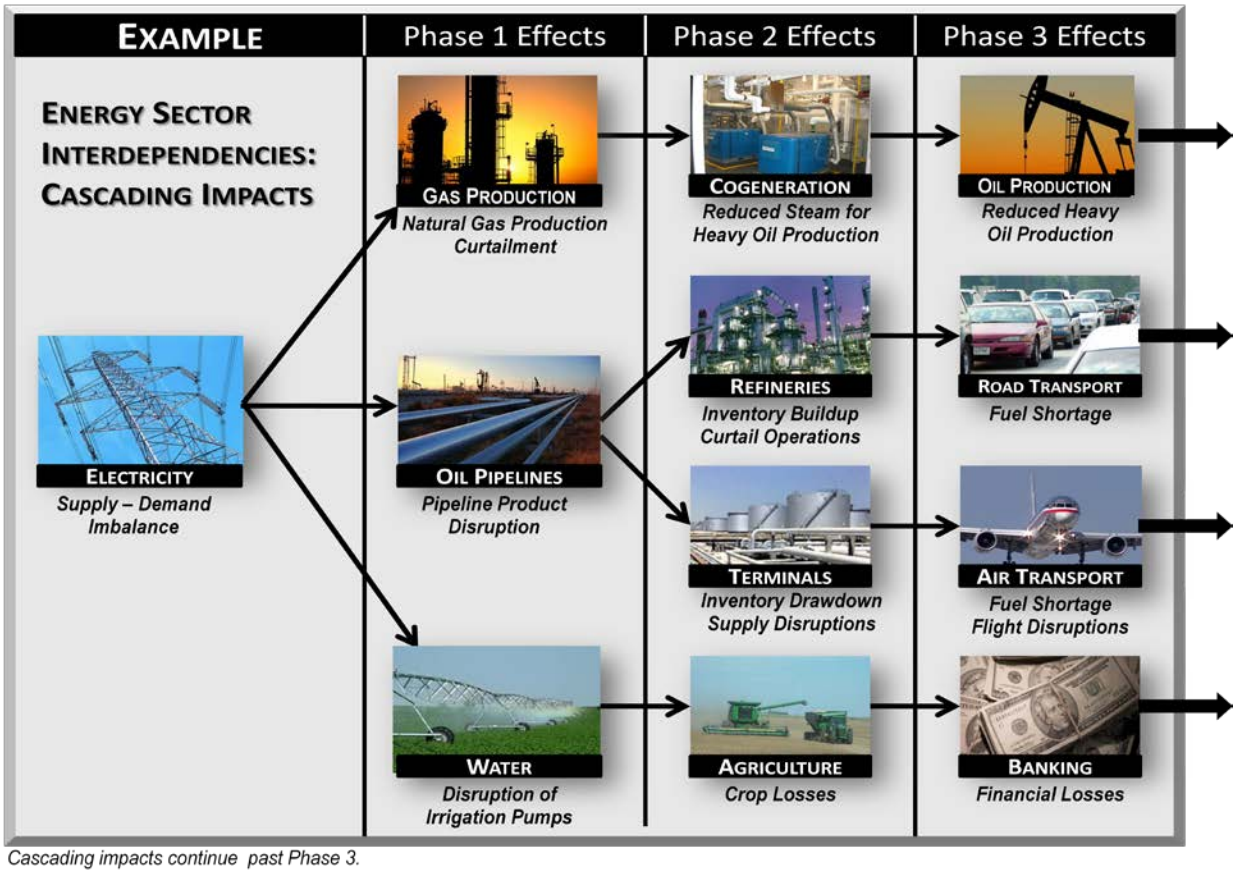
LNG is not new. It has been successfully transported and used for almost 100 years. But, LNG is likely to play an increasingly critical role in diversifying the nation's energy mix with our country's changing energy climate. LNG alone cannot meet the growing demand for natural gas. However, LNG is a key component of our nation's three-pronged natural gas supply mix which includes domestic production, Canadian imports, and LNG.

LNG currently accounts for only two percent our natural gas consumption – less than one percent of the energy our nation uses. LNG is predominantly imported from Trinidad and Tobago and from Algeria. Indonesia, Malaysia, and Qatar are also the leading exporters of LNG. Russia and Iran have huge reserves of natural gas.

It does take a long time to invest in and establish a LNG supply chain. This includes building terminals to liquefy the gas, building ships to transport LNG to the United States and building LNG terminals and pipelines to gasify LNG and distribute to domestic markets. There are nine existing LNG import terminals in the United States. Several dozen others are at various stages of the regulatory siting process or have been approved, and are either under construction or waiting for market conditions to change before construction begins.

ENERGY SECTOR INTERDEPENDENCIES

Our national and economic security rest upon a foundation of highly interdependent critical infrastructures. Critical infrastructures are those systems and assets vital to the United States that the destruction of such systems and assets would have a debilitating impact on national security, the economy, public health or safety, or any combination of those conditions.



Critical infrastructures cover a large number of sectors. They include the electric power grid; oil and natural gas production, transportation, and distribution systems; telecommunications and information systems; water systems; transportation networks; the banking and finance industry; agriculture and food systems; and public health networks.

An interdependency is a two-way relationship between infrastructures where the operation of each infrastructure is influenced by the other. For example, the electricity infrastructure includes a nationwide power grid of long-distance transmission lines that move electricity from region to region, as well as the local distribution lines that carry electricity to homes and businesses. Much of our electricity originates at coal-fired power plants. These power plants require a dependable transportation infrastructure to deliver the coal necessary for the production of electricity.

Electricity is also required for petroleum refinery and distribution terminal operations. A power failure can shut-down the movement of fuel through pipelines. Gasoline and diesel are required by utility vehicles which are often needed to get workers to the field to restore power to the electrical grid. Telecommunication networks often use sophisticated computerized control and information systems, which rely on electricity.

Figure 5 gives an example of the interdependencies within the three energy sectors and potential cascading effects should one energy sector experience problems.

FIGURE 5

Cascading impacts continue past Phase 3.

Understanding the operational characteristics, complexity, magnitude, and scope of the nation's critical infrastructure will assist emergency managers and decision-makers to better protect the nation's critical infrastructures. Also, should an emergency occur, they will be better prepared to respond to, and recover from energy emergencies.

Chapter 3

Oregon Energy Profile

OREGON STATE ENERGY ASSURANCE PLAN

INTRODUCTION

Energy consumption in Oregon continues to increase according to DOE's Energy Information Agency (EIA). The most current EIA data (2008) shows that total Oregon energy use (petroleum, electricity, natural gas) was 1,105 trillion British thermal units (Btu), up from 707 trillion Btu in 2003. That ranks Oregon, on a per capita basis, 38th in the country in energy consumption.

Oregon only produces about one-third of the energy it uses. Of Oregon's 414.8 trillion Btu produced, most of that is classified as renewable energy, with the majority of that being hydroelectricity.

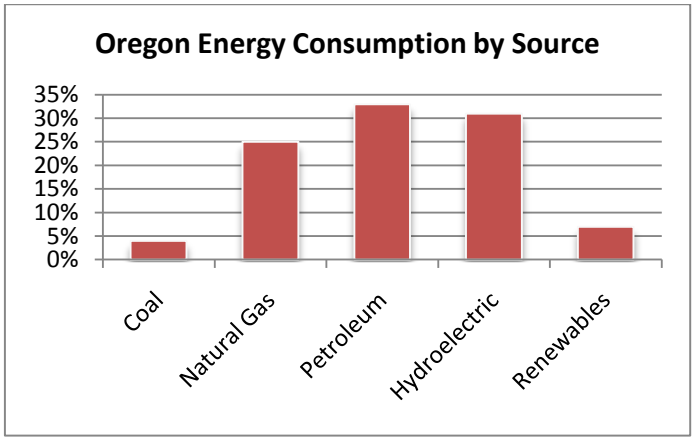


Figure 6: Illustrates the source of energy consumed in Oregon in 2008. About one-third of the energy used is petroleum.

The transportation sector uses the most energy in Oregon, followed by the industrial, residential and commercial sectors. Within the transportation sector, gasoline use made up 57 percent of that transportation energy in 2008.

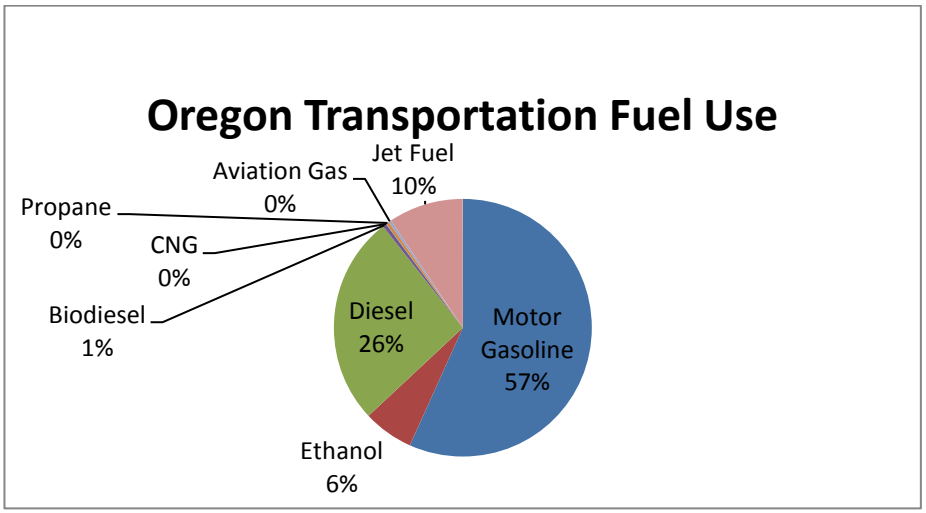

Figure 7: Gasoline makes up the bulk of Oregon's transportation fuel use.

OREGON ENERGY SUPPLY AND DEMAND

PETROLEUM

Unlike other Western states, Oregon does not have crude oil resources or refineries. Oregon imports 100 percent of its petroleum. Oregon, along with Alaska, Arizona, California, Hawaii, Nevada, and Washington form a nearly self-contained system of petroleum production and consumption, referred to by the federal government as Petroleum Administration Defense District Five (PADD V). Although the system is relatively stable, a major disruption in any part of the supply and distribution chain could create a severe and prolonged petroleum shortage, and/or significant price volatility.

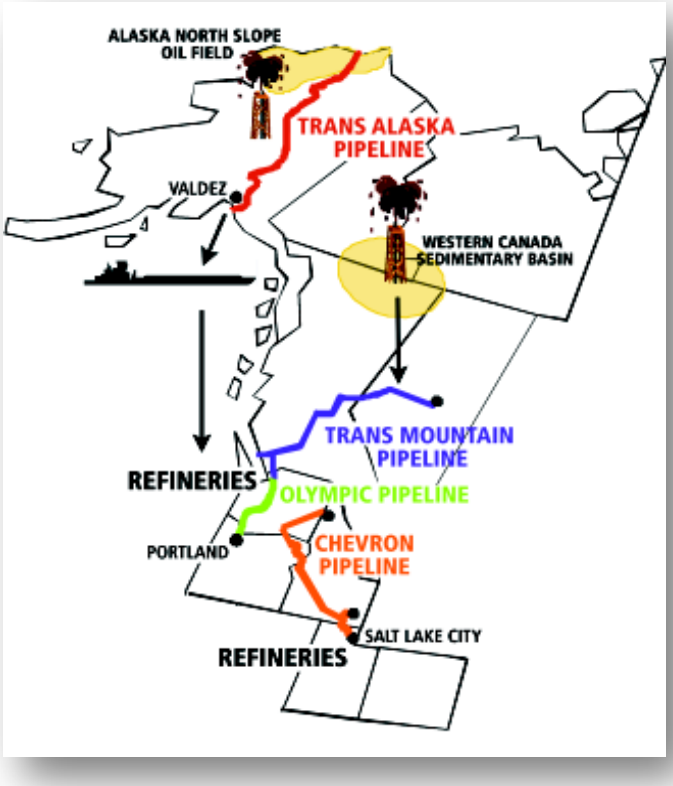

Figure 8: Illustrates Oregon's petroleum supply system. The majority of the crude oil comes from Alaska and Canada.

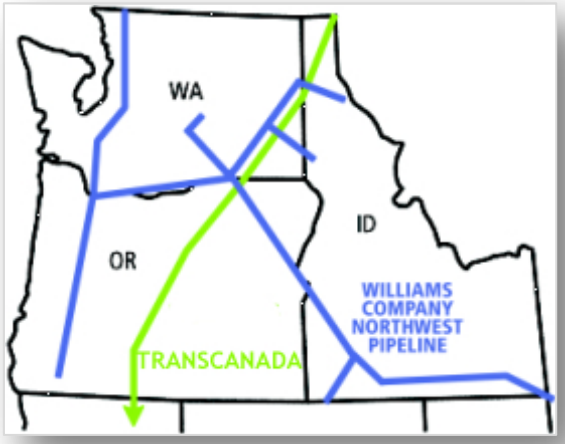
Figure 8 shows the major sources of Oregon's petroleum products. More than 80 percent of the crude oil eventually used in Oregon originates in the Alaska North Slope oil fields. The Trans Alaska Pipeline transports crude oil 800 miles from the oil fields on the state's northern coast to the Valdez terminal on its southern coast. From there, barges and tankers ship the crude oil to four refineries in the Puget Sound area of Washington and other destinations.



The Western Canada Sedimentary Basin is another significant source of crude oil for the refineries and for Oregon. The remaining crude, less than five percent, comes from the continental U.S., Mexico, Indonesia or the Middle East.

The Puget Sound refineries provide more than 90 percent of Oregon's refined petroleum products. The Washington refineries transport their products to Oregon and Washington markets via the Olympic Pipeline and barges.

Refineries in Salt Lake City and British Columbia provide remaining refined petroleum products to Oregon. Under normal conditions, only minor amounts arrive on tanker ships from California and the Pacific Rim countries of Indonesia, South Korea and Japan.

The bulk of Oregon's oil enters through the Port of Portland and is distributed statewide by tanker trucks, Columbia River barge service and the Kinder Morgan pipeline, which extends to Eugene. Some specialty petroleum products (jet fuel, lubricants, ultra-low sulfur diesel) enter Oregon on tankers from California Bay Area refineries.

In northeastern Oregon, petroleum products enter by truck or rail from Pasco, Washington. The Pasco delivery station receives refined product from a pipeline that starts in Salt Lake City, travels through southern Idaho and crosses through northeastern Oregon along Interstate 84. Pasco also receives petroleum product from barges that travel up the Columbia River from Portland. In southeastern and southern Oregon, a portion of petroleum products is trucked from Idaho and northern California respectively.

NATURAL GAS

Oregon imports 100 percent of its natural gas. Oregon receives natural gas from British Columbia, Alberta, Wyoming, Colorado and New Mexico. Two connected interstate pipelines deliver the natural gas.

Figure 9: Two natural gas pipelines currently serve Oregon customers. The Williams Company pipeline and the Gas Transmission Northwest (GTN) pipeline owned by the TransCanada Corporation bring product from the Rocky Mountains and Canada.

The Williams Company's Northwest Pipeline brings natural gas to Portland from British Columbia and the Rocky Mountain region of the U.S. British Columbia gas enters the U.S. near Sumas, Washington and roughly follows Interstate 5. Gas from the Rockies comes into Oregon near Ontario. One lateral pipeline transports gas from Washougal, Washington to the Portland area and another from the Willamette Valley to Grants Pass (not shown in Figure 9).

Natural gas from Alberta arrives in a Gas Transmission Northwest (GTN) pipeline. It enters the U.S. near Kingsgate, Idaho, and moves through eastern Oregon, leaving the state near Malin, before traveling on to California and Nevada. A lateral line (also not shown in Figure 9) transports natural gas from Klamath Falls to Medford. The GTN pipeline is owned by TransCanada and connects with the Williams Northwest pipeline at Stanfield, Oregon.

Three natural gas utilities serve Oregon:

- Northwest Natural serves about 80 percent of Oregon's retail customers, including Portland, the Willamette Valley and the coast.

- Avista Corporation serves parts of southern Oregon and La Grande.

- Cascade Natural Gas serves parts of central and eastern Oregon.

Northwest Natural receives natural gas from the Williams' pipeline. Northwest Natural owns underground gas storage facilities in Mist, Oregon and LNG storage facilities in Newport and Portland. Northwest Natural also has contracts to use LNG storage at Plymouth, Washington and underground storage at Jackson Prairie, Washington.

Avista obtains natural gas from the Williams Company's Grants Pass lateral as well as TransCanada's GTN pipeline and the Medford lateral. Cascade customers from Madras to Chemult receive natural gas from TransCanada's GTN pipeline. The Williams Northwest pipeline serves Cascade customers from Umatilla to Ontario. Cascade and Avista either own or have contracts to use natural gas storage facilities.

ADDITIONAL NATURAL GAS PIPELINES

The Ruby Pipeline, approved by FERC and currently under construction, will transport domestic natural gas 675 miles across four states from Opal, Wyoming to the existing Gas Transmission Northwest (GTN) pipeline near Malin, Oregon.

The Palomar Pipeline was proposed to link the GTN Pipeline near Madras, Oregon to the Williams Northwest Pipeline near Molalla, Oregon and a second phase from Molalla to a previously proposed LNG terminal called Bradwood Landing. Due to the bankruptcy of Bradwood Landing LNG along with changing market forces, the Palomar Pipeline is on hold.

According to the Northwest Gas Association (NGWA), the Pacific Northwest is home to more than 48,000 miles of natural gas transmission and distribution pipelines. NGWA expects natural gas demand to grow an average of about one percent per year.

PIPELINE REGULATION

The Federal Energy Regulatory Commission regulates siting of interstate natural gas pipelines as well as prices for the use of pipelines. The Oregon Energy Facility Siting Council (EFSC) sites large in-state pipelines.

OPUC regulates the rates Oregon's natural gas utilities charge their retail customers. Wholesale natural gas prices are not regulated. Many industrial customers buy directly from the wholesale market.

Retail natural gas rates generally include pass-through of the wholesale cost of natural gas to retail customers. OPUC sets retail rates so utility companies have the opportunity to earn a fair rate of return on their investments.

Natural gas utilities must prepare integrated resource plans for OPUC. These plans outline contracts to meet natural gas demand, proposed pipeline expansions, new storage facilities, and energy conservation budgets and programs.

LNG

As part of the current and future energy mix, the U.S. is looking to import natural gas, which when produced overseas, must be super-cooled and liquefied for ocean transport. It is expensive to liquefy, transport, and then convert to a gas again (regasify). Shipments of foreign LNG are currently being received at terminals along the eastern seaboard and in the Gulf of Mexico.

Figure 10: Northwest Natural Gas LNG Facility in Portland

In Oregon, there are two existing LNG storage facilities, owned and operated by Northwest Natural Gas. The above-ground facilities are located at the Port of Portland and Newport. Both facilities receive their supply through transmission pipelines and natural gas resources in Canada.

These facilities are used during peak load hours to ensure consistent delivery of power to customers.

There are also two proposals to build LNG import terminals in Oregon. Jordan Cove, located near Coos Bay, received FERC approval in December 2009. Oregon LNG proposed near Warrenton is currently making its way through the FERC process. Either or both projects, if built, would receive LNG from ocean going vessels, temporarily store it, and then regasify it before sending it out by pipeline to homes, businesses, electrical generating plants and industries in the Pacific Northwest as well as other parts of the Western United States. The earliest either terminal could be in operation is 2014.

JORDAN COVE ENERGY PROJECT

Jordan Cove Energy Project (JCEP) has proposed an LNG export terminal on an approximately 400 acre site located on the bay side of the North Spit of Coos Bay, Oregon. JCEP would include a marine receiving terminal, two full containment 160,000 cubic meter LNG storage tanks, and facilities to support ship berthing and cargo loading. Also proposed onsite is the South Dunes Power Plant. The 340 megawatt natural gas fired power plant's primary purpose is to provide power to the JCEP facility. However, the plant does have the capacity to provide power to the local electric grid.

Figure 11: Illustration of the Jordan Cove LNG export terminal upon completion.

JCEP could export up to one billion cubic feet per day of natural gas. The LNG terminal would be capable of loading LNG ships up to 148,000 cubic meters (m^3). The natural gas pipelines would consist of the existing NW Natural/Coos County Pipeline and a new, approximately 223-mile-long natural gas pipeline. The Pacific Connector Gas Pipeline is proposed by Williams' Northwest Pipeline Corporation, Pacific Gas and Electric Company, and Fort Chicago Energy Partners LP.

OREGON LNG

Oregon LNG proposed an LNG peak-shaving, liquefaction, and export facility located on the Skipanon Peninsula in Warrenton, Oregon. The approximately 96 acre site is owned by Oregon Department of State Lands and leased to the Port of Astoria. The Port has in turn leased the land to Oregon LNG for 65 years.

The Oregon LNG Project would include a marine receiving terminal, two full containment 160,000 cubic meter LNG storage tanks, and facilities to support ship berthing and cargo loading.

Oregon LNG's peak-shaving capacity is projected at 0.5 billion cubic feet of natural gas per day with an export capacity at 1.3 billion cubic feet of natural gas per day.

Figure 12: Illustration of the Oregon LNG import-export terminal upon completion

Product could also be transported from an 86-mile pipeline that would connect the terminal to the existing Williams Northwest interstate natural gas pipeline in Woodland, Washington. The LNG terminal would be capable of loading LNG ships up to 260,000 m^3.

ELECTRICITY

Oregon's fuel mix varies based on hydroelectric conditions, with natural gas typically filling the void in years when hydroelectric conditions are poor. Still, hydro and coal make up the bulk of Oregon's electricity supply. Natural gas provides between seven and 15 percent of Oregon's electricity.

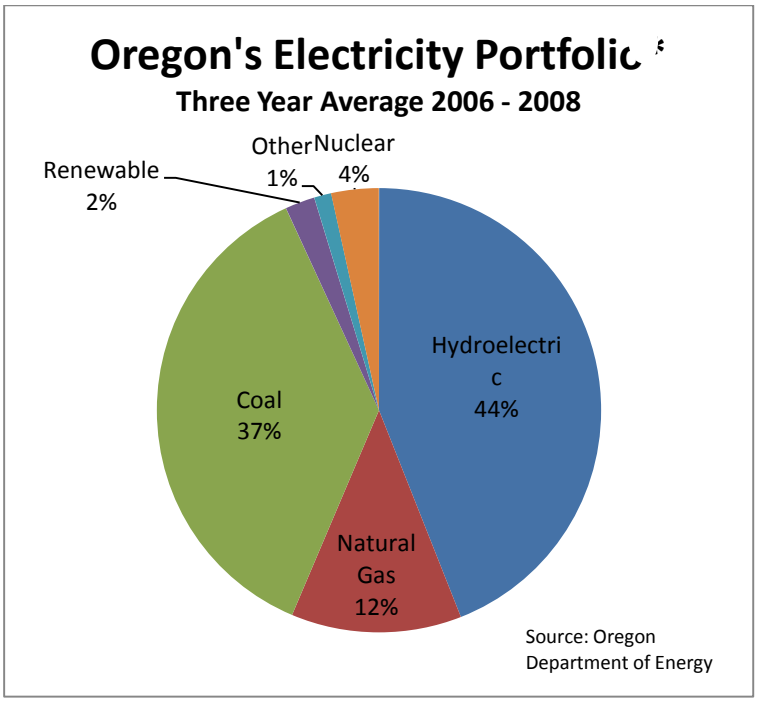


Figure 13: Where Oregon gets its electricity. Oregon's 2006-2008 fuel mix shows that electricity comes mainly from hydropower plus instate and out-of-state coal.

Hydropower comes primarily from large dams on the Columbia and Snake River systems.

Coal power comes from Portland General Electric's (PGE) Boardman plant in northeast Oregon and from plants in Utah, Wyoming, and Montana.

A number of natural gas-fired power plants in Oregon are located in the northeast part of the state near Hermiston and Boardman. Other plants are located in Clatskanie and Klamath Falls.

The implementation of Renewable Portfolio Standards, which require a certain percentage of electricity generation from renewable resources – both in Oregon and other states – has helped spur the development of wind energy. Northeast Oregon has seen the addition of several thousand wind turbines in the past decade, with more being added. Despite this growth, it still provides only a small amount of Oregon's electricity.

Nuclear power comes to Oregon's consumer-owned utilities through the Bonneville Power Administration (BPA) from the Columbia Generating Station near Richland, Washington.

ELECTRICITY TRANSMISSION

Nationwide, new construction to increase electrical energy transmission has lagged over the past 25 years, while the demand for energy has continued to increase. The American Society of Civil Engineers reports that, "The transmission and distribution system of the United States has become congested because growth in electricity demand and investment in new generation facilities have not been matched by investment in new transmission facilities."

Regionally, a number of studies indicate that the electric transmission system in the western United States is inadequate to meet future energy demands and load allocations. There is already a lack of capacity in the existing electric transmission grid and energy generation from renewable sources - - geothermal, wind, solar, wave, biomass - - is increasing the need to expand transmission capacity.

Since many of these renewable energy sources are located in remote areas far away from existing transmission grids and are often located away from high-use, urban and industrial areas where demand is greatest, pressure to develop new transmission capacity is mounting.

Forecasts of future energy demands in Oregon over the next 20 years range from an increase of as much as 45 percent over current demands according to PGE to approximately a 30 percent increase over current demand by the Northwest Power and Conservation Council. While the rate of demand is variable from different sources, there is agreement that demand for energy will increase in the region. Demand is expected to increase for a variety of reasons including home electronics, the development of electric vehicles, and in some areas, the expansion of health care facilities for the elderly.

ORS 469.470 authorizes EFSC to oversee the development of electric transmission lines that are equal to, or greater than, 230 kV; longer than 10 miles in length; and routed across more than one political subdivision in the state.

There are three electric transmission projects currently proposed in Oregon that are making their way through the regulatory processes.

- Big Eddy-Knight Transmission Line, proposed by BPA is a 500-kilovolt line from The Dalles, Oregon to a proposed new substation four miles northwest of Goldendale, Washington.

- Boardman to Hemingway would bring a single circuit 500-kilovolt (kV) transmission line approximately 298 miles to connect the power plant near Boardman, Oregon and the planned Hemingway substation near Murphy, Idaho.

- PGE proposed to construct Cascade Crossing, a single and double circuit 500-kilovolt (kV) transmission line 210 miles from Boardman to Salem. The proposal includes three new substations, and potential upgrade of portions of the transmission system in the Willamette Valley.

Another BPA project, which would have run a 70 mile-long 500-kilovolt transmission line from Castle Rock, Washington to a new substation near BPA's existing Troutdale Substation, is on hold.

U.S. Energy Information Administration

The U.S. Energy Information Administration (EIA) website includes information on Oregon's energy supply and demand from 1960 through 2010. The State Energy Data Systems (SEDS) can be accessed at www.eia.gov. EIA is the statistical and analytical agency within the U.S. Department of Energy (USDOE). EIA collects, analyzes, and disseminates independent energy information to promote sound policymaking, efficient markets, and public understanding of energy and its interaction with the economy and the environment.

The USDOE Organization Act of 1977 established EIA as the primary federal government authority on energy statistics and analysis. EIA conducts a comprehensive data collection program that covers the full spectrum of energy sources, end users, and energy flows; generates short- and long-term domestic and international energy projections; and performs informative energy analyses. EIA disseminates its data products, analyses, reports, and services to customers and stakeholders primarily through its website and the customer contact center. EIA programs cover data on coal, petroleum, natural gas, electric, renewable and nuclear energy.

Information on electricity consumption can also be found on ODOE's website at http://cms.oregon.gov/energy/pages/oregons_electric_power_mix.aspx.

Chapter 4

Potential Role of Renewable Resources in Energy Assurance Planning in Oregon

OREGON STATE ENERGY ASSURANCE PLAN

INTRODUCTION

Oregon has significant renewable energy resources. For decades, Oregonians have benefited from hydropower generated by dams on the Columbia River and elsewhere in the state. In recent years, we have seen tremendous growth primarily in northeast Oregon in harnessing wind energy – although it still generates only a small percentage of our electricity.

Across the state, other opportunities exist for developing renewable energy resources, such as solar, geothermal, wave and biomass. The production and use of alternative fuels is also increasing. The state is actively recruiting these industries and encouraging technology innovation, manufacturing, and installation.

Renewable energy resources will not replace conventional energy resources, such as coal, oil and natural gas – at least not in the near future. But renewable energy resources may provide some assistance in the event of an energy shortage or emergency.

The most promising of the renewable energy resources to assist emergency responders are alternative fuels such as biofuels. These could potentially be used to fuel emergency vehicles when conventional gasoline and diesel are unavailable or in short supply.

Also promising is not a resource – but a technology – to make more efficient use of both conventional and renewable energy resources, called Smart Grid.

These are explained in greater detail later in this chapter.

OREGON RENEWABLE RESOURCE PORTFOLIO

Oregon's abundant supply of renewable energy resources can reduce the state's dependence on conventional energy. This includes hydropower, wind, solar, geothermal, wave, biomass and alternative fuels. All renewable energy sources can be used to generate electricity. Solar, geothermal and biomass also can supply heat. In addition, biomass can be used to fuel vehicles.

HYDROPOWER

As mentioned in Chapter 3, hydropower provides more than 40 percent of Oregon's electricity. BPA markets power from 31 hydropower facilities in the Northwest, 14 of which are located in Oregon. These facilities account for 82 percent of all power marketed by BPA.

Figure 14: The Dalles Dam in the Columbia River Gorge

Hydropower also provides 26 percent and five percent of the electricity for Oregon's two major investor-owned power providers, PGE and Pacific Power, respectively.

WIND ENERGY

Most of Oregon's wind development takes place primarily in the central and eastern Columbia River area and in northeastern Oregon, which includes Sherman, Gilliam, Morrow and Umatilla counties.

Oregon added the most wind capacity - 175 megawatt (MW) - of any state in the country during the third quarter of 2010, according to a report issued by the American Wind Energy Association. Current operational wind projects offer a total capacity of nearly 2,100 MW. Projects approved and awaiting construction make up about another 3,000 MW. Oregon is also home to the North American headquarters of wind turbine manufacturer Vestas and wind farm developer and operator Iberdrola Renewables.

Figure 15: Wind turbines in Eastern Oregon

Wind farm proposals of 105 MW and above go through Oregon's EFSC process. Developers of less than 105 MW may also choose to go through EFSC, or through the local county land-use process.

SOLAR ENERGY

Solar energy is Oregon's largest potential renewable energy resource. There are three primary ways in which this energy is harvested: as direct light into buildings for light and heat; to heat water using roof-mounted collectors; and to convert sunlight to electricity using photovoltaics (PV). Each solar harvesting approach is unique with its own technology and market constraints.

The residential Solar Electricity PV market experienced significant growth in Oregon in 2010 with more than 1,000 tax credits issued compared to 400 credits in 2009.

Figure 16: Solar panels on the roof of the Oregon State Capitol

Many factors are attributed to the expansion in the residential PV market in Oregon. The combination of state and federal tax credits with cash incentives offered by the Energy Trust of Oregon has greatly reduced the expense of these systems. Long-term support for PV installations within the state has allowed the local industry to expand, mature and streamline costs. The presence of large PV manufacturing facilities in the state, such as SolarWorld, has also raised the profile of the technology.

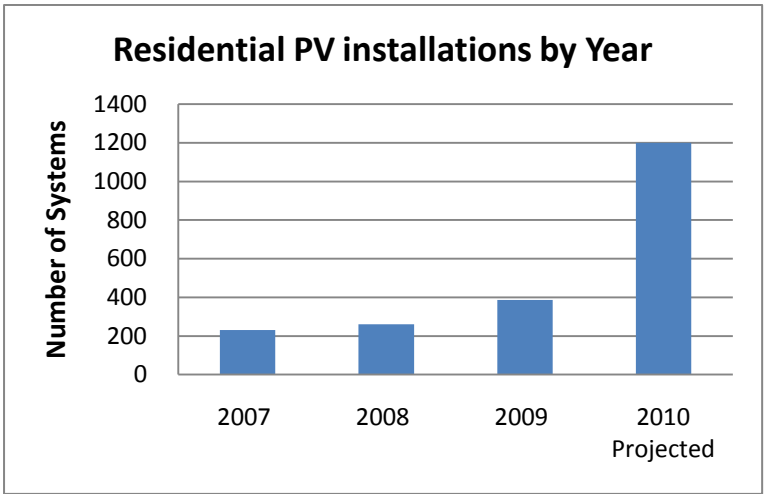

Figure 17: Installation of residential solar electric systems has increased in Oregon.

However, the primary factor increasing the number of PV systems installed in the state is declining system cost. Another factor increasing the number of residential PV systems installed in Oregon have been bulk purchasing agreements organized by cities and neighborhood associations. These efforts commonly known as "solarize" programs have been organized in Portland, Beaverton, Salem and Pendleton. Many more communities throughout the state are considering similar programs that are likely to be launched in 2011.

GEOTHERMAL ENERGY

Geothermal energy comes from the heat of the earth. It has a small environmental footprint, the ability to produce energy consistently around the clock, and emits little or no greenhouse gases. Geothermal energy is used in Oregon to dry agricultural products, for aquaculture

(raising fish), for space heating, to heat greenhouses, and to heat swimming pools at a number of spas and resorts.

Figure 18: Oregon hot spring near Alvord Desert

Oregon homes and businesses use geothermal energy for heat. The first commercial electric facility came online in 2012. The main barrier for development of geothermal electricity generation in Oregon is the cost and risk of drilling. The state Department of Geology and Mineral Industries (DOGAMI) is conducting a detailed survey of the Great Basin (southeastern) part of the state to fine-tune knowledge of sub-surface opportunities and relieve some of the risk of "dry holes."

ARRA awards will assist Oregon to research technology to extract energy from geothermal systems that may not have enough water; test innovative exploration and drilling techniques in south central Oregon; and develop technologies to identify fault lines. ARRA funding will also assist Oregon in developing a national geothermal data system focusing on high heat flow areas in the Cascades, central Oregon, southeast Oregon and parts of northeast Oregon. These are the locations where geothermal resources are most likely to be found.

WAVE ENERGY

Oregon's coastline has steady winds, strong waves and access to transmission networks—the three key ingredients for a successful ocean wave energy program. Wave power is the transport of energy by ocean waves, and the capture of that energy for electricity generation, water desalination, or the pumping of water into reservoirs.

The non-profit Oregon Wave Energy Trust funds independent research and development under the state's Oregon Innovation Council, fostering growth and evaluation of wave energy development potential on Oregon's shores.

Figure 19: Strong winds and waves on the Oregon Coast

Ocean Power Technologies recently selected Oregon for the first commercial-scale facility of its type in North America, which will generate approximately 1.5 MW of electricity off the Oregon coastal community of Reedsport.

As recognition of the state's leading position in this industry, Oregon was recently chosen by DOE/OE to host one of only two National Marine Renewable Energy Centers in the country to facilitate technology development, inform regulatory and policy decisions, and close key knowledge gaps.

BIOMASS FOR ELECTRICITY AND HEAT GENERATION

Biomass has long been a significant contributor to Oregon's energy mix. For decades, Oregon has been using these resources to provide fuel for the generation of electricity, production of heat, and manufacturing of fuels. Oregon has large amounts of biomass resources, which includes agricultural residues and waste, forest slash and mill residuals.

Biomass is used in Oregon to produce thermal heat for the forest products industry, heat and electricity at wastewater treatment facilities, and wood pellets that heat homes, schools and hospitals. The Oregon pellet manufacturing industry is a national leader in producing high quality engineered fuels.

Figure 20: Biomass in the form of wood chips

There are currently more than 45 industrial facilities that use woody biomass for energy production. These include electricity and heat produced at forest products industries such as lumber and paper mills. The energy is used to generate electricity, provide heat for drying kilns, or generate steam used for industrial process applications. Lower value materials are used as chipped fuel in industrial boilers to generate heat and electricity throughout the state.

A growing area of the bioenergy sector is in the production and use of biogas. Biogas is produced through the breakdown of biomass into methane that is used to produce electricity. Methane produced in the wastewater treatment process is captured and used to produce heat and electricity in at least 29 wastewater treatment facilities around the state.

Figure 21: Dairy operation in Oregon

Building on the early work by the Port of Tillamook Bay and various dairy operations, a number of projects are under construction and development to use manure and other agricultural wastes to generate electricity. These facilities address a waste management challenge while also generating renewable energy and reducing greenhouse gas emissions.

Landfills are another source of renewable energy from biogas. Landfills in Oregon have installed methane capture systems and use the gas to produce electricity and where possible, capture the heat for thermal applications such as food processing or heating greenhouses.

Biofuels

INTRODUCTION

Not only can plant and waste products be used to produce heat and electricity, biomass can also be used to produce alternative fuels or "biofuels." Biofuels provide opportunities for Oregon to become less dependent on fossil fuels.

Biofuels account for a growing part of the United States' and Oregon's transportation fuel mix. As a result of the 2007 Renewable Fuel Standard legislation passed in Oregon, more than one hundred retail stations in Oregon offer alternative fuels. Approximately 150 million gallons of biofuels are consumed each year in Oregon. Currently, about 40 million gallons per year are produced in Oregon.

TYPES OF BIOFUELS

Ethanol and biodiesel are the only two biofuels used in Oregon and in the Pacific Northwest, because both have defined product standards for modern motors.

ETHANOL

Ethanol is the most widely used biofuel in the United States. Nearly all of the current domestic ethanol production involves fermenting the starch fraction of corn, with 1 bushel of corn producing at least 2.8 gallons of ethanol.

Figure 22: Midwest Ethanol production facility

Ethanol is an alcohol that burns cleanly, producing fewer smog-forming carbon monoxide, nitrogen oxide, and greenhouse gas emissions than gasoline. Ethanol can also be produced locally.

Unfortunately, ethanol has only two-thirds of the energy of gasoline per gallon. This results in lower gas mileage. Ethanol cannot be transported through conventional oil pipelines along with gasoline, because it picks up excess water and impurities. As a result, ethanol needs to be transported by rail, trucks, or barges, which is more expensive and complicated than sending it down a pipeline. The greatest limit on ethanol is the availability of sugar and starch feedstocks.

ETHANOL AVAILABILITY IN OREGON

The state's first ethanol facility is located in Boardman. Pacific Ethanol began operations in October 2007 and produces 40 million gallons per year. Pacific Ethanol relies on corn imported by rail from the Midwest for producing Ethanol. Currently in Oregon, only blends of up to 10 percent (E-10) and 85 percent (E-85) ethanol can be sold. These are the only blends that meet Oregon-required American Society for Testing and Materials standards.

Ethanol is usually blended with gasoline and any gasoline engine can burn blends that contain low percentages of ethanol. However engines need some modifications to use fuel blends containing more than E10. The auto industry is making "flex-fuel" vehicles, which are capable of burning both regular gasoline and gasoline ethanol blends of up to E85.

OREGON ETHANOL FUELING LOCATIONS

There are a limited number of ethanol fueling locations in the state. Currently, motorists can fuel up with E10 and E85 in Aurora, Eugene, Milwaukie, Portland, and Salem.

BIODIESEL

Biodiesel is an alternative or additive to standard diesel fuel that is made from biological ingredients instead of petroleum (or crude oil). Biodiesel can be produced by combining any kind of oil or fat, including waste vegetable oils, virgin vegetable oils and animal fats with an alcohol (commonly methanol). It is non-toxic, renewable, and biodegradable**.** Because biodiesel essentially comes from plants and animals, the sources can be replenished through farming and recycling.

Figure 23: Oregon retail biodiesel fueling station

One of the great advantages of biodiesel is that it can be used in existing engines, vehicles and infrastructure with practically no changes. Biodiesel can be pumped, stored and burned just like petroleum diesel fuel, and can be used pure (B100) or in blends with petroleum diesel fuel in any proportion.

Blends are indicated by B##, which correspond to the percentage of biodiesel in the blended fuel. For example, a 20 percent blend of biodiesel with 80 percent diesel fuel is called B20. When biodiesel is first used in a vehicle, it may release fuel tank deposits which can lead to fuel filter plugging. After this initial period, a user can switch between biodiesel and petroleum diesel whenever needed or desired, without modification. Certain older vehicles built before 1993 may require replacement of fuel lines which contain natural rubber, as biodiesel can cause these lines to swell or crack.

Also, in some engines, there can be slight decrease in fuel economy and power**.** On average, there is about a 10 percent reduction in power - it takes about 1.1 gallons of biodiesel to equal 1 gallon of standard diesel. Other drawbacks include availability and cost.

BIODIESEL AVAILABILITY IN OREGON

Oregon uses 720 million gallons of diesel annually and about 11 million gallons per year of biodiesel. The state's largest producer of biodiesel, SeQuential Pacific Biodiesel, which is located in Salem, is capable of producing five million gallons annually. SeQuential opened at the end of 2008. In March 2010, the plant reached 82 percent capacity. At near capacity SeQuential still produces less than half of the biodiesel consumed in Oregon. The state imports more than 50 percent of its soy-based biodiesel from large producers from the Midwest. About 90 percent of the biodiesel produced in Oregon is processed from waste vegetable oil from restaurants.

OREGON BIODIESEL FUELING LOCATIONS

Figure 24: Biodiesel sold at the pump

There are certainly more fueling options for biodiesel in Oregon. Currently, motorists can fuel up with B5, B20, B99, and B99.9 blends at fueling locations in the cities of Astoria, Bend, Central Point, Coburg, Corvallis, Eugene, Gresham, Hillsboro, McMinnville, Medford, Mt. Angel, Lakeview, Phoenix, Portland, Salem, The Dalles, Terrebonne, Tigard, and Woodburn.

PROJECTED BIOMASS PRODUCTION CAPABILITY IN OREGON

Even though Oregon's biomass industry is a diverse and growing industry, the industry's future will rely on crop production. The average acre used for wheat or grass seed production can yield about 100 gallons of biodiesel if planted with canola or camelina.

Biodiesel or ethanol facilities that produce more than six billion British Thermal Units (BTUs) per day are subject to the State of Oregon siting process managed by EFSC. Six billion BTUs is equivalent to 18.6 million gallons per year of biodiesel or 28.8 million gallons per year of ethanol.

Table 4:1 summarizes the current known bioenergy facilities in the state. There are other facilities in Oregon that are small in scale and production or are not included in the data set. This information was gathered using surveys administered by ODOE.

TABLE 4:1 OREGON BIOENERGY FACILITIES			
TYPE OF FACILITY	**# OF FACILITIES**	**ANNUAL PRODUCTION**	**BIOMASS UTILIZED**
WOODY BIOMASS: Electric generating stations, steam plants, and co-generation facilities	>45	Electric Capacity of 238 MW plus unknown steam use for process and heat energy	>3.4 million tons of forest slash, mill residuals, pulping liquor, urban wood and yard debris
PELLET MANUFACTURERS	9	Approximately 550,000 tons of pellets capacity	802,000 tons of sawdust and wood residuals
ETHANOL & BIODIESEL	9	Approximately 36 million gallons of ethanol and over 4 million gallons of biodiesel	Current feedstock include corn, agricultural wastes, canola, and yellow grease
BIOGAS: Anaerobic digestion, not including wastewater treatment	3	Approximately 1.8 MW	>17 million gallons of manure and other wastes
BIOMASS HEATING: Schools, public buildings, other facilities	>5	Heat for buildings	Approx. 400 tons of wood chips or pellets
LANDFILL GAS	>4	>14 MW	Methane collection from landfill

There are also a number of facilities in the planning or construction phase. Table 4:2 contains a summary of planned facilities in Oregon.

TABLE 4:2 BIOENERGY FACILITIES PROPOSED IN OREGON			
TYPE OF FACILITY	**# OF FACILITIES**	**ANNUAL PRODUCTION**	**BIOMASS UTILIZED**
WOODY BIOMASS : Electric generating stations, steam plants, and co-generation facilities	~12	Electric Capacity of over 150 MW plus unknown steam use for process and heat energy	>1 million tons of forest slash, mill residuals, pulping liquor, urban wood and yard debris
PELLET MANUFACTURERS	2-3	Over 100,000 tons of pellets capacity	100,000 tons of sawdust and wood residuals
ETHANOL & BIODIESEL	2-3	Approximately 30 million gallons of ethanol and over 4 million gallons of biodiesel	Current feedstock include corn, agricultural wastes, canola, and yellow grease
BIOGAS: Anaerobic digestion, not including wastewater treatment	6	>6 MWh	>1 million gallons of manure and other wastes
BIOMASS HEATING: Schools, public buildings, other facilities	~8	Heat for buildings	Approximately 1,200 tons of wood chips or pellets

These numbers are estimates based on projects that have begun construction or permitting, have applied for state incentives or have expressed an interest in moving forward. These estimates will change as new projects will emerge and current projects may be postponed.

OREGON BIOMASS FEEDSTOCK GROWTH POTENTIAL

Based on estimates from biomass inventory and assessment studies conducted during the past decade, a range of 424-to-524 million gallons of gasoline-equivalent biofuel and other alternative transportation fuels could be produced each year from Oregon biomass feedstocks. This represents approximately 20-to-24.6 percent of Oregon's consumption of gasoline and diesel (2.172 billion gallons as of 2008).

If only waste sources of biomass were used, and no crops, 182-to-282 million gallons of gasoline-equivalent biofuels and compressed natural gas could be made from biomass waste in Oregon. This represents approximately 8-to-13 percent of Oregon's current consumption of gasoline and diesel.

TABLE 4:3
FUEL PRODUCTION FROM AVAILABLE OREGON BIOMASS

SOURCE	POTENTIAL FUEL VOLUME PRODUCED (millions of gallons of gasoline equivalent/yr)
FUEL FROM WASTE	
1. Forest residue	58 to 132 *(dependent on price paid)*
2. Agricultural residue (corn and wheat only)	13 to 32 *(dependent on price paid)*
3. Urban wood waste	11 to 19 *(dependent on price paid)*
4. Mill residues	1
5. Orchard and vineyard prunings	6
6. Grass straw residue	33
7. Greenwaste	18
8. Mixed Waste Paper	41
9. Biogas	0[1]
Total Fuel from Waste	182 to 282
FUEL FROM CROPS	
Expiring Conservation Reserve Program planted to biofuel feedstock	239
Existing crops	13
Total Fuel from Crops	252
TOTAL	**424** to **524**

INTEGRATING BIOFUELS INTO ENERGY EMERGENCY RESPONSE STRATEGIES

Both ethanol and biodiesel are renewable source of energy. Both can be produced domestically and can contribute to the lowering of U.S. and Oregon dependence on imported oil, increasing our energy security.

ODOE is in the process of inventorying all ethanol and biodiesel production facilities in the state. This includes information on the volume and storage capacities. While ODOE has information on larger biodiesel and ethanol producers in the state (producing more than 18.6 million gallons per year of biodiesel or 28.8 million gallons per year of ethanol), because of the state energy facility siting process, little is known about the small and seasonal biofuel producers in Oregon.

The goal of this data collection is to assist ODOE emergency planners and decision-makers in determining whether adequate resources are available in state to rely on ethanol and biodiesel for fueling emergency vehicles during fuel disruptions when conventional gasoline and diesel are unavailable.

Also, many critical facilities (hospitals) use diesel powered generators on-site for backup power in case normal electric service is interrupted. The ability of these facilities to continue operations depends on the capacity of the on-site generators and the available fuel supply. If adequate biofuels are accessible, diesel powered generators may be supplemented with alternative fuels to provide additional capacity and/or extend the fuel supply. This enables critical facilities equipped with backup generators to maintain normal or near normal operations for longer periods in case of a serious or extended power outage.

Renewable energy resources can add value to the entire emergency response effort by providing additional reliability and resiliency.

LOW CARBON FUEL STANDARD

The Oregon Legislature's adoption of House Bill 2186 in 2009 provides industry the incentive to build the necessary infrastructure to support an increase in biofuels production or at the very least increase imports into Oregon to meet demand. The Oregon Department of Environmental Quality (DEQ) is responsible for implementing the carbon fuel standard for transportation fuels. Oregon's standard would reduce the average amount of greenhouse gas emissions per unit of fuel energy by 10 percent from 2010 to 2020.

DEQ is in the process of setting up a registration system to start collecting data on biofuels in the first half of 2013. This includes collecting information on: 1) companies importing biofuels to Oregon; 2) types and volumes of biofuels imported into Oregon; 3) where the biofuels originate and end users; 4) how biofuels are transported; and 5) carbon intensity. This data collection will allow DEQ to establish a biofuels baseline before it develop a reduction program

and allows ODOE to determine if adequate alternative fuels exist to supplement emergency response strategies.

ESTABLISHED BIOFUEL FLEETS IN OREGON

Many large government fleets in Oregon already use alternative fuels. This includes the City of Portland, Multnomah County, and the State of Oregon. The City of Portland has used B-20 in many of their diesel vehicles since 2004.

In 2006, the Portland Water Bureau (PWB) began using B99 (99 percent biodiesel, 1 percent diesel) in its city-owned, diesel-powered vehicles and equipment from spring through fall and B50 (50 percent biodiesel, 50 percent diesel) in the winter. The biodiesel used by PWB is locally produced. The city's partners in the effort, Oregon-based Star Oil and SeQuential Pacific Biodiesel, blend and distribute the fuel, while regional farmers (from Oregon, Washington, Idaho, and Montana) grow the seed crops that eventually become the feedstock for B99. PWB's approximately 144 vehicles, ranging from backhoes and forklifts to dump trucks and tractors, run on B99.

Since 2002, Multnomah County has used biodiesel for its fleet. Multnomah County reported no capital costs, engine modifications, or changes to infrastructure have been required. Also, no significant performance issues have been experienced. Continued use is expected.

In 2003, the Oregon Department of Administrative Services (DAS) began replacing the state's fleet vehicles with flex cars, compressed natural gas vehicles, and hybrids. DAS currently uses B20 for diesel vehicles at state motor pools and E85 for flex cars.

Since 2004, the Oregon Department of Transportation (ODOT) committed to replacing its older fleet with hybrid vehicles in their sedans and dump and bucket trucks. ODOT also replaced its older light fleet with diesel engine vehicles using biodiesel. ODOT's fleet currently has 59 E85 vehicles and added two plug in hybrid electric vehicles. In addition, 24 percent of the ODOT fleet currently uses B-20 bio diesel and plans to reach 30 percent use by 2012. The department is also continuing to expand its use of ethanol with E10 and E85.

Smart Grid Technologies

INTRODUCTION

The term "smart grid" refers to a modernization of the electricity infrastructure to maintain a reliable and secure system that can meet future growth. It is characterized by a two-way flow of electricity and information that creates an automated, widely-distributed electricity network. It will monitor, protect, and automatically optimize the operation of its interconnected elements. This includes energy generators; the high-voltage transmission network and distribution system; industrial users and commercial building automation systems; energy storage installations; and residential consumers with their thermostats, electric vehicles, appliances, and other household devices.

Smart grid will incorporate information technology, sensors, and distributed computing to collect and analyze data to deliver real-time information. This information will be used to instantly match electricity demand with supply from all available sources, incorporating both traditional generation and wind, solar and electricity storage. The smart grid will enable a "just in time" balance of supply and demand at the device level.

SMART GRID BENEFITS

Potential smart grid benefits are numerous and are summarized below.

POWER RELIABILITY AND QUALITY – The smart grid provides a reliable power supply with fewer and briefer outages and higher quality power through the use of digital information, automated control, and autonomous systems. The smart grid is resilient, but when an outage does occur, it recovers faster in emergencies and limits the extent of outages.

SAFETY AND CYBER SECURITY BENEFITS - The smart grid continuously monitors itself to detect unsafe or vulnerable situations that could detract from its high reliability and safe operation. Cyber security features would need to be built into all systems and operations, including physical plant monitoring, and access control for confidentiality, integrity, and privacy protection of customer data.

ENERGY EFFICIENCY BENEFITS - The smart grid is more efficient, reducing energy consumption, peak demand, and energy losses in transmission and distribution systems. Such efficiencies can help to defer the construction of new centralized generation plants to meet electricity demand.

ENVIRONMENTAL AND CONSERVATION BENEFITS - A smart grid will aid in reducing greenhouse gases and other emissions by managing the network to access efficient and low-emission energy sources, reliably integrating variable renewable energy sources, and enabling the replacement of gasoline-powered vehicles with plug-in electric vehicles.

DIRECT FINANCIAL BENEFITS - While smart grid developments require capital investment, programs would be designed so that benefits outweigh costs over a suitable time period. Customers will have pricing choices and access to energy information to manage energy use for financial benefit. Entrepreneurs will accelerate technology introduction into the energy generation, distribution, and storage markets.

INTEGRATION OF RENEWABLE ENERGY RESOURCES - Smart grid enables the integration of variable renewable energy resources, such as wind, hydro, and solar energy, to supply power to the grid when the energy is available. Traditionally, the problem with some sources of renewable energy, particularly wind and solar energy, has been that they may supply power intermittently causing rapid power fluctuations on the grid. When the variable energy resource is not available, other sources must be ready to meet demand. Alternatively, to maintain system reliability, demand must be reduced to match the available supply.

The smart grid will enable a variable energy supply and maintain system reliability by monitoring and predicting variable supply resources. It will be able to automatically bring in other power supply resources to meet demand, or reduce load to match the supply. The smart grid will use sensors and dynamic line rating systems to enhance the visibility and monitoring of the transmission grid, and to maintain and potentially improve its reliability in the presence of large variable sources of electricity. Modern computing applications will receive and analyze real time information and perform modeling, decision-making, and control actions. Instead of control devices operating independently based on local measurements, networked smart grid applications will analyze data from multiple devices, allowing broader and more coordinated operations that adapt to actual situations and stabilize the grid.

The smart grid also enables the ability to address transmission congestion created by insufficient transmission capacity. By managing congestion, the smart grid can ensure that remotely located wind generation is not constrained from reaching load centers.

SELF-HEALING POWER GRID - "self-healing" means that the grid detects problems in real time, isolates the problem, and keeps the grid operating. Currently, power grids may experience cascading failures in emergency situations where outages are poorly contained. The technologies for containing cascading failures continue to dramatically improve. The smart grid may improve the evaluation of power system behavior in real time; prepare the power system to withstand credible combinations of contingencies; prevent wide-area blackouts; and accommodate fast recovery from emergency to normal conditions. The smart grid will utilize fast-simulation and modeling tools to gather information, make decisions and control actions. The tools will be located in a combination of central and widely distributed positions.

In an emergency outage situation, the self-healing smart grid provides the capability to isolate the problem areas while keeping the rest of the grid operating and avoiding cascading failures. The problem areas can be repaired and restored with minimal impact on the wider area.

SMART GRID APPLICATIONS
